5710. You think it would enable fishermen to catch fish which otherwise would be driven to sea by floods? Many a time they could do a week's work by using the meshing-net. In the length of nets I have always been opposed to a long length of net; I think 150 fathoms of 2-inch net is sufficient for any man. In the garfish net I approve with Mr. Smith. It ought to be allowed 150 fathoms as well as the 2-inch net; I approve of that.

5711. You speak more particularly as to the use of nets in George's River and Botany, not as to their use in the lakes? In the lakes 300 or 400 fathoms would be better. The more fish that go into the market the less money for all fishermen, if one uses a long length in the lakes they will all use it.

5712. You mean under existing circumstances that it does not matter if there is a large or small supply, you get the same prices; but supposing means were adopted for distributing the fish not alone in the suburbs, but throughout the country, and there was the demand, would it be a proper thing to give them the length of line? Under the rules carried on now it is an every-day occurrence to see fish in tons left on the Woolloomooloo Market floor.

5713. What is done with those fish? Sometimes we put them in the freezing-room; many a time we leave them on the floor, because it is not worth while to preserve them as it would only glut the market the following day.

5714. What becomes of those that are left? I believe they are destroyed.

5715. Tons of them? I have seen tons of them.

5716. Are you of the same opinion in regard to the altered conditions in the administrative authority in any new Act that may be framed? I am.

5717. You think the Fisheries Act has not been administered satisfactorily? I do.

5718. And the fishermen would hail with delight a change in that direction? Yes.

EVIDENCE OF THE FISHERIES COMMISSIONERS.

MONDAY, 1 APRIL, 1895.

[The Commission met at the Offices, Bligh-street, at 10.15 a.m.]

Present:—

FRANK FARNELL, ESQ., M.P., PRESIDENT.

THE HON. R. H. D. WHITE, M.L.C.

James Charles Cox, Esq., M.D., President of the Fisheries Commission, sworn and examined:—

5719. *President.*] You are the President of the present Fisheries Commission? I am.

5720. How long have you held that position? I have held it since 1882 or 1883—somewhere about that. I was appointed after the late Sir William Macleay resigned.

J. C. Cox, Esq.,
M.D.

5721. Were you one of the first members appointed to the Commission? No; I took Sir William Macleay's place. 1 April, 1895.

5722. How many gentlemen are associated with you on that Commission at the present time? There are the Hon. S. H. Hyam, the Hon. W. R. Campbell, Mr. J. R. Hill, and Dr. Ramsay.

5723. How often are you supposed to meet? Once a week. Wednesday is the regular Board day. We meet at other times as may be arranged.

5724. Have all the Commissioners attended pretty regularly? All except Dr. Ramsay. He has been ill for a long time. We asked him to resign in consequence of his not being able to attend.

5725. Have you, as a body, made any representations to the Government with a view of bringing about legislative reform in respect to the fisheries of the Colony? Yes; we have sent in two Bills. The first Bill we sent was in 1883. It accompanied the Annual Report for that year. The Commissioners then consisted of Messrs. G. F. Want, J. H. Geddes, F. A. Thomas, E. P. Ramsay, and myself as president. Then we sent in a second Bill.

5726. Accompanying the Report for 1890? Yes.

5727. Did the Government act upon your recommendations as contained in the Report of 1883? They never took the slightest notice of those recommendations.

5728. Did they act upon your recommendations as contained in the Report submitted to Parliament for 1890? No; we went deputation after deputation. I used every possible personal influence with Sir Henry Parkes, and with the late Sir Alexander Stuart particularly and Sir George Dibbs; the extraordinary thing is, that while those Bills have been absolutely ignored by the Government for these past eleven years, they have passed I think it is four Bills connected with the Fisheries through the House. The Port Hacking Bill and the Amended Port Hacking Bill, the Inland Fisheries Amended Bill, the Length of Nets Bill, and the Sunk Nets Bill—no less than five Bills. These have been passed in the Assembly since the recommendations of 1883.

5729. Was the Bill submitted in connection with the Report for 1883 the same as the Bill submitted in connection with the Report for 1890? No; the Bill was very much improved. We found important defects in the first Bill which were removed in the Bill of 1890.

5730. You have stated that you urged the Government to proceed with the 1890 Bill in order that it might be passed into law? Yes; not only personally, but frequently by deputations from the Commissioners.

5731. You are, of course, aware of the provisions of the present Fisheries Act;—in what direction, if any, would you like to see the present Act amended? Take the 11th section of that Act. The defect in this section is that there is no penalty for improper length. A man may have any length of net, but it must not be less than the respective dimensions, no limit is given to the length of the wings of a garfish-net. A man can actually have any length he likes. That is a very serious defect. It has been practised to a fearful extent.

5732. Was that defect remedied in the Bill you submitted for the approval of the Government? Yes. In section 12 it says:—"Every net" and so on "shall be deemed to be an unlawful net, if the mesh of such net shall measure diagonally when prepared for use," and so forth, "less than 3 inches in any part thereof"? Yes; this section was not repealed in the Inland Fisheries Act, which gives 4 inches; so that we have two different sizes of meshes for the inland-fisheries net. In section 13 it says, "Nothing in this section contained shall apply to a *bonâ fide* meshing-net having a mesh not less than 4 inches ascertained as aforesaid, and not exceeding 60 fathoms in length, when set as a meshing-net." Well, 60 fathoms is not long enough for a meshing-net. Meshing-nets should not be permitted to be used for stalling. I would not object to see a meshing-net a mile long if used in large waters, such as Lake Macquarie; by that means we could catch large whiting, and mullet, and good-sized bream. But I say do not allow the meshing-net to be used for stalling purposes.

5733. As to the meshing-net, should it be reduced or lengthened? The meshing-net should be lengthened, so as to allow of its being used in shoal waters.

5734. What length would you suggest? I would recommend about 88 fathoms, and not less than 4 inches in the mesh.

5735. Is it not likely that a good many marketable fish escape at the present time owing to the use of the 4-inch mesh? I have no doubt about it. But what you want to get in these meshing-nets is fish that do not frequent the shoal waters. There is no limit apparently to the depth of these nets. We have been very anxious to put a stop to the sunken-net business, but through nets not being limited as to depth the Legislature put in the words, "Not having a cod or purse." The result was that it legalised the very thing we wanted to stop. What did the fishermen do then? They cut off the cods and purses, and they killed more fish than ever, through attaching the lead-line to the cork-line, but leaving a space, fastening up the ends of nets, and dragging them as a great bag along the bottom. I want you particularly to look at the 14th section of the Act; it says:—"If any person shall sell, or consign, or expose for sale, or have in his possession or on his premises, any fish of any of the species mentioned in the second schedule hereto of a less weight than that set opposite the name of such fish in such schedule," and so forth. Under this section we cannot prosecute. Prosecution can only be effected when fish are offered for sale. The offenders get out of it by saying the fish found in their possession are for their own consumption, and are not

J. C. Cox, Esq., not intended for sale. Now take the 16th section:—"It shall not be lawful for any person to catch or attempt to catch prawns by means of a net, or by any other mode of capture, during the months of June, July, August," and so on. These months are absurd. This ought to be left to the discretion of the Commission. The law was made for the Hunter River, but these months are not suitable. It should be, "That the Commissioners can declare it unlawful to catch prawns during certain months;" but the matter should be left to the discretion of the Commission.

M.D.
1 April, 1895.

5736. You would give power to the Commissioners to make closures when they thought fit to do so? Exactly, for fit and proper reasons.

5737. Have you any suggestions to offer in regard to the prawn-net;—do you think the length and mesh are sufficient? It is a very destructive net at present. It has 15 fathoms of 1-inch mesh; that is the regulation. My impression is that as a prawn-net it is small enough.

5738. Do you think it would be better in the interests of the fisheries to forbid the use of the prawn-net altogether;—are not certain classes of fish deprived of their food supply by the use of that net? Prawn-fishing is a great industry. My advice is to leave the prawn-net as it is. Then again, in the 17th section:—"It shall be lawful for the Governor from time to time to declare, by proclamation to be published in the *Gazette* and in some newspaper circulating in the nearest police district, that the whole or any defined portion of any tidal river, inlet, estuary, lake, lagoon, or arm of the sea shall be closed against the use of fishing-nets for such term, not in any case to exceed two years, as the Governor shall think fit." That should be:—"It shall be lawful for the Governor, on the recommendation of the Commissioners, to declare that the whole or any portion of any water shall be closed for such term as the Commissioners shall think fit." The fact is, we may like to close waters for twelve months. I think if that section were made to read "as the Commissioners shall think fit" it would be better all round.

5739. You do not want the period of thirty days to be allowed to elapse before you issue your proclamation? No; it is better for us to have the power to keep these waters closed for as long a time or as short a period as we may think right. That portion of section 17 which says "such proclamation shall only be issued when the Commissioners shall report to the Governor that the natural supply of fish in the waters proposed to be closed has been exhausted by net-fishing or otherwise" does not extend to the use of prawn-nets in those waters.

5740. Have you had a test case upon that question? Well, I am sick and tired of it; it is not net-fishing; it is prawning. They have got out of it over and over again; my advice to you is to wipe out the thirty days between the expiration of one proclamation and the commencement of the other. Section 18 says, "If any person, after the expiration of thirty days from the date of any such proclamation or extended proclamation, and during the currency thereof, shall cast, haul, stake, fix, or place any net of any kind whatever, for the purpose of taking or capturing fish within the limits of the tidal waters or area defined in such proclamation," and so on. Now, we have often caught men using prawn-nets in those waters, but we cannot touch them. Our young fish are being ruined by it; we cannot touch them. Section 19 refers to the boats used, or intended to be used, for catching for sale any of the varieties of fish, whether marine or fresh-water, enumerated in the first schedule. This should be the first and second schedules, and there should be a third schedule including prawns. You will also see that in this section it says, "Every boat licensed under this section shall have painted, in legible letters, in such conspicuous place as may be prescribed by the regulations, the name of her owner and the words licensed fishing-boat." I want the man's name, his surname, and his initials or his number, and the letters L. F. B. painted on the boat in 4-inch letters. If this were done anybody could go and see what boat was poaching in closed waters. Section 20 is as follows:—"Every person employed in catching for sale, fish, lobsters, or prawns, in or upon any tidal waters, shall pay an annual license fee of 10s. to the Colonial Treasurer." As a result of this section, all those men who catch those enormous numbers of fish, crayfish or lobsters in our inland waters give us no revenue. The section says "in or upon any tidal waters." It should be "tidal and inland waters."

5741. So that the fishermen who fish in the Murray River, and reside on the Victorian side, pay nothing to the Government for catching fish? They do not. Section 22 says, "It shall not be lawful, by the explosion of dynamite or any explosive substance, or by means of any poisonous or noxious thing, to destroy or take fish in any tidal or other waters in New South Wales." I want the Commission to insert the words "to attempt to destroy" before the word "destroy," in order to prevent the destruction of fish. Section 24 says, "Every person who shall be found using a fishing-net of any kind whatsoever in any waters in New South Wales," and so on; that ought to be, "In any tidal or inland waters." Further on it says, "Shall on demand give his true name and residence to any inspector, Justice, officer of police, &c." I think the word "Commissioner" ought to be inserted before the word "inspector" in that section. I have seen men over and over again fishing illegally, and I, as a Commissioner, could not touch them. In the same section I would also advise that the words "or over which they ebb and flow," after the word "waters," should be expunged. In section 25 it says, "Any inspector, officer of police, or constable," &c., "may at any time enter any premises or dwelling," and so forth. I would like the words "Customs officer" inserted after the words "officer of police," and I would like the word "place" inserted after the word "premises." Men have evaded punishment several times by saying they have not got their nets on their premises; but at the same time the nets may be in a place which may be some place on their own grounds. I think we ought to have power to go anywhere. At the end of this 25th section it says, "And every net so seized shall be taken before a Justice, who, on inspection thereof, shall, if satisfied that the same has been so used as aforesaid, or is an unlawful net, order the same to be forfeited to Her Majesty." Now, how is a man to be satisfied with that?—he has to be seen using the net. I would suggest you omit the words "if satisfied that the same has been so used as aforesaid" without having seen it used. Then, as regards the private fisheries, my views are embodied in the Bill accompanying the Report of 1890.

5742. Do you recommend that these fisheries be retained, or that provision be allowed for the carrying on of private fisheries? I have nothing to suggest further than what is contained in the Act.

5743. You think that although the provisions have not been availed of they may be later on? Yes; I would leave it open; I am inclined to advocate these industries.

5744. Do you consider the provisions of the Oyster Fisheries Act sufficient to meet the development of the oyster fisheries of the Colony? No, I do not. I have found practically that the processes under the Act are comparatively a failure.

5745. You refer to the system by which the leases are taken up—the small areas? Yes.

5746.

5746. Would you suggest that larger areas be made available? I would suggest that power be given to the Commissioners to lease large areas. This 100 yards business is an absolute fraud. I think myself it would be better if the Commissioners had power to let such places as Port Stephens, Gosford, the Manning, the Richmond, the Macleay, and other rivers, to have the option of either leasing them as a whole or one side of them. I believe it would be a good principle to let them by tender or by public auction.

J. C. Cox, Esq.,
M.D.
1 April, 1895.

5747. Do you think the system of payment by results would be better, providing you let the larger areas, requiring the lessees to pay a royalty, under certain stringent conditions as to working the leases properly? Yes; I think that would be a good thing.

5748. Has the supply of oysters increased during the last twelve months? The increase in the number of bags of oysters taken from our beds in 1894 over the previous year, was about 2,250. In 1894, 7,523 bags were taken off our beds; in 1893, 5,265 bags; the figures are approximate in our case. In all there were 6,776 bags of oysters imported into New South Wales in 1894, against 7,355 for 1893.

5749. Where did those imported oysters come from? There were about 3,208 bags of oysters from New Zealand in 1893, and about 2,550, in 1894. South Australia sent 254 bags in 1894, as against 76 in 1893; Victoria, 52 bags in 1894, as against 8 in 1893; Queensland, 4,061 in 1893; and 1,536 bags in 1894. In 1894, 328 bags of oysters came to Sydney from Port Stephens; in 1893, 465 bags came from the same place.

5750. Is it your opinion that the bags of oysters sent from Port Stephens came altogether from the leases, or do you think the Crown lands have suffered? I think the Crown lands are simply becoming denuded. I find there has been an increase in the output from some of the leases, but the increase from others must be looked upon with great doubt. It is evident that the increase has been caused by overstripping the leases and robbing the Crown lands adjacent thereto. This abuse has increased considerably since we had to retrench in the Fisheries Department. The Commissioners are aware of this great robbery and injustice which is being done to Crown lands, and they issued a circular cautioning all lessees against it. This is as far as the law will permit us to go. According to the present Act the leased beds must be denuded of oysters before the Commissioners have power to put the law in motion. I desire to put that very strongly to the Commission. The result is that when they have exhausted their leases they ask for cancellation, and these exhausted lands are thrown back on the hands of the Fisheries Commission, and they are useless for some years to come, and we have no power to stop it. Others take up leases, wilfully neglecting the cultivation of oysters, and systematically robbing the adjacent Crown lands. In fact, the piece of 100 yards they have taken up has been only made the excuse for getting a footing into the magnificent Crown lands and other leases that contain good oysters, which they stripped. If a man is caught taking oysters from Crown lands he simply says the oysters are for his own consumption. In this way the 15th section of the Oyster Fisheries Act is availed of. There is another objectionable thing that goes on: We lease a moderate area; a man has a number of those leases; he is in the midst of a magnificent Crown land area of oysters. He takes the oysters off the Crown lands, boats them to his own 100 yards lease, bags them, and then brands them with his own lease number, and in that way they get into the market. I find by experience that a number of lessees make application to be released from their leases under the excuse that the oysters on them are destroyed by worms. The real fact is that the lessees have stripped every oyster off their leased area and as many as they can off the adjacent Crown lands, and then they throw the thing up and pretend it is no good. It is the man worm that is the trouble; it is not the ordinary worm. In this way Crown lands suffer most fearfully. I beg to impress upon the Royal Commission the importance of putting down this villainous destruction of our oyster-beds.

5751. Under the present Act there is a provision which allows people to go on to Crown lands and take oysters for their own consumption;—do you think that should be so amended as to prevent them from carrying oysters away from Crown lands? My advice is to embody in your Bill a provision stipulating that no one be allowed to take oysters away from those areas. Let each person eat as many as he can, but it is quite enough destruction for them to walk over and trample on the oysters without taking them away in bags.

5752. As to the conveyance of oysters to market, do you think there should be more stringent provision made in respect to the marking and branding of bags of oysters? I think it should be as stringent as you can possibly make it.

5753. Are you of opinion that if a stringent provision to that effect were embodied in the Act it would be the means of finding out some of these oyster-stealers? Yes; but I think if the small areas were abolished that would remove the whole difficulty. The fact is this, within my knowledge, that a man taking oysters off Crown lands has borrowed the branded bags of a lessee and got the stolen oysters to market by that means.

5754. You told the Commission that lessees have pleaded the destruction caused by the worm disease as an excuse for asking for the cancellation of their leases;—can you say whether the worm has been destructive to those oyster-beds? Fearfully destructive to a number of the areas taken up. The Hunter River has been terribly attacked, and so has the Hawkesbury and other places. Other places, on the contrary, seem to be quite free from the disease. I have here an exhibit showing the enormous growth of young oysters. [*The witness here produced an oyster shell taken from a bed at Camden Haven which was literally covered with spat.*] We have found out that one great cause which now prevents the oysters from taking to the rocks or the foreshores is that the surfaces of such rocks and foreshores have, in consequence of navigation and drainage, become so slimy that the young spat cannot affix to them. If you place clean shells or pieces of slate or even clean broken stones in any locality where the oysters are spatting they are immediately covered with young oysters.

5755. In cases such as you have mentioned in which lessees desire to throw up their leases, owing to the ravages of the worm, would not the system of paying by results relieve them and the Government altogether from any obligation? Yes, if the areas were large areas.

5756. Can you tell us whether the areas taken up in 1894 have increased as compared with 1893? There has been a greater demand for areas for oyster culture during 1894 than there was in 1893. In 1894, 4,650 yards of foreshore were applied for. About 1,100 yards of this were applied for on the Clyde River, 500 in Wallis Lake, 500 in Botany, 500 in Twofold Bay, and the balance in small scattered areas.

5757. How do you account for the application for 500 yards of a lease in Botany Bay, when it is understood no leases have ever been taken out in that place before? I fear that it is to gain residence and access principally to the shores of the bay.

- J. C. Cox, Esq.,
M.D.
1 April, 1895.
5758. And not with a *bonâ fide* intention of carrying on oyster culture? No; in my opinion that is so.
5759. What do you consider the best known grounds for the development of the oyster? I think Cape Hawke is one of the best; Port Stephens, the Clarence, and the rivers to the north.
5760. During your experience which waters have you found most congenial to the development of the oyster;—that is, in which waters have they made the quickest growth? The beds in the river north of Port Stephens.
5761. How do you account for the quicker development in the northern rivers than in the southern rivers? I suppose there is more feed for the oyster in those rivers.
5762. Have you ever noticed any evidence of deep sea oyster deposits on our coast? I have not. I went out with the "Challenger" dredging. I have been out several times dredging, but never came across what I call a genuine bed of oysters. We did come on them occasionally in small numbers.
5763. Have you ever heard of a deep sea bed having been discovered at Jervis Bay? Yes; outside you mean. I think it was in the mouth of the bay. It was a long time ago; I have not paid so much attention to these things lately.
5764. Do you know whether experiments have been made in trying to propagate the Stewart Island oyster in New South Wales? We have placed them in different positions on several occasions, but they were stolen by the men; that was in former years, not recently. I am of opinion that the Stewart Island oyster is merely a variety of the mud oyster found on the New South Wales coast, and on the coasts of Victoria and South Australia.
5765. The Stewart Island oyster is a deep sea oyster, is it not? Yes; it is, but it is a bad oyster to carry.
5766. Can you give the Commission any information with regard to the number of fishermen's and fishing boat licenses issued in the Colony for 1895? I have the list for February, 1895; the number of fishermen's licenses issued was approximately 133, and the number of fishing-boat licenses was approximately about sixty.
5767. Can you give us an idea of the quantity of fish received at the Woolloomooloo Market in 1894? In 1894 there were 42,272 baskets of fish received at Woolloomooloo and sold there. In 1893 there were 41,024 baskets, showing an increase in the number of baskets of fish sold in 1894 by 1,248 baskets. At the Redfern Market there were 20,000 baskets sold at fair prices in 1894. Of the baskets sold at Woolloomooloo in 1894, 1,076 were condemned as unfit for human consumption, whereas, in 1893, only 753 baskets were condemned. In 1894 twenty-eight baskets of fish were sent to charitable institutions as they were undersized. Of the schnapper, which were sold by dozens in 1894, 4,711 dozens of schnapper were sold at the Woolloomooloo Market, whereas in 1893, only 2,585 dozens of schnapper were sold in the same market, showing an increase of 2,126 dozens of schnapper for 1894. This is exclusive of red bream, which totalled 7,000 dozens sold at Woolloomooloo, so that in all 11,711 dozens of schnapper, large and small, were sold in 1894 at that market. During the same year 9,021 dozens of flathead were sold at Woolloomooloo, while, in 1893, 2,921 dozens of the same class of fish were sold, showing a big increase for last year. The number of whiting sold in 1893 was 5,031 dozens; in 1894 it was 8,181 dozens. In 1893, 1,244 dozens of flounders were sold, and, in 1894, 1,746 dozens. In 1894, 1,095 dozens of kingfish were sold, whereas, in 1893, the number sold only totalled 409 dozens. Jewfish, 1893, 6,895 dozens; 1894, 17,529 dozens; sea mullet, 1894, 12,494 dozens. The number of baskets of prawns sold at Woolloomooloo in 1894 was 5,678; in 1893, 3,949 baskets were sold. Although there is a general increase in the quantity of fish sold, the market revenue for fish disposed of in 1894 was only £25,368, whereas, in 1893, the fish sold, although the quantity was smaller, realised in market revenue £29,647. Thus, 42,270 baskets of fish in 1894 brought less than 41,024 baskets in 1893 by £4,279; therefore, I consider the fishermen are out of pocket to that extent.
5768. Do you think that as a consequence of the greater supply during 1894 the consumer received his fish at a cheaper rate? Certainly not. I live at North Sydney, and it is simply scandalous the prices we have to pay for fish. The prices paid to the hawkers are simply scandalous.
5769. The fish you refer to as having been sold during the periods specified, where did it come from? 11,574 baskets came from Lake Macquarie, 13,888 baskets from Tuggerah Lakes, 5,740 from the Hawkesbury River. Port Jackson takes fourth place. There was a large increase both in fish and prawns from Port Jackson during 1894. The number of baskets sold as coming from Port Jackson in 1894 was 6,938; in 1893 it was 3,923. During 1894 Lake Illawarra sent 5,188 baskets of fish to Sydney, and 1,000 baskets to the Wollongong district generally. This is a decrease of 936 baskets from Lake Illawarra as compared with 1893.
5770. About the Murray River fish, are you aware whether many consignments of fish leave New South Wales for Victoria? Yes; an enormous quantity leaves this Colony, much more than is forwarded to Sydney. In 1894, 28,806 lb of fish were sent to Victoria *via* Moama, and 25,582 lb. *via* Koondrook, an increase of 3,312 lb. on the previous year.
5771. Of course that would be the fresh water fishes? Yes.
5772. Are you satisfied with the manner in which the Woolloomooloo Market is conducted? I am not, and I never was. I am of opinion that the fish, from the time it leaves the fishermen's boats until it is sold in the markets, should be placed in charge of the Commissioners, and they should be responsible for it to the fishermen. I know as a fact that the fishermen are not only robbed of their fish in transit, but the commissions they have to pay are so heavy that they do not receive anything like an adequate return for the fish they catch.
5773. Do you think if the fishermen received one-half of what the consumer pays for fish he would have a fair return? I really do; but I think they ought to receive more than that.
5774. Would it be advisable to bring the fishermen into closer contact with the consumer? I think it would.
5775. As to the number of sales which should be conducted in the Woolloomooloo Market, would you approve of greater facilities being afforded for the sale of fish, in order that the public might have a better opportunity of obtaining supplies? I would recommend that there should be a sale of fish early in the morning and another in the afternoon, that is by public auction. The fish market should be opened all day for the retail of fish.
5776. Would you allow the fishermen to sell direct to the general public? I would have no objection to that; let them take a stall in the market; I think they might be allowed to sell from the stall.
5777. Do you recognise the necessity for having auxiliary markets? I do; I recommend that there should be a market established for the sale of fish in each of the principal suburbs of Sydney; for instance, North Sydney, Balmain, Paddington, Waterloo, Newtown, and other places. 5778.

5778. Are you satisfied with the manner in which the fish are displayed in the Woolloomooloo Market? J. C. Cox, Esq.,
I am not. I think it is simply revolting to see the manner in which they are placed on the floor; they
M. D.
are sometimes trodden on, and men occasionally spit on the floor. I think they should be exhibited on
1 April, 1895.
raised trays. I say it to the credit of the Fisheries Commission that they have waited as a deputation on
the Mayors of the City, particularly Sir William P. Manning, when they heard that a new market was to
be built down in Paddy's Market so as to have better provision made for the sale of fish and in order
to point out that it was necessary to have cool chamber accommodation provided for the storage of fish.

5779. Would you advocate the sending of gutted fish from the different fishing grounds to market?
Yes; I think that is a most important matter. If I had anything to do with it as a Commissioner I would
insist upon all the fish being gutted prior to their leaving the fishing-grounds. It is because this is not
done that the weight of fish in the baskets forces out the contents of the intestines of the fish in the
baskets and causes decomposition. I exhibit a red bream weighing 6 ounces, not gutted, which I
obtained from the market this morning, and it is now unfit for human food.

5780. Do you consider that the different species of edible fishes found in the New South Wales waters
compare favourably with fishes found in other parts of the world? Our edible fishes are not to be com-
pared with the edible fishes of New Zealand, but if you include Lord Howe Island, which is a province
of New South Wales, that is one of our most valuable and I will say one of the most neglected of our
fisheries. The fisheries of Lord Howe Island, which is nearly 400 miles to the eastward of our coast,
swarm with good edible fishes. Those fisheries ought to be largely developed.

5781. I notice from the returns you have given us that there was an increase in the supply of prime
fish in 1894 as compared with 1893? Yes.

5782. Can you account for that? I think it is in this way: A good class of fishermen apparently are
taking up the fishing industry, and there is evidently an increase of fish coming from outside of the
harbours. It is in the line fishing particularly that the increase is apparent.

5783. Do you know of any neglected branches connected with the fishing industry in New South Wales?
In my opinion there are several of our fisheries that are quite neglected. I should be very glad indeed
to see this Royal Commission commence proceedings to investigate this matter either immediately or in
the future. In the first place we have a number of true herrings on the coast of New South Wales and
in the fresh waters. There is the maray, the *Clupea Sagax*; this is a pilchard which should be due off the
coast before this present time. It is a fish which might be turned to very valuable account; indeed, a
very valuable industry might be created in connection with its capture and cultivation. It is an excellent
eating fish, and I would recommend strongly that the habits of this fish and everything connected with it
be investigated, if possible, by this Commission. Then we have an enormous herring here. I got three
of them this week; they were 15 and 18 inches long; they were caught in a drift net off Botany. I refer
to the *Megalops Cyprinoides*, a magnificent large herring. From what I have observed I think it
generally precedes the great shoals of maray which frequent this coast. It is a fish found more
abundantly in the Indian Ocean. We know scarcely anything of its habits on this coast. Then we have
another beautiful clupea on this coast very like *Clupea Sundaica*, which, if it could be caught in shoals,
would be of very great value for tinning purposes; we have also a beautiful fish like our fresh-water
herring, called *Diplomystes Sprattelloides*. This is a fish described by Mr. Ogilby. We do not know any-
thing as to its real habits. It is seen frequently down about Maroubra Bay, a little earlier than this;
some have been found on the shores lately, as if they were merely an offshoot of an immense shoal. We
have also the herring called *Clupea Novæ Hollandiæ*, existing in great abundance in our fresh waters.
I think this fish would be good and of great value if preserved as sardines. There is another herring,
Sprattelloides Delicatulus, which has been recently caught in great abundance on the shores out at
Maroubra Bay, but it is absolutely discarded by the fishermen, I presume because they do not know
its true value. In addition to this we have a beautiful fish on this coast the *Engraulus*. This is a true
anchovy, and I believe, if studied, it might be turned to great commercial advantage. I have some
specimens here in a bottle; these specimens were obtained at Maroubra Bay; they were thrown up in
considerable quantities on the beach. We do not know their habits in these waters, but the habits of this
fish is very ably worked out as it exists in the Mediterranean. On one occasion while netting with the
late Sir William Macleay, a little east of Clontarf, in Middle Harbour, a net was shot, and it came up
absolutely loaded with these anchovies and other fish. It was the greatest haul I have ever seen. It only
shows us that there is a neglected industry connected with these fishes.

5784. Have we any whitebait frequenting our coast or the inlets? Not that I am aware of; a large
quantity of whitebait is brought in a frozen state from New Zealand. It is a true *Galaxias*; it is a
delicious fish. I do not think we have them on our coast, but we do not know. We have *Galaxias* in
great abundance in the rivers of New South Wales, but we do not know that they have ever appeared
in sufficient quantities to permit of the establishment of an industry in connection with their capture and
preservation.

5785. Can you tell the Commission of any other neglected industries in connection with our fisheries?
Yes; I think there is a fair prospect of the sponge industry being developed on the coast of New South
Wales; this is a matter which should not be neglected. There are upwards of 400 species of sponges on
our coast, and the sponges here seem to develop and live quite as well as in any other part of the world.
We have no fine samples of the domestic sponge, the *Uspungia Officinalis*, which include the fine sponges
and the coarse sponges. We have many large soft cup-shaped sponges on this coast, which might be
made of commercial value if properly treated. We have discovered there is a magnificent sponge now
found at Fiji, nearly as good as the Mediterranean sponges when properly treated. If these sponges
exist and thrive on the coast of New South Wales; as we know they do, I see no reason why sponge
gardens should not be established here by the importation of the better forms of sponge from the Medi-
terranean. It would be an easy matter to import them, and I think it would be worthy of consideration.
It might be a good thing to send an experienced man to the Mediterranean to study the growth and
development of the sponges in that part of the world, and to bring out several different varieties with
him for growth in our own waters. There is an excellent dissertation on the sponges in the *Encyclopædia
Britannica*. The sponge is of enormous value; the value of the sponges used in England alone is
astonishing. I understand from what I have read that the *Uspungia Officinalis* has been imported to the
southern parts of California, where it is now successfully propagated, and forms a thriving industry.

5786. At what place would you suggest the establishment of a sponge garden—what place do you consider
best

J. C. Cox, Esq.,
M.D.
1 April, 1895.

best suited for the propagation of sponges? I believe Port Stephens could be transformed into a most admirable garden for the cultivation of sponges, and I would very much like to see an experiment in that direction made by the Government in the waters of Port Stephens. You do not want deep waters, you want clean peaceful waters; as far as I have seen Port Stephens would be the best place for a sponge garden. A large portion of Port Stephens could be specially reserved for these experimental purposes.

5787. About the whaling industry, can you give the Commission any information regarding the possibility of the revival and development of that industry? That was a very valuable industry; it should come under the control of the Commissioners of Fisheries; there has been for years an indiscriminate destruction of whales from the south of Tasmania to New Zealand, and on the Australian coast. We have evidence beyond doubt that the whaling industry was of immense importance in bygone years. I would strongly recommend this Royal Commission to consider the propriety of having one universal law throughout the Colonies regarding the capture and destruction of whales in the adjacent seas. I think the revival of the whaling industry is a matter that might well engage the attention of this Royal Commission.

5788. As to the capture of turtles, can that be prosecuted with any success in our waters? I think not in New South Wales waters. I do not think they would propagate sufficiently to make it worth our while to protect them. We might back up the efforts of the Queensland people in carrying out the laws made for the protection of turtles, and seals also. The sealing industry should have consideration, although we are not so much interested in that as probably some of the southern Colonies are, but it is an industry that should be placed under one general law, in order that the seals may be protected.

5789. The seal found on our coast;—is it of commercial value? Do you mean the seals found at Seal Rocks?
5790. Yes? No. The seal that is of commercial value does not frequent too warm waters. Some of the seals found on our coast we sent to the Fisheries Exhibition in 1883, and the people in London were astonished to find out that that seal had never been seen in England since Captain Cook's time.

5791. With respect to the development of the crayfish fisheries on the coast, are those fisheries as prolific as they were? I should say not. The destruction of the crayfish just now on some of our best grounds is very great. Broughton Island is absolutely taken possession of just now by numbers of foreigners who have not taken out licenses. We do not know what destruction is carried on there, and we have no power to stop that destruction. I believe the crayfish industry on the coast is being very much abused.

5792. When do the crayfish spawn? I have not paid special attention to that. I would not venture an opinion.*

5793. Do you think the administrative authority should have power to close certain waters in order to allow crayfish to breed? Yes, I do. I would prohibit fishing in certain places where they breed in abundance. On one occasion I was at Kurnel, near Botany, and I saw people catching young crayfish in hundreds and killing them. I was astonished at the destruction going on. I would punish people who have crayfish under a certain size and weight in their possession.

5794. I suppose under no circumstances would you allow crayfish to go into the market while in the berried stage? Well, I will hardly say that, because if crayfish have cast their spawn they are watery and distasteful. I think the public likes food of that class to be of a good character. If certain portions of the coast are protected during their breeding season, that would meet all requirements.

5795. Are the crayfish found in Sydney Harbour the same as the crayfish found in Port Stephens, and do they develop to so great a size? The crayfish in Sydney Harbour, Botany Bay, and Port Hacking are not nearly so fine as those found in Port Stephens, but I think they are only varieties of each other. Mr. Whitelegge, of the Australian Museum, would be able to afford the Commission information regarding the crustaceans and sponges.

5796. Regarding the development of our deep-sea fisheries, has any experiment been tried by the Fisheries Commission in trawling? We engaged the "Rachel Thompson," a well-boat, to go south to Jervis Bay and catch schnapper and fish of that class. She got a very large number, and brought them to Sydney in very excellent order. It was a most successful experiment as regards conveying fish alive in well-boats to Sydney. When the fish got here the Commission thought they would sell them, and we sent them alive to the market for sale, but we were absolutely boycotted, and dealers would not buy one of them. I had to get drays and send them round to the hotels giving them away.

5797. Have the Fisheries Commission made any experiments in trawling? I went out two or three times in the "Challenger." We trawled from Broken Bay to Woollongong. The trawls were badly damaged and they did not catch many fish. I fancy they would have caught fish, but the trawl was destroyed owing to their not knowing the grounds over which they could use the trawl with safety. The waters along our coast were not so well mapped out then as they are at the present time. The experiment made by the "Challenger" in trawling was not successful, for the reason I have stated. The Fisheries Commission attempted to do some little work, as much as they could get money for, outside. They met with moderate success, considering that they did not know actually what place to trawl over. We got a new flathead, a fish we had never known of before; we got this flathead in abundance. Among other fish that came up in abundance was nannegai, very fine specimens; they were got off Botany. I am quite sure that the trawling industry may be developed if due care is taken in the matter, and particularly if the bottoms over which the trawl can be drawn are mapped out. It is not likely anyone will try experiments in trawling, and risk valuable gear until the bottoms are mapped out. A very extensive trawling was tried on this coast years ago by the late Sir William Macleay. He chartered a sailing vessel, the schooner "Peaben," and had her trawling for fish and other marine products from Port Stephens down south. As a result of his experiments he obtained a very large assortment of marine fauna. His experiment was not altogether a success as regards fish; it was more successful as regards other marine products.

5798. Are you of opinion that the Government should make an experiment in trawling before people can be induced to enter into the trawling industry? I am of that opinion. I think two things should be done; one should be to induce the Admiralty to make a good map of the surfaces on this coast for about 3 miles or more, and then the Government should authorise experiments in trawling, to ascertain what success would attend the starting of the industry in these waters. That is my firm opinion. I do not believe in anybody pooh-poohing this thing, and concluding that trawling will not be a success on account of the comparative failures of the experiments hitherto tried.

5799. Do you think the fisheries of Lord Howe Island could be made of value to this Colony? I do. I most particularly emphasise upon this Royal Commission the advisability of giving this matter their most

serious

* NOTE (on revision):—July and August to the north, and later to the south.

serious and earnest attention. I look upon Lord Howe Island as the best fishing-ground we have in connection with the coast of New South Wales. Fish life is excessively abundant there, and all the best qualities we have on this coast are to be found in the waters surrounding that island. I believe the fish, if obtained, could be brought up to Sydney and to other markets in well-boats or in cool chambers. I would like to see the laws which govern the New South Wales fisheries extended to Lord Howe Island, in order to place those fisheries under proper control. Elizabeth Reef, some distance from Lord Howe Island, is also a very valuable fishery.

J. C. Cox, Esq.,
M.D.
1 April, 1895.

5800. As to the administration and control of the fisheries, has your staff been sufficient for the proper supervision of our fisheries? Not recently. We have had a staff sufficiently large to place the fisheries under proper control.

5801. Who is responsible for such a state of things as that? The Government.

5802. Did they curtail the vote for the Fisheries Department? Yes; to a very serious extent.

5803. Did the Government simply reduce the amount, and leave the Fisheries Commission to make the best arrangements they could? They simply told us we must reduce it by a certain sum.

5804. And the result of that action has been the want of supervision of some of our fisheries? Yes.

5805. You have had a long experience in connection with the administration and control of the fisheries of the Colony as President of the Fisheries Commission, and you have taken an active interest in regard to those matters;—do you think that the Commission as a body could be improved upon? I do. I think it ought to be absolutely changed.

5806. What would you suggest? I think the Fisheries Commission should be an absolutely independent body, free from all political and other influences, and it should be the object of the Fisheries Commission to make the Department self-supporting. My feeling is this—it is not the feeling of others with whom I am associated—my recommendation would be to form a Board, and that there should be a head man over the fishing industry. I would pay him well, give him a good salary, and place him over the fisheries of the Colony. I think it would be better to place another person over the oyster industry, and give him a good salary also, and in addition to that I think there should be one or two good business men, perhaps three good men, placed on the Board, men who would take an interest in the industry, one of the three to be chairman. These gentlemen should receive remuneration for their sitting. I do not see, myself, why gentlemen who give their time and attention to an important industry of this sort should do so without some remuneration.

5807. Would you give the fishermen any representation on the Board you suggest? I would not put a man on the Board unless he was a man of intelligence and independence. I think it might be dangerous to put a man on the Board who gets his livelihood by fishing or oyster culture. You can always consult them.

5808. In respect to fish acclimatisation, have you been assisted by the Government in carrying out that branch of the industry? Yes; they have assisted us for the last few years in introducing the fry of trout in particular.

5809. Would it be possible to stock many of our rivers which at present contain no fish life with different varieties of fish? Yes; particularly the waters of the Monaro district, the heads of the Snowy River, the Murrumbidgee, and all the New England waters, and also the heads of our other rivers that are fresh and cool, I think we might stock them successfully with fish.

5810. Do you think we could successfully propagate some of the best specimens of our fresh water fishes, and liberate them in waters where they do not now exist? Yes, I do; the last consignment of trout we obtained came from Ballarat. The trout were about twelve months old, and I hear they have the appearance of being ready to strip very soon. They are out in ponds at the Prospect Reservoir, and it will be a very interesting experiment, and will form an answer to your question. The fish we have at Prospect have lived and thriven well; they have grown enormously; and I am led to believe that they are progressing towards the reproduction of their species.

5811. Would it be a wise thing, from a national standpoint, to establish a fish hatchery on a large scale in order that the several inland waters of the Colony might be stocked with suitable kinds of fish life? It would, and I recommend that it should be done. I strongly recommend that; I wish it had been carried out long since.

5812. Is it advisable that the Government of New South Wales should take joint action with the Victorian Government with a view to preventing the depletion of the Murray River fisheries? It is, and I think very active measures should be taken, not only to protect the fish in the Murray and other fresh waters, but also to propagate them.

5813. Would the stocking of rivers, lakes, and creeks at present containing no fish life tend to purify the waters? Yes; I believe a good class of fish such as the trout would very materially help to purify the waters supplied to town and cities. That very question came before me some time ago. We know that the water supply of the city of Sydney is at times swarming with shrimp life, so much so that it becomes a serious block to the drainage and the strainers, and as a consequence the pumping-gear suffers. I think the Water and Sewerage Board were of opinion that it would be advisable to introduce a fish that would put a stop to that class of life, and if that were done it would be a benefit to the community. I think the question of stocking our waters with suitable fishes is one that should engage the attention of the Government and the Commission.

James Richard Hill, Esq., a Member of the Fisheries Commission, sworn and examined:—

5814. *President.*] Your name is James Richard Hill, and you are one of the Fisheries Commissioners charged with the administration of the Act of 1881? Yes.

5815. How long have you been a member of that Board? Seven or eight years.

5816. You are not one of the original members of the Board? No.

5817. I understand you have given a great deal of attention to the administration of the Act, and also taken considerable interest in the Department? I have taken a fair interest in the whole of these things, not more than others; if giving proper attendance to one's duties there, and trying to work according to one's lights constitute attention, I have done that. I have done no more probably than others.

5818. Would you call yourself a regular attendant at the meetings of the Board? Unquestionably; I think I have only missed about four or five times altogether.

5819. Does the same reply apply to all the members of the Fisheries Commission? I would rather let every man speak for himself.

5820.

J. R. Hill,
Esq.
1 April, 1895.

J. R. Hill, 5820. Have you attended on occasions when a call has been made, and you have been the only one present? Very rarely; I think such a thing might have happened. I daresay it has happened more than once, and I have gone away immediately it has happened.

Esq.

April, 1895.

5821. Do you know whether it has happened that two members only of the Board have attended a meeting? Yes, frequently.

5822. Has business been transacted on such occasions? No business of importance has been done at such meetings for the last few years, ever since the Parliamentary inquiry. There has been no business transacted, except what might be termed formal business, laying papers on the table, and diaries, and such like, and paying accounts.

5823. Did you give instructions at a meeting composed of two members to ignore an order of Parliament for the production of returns? Never; the very opposite. I should think on all occasions when an order of Parliament came it was filled up and returned with alacrity.

5824. Do you remember a return being moved for by myself in October, 1893, asking for information, and do you also know that that information has not yet been given? I do not know what you refer to.

5825. I will tell you, if you will give me your attention; I will read the series of questions I moved in the House to which I refer:—

MR. FRANK FARNELL to move, That there be laid upon the Table of this House, a Return showing,—

(1.) Which tidal waters in New South Wales have been inspected and reported on by the Chief Inspector of Fisheries or by the Commissioners of Fisheries or by the (so called) Travelling Inspector of Fisheries, or by any officer of the Department located at head quarters.

(2.) Which of the Commissioners, or which officer of the Department, made the inspection (if any) referred to, giving date of each inspection and the result of the inspection.

(3.) How many Commissioners' minutes, instructing the Chief Inspector of Fisheries to visit waters under the control of the Commissioners, are on record.

(4.) How many of those instructions have been carried out, and how many have not.

(5.) The names of all the tidal and oyster-breeding waters that are at present without local supervision.

(6.) If any officer of the Department has been instructed to inspect and report upon the oyster fisheries of the Colony since 1st January, 1890, giving name of officer, and date of inspection (if any).

(7.) If any application for area for oyster culture has been refused since the 1st January, 1890, because there is no officer of the Department located on that particular oyster-bearing water, giving name of applicant and area applied for.

(8.) The possible revenue lost to the country through leases for oyster-culture having been refused to applicants, giving names of applicants, locality, area applied for, and rent payable for the fifteen years under the Oyster Fisheries Act.

[Passed October, 1893.]

That is a return moved for and passed by Parliament. It was sent on to your department for you to fulfil your part. That return has not been forthcoming. I would like to ask you whether any instructions were given, at any meeting at which you were present, that that return should not be complied with? The very opposite. I know of no reason why the return should not be given. I suggest you should call for the books. The books are a faithful impress of what is done at the meetings. Never, under any circumstances, has there been the slightest disinclination to give information asked for by Parliament.

5826. Supposing any member of the Commission gave instructions that that return was not to be prepared, would the Secretary to the Commission be justified in carrying out the directions given him? Certainly not. He would bring the matter before the Board. I do not believe it would be done.

5827. In connection with your Annual Report for 1890, I understand there was a Bill accompanying that Report which was the outcome of some consideration given by the members of your Board;—do you remember the lines on which that Bill was framed? I cannot remember the details of it. We submitted a Bill to the Government which we had given consideration to. Mr. Thompson had taken notes as to various questions and defects, and this Bill was the correction of those defects, and it embodied other things necessary or desirable. A great deal of consideration was given to the Bill.

5828. Did your Commission make any attempts to urge the Government to proceed with the necessary legislation? I think some members of our body—I was not one of the deputation—interviewed Sir Henry Parkes on the question.

5829. And has anything been done as the result of that interview? Not that I am aware of.

5830. Do you consider the provisions of the present Act are all that could be desired? No; I think it a very faulty Act.

5831. Do you think you, as Commissioners, have sufficient power given you to administer the fisheries properly? No; I think the Act is very defective in many points. I think, from recollection, there are many points which are very defective.

5832. In regard to the matter of hauling-nets, or nets generally, do you consider the provisions for the use of nets are satisfactory? No; very unsatisfactory.

5833. Do you think the length of the hauling-net, as given by the amending Act, is sufficient—that is, 300 fathoms? Yes; it is ample for some places. I would not like to say it is sufficient for other places, like Lake Macquarie—probably it is not sufficient for Lake Macquarie—or some portions of Tuggerah. The length allowed by the principal Act, 150 fathoms for a hauling-net, is quite ample for Sydney Harbour and Botany, I think.

5834. As to the mesh, is there room for any alteration? No; not for the hauling-net. It is a very good mesh.

5835. As to the meshing-net, are you satisfied with the length of that? I think there is so little meshing done it is immaterial. The 4-inch mesh is a very good-sized mesh. I think, from recollection, that is a meshing-net.

5836. Supposing it is found necessary to use that net more extensively, can you see any harm in extending that net to 150 fathoms, providing the mesh is retained? My opinion is that the length of the net should be in the hands of the Commissioners, who would have the power then to be able to lengthen or shorten it as circumstances may be. Under existing circumstances that can only be done when the Governor and the Executive Council agree to it; all these alterations are made not by the Commissioners, but by the Government on the recommendation of the Commissioners.

5837. Can you mention an instance where the Government have ever refused to carry out the recommendations of the Commissioners? No; but an occasion may arise where the Government may send a recommendation back to the Commissioners in the case of an agitation arising against the recommendation.

5838. Would it not be better to vest sole control in a body such as you are, rather than to have the interference of the Government, which might mean political influence? Since I have been on the Board political influence has had no effect.

5839. Perhaps it was never attempted? I do not think it has been until lately, but the Commissioners have not moved from their position.
5840. Can you tell the Commission in what way political influence has been attempted? Various members of the Legislature have approached the Colonial Secretary with reference to certain matters, but we have not moved from our purpose.
5841. Was that in regard to the oyster leases? Yes, and other matters; we have not been swayed by political influence, and if all the Members of Parliament in the country were to ask us to close a thing against our determination we would not to be influenced *per se*, because the men were Members of Parliament. We might be influenced by the arguments they used against ours; if they showed us reasons we would certainly take them into consideration.
5842. I suppose you do not object to Members of Parliament being the mouthpieces of individuals who have grievances? We cannot object; but I think it is wrong for Members to be the mouthpieces. I will give a reason: My reason is that the Commissioners will always do what is fair and right, according to their lights, without any outside influence of any kind.
5843. What is your opinion about the garfish-net, as now used? I think it is a very good length—90 fathoms—30 fathoms bunt, and 30 in each wing. I hold the opinion that if the mesh were smaller it would kill less fish; and further, I would not object to its being a smaller mesh. I would take very great care to see it was emptied in the water before it was hauled to land. I have noticed hundreds of very valuable fish—whiting, and small fish of that kind—meshed in the garfish-net. If the mesh were smaller that would be obviated.
5844. Would not that argument apply with equal force to the mesh of the bunt of the hauling-net? Yes; but you cannot well empty all these hauling-nets into the water before you get them to land, and if you apply it on the same principle you would have to bring them down to three-quarters of an inch mesh. They would not use that; they could not haul the net in.
5845. In respect to the prawn-net, is that destructive to small fish? No doubt it is.
5846. Would it be a good thing to discontinue the use of that net altogether? I do not think it would be fair to the consumer. I should confine the use of the prawn-net to very limited areas, as is done now.
5847. Would you like the Commissioners to have power to decide upon what closures should take place, at what time of the year, and so forth? The later Act, I think, gives power, because we have closed prawning. We can, under the "Sunken Nets Act," restrict those nets to certain localities.
5848. Would you like to have discretionary power as to closures for prawn-fishing? I think we have it in the "Sunken Nets Act," the better kinds of marketable prawns are always caught with sunken nets.
5849. On the whole, then, you do not think there is any great necessity for making any alteration in the length and meshes of the nets at present in use? I do not think there is. I would stop the use of sunken nets excepting in those localities for prawn-fishing that are specifically laid down during certain months of the year.
5850. As to the matter of closures, you have had, as a Commissioner, to agree on many occasions to the recommendations for closures in certain parts of the Colony? Yes.
5851. How were you actuated in making those closures—by the reports of the local inspectors? And our own knowledge.
5852. Do you mean knowledge gained by visits to those fishing grounds? Sometimes, yes. Many of us have been up Middle Harbour and Parramatta River, when we have closed it, but principally by the reports of inspectors.
5853. Have you visited Lake Macquarie? I was never there in my life.
5854. Have you ever been at Tuggerah Lakes since you have been a Commissioner? No.
5855. Have you ever visited Lake Illawarra officially? Not officially.
5856. Have you ever visited the Hawkesbury River fisheries officially? No, not officially. I know the Hawkesbury River.
5857. Have you visited Brisbane Water officially? Yes, about two and a half years ago.
5858. Was that about the time of the expiration of the proclamation closing those waters? I forget when it was; I think Dr. Cox, Mr. Campbell, and I visited Brisbane Water officially.
5859. What was the object you had in view in visiting Brisbane Water? To see how much of it could be kept open, and how much left closed. It was about two and a half years ago.
5860. Was there an agitation about that time for the waters to be kept closed? I think there was.
5861. What was the result of your visit? I think the result was that we elected to open certain sections of it. We found it teeming with thousands of mullet.
5862. Did you make your experiments in the day-time, or at night? In the day-time.
5863. Do you know whether you recommended that the whole of the Broadwater and the creeks running into it be closed, and that the entrance be left open? I really forget what we did recommend; the books would show.
5864. I suppose you would not know what portions of Brisbane Water are open or closed now? Not without consulting the books.
5865. In all cases where you have asked an inspector to report on the supply of fish have you acted upon his recommendation? As far as I recollect we have.
5866. So that if an inspector reported that certain waters should not be closed, you, as a Commission, would not be a party to a closure without having made either a personal or another inspection? I do not think we have ever closed waters against the opinion of an inspector, unless we have had a higher authority to guide us afterwards. I think there have been occasions when an inspector has recommended a closure, and we have sent a higher authority to examine, and we have followed the advice of that higher authority.
5867. Are you aware that the Commission have made closures at Lake Macquarie, Tuggerah Lakes, and elsewhere? We have made closures at various places.
5868. What was the object of those closures? To protect the fish; to give them a chance to go to the breeding-grounds. If you allow a net man to fish persistently at the entrance the fish do not get a chance to go up into the breeding-grounds.
5869. Whilst you have done that in many cases, are you aware that you have not carried out that policy in Brisbane Water? Very likely, because it is not suitable for net-fishing.
5870. Whilst those closures might have been justifiable, have you always had supervision over them to protect them? As far as we are able.

J. R. Hill,
Esq.
1 April, 1895.

- J. R. Hill,
Esq.
1 April, 1895.
5871. Are you aware that the closures at the Tuggerah Lakes have been left without supervision, without any control for several months until lately? Every now and again we sent men there.
5872. Are you aware that the fisheries in the Shoalhaven and Crookhaven Rivers have been left uncontrolled? Very likely; we have not the means of controlling them.
5873. Do you mean by not having the means that Parliament has not supplied you with funds;—has any application been made to the Government for funds for the purpose? The Government have absolutely told us they would only give us so much to carry on the work. A year ago we were told our funds were to be cut down to so and so. We had to get rid of a lot of our men in consequence of that.
5874. About how much did they take off? I cannot recollect.
5875. Do you know how many inspectors had to be dispensed with? I cannot recollect; the books will show.
5876. I should have thought that when there was such an inroad as that you would have been able to remember? I have plenty of other things to think of besides that,—that it is my business to think about.
5877. Did that request come from the Government, or was it a suggestion from the Commission to the Government? If it was made by any member of the Commission I never heard of it.
5878. Of course you are aware of the fact that the services of several of the inspectors were dispensed with on the score of retrenchment? No doubt.
5879. Do you know whether any of the salaries were reduced? Yes.
5880. On what basis were they reduced? I cannot recollect.
5881. Do you know whether salaries under £200 per annum were reduced by the Commission? I cannot say, the books will tell you.
5882. You are of course aware of the fact that some honorary inspectors were appointed? Yes.
5883. Did they receive any allowance? Before this reduction?
5884. Yes? If the allowance means salary, I think, Mr. Bayly was allowed forage for a horse for a limited period. Mr. Bayly used to have 10s. per week; that was for a limited period.
5885. Have his services been dispensed with? Yes.
5886. On what grounds? It created a good deal of dissatisfaction that these men were honorary men; they were looked upon as being spies. There is a good deal of difference between a man doing his duty and a man being a spy—that is my impression.
5887. Was there any complaint as to the want of attention to the duties they undertook to perform? I think Mr. Bayly was indefatigable. I do not think I ever saw him in my life, but if you judge by his reports he was indefatigable.
5888. In regard to the permanent assistant inspectors, do you know that some of them are actually in receipt of less money than when they were appointed? Yes; under retrenchment they were cut down; we thought in the interests of the men it would be better to retain their services at the lower salary, so that if times improved, and the Government gave us more money, these men would still have a decent billet.
5889. What is your opinion of the fisheries of the Colony at the present time, as compared with the time of the passing of the Act;—are they improving? They are very much worse, no doubt about it.
5890. To what do you attribute that? Various causes. I think the fisheries of our harbour have probably been interfered with by the deposits of sewage matter, and by the enormous number of line fishermen who catch immature fish.
5891. Amateur line fishermen? Yes; and by the deposit of silt outside the grounds where the fish feed, and also by the steamer traffic. It is within my knowledge that valuable schnapper-fishing grounds outside are now covered with silt that has been deposited there, and if you put a kellick-stone down and haul it up again, you will find a lot of this black mud, and those places used to be clear feeding grounds for the fish. Then again, where one amateur used to go fishing ten or fifteen years ago, there are probably ten or a dozen now, and the schnapper do not get a chance, when fellows in the authorised fishing grounds in the harbour catch 10 or 12 dozen red bream—the schnapper have no chance of growing, because those red bream would grow into schnapper if they were allowed to remain in the water long enough. I am quite satisfied that the amateur fishermen, the line fishermen, do an immense amount of harm to the fishing industry, and I want to emphasise this statement.
5892. Would you license amateur fishermen? I hardly know; I have given no consideration to that question.
5893. Have you paid much attention to the oyster fisheries? Yes.
5894. Do you believe in the system now in vogue under which areas are taken up? I would prefer to lease large areas by auction. It would be more beneficial to the industry.
5895. Would you lease an arm of a river, or a river, or —? I would take a section of a river, and take into consideration its adaptability for oyster culture. I would take a good large section, and give a good man the chance to cultivate oysters properly.
5896. Would you impose a charge, as at present, so much per 100 yards? I would have a minimum, and I would put it up to auction.
5897. What would you think of a proposal for the lessee to pay according to results, and be bound by stringent conditions to work his lease properly? I think the Government might be done that way. They would remove the oysters at all times, and the Government would not get a fair revenue, and the man would take the view that the better he did by his individual effort, the more he would be taxed.
5898. But supposing we were to provide against that by compelling lessees to brand their bags of oysters? They have to do that now, and we know what a trouble it is to get them to do it.
5899. Supposing it could be worked so as to prevent the Government being got at? I think the principle is wrong. For argument's sake, let us say two men take up 1,000 yards each, paying the Government a minimum rental of £10 for 1,000 yards, and they have to pay a royalty as well on each bag of oysters. One man by his individual efforts secures from that lease 1,000 bags. You are going to make him pay a royalty on that. The other man may not get 100 bags, although each water may be exactly alike—that is, you are putting a tax upon energy.
5900. Leaving out the provision as to the deposit, which I never intended should come into this subject, would it not be more satisfactory to lease a large area, or an arm of a river, and have a system of payment by results? I think the principle is wrong.
5901. Do you know whether any of our oyster-beds have been attacked by disease? Yes.

J. R. Hill,
Esq.

1 April, 1895.

5902. What effect has that had on the leases? It has done a great deal of damage, in the Hunter River especially. The oyster disease has been in existence from time immemorial, if you may judge from the oyster shells got inland, which bear traces of the disease.

5903. Have many applications been made to your Commission for the surrender of leases on account of the ravages of the worm? We have had a large number of applications from various causes.

5904. Speaking of the system which has been alluded to in the previous question, do you not think it would be fairer to institute a system of payment by results, rather than to compel a man to pay for two or three years, while his oyster-bed, which has been attacked by the disease, is becoming resuscitated? I think the principle is wrong. A man will not give as much in the Hunter River, where the worm has been, as he would for another place where there is no disease.

5905. But you will admit the Government should receive something for the use of its property? No doubt. I would have a minimum, that minimum to be gauged by the value of the water in the opinion of those who had the gauging of it.

5906. In regard to the system at present in vogue, do you believe in the indiscriminate way in which people are allowed to take up 100 yards of an oyster lease in between larger leases? The Commissioners have set their faces against these 100-yards leases where it is believed they have been taken up for the purpose of injuring other people, and not for oyster cultivation.

5907. You have taken the precaution, believing these areas would be taken up for that purpose, and you would not grant them? The information is given to the Commissioners by their inspectors that certain applicants for leases are night prowlers, who have been taking oysters from other people's leases, and cannot be caught. They want the 100 yards for the purposes of fences, as it were.

5908. Are you not aware that they also take oysters from the Crown lands? Yes; I think one or two have been punished lately for that.

5909. Do you believe in that provision which allows the public to take not more than a peck of oysters from off Crown lands? I think it is abused very much.

5910. Would you allow people to eat what they like, but to take none away? Yes.

5911. Now, in regard to the closures in the Parramatta River and Port Jackson? My opinion is, that if you close it against net-fishing it should be closed against line-fishing also. I am quite satisfied that the line fishermen do an immense amount of mischief, and that very few net men do much mischief. I have watched hundreds of nets being drawn to shore, but I have not seen many valuable fish destroyed. I have heard that such is the case, but I have not seen it. I have, on one or two occasions only, seen little red bream landed. I saw an Italian bring some in once, and I expostulated with him as to the impropriety of what he was doing. Very rarely has it happened that I have seen net men destroy young fish—I am speaking of the result of my personal observation—but I have seen line men catch young red bream ten and twenty dozen at a time. They do mischief to the schnapper fishing.

5912. You contend, then, that not much credence can be given to the statements made that bushels of young fish are seen on the different hauling-grounds? I give the results of my own observation.

5913. Are not sunken nets largely used by foreigners? Nearly all by Greeks and Italians.

5914. Do you know whether the question has been asked of them, when they apply for a fishermen's license, whether they have been naturalised or not? I do not know.

5915. Do you think we should grant a license to aliens? A very broad question is involved in that—it is hard to say.

5916. You refer to one matter which you think acts detrimentally to the fishing grounds of Port Jackson, that is, the emptying of silt within a certain distance of the Heads? I am quite satisfied it is.

5917. Could that be avoided by the punts going further out to sea? Yes; I have seen them empty silt in fine weather miles nearer to the shore than it should be emptied.

5918. What would be a fair distance to take the silt out in order to prevent the destruction of the feeding grounds? Eight or 9 miles at least. There is always a big southerly current in summer time, and northerly current in the winter. It is a scandal that they should be permitted to empty the silt so close to the Heads.

5919. You have had experience in deep-sea fishing? Yes.

5920. Do you know anything about well-boat fishing? I have seen some very fine well-boats in New Zealand.

5921. Did the system work satisfactorily? No; it was a commercial failure.

5922. Why was that? I cannot say; yet they had the proper class of boats from Tasmania, and so forth.

5923. Was it because of the want of a proper demand for fish? Probably it was.

5924. Do you know anything of the system as it is pursued in Tasmania? I have been in Tasmania, but I have never seen the system there. I never examined the well-boats, or went out in them; any knowledge that I have is theoretical.

5925. Would you be surprised to know that the price obtained for live fish in the Hobart market is 60 per cent. more than that obtained for dead fish—that it makes a difference of 60 per cent. to the fishermen? Very likely.

5926. If the well-boat system of fishing is conducted satisfactorily and successfully in other Colonies, is it not quite likely that it would be successful here? I only know it was tried twenty-five years ago here, and it was a dead failure commercially. I think it was tried six or seven years ago, and it was a failure.

5927. Did they take the proper precautions twenty-five years ago to keep the fish alive? I think so, as far as I recollect.

5928. Would it surprise you to know that there are well-boats trading on our coasts at the present time, and that the well-boat system in being conducted profitably? On our coast?

5929. Yes? I was not aware of it.

5930. Do you not think it would be a step in the right direction to get schnapper from the distant fishing-grounds and bring it alive to the Sydney Market? No doubt about it.

5931. Have your Commission ever experimented in trawling? Yes; once or twice we did. We experimented in Botany; we got nothing worth having. Before I was a Commissioner I believe they made other trials outside.

5932. Do you think a sufficient trial was made to warrant a proper trawl survey being made of the coast? I think the coast should be surveyed first, and then you can trawl afterwards.

5933. Did your Commission ever recommend the Government to purchase a proper trawling steamer for experimenting on the coast? No, not in my time. I think we never made any recommendation of that sort.

5934.

J. R. Hill, Esq.
1 April, 1895.

5934. Supposing I show you the recommendation? I do not think so.
5935. I have here the Report of the Fisheries Commission for the year ending December, 1888, would you mind reading the paragraphs I have quoted:—

The Steam Launch.

“The small steam launch now used by the Department is, we regret to say, altogether unfit for the various services she is required to perform, and which, because of her unfitness, are necessarily much circumscribed. In spite of repeated efforts to improve her speed and stability, this launch is still a slow and dangerously unstable vessel; nor can she carry coal or water sufficient for even a short trip to the upper waters of the Hawkesbury. Against a very moderate head wind she is unable to make any respectable headway, and it has been found impossible to bring her from so short a distance as Botany or Broken Bay to Sydney, unless in exceptionally calm weather. She is altogether unequal to any experiments in trawling, except in smooth water, and even then she can do nothing with a moderately heavy beam trawl. She is too small to carry even a dingy on her decks, and her accommodation in wet weather for the single engineer who composes her crew is practically limited to standing room, as her small cabin is generally required as a supplementary coal bunker. We strongly recommend the Minister to direct her to be sold or converted to some other purpose for which, possibly, she may be found suitable, and that a vessel be built for the Department capable of fulfilling the various and, in some respects, exceptional requirements of a serviceable fisheries tender. Such a vessel should be of at least 70 tons (builders' measurement), and should be so designed as to allow of at least four or five days' coal being stowed in her bunkers; to give deck room for two useful fishing boats; to be masted and otherwise fitted so as to provide the means of trawling and shooting drift nets and purse-seines at sea; of allowing ample storage for oysters and fish, and especially for the safe carriage of young fry for purposes of acclimatisation. A high degree of speed would not be necessary. What is of more importance is that the vessel should be a good sea-boat, capable of ensuring a passage to and fro between the home fishing stations, and of providing the necessary accommodation for the services to which she could be devoted so beneficially. Such a vessel could be employed on the ordinary towing and other departmental services when not specially employed on duties connected with the Department of Fisheries.

“Without such a vessel we do not hesitate to give it as our deliberate opinion that none of the important benefits, experimental and protective, expected by the fishermen and the general public from this Department can even be attempted, much less effected, by those upon whom the Legislature has cast the grave obligation of developing the fisheries of the Colony.

“We do not make this recommendation lightly, or without having given due consideration to the cost which the character of vessel indicated would entail; nor have we forgotten that, for reasons given in an earlier part of our report, the Department of Fisheries is no longer self-supporting. But we are constantly being reminded, both in Parliament and in the Press, that much more is expected of the Department of Fisheries than it has yet been in a position to accomplish or even essay, and we are made painfully conscious of the weakness and limitation of our efforts by the nature of the material with which we have to work. In the entire equipment of our Department, feeble and insufficient as it is in many respects, there is nothing which so denotes impotence as the vessel with which we are supposed to carry out the duties connected with the periodical closing of fishing-grounds and the protection of fish for reproductive purposes in waters known to be their natural nurseries, while, in connection with the oyster fisheries, this vessel has never been, and can never be, of the slightest use?”

That is quite right.

5936. It is very clear for all purposes? But it was not intended to be used as a trawler.

5937. I suppose we should be perfectly correct in concluding that your Commission were of opinion that experiments should be made in trawling? No doubt, if we had the means of doing it. I recollect certain places were said to be very good trawling-grounds, and if we had a vessel capable of carrying a beam trawl we should be able to carry out experiments without any great expense; but we had no idea of building a steamer for trawling alone. We wanted a steamer for the purposes of the Department.

5938. Do you think we have fishing-grounds outside that might be trawled over? I would not like to say. We can only tell that by making a proper examination of the coast. The result of the experiments made by the “Challenger” do not show we have any good grounds.

5939. These experiments were made on behalf of the Admiralty? Yes; but she did trawling.

5940. Did the “Challenger” make a complete survey? I cannot say.

5941. Do you know where we can obtain a report of the experiments made by the “Challenger”? At the Public Library, I should think.

5942. Do you remember that some time ago Parliament voted £100 in order to allow experiments being made by your Commission? I cannot recollect it.

5943. However, nothing was done? I cannot recollect exactly the circumstances. If it be in my time it may probably have reference to our requesting the Government of the day to induce the Admiralty to give their opinion about the grounds outside. I think you will find in the archives of our Department that it has been stated that the Admiralty had some very valuable charts which we could get if we applied for them through the then Prime Minister. We did apply through the then Prime Minister to the Admiralty for the charts containing the information with reference to the bottoms, but we never got them. There are some very valuable charts in existence. Mr. Thompson will probably recollect the circumstance. I have a distinct recollection of the Prime Minister of the day being asked to obtain for us some very valuable charts, which gave the soundings and the bottoms right along the coast for a considerable distance. I think we asked the Government of the day to get a survey made from Newcastle to Shoalhaven, so that trawling could be tried. There would be records of this in the Fisheries Department.

5944. Did the President of your Commission ever bring under your notice a proposal to properly equip the “Thetis”? Yes; he did.

5945. Well I may inform you that it was in connection with that, that the £100 was voted. Yes; but I think Mr. Thompson went and examined some boats; they were found unsuitable; I think, before the Commission could go in for trawling they would think it necessary to have charts showing the bottoms.

5946. In regard to the question of fish acclimatisation, do you remember a sum of money, £750 in all, being voted on the estimates for fish acclimatisation? I do not recollect that particular sum; we have had several.

5947. It was for the purpose of establishing a fish hatchery at Berrima—has anything been done towards establishing that hatchery? I do not think so.

5948. The Commission have been the means of distributing a lot of trout fry in various parts of the Colony? Yes; that is so.

5949. As a rule have the reports received from the different districts in which the fry were liberated been satisfactory? My experience of that is that you do not know much about it for years. I have seen a great deal of that sort of thing in New Zealand. Although we turned out fish by the hundreds of thousands the results were not appreciable for years afterwards. I think we should not look for results for years, especially in big rivers like some of the rivers in this Colony in which we have liberated fry.

5950. Still I suppose you have every reason to believe that your experiments have turned out successfully in the Snowy River? If you may judge from the two or three trout that have been caught I think in the

the Snowy River, you may be assured that some of the rivers in New South Wales are admirably suited for that fish. If you will permit me to make a suggestion, I would say that Mr. G. A. Murray, of Mittagong, has done more in the way of acclimatising trout in this Colony than any other person I know of; he will gladly give you any information in respect to the question.

J. R. Hill,
Esq.
1 April, 1895.

5951. You have been compelled, owing to the limited area at your disposal, to liberate the fry at an age when they should not be liberated? No doubt; but if you are going to carry them a long way, the smaller fish will do well.

5952. About the crayfish industry, have you noticed that large consignments of crayfish go to the market? Yes.

5953. I believe they are in prime condition when they are in roe? When it is inside; unfortunately they are brought here for sale when they are in the egg state. When the coral is inside they are best, but when the eggs are outside, attached to the tail, they should not be killed.

5954. Would you favour a provision in an Act preventing the sale of crayfish when in that condition? I would most unhesitatingly. They do an immense deal of harm by taking them in that state. At Broken Bay crayfish used to be found in tens of thousands, but they are almost cleaned out now; it is the same at Port Stephens; they killed them when the eggs were attached to the tail, and they are nearly cleaned out there.

5955. I believe you have paid frequent visits to the Woolloomooloo Market? No; we have nothing to do with the markets, that is a matter for the Municipal Council.

5956. Have you watched the mode of procedure in connection with the sale of fish at that market? I have seen it; but I look upon that as a matter outside of our Act.

5957. Do you think the market is centrally situated for the conduct of business? I think it is a very bad place.

5958. Do you think the system of throwing the fish on the floor for sale is a good one? A very bad one.

5959. Do you think matters might be improved upon by holding two sales a day in the market instead of one? There should be a sale at 2 o'clock or thereabouts, so that people could get fresh fish, especially in the summer-time. In company with some of the Commissioners, I went with a deputation to the Mayor, Mr. Manning, and asked him, in carrying out the design in the new markets to be erected in George-street, to have a place set aside for the reception of fish, a place where the fishermen could retail their fish if they liked, and keep them in a cool chamber. In that way people could go and get fresh fish at any time.

5960. Then you would favour the adoption of some means by which the fishermen could be brought into closer contact with the consumer? Yes, unquestionably; I think it might be done in the George-street markets. They could have a cool chamber in the basement where fish could be kept ready cleaned, and the public could go and purchase when they liked. I do not see why the fishermen should not be able to do what Chinnery does—sell their fish fresh and cool.

5961. Have you ever noticed any shoals of fish on our coast going from the south to the north? Yes; hundreds of times.

5962. Can you tell us what fish they were? Mackerel, bonito, herrings in thousands, mullet, kingfish, salmon, the herrings wider out—much wider out.

5963. The Commission are anxious to ascertain whether it is the true herring that travels on this coast? There is no doubt about it. The people who write about the herring not being on our coast do not understand the question. The herrings are here in thousands beyond all doubt. The week before last I saw a number of boys with a whole string of them in Rose Bay.

5964. Would that be the southern herring? The ordinary herring; on one occasion I was fishing off the South Head, and I caught a big shark there. I disembowelled the shark, and I found between twenty and thirty of the true herring—*clupea sagax*—inside him. That was in recent years.

5965. Do you think these shoals of herrings should be caught and turned into a marketable commodity? I cannot say; I think a herring-net ought to be tried; the experiment ought to be tried at the proper season.

5966. Have you noticed the season at which the shoals of fish make their appearance? Yes, I have; the principal season is about March, April, and May. They have been coming into the market here, I know, during March.

5967. Do you think there is a possibility of a great development taking place in fish smoking, canning, and curing? There ought to be a great field for such an industry if it is properly looked after.

5968. I suppose it simply wants enterprise and practical men to start and carry on such an industry? Yes; enterprise.

TUESDAY, 2 APRIL, 1895.

[The Commission met at the Offices, Bligh-street, at 10 a.m.]

Present:—

FRANK FARNELL, ESQ., M.P., PRESIDENT.

THE HON. R. H. D. WHITE, M.L.C.

The Hon. Solomon Herbert Hyam, M.L.C., a Member of the Fisheries Commission, sworn and examined:—

5969. *President.*] Your name is Solomon Herbert Hyam; you are a Member of the Legislative Council, and one of the Fisheries Commissioners? Yes.

5970. How long have you been a member of the Fisheries Commission? About nine years.

5971. You were not a member of the first Board? No.

5972. During the period you have been acting as a Commissioner have you had a good opportunity of ascertaining the defects in the present Fisheries Act—speaking generally, what would you say of the Act as it stands? I have always held the one opinion, which is, that the Act is, in many respects, defective.

5973. Have you, as a Commissioner, made representations to the Government with a view of having a new Act placed upon the Statute Book? Yes; as one of the Fisheries Commissioners I helped to prepare a new Bill, which was handed over to the Colonial Secretary some two or three years ago.

5974.

Hon.
S. H. Hyam,
M.L.C.
2 April, 1895.

- Hon. •
S. H. Hyam,
M.L.C.
2 April, 1895.
5974. Would that be a Bill which accompanied the Report of the Commissioners in 1890? I do not know. It was sent to the Colonial Secretary with a request that it should be brought before the House as soon as possible, in order to have it passed into law.
5975. Prior to that, had you taken any action to urge upon the Government the necessity for proceeding with legal reform in that direction? I am not certain; I think we did; not in an official way, but we have, times out of number.
5976. And although you made those representations, no good result has followed? While I was a Member of the Lower House I urged the Government to have alterations effected in the Fisheries Act.
5977. During the time you have been on the Commission have its members attended regularly? Well, I can say for Mr. Hill, Dr. Cox, and myself, we have attended regularly. I have never been absent unless through illness or being away from Sydney.
5978. With regard to Parliamentary returns, when a request has been made for the Fisheries Commission to supply certain information, do you know whether the Commission has refused to supply such information? We never refused.
5979. Do you think it is likely that any one member of the Commission would give instructions that returns should not be prepared without consulting other members of the Board? I cannot say. I know I would not. I would rather that the Commission as a body gave instruction than one individual.
5980. In the Report for 1893 I notice the expenditure is reduced to £3,000;—do you consider that sufficient for the proper working of the Department? I think it is totally inadequate.
5981. Do you know whether the Commissioners recommended that the amount should be fixed at £3,000, or did the Government do so? It was done behind the backs of the Commissioners, in this way. Reduced estimates were submitted to Parliament and passed. The Commissioners felt retrenchment was necessary at that time, and we did not offer any strong protest against the reduction, although we felt it would cripple the Commission a great deal by reducing our staff.
5982. Are you aware that reductions in several salaries have taken place? Yes.
5983. Are you also aware that reductions have been made in salaries under £200 per annum? I cannot say. We may have done so; it is hard to remember.
5984. Have the Commission made any application to the Government, asking them to restore the amount formerly granted, in order that the Department might be worked efficiently? I do not think so.
5985. The Commissioners meet once a week? Yes: on Wednesdays.
5986. Have they ever made any official visits to the fishing grounds in the Colony? Yes.
5987. As a body? Yes. Well I do not say the whole of them, but as an individual Commissioner, I visited the inland fisheries in the Bourke district, the Hay district, the Deniliquin district, and the Albury district. I visited most of the southern coastal districts, and I have been as far north as Port Stephens.
5988. Could the visits you made be termed official visits? Yes; I spent a considerable time in the southern districts, and in the north at Newcastle, Lake Macquarie, Tuggerah Lakes, and the Hawkesbury.
5989. Do you usually notify the local inspector of your intended visit? No; I think it better to go incognito. I have met the inspectors there just casually.
5990. Can you tell the Commission of any occasion you have visited the fisheries when another member of your body has accompanied you? Mr. Hill accompanied me to Pittwater on one occasion, Mr. Hill and Dr. Cox to Botany, Mr. Hill, Mr. Campbell, and, I think, Dr. Cox, to George's River.
5991. How long is it since those visits were made? I think the visit to Botany was about four years ago. We went there trawling. We visited Pittwater about three years ago, and George's River about two and a half years ago.
5992. Do you know whether any of your colleagues on the Commission have made official visits to Lake Macquarie, Tuggerah Lakes, Lake Illawarra, and the Shoalhaven and the Crookhaven Rivers? I think Dr. Cox made an official visit to Lake Macquarie and the Tuggerah Lakes.
5993. Are you sure the visit of Dr. Cox to the Tuggerah Lakes was not of a private character, more of a scientific nature, rather than in connection with the development of the fisheries? That I cannot answer.
5994. Do you remember the last occasion you visited Brisbane Water, what was the object of your visit? It was in connection with the opening of those waters. It was objected to by the Railway Commissioners. I went down by train, got a boat, pulled down. My son was with me, and I had conversation with different people there. The result was I think we did the right thing.
5995. Did you visit that place with Mr. Campbell and Mr. Hill? No, I did not.
5996. You do not know who accompanied them? No; I know they went. There were at Kincumber, I know.
5997. What was the result of your visit, and the visit made by Mr. Hill and Mr. Campbell? We were satisfied that the action we had taken in the past was in the interests of the fisheries, and we did not alter any arrangements that had been made.
5998. In regard to these closures, is it not a rule that the Commission shall receive a report from the local inspector before making the recommendation or acting in such matters? Yes.
5999. Do you know whether a report was obtained in regard to Brisbane Water from the local inspector? I think so; I think we acted upon his recommendation. I saw the Secretary for Railways; he asked us not to be too stringent in our rules, if we could see our way to leave things as they were it would prove beneficial to the railways. That was the reason I went down; I told him I would do what I could to sift the matter thoroughly. I think there were other interests involved as well as the fishing interest.
6000. Do you know the closures at present in existence there? Yes; I spoke about it one night in the House when Mr. Pigott moved to bring in a Bill to have the whole of Brisbane Water closed against net-fishing. I combated that, and successfully too.
6001. Do you believe, as a general rule, in closing the entrance to lakes? I do; I think that should be a hard and fast rule; fish are migratory, so that the fish in entering and leaving the lake should not be intercepted. Continual hauling the net at the entrance to a lake would scare the fish away. It is a wise thing to close the entrance to all lakes. Of course I know the fishermen object to it.
6002. Then, I suppose, in order to make a closure thoroughly effective you think it necessary to have good supervision? Quite so.

Hon.
S. H. Hyam,
M.L.C.

2 April, 1895.

6003. Are you aware that on the Tuggerah Lakes the closures have been left without supervision for months and months? Not so bad as that. I know we are very much hampered in consequence of the small number of inspectors. A visit is occasionally paid to the Tuggerah Lakes.
6004. Are you also aware that the Shoalhaven and Crookhaven Rivers have been left without supervision? They are occasionally supervised by Inspector Benson; he is stationed at Wollongong.
6005. Do you think the dimensions of a hauling-net are fair and reasonable? Under certain conditions and in certain waters they are not. I had an amendment inserted in Mr. Edden's Bill; the Commissioners approved of the Bill to a certain extent, and the amendment was that the length of net should be increased on the recommendation of the Commissioners; discretionary power was given to the Commissioners.
6006. As to the mesh of the hauling-net, do you think the bunt proves more destructive than the smaller mesh would be? I have done a lot of net-fishing in my time, and I am satisfied that the prawn-net is the net that does the damage. I think the hauling-net is a fair net.
6007. Have you ever noticed that when the net is hauled to the shore the bunt would contain a great number of compressed fish—small fish that were meshed in it? You will find some, especially the immature schnapper—the red bream. I have found mullet and whiting meshed in it; I have noticed young black bream, but not a great many.
6008. In regard to the meshing-net;—do you think we might fairly allow a greater length for that net? I think there might be a danger in that. The meshing-net will not catch the small fish. In meshing harm is done by frightening the fish away. When the meshing-net is put down a good deal of noise and splashing goes on, to induce the fish to go into the net. I think meshing, under certain restrictions and conditions, might be carried on a little more extensively than it is.
6009. Do you look upon it as less destructive than any other net? Certainly.
6010. Would you have any objection to extending it to 150 fathoms? I do not think I would like to do that. I think, under certain conditions, I would extend it a little more.
6011. Would you interfere with the mesh? I would not make it less than 4 inches.
6012. But are you aware that at the present time quantities of marketable fish escape through the 4-inch mesh? Well, although the fish may be legally marketable it is just as well they should escape.
6013. About the garfish-net;—are you satisfied with the length and mesh of that? Yes; although the garfish-net is destructive to immature fish other than garfish, still I do not see how we are to alter it. I think there is a rule that the garfish-net must be emptied in the water, and if that rule is adhered to the small fish and other varieties are thrown back into the water.
6014. You said something about the prawn-net;—would you discontinue the use of that net altogether on account of its destructiveness? Well, it is such a hard thing to do; prawns are a great delicacy. I think a great many places should be closed against prawn-fishing. What I object to most is the way these foreigners fish. I do not think they are a desirable addition to our fishing population, and they are hard men to deal with.
6015. Do you refer to the use of the sunken net? I do. I have always had a great antipathy to the use of the sunken net.
6016. Would you favour the reservation of certain waters for prawn-fishing, and would you give discretionary power to the Commissioners as to when those places should be opened? Yes; I would.
6017. Do you believe in the retention of that provision which gives the inspector or the informer half the penalty recovered? No.
6018. Do you believe in confiscating fishermen's nets—in taking away their tools of trade for a first offence? I have always been inclined to deal leniently with people for the first offence, and I think the Commissioners have shown a disposition to do that on all occasions. I would always give a man a chance. We have an Act given to us, and we must administer that Act as it is.
6019. Do you think the Oyster Fisheries Act is satisfactory? I do not.
6020. Would you be inclined to alter the system under which leases are issued by the department? I would as regards the area. I would not lease land in very small areas, because my experience is that the man who takes up 100 or 200 yards takes his lease up somewhere adjacent to a man who has a large area. I know of my own knowledge that the man holding the small area does not cultivate oysters, he merely takes the oysters from the lease when he takes it up, and he poaches on his neighbour and on Crown lands. The man who has a large lease is the man who takes the most interest in the cultivation of oysters and looks after the cleanliness of his beds, and, as a rule, he is law-abiding.
6021. Would you support the leasing of large areas, such as the arm or the whole of a river? I would; the whole of a river.
6022. Providing, I suppose, there were stringent provisions as to the proper cultivation of the oyster? Yes; certainly.
6023. Would you be inclined to allow that area to be taken up on the basis of payment by results? I do not think I would, for this reason; a man might neglect his lease, and there might be no result from the lease.
6024. But supposing you had a stringent provision compelling him to work his lease, and power were given to the Commission to cancel the lease if he did not work it properly? I do not believe in it. It is an innovation greatly sought for in other branches of industry, but I do not think it would be a good thing.
6025. Are you aware that the ravages of the worm have proved most destructive in connection with many leases? Yes.
6026. Are you aware that those beds have been rendered unproductive by the worms in some cases for a period of two or three years? Yes.
6027. Are you aware also that although that state of things has existed, and no return has been obtained from the leases, the lessees have had to pay the rent due on those leases? I am aware of that.
6028. Then, I ask, would it not be fairer, under those circumstances, the disease being brought about probably by an act of the Almighty, to make those people pay a certain amount per bag, according to results, than to charge them so much per annum per 100 yards? I look upon it as a dangerous precedent to establish.
6029. Do you think it would be better to submit the whole area to public auction? I think that would not be a bad idea; it would be a very fair thing.
6030. Are you acquainted with the present condition of our oyster fisheries;—are they improving? I am certain they are improving in many respects. Of course, in the Hunter River, I must compliment the
the

Hon.
S. H. Hyam,
M.L.C.
2 April, 1895.

the principal lessee there, Mr. Gibbins, on the way in which he has endeavoured to fight the worm disease. A great many people think this worm disease is new, but I discovered the disease forty years ago in the Shoalhaven. Before now I have dug up some of the kitchen middens, and have dug up oyster-shells which must have been there perhaps 200 or 300 years, and I have discovered traces of the disease in them. When I was in Western Australia they were dredging in Perth water, thousands of tons of oyster-shells, and I looked at some of them and I found this very worm disease had existed in those oysters. The disease is no new thing on the different parts of the coast of this continent.

6031. But there has been an absence of the disease for a number of years, and it has shown itself again? Yes; it is like rust in wheat and other things.

6032. In the Act there is a provision allowing people to go on to Crown lands and take away not more than a peck of oysters for their own consumption;—do you believe in that provision? I would abolish that. It is a thing that can be abused. Let them eat as many as they like while they are on the ground.

6033. What is your opinion generally of the oyster fisheries of New South Wales;—is it possible that all the beds may become resuscitated, and that we may be able to supply ourselves with oysters instead of importing them from other Colonies? I am certain we can do it now. I do not think we want foreign oysters here at all. I do not believe in the system of depositing culch on the beds. I favour the system adopted in France and America, which is tiles, brushwood, and I believe the latest thing is fine wire-netting, and the importance of that is that after the spat fixes itself to the wire-netting the action of the water destroys the netting, and the young oyster is set free without any trouble or labour such as knocking it off the tiles or other substances, which very often injures the oyster and kills it.

6034. The experiments that were made in trying to introduce the New Zealand oyster, were they a success? No; the Commissioners imported some Stewart Island oysters, and we gave them to different people, but we did not experiment with them ourselves. The Stewart Island oyster is a very fine oyster, and I think it belongs to the mud-oyster, or it is allied to the English native oyster. I think it must be very closely allied to that oyster.

6035. Can you say where those oysters were deposited? I cannot say; it is a good while ago. I fancy some were sent to the Clyde River.

6036. Would it be reasonable to suppose that the difference in salinity and density of water would account for the oyster not growing here? Salinity has a great deal to do with the growth of the oyster. Those Stewart Island oysters were taken from very deep water. In 1849 I was in a boat belonging to a whaler at Jervis Bay, and right in the very centre of Jervis Bay they found a fine bed of mud-oysters. They got them in any quantities. They would be in about 10 or 12 feet of water at low-tide. Of course the water is very saline there. I have a theory concerning the presence of those oysters in Jervis Bay. It is this: back from this particular part of Jervis Bay there are a good many little lagoons containing fresh water. Now it is quite possible that the outlet of these lagoons may be in the particular neighbourhood where those oysters were found. My experience goes to show that the oyster does best where fresh water can get to them.

6037. Is that the only instance you know of, showing evidence of deep-sea oyster deposits? I have heard of others.

6038. Do you know if it is a fact that some of the lessees of small areas borrow the bags belonging to the larger lessees, and that if they do not fill those bags from the lease they hold they fill them from Crown lands? I do not know that of my own knowledge, but I have been told it is true, and I have not the slightest doubt it is true.

6039. Have the Commissioners made any experiment in trawling? Yes; I assisted at one experiment made by the Commission at Botany Bay, about four or five years ago.

6040. What was the result? We got a lot of ground-fish of an inferior order and a few soles.

6041. In what depth of water was that? About 16 or 18 feet.

6042. Have the Commission made any actual experiment outside in the offing fisheries? No, we had no appliances; we intended to do so, but found the cost would be too great. I think before anything is done with regard to trawling on our coast a survey should be made of the bottoms to show what grounds are suitable.

6043. Would not an ordinary trawl survey suffice? I cannot say; the Admiralty made a survey, but it was rather incomplete. I think the Admiralty have a lot of ships here which could be very well engaged on such work.

6044. Do you think it is possible that grounds exist off our coast that could be trawled with success? I know there are grounds that could be trawled, but whether successfully or not I cannot say. My impression is that trawling will not be a success in this country if carried out in the daytime, the water is so clear. In dull heavy weather trawling might succeed; I know of extensive grounds—there is the Shoalhaven Bight, and the Bight off Narrabeen, and Manly Bight. A great many of these places could be fished and fished successfully too, and especially the Bight off Lake Macquarie.

6045. Can you see any harm in the Government making an experiment in trawling? Not the slightest; I wish somebody would make an experiment in trawling.

6046. Have you any knowledge of the well-boat system? Yes, I have seen them; the chief fish you can catch on this coast to put into the wells is schnapper, and I am afraid the schnapper is a fish that will not take kindly to the well.

6047. How long is it since you saw a well-boat? Four or five years ago. I have seen them on three occasions.

6048. Do you know there is a process adopted which prevents the possibility of fish knocking themselves about in the well, I mean pricking the fish? When the Dogger Bank fishermen catch fish they prick them; I have not seen it done.

6049. Do you know whether the fish you saw in the well-boats were pricked forward of the ventral fin? I do not know.

6050. Your experience has not been extensive in regard to the use of the well-boats? Oh, no.

6051. If they have proved a success in the other Colonies do you think they might prove successful here? Oh, I think so; I should like to see a well-boat so constructed that the schnapper would live in it a week or two. I think it would be a great thing for the Colony, and a great thing for the fish supply of Sydney. I hold the opinion that the schnapper is one of the fish of the world. I do not think it is possible to beat a good schnapper when it is in real good condition.

6052. Would it not be a great advantage to the consumer to be able to obtain his fish alive? Yes, it would; and I am so satisfied that fish, as we get it now, is so often unfit for use that I seldom eat fish.
6053. Are you satisfied with the manner in which business is conducted at the Woolloomooloo Market? Not by any means, and I am very emphatic in what I say about that—not by any means.
6054. Would you favour the idea of bringing the fishermen into closer contact with the consumer than at present? Certainly I would.
6055. Would you have some improvement made in the method of displaying fish at the market? Yes.
6056. What would you suggest? A deputation from the Fisheries Commission waited upon the Mayor when the new markets in George-street were about to be erected. We suggested a plan whereby the fisherman would be able to take his fish to a cool chamber, and at the same time fish could be kept in the cool and effectively and properly displayed. The consumer could go in and select his fish, and have it sent home as he liked. If that were done the mother of a family, or anyone else, could go and select fish and take it away, or have it sent home. I think fish should be kept in a cool chamber.
6057. Do you favour the system of showing fish upon raised tables rather than of displaying them in heaps on the ground? Yes; putting fish on the ground is a most objectionable plan—a most filthy plan. The tables should be of slate, stone, or marble.
6058. Would you favour more than one sale in the market during the day, or would you keep it open all day? I would have the market open all day. That is one thing I cannot understand. We call it a fish market, and yet fish is only sold there at an early hour in the morning. I would give the fisherman an opportunity of selling his own fish in the open market, and at any time in the day.
6059. Would you favour the establishment of auxiliary markets—that is, taking it for granted we are going to retain the Woolloomooloo Market? Yes; I am in favour of establishing auxiliary markets wherever necessary, in all the big suburbs, such as North Sydney, Balmain, Newtown, Redfern, Waterloo, and other places.
6060. Do you think there is any possibility of a revival of the whaling industry in New South Wales? Well, I give the Commission my own opinion: I do think it is possible that the industry can be revived, and I have thought so for some time.
6061. I suppose you know that the whaling industry was very successfully carried on in this Colony some years ago? Yes; I have seen all the necessary operations for the capture of whales. I have seen the whalers come into Jervis Bay and try out. I have seen vessels catch whales—humpbacks, and black-fish, small whales—in Jervis Bay. I saw two sperm whales about 10 miles off the Heads of Jervis Bay some years ago. I am very glad to see the Royal Commission is taking up the question of the whaling industry. Of course the present Fisheries Commission cannot take it up. It is an industry that could be revived and ought to be revived. Sydney ought to be one of the biggest whaling ports in the world.
6062. You have given some attention to the inland fisheries of the Colony? Yes.
6063. Are you aware that at the present time Victoria reaps great benefit from the Murray fisheries? Yes; I am painfully aware of that. Nearly the whole of the fish caught in the Edwards River at Deniliquin, in the Murray River at Moama, and at different points between Moama and Albury, and the fish taken in the fish-bearing lagoons in that part of New South Wales—and they are pretty numerous—gravitates to the Melbourne market.
6064. What control has the Fisheries Commission over the Murray River waters? The only control that we have is the small closures that have been made, and as to the size of nets and modes of fishing.
6065. Have you not one or two honorary inspectors down there? Yes, we had paid inspectors, but had to discontinue their services on account of retrenchment.
6066. Is it not a fact that there are numbers of fishermen fishing in those waters who reside on the Victorian Border? Yes; that is so.
6067. So that if those people are guilty of any offence against the Fisheries Act there is no means by which the Fisheries Commission in Sydney can punish them? I do not see how we can.
6068. Do you think joint action ought to be taken by the Governments of New South Wales and Victoria in order to take steps for the protection of the Murray River fisheries, so as to prevent the depletion of those waters? Yes, I think so; action should be taken. There should be an agreement between the two Colonies. Something should be done to protect the fish and to prevent the fishermen destroying the fisheries in the way they have done in the past and will continue to do in the future unless some check is put upon them.
6069. I suppose they send their fish to Melbourne because it is the nearest market? Yes; when I was in Deniliquin I saw about forty baskets put into the train at 3 o'clock in the afternoon, and they were in Melbourne at 12 o'clock that night. They go right through; they are never untrucked.
6070. Do you think if the Railway Commissioners were to place a refrigerating car on the Southern Line much of that fish could be brought to Sydney? Yes; perhaps from Albury, Wagga Wagga, and the Darling and the Macquarie.
6071. What varieties do they catch there? Nearly all the edible fishes belong to the perch family—Murray cod and perch.
6072. Do you know what is commonly called the codfish in salt water is identical with the codfish in fresh water? Yes, almost identical.
6073. Is it brought into consumption at all? Yes; I am told it is a very superior fish.
6074. Would it not be possible to introduce the fish found in the Murray and its tributaries into some of the waters in New South Wales that contain no fish life? We have been endeavouring to do this, but the trouble is to get the young fish. We purpose introducing some of them into the upper reaches of the Nepean. It is possible to introduce the Murray cod into waters in which they do not exist now, because they have been introduced into Lake George where they did not once exist.
6075. Then you think something might be made of our inland fisheries—something more than at present? Certainly I do.
6076. Have you ever seen any shoals of fish on the coast? I have; I think I was about one of the first to notice them.
6077. What kinds of fish were they? The fish I know of could be made of great commercial value if proper means of capture were employed—I mean the herring-net. There are shoals and shoals of herrings going along this coast. I think they migrate about March and April. I was outside one time, and I got in the middle of a shoal. They were that thick that we could bail them up with a bucket. The

Hon.
S. H. Hyam;
M.L.C.
2 April, 1895.

Hen.
S. H. Hyam,
M.L.C.
2 April, 1895.

fish I speak of is the *Clupea sagax*. I have seen thousands of what I believe to be *Clupea Nova Hollandia* in the fresh water in the Shoalhaven River, just at the foot of the rapids. That fish is a great delicacy, and would preserve well if they could be caught in any numbers. It is a very widely-distributed fish. The *Clupea sagax* makes its appearance off our coast in countless millions. It is allied to the English pilchard. It could be made of immense commercial value, to my mind. When preserved it is one of the most delicious fishes in the world. I have tasted them preserved.

6078. Would they be the same fish as those frequenting the New Zealand coast? Yes; it is a most remarkable thing; these fish make their appearance on the Victorian coast in about March. They come in in immense numbers, and they migrate as far north as Point Danger; on getting there they strike away to the east. I imagine they go east in order to get back to the coast of New Zealand. They are what is known as the celebrated Picton bloater. I have caught them in roe. They make their appearance in Sydney Harbour occasionally, especially when attacked by sharks, porpoises, or birds. As a rule they do not enter the harbours. They are moving northward along our coast for a period of five or six weeks, in immense shoals. Something ought to be done to capture those fish and turn them into a commercial product.

6079. Then there are the shoals of sea mullet? Yes; that is one of the finest fishes in the world for commercial purposes. It is a grand fish, and quite equal, if not superior, to the best American salmon when canned. It is magnificent eating fish when smoked.

6080. Have you noticed that the maray makes its appearance in great numbers as the sea mullet does? Oh, yes; I fancy the sea mullet, as a rule, breeds in the rivers and inlets, and when it is a mature fish it goes out to sea periodically, the same as the black bream, which unmistakably goes to sea.

6081. I suppose you would be fortified in making that statement in regard to the sea mullet breeding, by the fact that you have observed the fry in the rivers? Yes, myriads of them in all rivers and inlets. I have visited the rivers. The sea mullet is essentially a river fish. I have seen the Shoalhaven River absolutely black with them.

6082. Do you say your statement in regard to the sea mullet applies to the black bream? Yes; they all spawn in the inlets and rivers.

6083. In respect to the schnapper, where do they spawn? In inlets like Broken Bay, Cowan Creek, and in sheltered or partially-sheltered bays, although you will find large quantities of the immature schnapper—the red bream—in the Hawkesbury River and the Hunter River; that is, when the water is not too fresh. I have caught them a long way up the Karuah River, in Port Stephens. I am almost sure the schnapper breeds in the different inlets on the coast. I look upon Port Stephens as a great breeding-ground, Newcastle to a limited extent, and the Hawkesbury River, certainly in the river proper, and in the great creeks which are really arms of the sea, and Sydney Harbour.

6084. When do the mullet and black bream begin to show the migratory habit? The mullet in April, and the black bream generally form into schools about April. The black bream is very prime now.

6085. Speaking generally, would you consider the different species of edible fishes we have off the coast, and in the inland waters of this Colony equal to the best species of fish caught elsewhere? I think, for a climate such as we have, our fish are second to none in the world. I think our fisheries are of great commercial importance. The whole of our fisheries should be developed, and made of great value.

6086. Would you, knowing the qualities of our fish, be prepared to state that it is quite possible to have those fish cured either by smoking, canning, or salting, and for them to be equal in flavour to the fish imported from New Zealand and elsewhere, which is now sold in Sydney? I cannot say. In New Zealand they have colder waters. Many of our fish will can well. The tailer will smoke well, and so will the mullet. I think the whiting could be treated in the same way as the Scotch haddock is treated. The mullet is the fish *par excellence* for smoking, canning, and drying. Schnapper, flathead, and mullet, would can well; and most unmistakably the *Clupea sagax*. That is the fish of great commercial value. We ought to can, smoke, and salt them. They are magnificent. I think our fishes bear favourable comparison with most of the fishes possessed by other countries.

6087. Do you think it would be possible to introduce the salmonoids more freely in New South Wales waters? Yes; I would like to see the result of the experiment at the Prospect Reservoir. Different varieties of trout were hatched there under the supervision of the Fisheries Commission, and they are in trout-ponds constructed by the Water and Sewerage Board; some yearling fish from Ballarat were placed in another pond, and the young fry and the yearling fish are doing well. If the experiment is successful in those waters at Prospect, it shows that we can stock many more of our rivers. If we can rear trout and hatch them there, almost any of our rivers will carry trout. There is another fish which might be introduced into this country, especially in the lakes; I refer to the *Guarami*. It is not a predatory fish, it is chiefly a vegetable feeder. It would be a good thing to place them in lagoons and tanks to destroy the sub-aqueous growth of vegetation. This is a good edible fish.

6088. In regard to crayfish, do you think precautionary measures should be taken to save them from the wholesale destruction that is now taking place? I do; it is a great mistake that the fish should be sold here when full of roe.

6089. Should there be a close season for crayfish? Certainly; they should not be allowed to sell crayfish when in roe.

6090. In regard to the destruction of small fish, do you think amateur line fishermen should be licensed? I cannot give an opinion; but I say the amateurs should be brought within the four corners of the Act, so that you can punish them for taking fish under the standard weight. I unhesitatingly say that, because they may destroy scores of red bream daily, and each of those red bream, if let alone, would grow into good schnapper.

6091. Then you would compel them to return undersized fish? Yes, I would.

The Hon. William Robert Campbell, M.L.C., a Member of the Fisheries Commission, sworn and examined:—

6092. *President.*] You are a Member of the Legislative Council, and one of the Fisheries Commissioners? Hon. W. R. Campbell,
M.L.C.
Yes.
6093. How long have you been a Commissioner? About three years.
6094. Would you call yourself a regular attendant at the meetings of the Commission? No, I am sorry to say of late. 2 April, 1895.
6095. Why have you not attended more regularly? I was put on the Board. I am the holder of a station property which I have to attend to occasionally. Of late I have more work to do up there. I have been more worked during the last three months than previously. I proposed to resign, but they would not hear of it.
6096. I suppose you have made yourself acquainted with the provisions of the Fisheries Act of 1881? Pretty well.
6097. De you consider it satisfactory? In many ways it is not. It does not give sufficient power to the Commissioners to execute any ideas they may have. There is no elasticity in the Act that we can discover.
6098. Do you consider it a liberal Act? No, I do not. In which way do you mean?
6099. I mean liberal to the fishermen as well as to the administrative authority? It is not elastic enough.
6100. Do you know of any provisions which operate harshly on the fishermen? Well, I cannot call to mind any on this special occasion. We have received complaints from the fishermen that they would like the net longer in many cases, the mesh smaller, and some of the closed waters left open for fishing.
6101. During the time you have been a Commissioner, do you know whether any attempt has been made to induce the Government to bring about necessary legislative reforms, as far as the control of the fisheries is concerned? We have drawn up a Bill ourselves. It has been printed and laid before the Chief Secretary, not only of this Government but the last Government. We made certain alterations and suggestions.
6102. Do you complain that you have not had sufficient power given you as Commissioners? I do not make any complaint. I think we have objected to the present Act in many ways.
6103. Has no attempt been made to bring about the necessary reforms indicated by you as a body? Apparently not; I think you, Mr. Farnell, know yourself it is a difficult matter to induce legislation of that kind.
6104. Can you tell me how long it has been found by the Commissioners that the Act is unworkable? Certainly before my time. We have had a meeting about it.
6105. But are you not of opinion that when you found you had a defective Act, and no action was taken by the Government with a view of altering it, that it would have been justifiable on your part to resign as a body? I am hardly at liberty to answer a question of that kind.
6106. Well, personally, would you have followed that course? I admit that I wished to resign, not on account of the Act but on account of the way it was worked, but they wished me not to resign.
6107. Do you know whether at any meetings of your Commission instructions were given to ignore the order of Parliament for the preparation of certain returns? No such thing I am quite positive has been done.
6108. Would it be possible for one member of your Commission to give instructions that certain returns should not be forthcoming? It is most unlikely; it would be most outrageous.
6109. Did you ever have placed before you a resolution moved by me in October, 1893, asking for returns regarding certain matters connected with the working of the Fisheries Department. Do you remember such a resolution having been carried, and it having been submitted to the Fisheries Commission in the usual way, in order that the returns might be prepared by that Department? I do not remember it.
6110. Do you remember if instructions were given to the effect that that return should not be complied with? Certainly not.
6111. Have the Commissioners as a body ever visited any of the fishing-grounds in the Colony? I have attended Mr. Hill at Gosford and Botany, and I have been with Dr. Cox to Port Stephens, and I think nearly all the Commissioners, Mr. Hill especially, have taken great interest in the fishing-grounds. Of course Mr. Ramsay has been ill for a long time.
6112. Have you, in company with other members of the Fisheries Commission, ever officially visited any of the fishing-grounds in New South Wales? Yes. I went with Mr. Hill out to Botany, when the fishermen wanted us to open the waters in George's River, and also when the line men wanted us to close waters at Gosford.
6113. Are those the only two occasions you can remember on which the Commissioners officially visited the fishing-grounds? I am only speaking about myself for those two occasions.
6114. Who accompanied you on the occasion of your visit to Gosford? Mr. Hill and some fishermen.
6115. Who were they—were they the Newtons from Watson's Bay? I cannot say. I daresay he did; men were fishing there.
6116. At whose request was your visit made; I mean who made the request in the first instance? I suppose some of the fishermen.
6117. Was it the Newtons? I do not know; I am not intimately acquainted with any of the fishermen.
6118. Did you open the waters the fishermen desired to have opened in Brisbane Water? I think we did. We closed the waters so as to give the line fishermen a little more liberty, as they considered the fishermen were netting too much water. After seeing for ourselves we closed portions of the waters and opened another portion.
6119. Do you know whether the inspectors reported in favour of the line of action you followed? I am not sure whether our Secretary approved of what we did.
6120. You were bound as Commissioners to make an experiment, in order to ascertain whether the fish supply was exhausted before making closures? We were not bound.
6121. You were bound by the Act to have some grounds on which to make your closures? Yes.
6122. What did you do to ascertain the supply of fish? We sent out inspectors, our Secretary, and we went ourselves. We hauled and were satisfied the closure was required.

- Hon. W. R. Campbell,
M.L.C.
2 April, 1895.
6123. Do I understand that you closed the whole of the Broadwater and certain creeks and left the entrance to Brisbane Water open to net fishing? We left some parts open.
6124. Do you believe in allowing the fish free ingress to a lake? Yes, if possible.
6125. Have you closed the sea entrances to the Tuggerah Lakes, Lake Macquarie, and Lake Illawarra? I think they are not closed exactly; it is to prevent the fishermen fishing right in the mouth of the entrance.
- 6125½. Can you tell us how it is you did not close the entrance to Brisbane Water on the same grounds? No; I cannot give you a detailed account of that. There was a great deal of trouble taken for that Brisbane Water closure.
6126. Do you remember a reduction having been made in the staff of your Department? Yes; when the amount voted was reduced by Parliament.
6127. Was it not the wish of the Commission or some member of the Commission that the estimate should be reduced? I do not understand it that way. The Government reduced the amount for the Fisheries Commission; it went before Parliament, and Parliament approved of it.
6128. Was it the desire of the Commission that the department should be reduced as far as the staff and as far as the expenditure were concerned? Certainly not.
6129. Did you enter any protest as a Commission against the Government reducing your annual grant? Nothing in writing. I think several of us did not think it was the proper thing to do; but as a matter of economy we had to suffer.
6130. Do you remember that at that time Parliament directed there should be no reduction in salaries under £200 per annum? Yes.
6131. Do you not know as a matter of fact that you, as Commissioners, reduced several of your inspectors who were receiving very much under £200 per year? We did. I have no doubt we acted in the best manner.
6132. And although you were deprived of the services of several members of your staff you were content without entering a written protest to the Government? I do not think we did send in a written protest; neither do I think it was necessary.
6133. Is it not a fact that several waters were left without supervision owing to the action of the Government in reducing the amount annually paid to you? We have complained about that. We did the best we could under the circumstances.
6134. Taking the condition of the fisheries at the present time and comparing it with their condition before the Act of 1881 was passed, what would you say of them now? I cannot give an opinion.
6135. Do you know whether the Commission have recommended any additions to the inspectorial staff since the retrenchment took place? I am not certain.
6136. Do you know whether any honorary inspectors were appointed? Yes; one or two.
6137. Did they do good work? Most of them did. We have thanked them for their assistance.
6138. Why are they no longer helping you? We did not think it was necessary.
6139. But as a matter of fact are you not aware there are several waters left unprotected and without any control whatever? No; I am not. Our chief inspector constantly proceeds to all those places.
6140. But he cannot travel sufficiently often to be able to exercise proper supervision over those unprotected fisheries? Quite sufficient.
6141. Tuggerah Lakes were left for six months without supervision;—is that proper supervision? They were never left without supervision for six months or six weeks.
6142. Do you consider supervision means a casual visit of a travelling inspector? Yes; and quite sufficient too with our present income.
6143. Do you know whether the Crookhaven and Shoalhaven Rivers have any local supervision? There is an inspector on the northern side; he occasionally goes there.
6144. How often would you say he has been there within the last twelve months;—would you say he has been there once? Yes, I would; he was down there not very long ago.
6145. Do you know whether there is any supervision over Narrabeen and Dee Why at the present time? I cannot say; I have not been in town for two months.
6146. Was not Mr. Paget Bayly an honorary inspector for those lakes? Yes.
6147. Why were his services dispensed with, considering he was receiving no salary, and was doing good work? We thanked him for what he did, and we did not wish to have his services any longer. I disapprove of these honorary men altogether. I think it is the greatest mistake in the world; an unpaid man is not in the same position as a salaried officer.
6148. Do you think the inspectorial staff is sufficient at the present time for controlling the different waters? It is as much as we can possibly afford.
6149. In respect to all the closures that have taken place since you have been a Commissioner, are you satisfied that on each occasion a report was obtained from the proper officer as to the necessity for the closure? No doubt inquiries were made by the proper officer.
6150. Do you know of any occasions when recommendations of the inspectors have been ignored? I only know of one case.
6151. You do not know of any case in which the local inspectors have recommended a certain course of procedure, and the Commissioners have gone directly opposite to that recommendation? I only know of one case.
6152. Do you allow your Secretary in at all your meetings? Yes.
6153. At all times? Yes.
6154. Have you ever known occasions when the officer of your department, acting as Secretary, has been asked to leave the room whilst the Commissioners have considered certain matters? Yes; when the Secretary's salary was under discussion; that is the only instance to my knowledge.
6155. Would it be advisable to license amateur line fishermen? It would be an invidious thing to do. I think in England they pay a license. I know that line fishermen catch hundreds of young fish and destroy them.
6156. Should we not have legislation to prevent the destruction of undersized fish by line fishermen? I would prevent the destruction of small fish as much as possible, but it is a most difficult thing to legislate upon.
6157. Do you believe in closing waters within a convenient distance of a populated area, to give amateur line fishermen an opportunity of having a day's fishing? Yes; so long as they do not interfere with the genuine

genuine fishermen. I have always advocated that the summer-time is the time we should allow fishermen to fish in Sydney Harbour and places adjacent to Sydney, but in the winter when they can go further afield; they should go elsewhere.

6158. Are you satisfied with the working of the Oyster Fisheries Act? It has not worked very satisfactorily I admit. Hon. W. R. Campbell, M.L.C.
April, 1895.

6159. Would you make any change in the system of leasing areas for oyster culture? I think the majority of them would favour leasing larger areas and put them up by auction, but then you might not get the best men.

6160. Do you believe in that provision allowing people to go indiscriminately on to Crown lands and take not more than a peck of oysters at a time? They ought really only to take what they can eat; let them eat the oyster on the Crown lands.

6161. Do you think that system is open to abuse? It is abused.

6162. In regard to crayfish, do you believe in providing a close season for crayfish? That is one of the things we really do not understand thoroughly about the crayfish. I personally am not very cognisant of the subject. I would be afraid to give an opinion as to how we should legislate to protect them.

6163. Do you think it would be desirable to have a stringent provision incorporated in an Act to prevent the female fish being brought to market when in the berried or coral state? It would be a very good thing indeed; I believe in that unquestionably. There cannot be any two opinions about that. It could be done easily enough.

6164. Have you ever had anything to do with well-boat fishing? I have seen well-boat fishing in Tasmania, where it has been attended with excellent results. The trumpeter that they catch in Tasmanian waters is a very quiet fish, but our schnapper is a wild fish, and he will injure himself when placed in confinement. Fred Want had some in a well-boat at one time.

6165. Did they prick the schnapper? I do not know whether they did. It did not succeed financially, but the fish were very quiet in Tasmania.

6166. Have you ever noticed any shoals of fish passing along our coast from the south to the northward? Yes; in the olden days, when I was on the coast, I used to see large shoals of fish.

6167. Have you ever seen any shoals of the *Clupea Sagax* on our coast? I have seen them constantly.

6168. At what season of the year did they appear? About May.

6169. Do you think they could be made a marketable commodity of? We have not got the population yet. In Scotland every one helps, from the fisherman down to the youngest child. Years ago people tried to get others to enter into the industry, but the difficulty is the high wages.

6170. Have you devoted any attention to the inland fisheries? Yes; on the Macintyre River we have splendid fishing—what we call the bream. Of course we have the cod and the perch. The perch is a splendid fish with the rod and line.

6171. Seeing that Melbourne draws a great portion of her fish from the River Murray, do you not consider it necessary that joint action should be taken by the Governments of Victoria and New South Wales to prevent the destruction of fish in that river? I am sure Victoria would be only too glad to take joint action with New South Wales in the matter.

THURSDAY, 9 MAY, 1895.

[The Commission met at the Offices, Bligh-street, at 10.30 a.m.]

Present:—

FRANK FARNELL, Esq., M.P., PRESIDENT.

THE HON. R. H. D. WHITE, Esq., M.L.C. | L. G. THOMPSON, Esq., J.P.

Mr. Frederick William Smithers, Acting Secretary to the Fisheries Commissioners, sworn and examined:—

6172. *President.*] What position do you hold at the present time? Acting Secretary to the Fisheries Commissioners. Mr. F. W. Smithers.

6173. What position did you hold prior to your appointment as Acting Secretary? Travelling Inspector of Fisheries. 9 May, 1895

6174. How long did you hold that position? From 1889.

6175. How long prior to that had you been in the Department? Since 1882.

6176. Had you had any previous experience in connection with the fisheries prior to your appointment? Yes. I was well acquainted with the whole of the fisheries, from Jervis Bay to Port Stephens, for years before I joined the Department.

6177. In what capacity were you enabled to gain a knowledge of those fisheries? Just for the love of the fisheries.

6178. Your duties as travelling inspector extended throughout the whole Colony? Yes.

6179. Have you exercised your authority in connection with the inland fisheries at any time? No.

6180. Have you, as an inspector, paid any attention to the inland fisheries? No, none whatever; only by putting a few trout in.

6181. Have you ever been instructed by the Commissioners of Fisheries to make visits of inspection to the inland fisheries? No, never.

6182. Owing to the extent of the fisheries of New South Wales, I suppose you would be travelling about during nearly the whole of the year? If I did my duty as I ought.

6183. What salary do you receive as travelling inspector? £220 per annum.

6184. And what allowance for expenses? Twelve shillings per day.

6185. Does that include a railway pass? It is exclusive of a railway pass.

6186. Were you appointed at that salary of £220 per annum? I was appointed as travelling inspector at a salary of £200 per annum; that would be £40 underneath subordinate officers at that time—Temperley and G. C. Benson.

6187. Was your salary made up to the same amount as those gentlemen were receiving? No; up to £220, in order to get out of a difficulty. A junior clerk in the office was getting £200, and an assistant inspector of fisheries was getting £200. It was to give me seniority that I got the £20.

6188. Did you suffer under the retrenchment scheme of the Government? Yes; first of all the Government took 10 per cent. off the £20. 6189.

- Mr. F. W. Smithers.
9 May, 1895.
6189. Did the Commissioners do that? The Commissioners then took off the whole £20. The Government first took 10 per cent. off the £20, and the Commissioners then reduced me by the £20.
6190. Are you aware that Parliament, at the time the retrenchment was made, directed that there should be no reduction in salaries under £200 per annum? Yes.
6191. In connection with the expenses of working the Department of Fisheries, do you think the amount voted by Parliament on the last estimates was sufficient to pay the necessary number of men required to conduct the department properly and successfully? No, far from it.
6192. Do you consider that the salaries received by some of the assistant inspectors are inadequate? I do.
6193. Do you think the fisheries have suffered from want of proper supervision? I do indeed.
6194. Do you know whether it was the act of the Government, reducing the expenditure in the Fisheries Department, or was it owing to suggestions on the part of the Commission that they could work the department on the basis of the amount voted for last year? That I have no proof of; I only heard so.
6195. During your visits as travelling inspector to the different fisheries, have you been satisfied that the inspectors are conveniently placed for the work of supervising the fisheries? No; they are not conveniently placed at all—most inconvenient. We have closed waters on the Parramatta River, and the men who supervise them live at Paddington. At Lake Illawarra the inspector lives at Wollongong, 6 miles from his work. The inspector at Wyong used to live 4 miles from his work; there is no inspector there now.
6196. So that there being no inspector, and the inspectors having their residences so far away from the fisheries, it is quite possible that closures are intruded upon by the fishermen? Yes; they cannot be more than half supervised, and owing to the inspectors not living on the water's edge it does not afford a means of trying experiments.
6197. Have you found all the inspectors in the service of the Fisheries Commissioners practical men? Well, they are quite practical enough, in my opinion, for their duties.
6198. As to the honorary inspectors, do you know why their positions were abolished? Yes; the one at Narrabeen, Mr. Bayly, he seemed to carry out his duty in a haphazard way, and the one at Lake Macquarie, Mr. Gorrick, he was altogether too severe upon the fishermen. There is practically no control over honorary men. On one occasion I wrote to an honorary inspector named Learoyd, asking him to meet me, and he wrote back to the effect that he was going to the Melbourne Cup, and would be back in three weeks.
6199. If it has been stated in evidence that the honorary inspector at Manly had been the means of inducing a number of fishermen to take out licenses, and pay fees to the Government, who had not previously held licenses;—would that be a fact? I doubt it very much.
6200. Is there any supervision exercised over Narrabeen and the other lakes at the present time? Whenever I can spare a man to go down.
6201. How often would they go on an average—once a week? Oh, no; I cannot spare them more than once in a month on an average.
6202. So that we may conclude the department is undermanned? Most certainly it is.
6203. Have any representations been made to the Government with the view of having the staff restored to the original number? I know the Commissioners have applied for the honorary inspector at Port Stephens to be put on a salary, and for the appointment of John Cain as assistant inspector of fisheries at Tuggerah. He will take Tuggerah and Brisbane Water.
6204. Have you, as Inspector of Fisheries, ever made any recommendations to the Commissioners? In what way?
6205. With respect to closures and other matters? Yes; I have often made recommendations as to closures.
6206. Have your recommendations always been acted upon? As a rule.
6207. Are there any cases in which the recommendations of the assistant inspectors have not been acted upon? Yes; one case at Port Stephens, as far as my memory serves me, where it was not done.
6208. Have you ever made any visits of inspection to the different fisheries in company with members of the Fisheries Commission? Yes.
6209. When and where? As to dates I could not tell you. I went trawling with the President and Messrs. Hyam and Hill. I have been to Lake Macquarie with the President, and since that down to Jervis Bay with Mr. Campbell.
6210. Was the visit to Jervis Bay an official visit? He wished to go down on an official visit.
6211. Who accompanied you besides Mr. Campbell? Mr. Pigott and Dr. Blaxland.
6212. Did the Fisheries Commission instruct Mr. Campbell to proceed to Jervis Bay? He told the Board he was going to have a look at the bay as to the facilities it had for sending schnapper to the markets.
6213. How long did he remain there? Friday and Saturday.
6214. Has any good resulted from the visit? He saw practically what is to be caught there, and the means for getting fish to market.
6215. Had not the Commissioners that knowledge before Mr. Campbell proceeded to Jervis Bay? I do not know.
6216. What inquiries did he make? He inquired from Dent about fish transit, and the expense of sending them to Sydney, and inquired as to the proceeds they get for fish.
6217. Has he made a report to the Commission concerning his visit? He told them at the board meeting yesterday.
6218. Were the members of the Commission much interested in getting that information;—was it new to them? No; it was not new to them.
6219. Does your minute-book contain any reference to his visit or to his report? No; it is all verbal.
6220. Can you give us any information respecting the other visits;—what object had the Commissioners in view in making those visits? One was to test the trawl in Botany.
6221. How long ago was that? About six years ago. The Commission also made a trip to Pittwater concerning closures.
6222. Who visited that water? Messrs. Hill and Hyam.
6223. What was the object of the visit? About closed waters.
6224. How long ago was that? About two years ago.
6225. What was the result of that visit? I do not know.
6226. Have they made any other official visits to the different fishing grounds of the Colony? Not that I am aware of.

Mr. F. W. Smithers.

9 May, 1895.

6227. Can you tell the Commission what the members of the Fisheries Commission did on those visits in order to satisfy themselves as to the correctness of their recommendations? I cannot tell what their recommendations were in regard to the visits.
6228. Did they haul a net or obtain local information on the subject of the fish supply? They did at Pittwater—they made inquiries. They worked all day with a net at Brisbane Water on another occasion, and on another occasion Messrs. Hill and Hyam worked all day with a net on George's River.
6229. You are referring to visits made about three years ago? Yes—Pittwater was about two years ago.
6230. What was the result of their experiments at Brisbane Water—did they close more water or did they amend the closure already made? I rather imagine they amended the closure.
6231. What portions of Brisbane Water are closed now? None at all.
6232. When did the proclamation expire? On the 30th of last month. I have instructions to visit the place and report upon it.
6233. You are aware of the provisions of the last closure;—what area did that closure embrace? From Webb's Reef upwards, closing everything from Webb's Reef upwards.
6234. But the main channel was left open, was it not? Yes; it would leave it open from Webb's Reef downwards to the sea.
6235. Where does the fish supply of Brisbane Water come from? At the present moment they are catching fish in waters that were closed.
6236. Are those fish of local production? Yes.
6237. Do you think it is a good thing to leave the channel open, seeing that that channel is the only means the fish have of entering Brisbane Water from the sea and leaving again? No.
6238. Do you believe in allowing nets to be used in any channel forming the entrance to a lake system? No.
6239. If your opinion had been sought you would not have recommended that that closure should have been made? I would not recommend a channel to be left open in any place.
6240. Have you, on the minutes of your proceedings, any record showing that the Commissioners have decided to visit officially any of the fishing grounds? I could not tell you.
6241. Since you have been officiating as Acting Secretary you have had to call the Commissioners together on several occasions? The usual Board meetings; I send out a notice.
6242. Do they attend regularly? At two meetings to which they had been invited a quorum was not present.
6243. Was any business transacted at those meetings? Yes.
6244. Can you give us the dates of those meetings? I cannot tell you the dates.
6245. Was the minute-book sent round for the third Commissioner to concur in what had been done by his colleagues? Yes; I took the minute-book round myself.
6246. Have you been satisfied with the provisions of the present Fisheries Act? No; I never was.
6247. Are you of the same opinion in that regard as you were in 1889, when you gave evidence before the Select Committee of the House, of which I was Chairman? Yes; that is in regard to the Act. You asked me a question then about it. I said, "Burn it, and start a fresh one."
6248. Have the Commissioners of Fisheries taken any action lately in the preparation of a Bill for presentation to the Government? No, there has nothing been done that I know of.
6249. There is nothing on the minutes showing that a Bill has been forwarded to the Government? Oh, yes, that is their old Bill; the Bill that was submitted by them in 1890.
6250. Has that Bill been sent to the Colonial Secretary? Yes; the Colonial Secretary sent a minute on a letter from the Royal Commission, and he wanted some information from the Fisheries Commissioners.
6251. What letter do you refer to? A letter sent by the Royal Commission in regard to leasing no further areas for oyster culture.
6252. So that the Fisheries Commissioners, instead of answering the point submitted to them by the Colonial Secretary, simply sent on the Bill of 1890? It is an open question, if you saw the Bill. The Fisheries Commissioners' minute on that letter reads: "We beg to recommend the Colonial Secretary's attention to the Bill recommended by the Commissioners in 1890, in which their views on this subject were embodied."
6253. Do you know the provisions of that Bill? Yes.
6254. Does it touch the question raised by the letter forwarded by this Royal Commission to the Colonial Secretary? I cannot say.
6255. Does the Bill of 1890 preclude the leasing of further areas for oyster-culture? No.
6256. I take it that the Colonial Secretary wished the Fisheries Commission to express their views as to the wisdom of discontinuing the issuing of further leases for oyster-culture? No; the minute was quite an open thing. You would hardly understand what he did want.
6257. As the letter forwarded by the Royal Commission only referred to one subject, and opened up the question of the wisdom of granting further leases for oyster culture, do you not think it only reasonable to expect that question should be dealt with alone? You had to reply to the Colonial Secretary's minute. He sent a paper up to the Fisheries Commissioners. I forget its exact terms.
6258. Did he not ask their attention to the matter? He asked their views, as far as I can remember. I am not certain of the wording of it.
6259. The Bill of 1890, have you read it? Yes.
6260. Are you satisfied with its provisions; do you consider them satisfactory? Well, taking the Bill right through, it is a vast improvement on the old Bill. Certain alterations could be made with regard to meshing-nets and minor details. The 1890 Bill is preferable to the Bill of 1881.
6261. Do you consider the Bill of 1890 deals properly with the question of the leasing of areas for oyster-culture? I have not given it enough attention to answer that question.
6262. What is your opinion as to the question of the development of our oyster-fisheries? I consider the old Act has almost totally ruined the oyster industry.
6263. In what way? It allowed too much freedom to the lessees. They did as they liked. There were no clauses in it to compel oyster-culture. I will give you an instance. There is Woodward, who had hundreds of areas, and got rid of most of them on the plea of worm-disease, so that oyster-culture could not be carried on.
6264. Do you mean that several of the leases were surrendered. Three parts of them, but when surrendered all the oysters had gone from them.

6265.

- Mr. F. W. Smithers.
9 May, 1895.
6265. Have the Commissioners always accepted the surrender of leases when asked by the lessee? No.
6266. Is it manifestly unjust that the surrender should be accepted in some cases and not in others? Woodward has all his leases surrendered.
6267. Do you remember some cases on the Hawkesbury River where a lessee named Seymour complained of the ravages of the worm disease, and asked that his leases should be surrendered? No; I do not remember that.
6268. You will remember it if you jog your memory—I was with you, and consulted you myself at the time? Seymour's case?
6269. Yes? I do not remember it.
6270. Do you remember summoning Seymour at the Ryde Police Court, and getting a verdict against him for arrears of rent? Yes.
6271. Was it not elicited in evidence, if not at the police court, in another way, that Seymour had applied for the surrender of his leases, and had been refused? I do not remember anything about Seymour having the worm on his leases.
6272. Do you know whether there are papers in existence in the Fisheries Department, acknowledging the receipt of his application to have portions of his lease surrendered, but at the same time refusing to surrender his lease? I do not know.
6273. You got a verdict against this man at the Ryde Police Court? Yes.
6274. Do you remember suing him in the District Court? Yes.
6275. Do you remember what he had to pay in full settlement after the allowance by the Government of one-third? Yes; that was my recommendation—about £43 in all.
6276. So that whilst this man was proceeded against, and compelled to pay this sum, others had their leases surrendered under similar circumstances? Yes.
6277. You have, of course, had something to do with the preparation of the report of the Commissioners of Fisheries for the year ending 31st December? Yes.
6278. Will you explain to this Commission the paragraph under the heading "Official Staff," which I will read to you:—

Official Staff.—To keep our expenditure within a certain limit we did not deem it necessary to increase our working staff, but reduced the number by dispensing with the honorary services of Mr. C. H. Gorrick, Assistant Inspector, stationed at Lake Macquarie, and Mr. Paget Bayly, stationed at Manly.

Can you make that statement consistent with the evidence you have given in regard to the want of supervision over our fisheries? Well, although those inspectors were acting—Gorrick was getting travelling expenses about 8s. or 10s. per day, and Bayly he was getting expenses and also £2 10s. per month for forage.

6279. What was the total amount of travelling expenses these gentlemen received during the whole time of their employment under the Commission? I cannot tell you.

6280. Did it amount to £20? I cannot tell you whether it would amount to £20.

6281. I notice the Commission take credit for having established a fish hatchery and ponds at the Prospect Reservoir in this report; do you know whether there are any fry in the ponds now? Yes; they were there yesterday; Mr. Bloxsome telephoned to me this morning. I am going up to-morrow.

6282. Who constructed the ponds at Prospect? I understand it was Mr. Bloxsome.

6283. Do you not think it would have been much better to have stated that Mr. Bloxsome or the Water and Sewerage Board constructed the ponds at the Prospect Reservoir? No; I do not think so; from what I understood from the Commissioners, Mr. Bloxsome consulted them, and it was a matter between him and the Department; there was a sum of £100 got for it by the Commission, but I do not know how it was spent.

6284. Was any of that £100 applied to the construction of the ponds? I have no idea.

6285. How many licensed fishermen are there in the Colony at the present date? There are seventy licensed fishermen and 329 boats at the present time.

6286. Do these figures show a decrease on 1894? No; they compare favourably with the previous year, that is, up to the present date.

6287. What is the number of oyster leases issued and in force up to date? About 340.

6288. How many lessees are there? —

6289. *Mr. White.*] Can you, from memory, tell me the annual income from oysters and oyster leases? The annual income at present is just under £1,000.

6290. Have you ever calculated what that is per bag for the oysters taken from the beds? No.

6291. Do you believe in the system at present in vogue for leasing oyster beds? No.

6292. What suggestions can you offer in lieu of that system? The same suggestion I made before the Chairman in 1889; I advocate the leasing of larger areas for oyster culture.

6293. Do you believe in letting small areas between different persons' leases? No.

6294. How does that income of just under £1,000 per annum compare with the income received a few years previously? It has dropped down; we were getting over £2,000 for leases some years ago.

6295. Fishing licenses—what is the amount received for them? For this year we have received £350 for fishing licenses up to date.

6296. How much for boat licenses? £329 to the 9th May.

6297. Have you ever gone into figures respecting what the other Colonies are making out of fishing licenses and areas for oyster culture? No, no more than getting a few returns; I have never seen the returns of the other colonies.

6298. Are you aware that the Queensland people get from 4s. 6d. up to 8s. per bag as a return on their oyster-beds? No, I never studied the question.

6299. Are you aware that the income from the oyster-beds in Queensland amounted last year to £4,700? No; I am not aware of that.

6300. *Mr. Thompson.*] You are familiar with the clauses of the Fisheries Act; the 16th section of the Fisheries Act of 1881 deals with the riddling of prawns? Yes.

6301. Well, are you aware that section has ever been acted upon? Never to my knowledge.

6302. Do you think the section is of any use; do you think that in future legislation that section might be expunged? Certainly.

OYSTER CULTURE.

TUESDAY, 30 APRIL, 1895.

[The Commission met at the Offices, Bligh-street, at 10.15 a.m.]

Present:—

FRANK FARNELL, Esq., M.P., PRESIDENT.

L. G. THOMPSON, Esq., J.P.

Mr. Frederick John Gibbins, oyster lessee, Sydney, sworn and examined:—

6303. *President.*] Your name is Frederick John Gibbins; you are an oyster lessee, and carry on business in Sussex-street? 88, Sussex-street.

Mr.
F. J. Gibbins.

6304. I understand you have gone in for oyster leasing on an extensive scale? Yes.

6305. What area of oyster leases do you hold in the aggregate? I have the whole of Camden Haven, and the whole of the oyster-bearing portion of the Hunter River.

30 April, 1895.

6306. How long have you held leases at Camden Haven? I have held some of those leases since 1884.

6307. Were you the first to take up those leases at Camden Haven? No; only a part of them. I purchased the remainder from other persons.

6308. About what area do you hold in Camden Haven? 14,615 yards.

6309. Have you surrendered any of the portions you took up at Camden Haven? Only one portion.

6310. On what grounds did you ask for the surrender of your lease? Because it was perfectly useless as oyster-bearing ground; it was some of the ground that Mr. Woodward took up. He had certain leases at Camden Haven, and I gave him £500 for his interest in those leases.

6311. So that the lease surrendered had been tried for oyster culture, but it proved of no good? Yes; if that particular piece of ground had been higher up the river I would not have surrendered it, but it is impossible to get ballast up the river. Some of the ballast we put out in the main river at Camden Haven, on the banks covered at high-water, is covered with spat, and this spat we chip off and lay it down on the banks, where the ground is always covered with water.

6312. Is that ballast always covered by water? Some portions of it; other portions go dry.

6313. Where do oysters thrive best—in the places which are only partially covered by water, or in places that are wholly covered? The places that are covered are better for oyster-growth than those that are uncovered.

6314. I believe you work your oyster leases in Camden Haven in a systematic manner? Yes, I do.

6315. Do you consider you carry out the proper conditions of oyster-culture? To the very letter, in my own interest. There are more oysters in Camden Haven than in all the rivers in the Colony. I had seven years of waiting and preparing the grounds before I got my returns. I had an oyster spat license, and I went all over the river collecting spat and putting it down on my beds.

6316. Have you many natural oyster-beds in Camden Haven? Yes; they are nearly all natural oyster-beds.

6317. Do you occasionally supply those natural oyster-beds with spat? Yes; some of the natural oyster beds in the main river have increased fully 100 yards in width. Of course, during the continuance of the licensing system they were perfectly denuded of oysters.

6318. In what depth of water are those leases? From about 5 to 12 feet.

6319. Have you any foreshore layings? Yes; we lay a lot on the foreshores.

6320. How do those oysters do? Very well indeed; I have had a lot in the market this year.

6321. Where did you get the spat? From off the banks.

6322. Is the spat subjected to similar conditions when laid down as it was at the place it was taken from? Exactly the same conditions.

6323. Then the only injury likely to occur to oyster layings in deep water is owing to the fact that the spat might have been taken from ground only partially covered by water during the day? Yes; those oysters would not have grown so quickly or so large in the deep water.

6324. How many men have you employed in Camden Haven? We have six men now oyster-getting; we had eight all the season.

6325. What would be the average output of oysters per week from Camden Haven? About seventy bags per week.

6326. Do they all go to the Sydney market? Some go to the Sydney market; about half go to Melbourne.

6327. Do you obtain better prices for your oysters in Melbourne than in Sydney? Yes, sometimes; but the depression in Melbourne has made a great difference. I think my returns from Melbourne would average about 30s. per bag; I have received as high as 70s. per bag from Melbourne.

6328. Is there anything to prevent inferior oysters being sent to Melbourne; I refer to oysters stolen from Crown lands? Nothing to prevent it.

6329. Are there any public oyster reserves in Camden Haven? Two.

6330. About what is their extent? One of 1,200 yards, and the other of 500 yards.

6331. Do you believe in that provision which allows the public to go on to these oyster reserves and carry the oysters away? At Camden Haven we have a different class of people to some of the rivers. It does not matter there, but it does matter in other places. The provision is a bad one where these oyster reserves are in close proximity to settled districts.

6332. Do you see any objection to allowing a person to eat what he can consume, on the spot, on the oyster reserves, without taking any away from the reserve? I do not see any objection to that.

6333. Have any of your beds been visited by disease? Not at Camden Haven.

6334. How do you account for the beds in Camden Haven being free from disease when other beds in different parts of the Colony have been severely visited by the disease—is it through constant working the beds? I cannot account for it in any way. We have different places. Take Port Stephens for instance, where the water is wonderfully pure and good—quite as pure as at Camden Haven—yet the disease exists there. It was reported that Mr. Woodward sent shells to the different rivers. He sent to the Clarence and Cape Hawke, and worm disease might have been carried there in that way.

6335. After dredging your oysters did you return the culch to the water? Immediately after dredging.

6336. You do not subject it to any drying process? No; the men make two hauls, and the oysters are then culled, and the culch is returned to the beds.

- Mr. F. J. Gibbins.
30 April, 1895.
6337. How long does it take an oyster to come to maturity from the spat stage—say three months after laying it down on your beds—in Camden Haven? About four years; it pays you better to leave them.
6338. Have you laid down any New Zealand oysters in Camden Haven? No; I am quite satisfied with the oysters I have there; I do not think there is anything in the world to beat the Camden Haven oysters. I spent £1,000 in buying people out up there.
6339. Now, with regard to your leases in the Hunter River, what area do you hold there? About 18,764 yards.
6340. Are they all deep water beds in the Hunter? All the principal beds are in the deep water; natural oyster beds. That last big flood we had in the Hunter ruined all the oyster-beds on the banks. We have never had any spat set since, that is anything of any consequence.
6341. Have you mangrove leases on the foreshores of the Hunter? Yes.
6342. And it is those leases that have suffered so much from the flood? Yes.
6343. Is that owing to the quantity of fresh water that comes down, and the mud and silt the fresh brings with it? Yes; the stuff settled on the oysters.
6344. The worm disease is pretty prevalent on the Hunter River, is it not? Yes; I have been eleven years fighting it.
6345. It attacks the foreshore leases as well as the deep-water beds, does it not? Yes, it does. I may say that through the intervention of Mr. Thompson, Mr. Whitelegge was sent up to the Hunter to have a look at the oysters. At that time we had great quantities of what we call bankers—oysters growing on the banks. We were laying those oysters down in other places, and Mr. Whitelegge showed us we were replenishing the beds with the worm. On becoming acquainted with that fact, we never laid another bag down.
6346. How long ago was that? About five years ago.
6347. Have you been dependent for the continuity of your oyster supplies on the natural product of the oysters? Yes; if we could only get rid of the worm we could supply the markets of Sydney and Melbourne. During the last four years of my lease under the old system, I took no less than 36,000 bags of oysters off it. That was a lease of the whole of the Hunter River under the Oyster Beds Act of 1868.
6348. Is it your opinion that those beds in the Hunter River would be equally prolific to-day if you could get rid of the worm disease? Yes; but I do not know about Fullerton Cove. There is no worm in Fullerton Cove to-day, but it receives the drainage of all that country at the back of Port Stephens.
6349. I suppose what you mean to infer is that the spat will not set in Fullerton Cove owing to the quantity of fresh water there? Yes, that is so.
6350. The drainage from the swamps has a detrimental effect upon the oysters? Yes.
6351. Have you made any artificial beds in the Hunter River? No.
6352. You have never tried laying any New Zealand oysters there? No, we do not want anything like that; our oysters are sufficiently prolific if they only get the chance.
6353. Were any of the leases held by you in the Hunter River cancelled? Two.
6354. For what reason,—were those leases unsuitable for oyster culture? Unsuitable for oyster culture.
6355. Is the worm the only disease that effects the oyster there? Yes.
6356. Did the worm disease render the beds unproductive for a period? Yes; I may tell the Commission that I have had the beds in the back channel all ready for the men to go to work upon on the 1st of January; they have been covered with marketable oysters, and on the last day of the same month the whole of those oysters have been ruined owing to the appearance of the worm. When the worm is bad the destruction is terrible.
6357. Can you form any idea as to the origin of the worm disease? I work that river, on an average, with nine or ten boats.* The more we work the river, under a careful system of working, the better the oysters become. When the worm is very bad we keep continually dredging and lifting everything that is bad. We put the oysters on the banks on the dry land; we put them there to die. Under my leasing system I work from nine to ten boats. I was strong in giving evidence against the licensing system. There were as many as seventy boats working on the Hunter River at one time. They were oyster-getting, and they cleaned the beds right out.
6358. Did you give that evidence before the Commission appointed in 1880? Yes; I did.
6359. Do your men return the cultch to the water in the Hunter? Yes; we are as careful of it as if it were sovereigns. We scatter it about all over the beds.
6360. Do you think it possible that the disease would be in some of that cultch, and that in returning it to the beds you are actually propagating the disease? No; the disease is very trifling. Mr. Whitelegge says it will all disappear some time or other.
6361. Do you believe in the present system of leasing? I do not.
6362. Would you favour the idea of leasing the whole of the river, or an arm of the river, instead of permitting persons to take up areas of 100 yards in extent here and there? I would.
6363. How would you provide for the State obtaining a proper return for the property so leased? I would be quite agreeable to pay a rental.
6364. Do you think it would be a good idea to let a given area, subject to certain stringent conditions as to proper working, and being, of course, subject to proper supervision, and allow the lessee to pay so much on every bag of oysters he took off the lease, rather than pay so much per 100 yards;—would not something like that meet those cases in which the worm disease has proved so destructive? Yes, it would; it would have suited me exactly on the Hunter.
6365. Do you think, speaking from your experience—and you have spent a considerable amount in the development of the oyster fisheries—that system would be fairer than the system under which you have been compelled to work? Well, I am in hopes of taking 2,000 bags of oysters from Camden Haven next year, and if I am to be under a bag rental it may come heavy. If I do not get a renewal of my leases, I shall be a very heavy loser. I have spent money for seven years in Camden Haven and had no return.
6366. But do you not think the system I have outlined would be fairer than charging at per 100 yards every year, especially if the leases are attacked by the worm and those holding the leases get no return from them—of course I am speaking generally;—do you think it would encourage people to go in for oyster-culture in a systematic manner? I think it would do away with the indiscriminate selection of leases and with oyster-stealing. I would rather have 100 yards of a good dredge oyster-bed than 1,000 yards of a bank. It would be more profitable.
6367. I understand you favour the leasing of large areas? Yes; in the interest of the country.

6368.

* NOTE (on revision):—This work was under the Act of 1868. At the present time I am working with an average of three boats.

6368. Then I ask you would it not be fairer for the lessor to pay by results? If the leases are held in large areas there will be a different class of people in the business. No one could object to the proposed system you have outlined, because the greater the number of bags of oysters you get the more you pay. It would be better for everybody. Nothing could be more just than the system as described by yourself.
6369. I suppose it is simply your present position in respect to the suggested system which would make it unsuitable to you individually? Yes; providing it is the intention of the Government to make any Act retrospective in its effect.
6370. What is the balance of your lease on the Hunter? In 1896 I apply for the renewal of my leases. I have from four to eleven years still to run in the Hunter and about the same in Camden Haven.
6371. Do you employ any artificial means for catching spat on the Hunter River? No; there is no occasion; it is a most wonderful place for spat-setting. I think spat sets nine months out of the twelve. We had some of the most wonderful sets of spat ever known last winter.
6372. That is unusual, is it not? Yes, in June and July—it was winter.
6373. Which do you consider the best waters for oyster-breeding in New South Wales? The Manning River and Camden Haven. I believe Camden Haven—I do not say this because it belongs to me—to be the finest oyster-bearing ground in the whole of the colonies.
6374. Do the Camden Haven oysters carry well? Yes, excepting at about Christmas time. At that period we always look for an enormous spawning time; then the oyster does not carry well.
6375. Have you come across any deep-sea oyster deposits? No.
6376. Is it reasonable to suppose that there are deposits of oysters in the deep sea? It is quite reasonable.
6377. As to the size of a marketable oyster, is that satisfactory to you? In our own interests, yes.
6378. I suppose your men have instructions as to the regulation dealing with the sending of under-sized oysters to market? Yes; every man's bags are branded.
6379. Have you any reason to suspect that oysters have been stolen from your beds? Yes, I know it. A fortnight ago I prosecuted two men for oyster-stealing in the Hunter.
6380. Were they stealing oysters for gain? Yes; and they were convicted.
6381. What were they fined? One man was fined £5 and costs, and the other £4 and costs. Those men do more harm in one day than my men would do in three months. They carry everything they lift ashore. They have done so much harm that I keep a man on the Hunter River in a boat constantly watching the leases night and day so as to prevent thieving.
6382. Is there no local inspector there? No; if I had not put a man to watch, all my oysters would have been taken.
6383. Then you have to pay for your inspector as well as pay your rent? Yes, I have. I am anxious to get the Hunter River right; I want the Commission to give me the whole of the river. There are men now applying for small leases, and if they obtain those leases I am done.
6384. Will you explain what you mean by that last statement? Well, if those men are allowed to take up 100 yards or 200 yards alongside my lease, they would be on that lease after a time; in point of fact, I should have to employ a man to watch each of my leases.
6385. If the whole of the river were leased to you no one would have a loophole or an excuse to get on your leases? Yes, that is so; I have applied for 500 yards in the back channel of the Hunter.
6386. Do you know whether the Fisheries Commissioners, or any member of that body, have visited your oyster fisheries at Camden Haven officially? No.
6387. Have they ever visited your oyster fisheries on the Hunter River? Not to my knowledge. If they had been there I should have been only too pleased to have given them every assistance.
6388. Respecting the administration and control of the fisheries of the Colony, do you think a change might be made with good effect? I think so.
6389. Is it your opinion that the present Fisheries Commission have shown that interest in the fisheries that was expected of them? I do not think they have had power enough. I have been to Mr. Thompson to have simple matters dealt with, but he has not had the power. It would be better if more power were given those men. They have done all they could, but the thing has been a farce. If men are to carry out an Act like that they should be paid for their work.
6390. Would you favour an alteration in the administration—would you favour the appointment of a practical man to control the fisheries? Yes; that would be a step in the right direction.
6391. Do you think it should be the duty of that gentleman to pay periodical visits to the different fisheries? Yes, I do. Whoever he may be, he should know as much about my fisheries as I do, and if I am not doing what I ought to do I should be made to do it. If such a state of things could be brought about there would be a great difference in the fisheries of the Colony to-day. The fisheries should be regularly inspected, and the head authority should be ready at all times to advise upon important questions.
6392. *Mr. Thompson.*] How do account for the occurrence of the deep oyster beds? At Camden Haven I have a lease where the pure sea-water breaks right in on to it; the oysters grow magnificently there. There seems to be a continual intermingling of fresh water with the sea water. There is a place called the Half-tide Rocks, on the Brisbane Water Bar, and oysters grow wonderfully there. I think the deep-water oyster beds occur where there is a proper intermingling of fresh and salt water.
6393. I suppose that would be water oozing up from the floor or bottom of an estuary and mixing with the salt water? Exactly.
6394. What is the difference between the rock oyster and the drift oyster? There is no difference whatever, it is all the one spawn.
6395. Do you know whether the spat of the drift oyster is heavy and does not float like the spat of the rock oyster? Yes; it is not so heavy.
6396. Then, I suppose the difference between a foreshore oyster and a deep-bed oyster is simply this, that the foreshore oyster is the spat from the deep-water bed which escapes and floats on to the foreshore? Yes.
6397. Have you ever cultivated foreshore beds from spat obtained from deep-bed oysters? I have tried the experiment on the Hunter, but they died.
6398. Do you think that the young spat from a deep bed will grow and thrive on a foreshore? Yes.
6399. As to aliens,—Italians, Greeks, and others,—would you refuse a lease to an alien until he had taken out letters of naturalisation? Most certainly I would.

WEDNESDAY, 22 MAY, 1895.

[The Commission met at the Offices, Bligh-street, at 11 a.m.]

Present:—

FRANK FARNELL, ESQ., M.P., PRESIDENT.

L. G. THOMPSON, Esq., J.P.

Mr. Peter John Baalman, oyster lessee, Sans Souci, George's River, sworn and examined:—

- Mr. P.J. Baalman. 6400. *President.*] What is your name? Peter John Baalman.
6401. Where do you reside? At Sans Souci.
6402. Are you a holder of any oyster lease in the Colony? Yes; 1,000 yards in George's River.
- 22 May, 1895. 6403. How long have you held that lease? From June last. The application was in six months before that.
6404. Did you take the lease up with the view of working a natural oyster-bed, or for the purpose of artificial culture? Both; to assist the natural facilities of the natural growth.
6405. Have you had any return from the lease since you have taken it up? Yes; I have taken some off, and notified the same to the authorities.
6406. What number of bags have you taken off your lease since you have held it? I cannot say for certain, between thirty and forty.
6407. Are they a good class of oyster? Yes; they will be as good as any in the country when they have had time to grow. When I took the lease it was skinned out by the pilferers.
6408. Have you had any previous experience in oyster-culture? Not personally; not in my own interest. I have seen plenty of it both here and in Boston, United States. I did not grow oysters there. I saw a great deal of it by my own casual observation.
6409. They systematically enter upon the matter of oyster-culture there, do they not? Yes; it is a great many years ago since I was there. They will only allow oysters to be taken off the beds when they have done spawning. The seasons for spawning here are different.
6410. Do you think the oyster has a certain season here for spawning? No; they spawn pretty well all the year round. They get into a certain condition and then they spawn.
6411. Have you noticed any disease in your oyster lease? Yes.
6412. What is it? A blister forms in the shell.
6413. What do you think is the cause of it? A worm.
6414. Have you found the worm under the blister? Yes.
6415. What created the blister? This worm gets in, draws mud in, and the oyster forms a thin layer of shell over it. I have seen very strong evidence of it.
6416. Have you thought out the question of finding some means of eradicating that disease? I think the only plan is when you drop across a patch which has the disease, to clear that patch out—to work it well, and to take away all the oysters. We find the disease mostly below the low-water mark, at half-tide it is not so bad.
6417. Where the sun has an influence upon the oysters the disease is not so bad? No; the deep-channel oysters are the worst. Three or four years ago a man was diving who had to give up all the deep-water beds on account of the disease. He shifted some of the channel oysters into shallow water to see if that would cure it, but it only spread the disease.
6418. Do you think the disease in the foreshore oysters came originally from the deep beds? Yes.
6419. Have you any deep beds in your lease? No, all foreshore.
6420. Are they mangrove oysters? Yes, all mangrove oysters; we pick the spawn off the mangroves and lay them on the shallow parts of the lease.
6421. Is that above low-water mark? Yes; they dry nearly every tide.
6422. Have you provided any means for catching the spat from your lease? I tried by placing oak-limbs with the leaves on.
6423. Did that answer? I have not seen any good yet.
6424. Has any spatting occurred since then? I think they have spawned two or three times, but not any large proportion of the spat has fallen.
6425. Where do you send your oysters to for purposes of sale? I have not taken many off, I have a boat-letting establishment and sell a good many locally. I have sent a bag a week for the last ten weeks to a place opposite the Cathedral—Woodward's.
6426. Were they free from the disease? Yes, you might get one diseased in a bag.
6427. Are there any other leases close to you? There is one opposite me, about a mile across the bay.
6428. As to the system under which the leases are granted, do you approve of it? Not the present system.
6429. Will you give us an idea of what you think would be a good system? I think it would be better for both the lessee and the country to lease larger areas at a reduced rent, and charge a substantial royalty per bag, it would give the *bona fide* lessee a sort of protection.
6430. Suppose that a lessee did not work his area, but left it, the Government would get no return at all in that case, how would you provide against that? I never thought of that; I hardly think a man would take up a lease without working it.
6431. Would you consider it a very proper provision, if oyster deposits were leased in this way, to insist upon the lessees taking the marketable oysters off, as they grow, subject to forfeiture of the lease if they did not do so? Certainly, there would always be a charge made for the land they took up, and it would not be altogether a loss to the Government or to the lessees if they did not work it. It is only mature oysters that throw off spawn, and where they have been skinned out there is no spawn floating about. It would not pay a man to have an oyster lease and pay for it and leave it at the mercy of the pilferers.
6432. You believe in the abolition of the practice of allowing small leases of 100 yards to be taken up? I do.
6433. Do you agree with the provision which allows people to take oysters from Crown lands for their own consumption being abolished, would you only allow them to eat whatever they can consume on the place? Yes; that is the only protection you can have to abolish the 15th section. They can have fifteen or sixteen

sixteen bags and the inspector comes along and they say they are for their own use, and I have known them to have stamped bags so that they could be identified. I also believe in a substantial license fee being paid by everyone who sells oysters. I would also like to see the size of a marketable oyster increased.

6434. What should be the size of the oyster? It is hard to say, I think the ring should be 2 inches; I think that is small enough. The ring should be increased from $1\frac{1}{2}$ to 2 inches.

6435. Are the oysters in George's River of rapid growth? Well, I have noticed at times they grow remarkably fast; you see them sometimes with a growth of one and a quarter inches long, which they make in a week, particularly just after a long drought and then a fresh.

6436. Have you put any layings down of other oysters, besides the locally produced oyster? A few by way of experiment.

6437. What kind? Some from Camden Haven.

6438. How did they do? I have not looked at them yet. I also tried a few New Zealanders, and a few Port Hackings, but I cannot say what the result is yet.

6439. *Mr. Thompson.*] Have you told the President what means you would adopt for eradicating the disease? I cannot think of anything but to take away all the oysters from the diseased patch—clear them right out and let them perish.

6440. And would you lay them down again as cultch? No.

6441. Would there be any harm in doing so? I would not run the risk.

6442. If you are going to take away all these oysters, how do you propose to supply your beds? We could lay down the New Zealanders.

6443. Where do you think the oysters originally come from—the open sea? No.

6444. Where do they come from? The bed of the river. I have had some experience of oysters at Torres Straits; you get a nice shell, but nothing in it; they only produce the shell, there is no fish worth mentioning.

6445. How would you account for the occurrence of oysters at Lake Macquarie, at the channel entrance? They are in the sea, I think, every kind I know of, a bit outside the Heads, and if you could bring the oysters into the river-beds they would improve.

6446. Then you do think the oysters come from the sea? They might have come from the various kinds of pearl oysters.

6447. Do you think these pearl oysters are on our coast? I can bring you some shells that came from Port Hacking.

6448. Would it not be possible that these oysters that you have on your lease might be the produce of oysters from the sea? It is possible; I have found them on various reefs and islands.

6449. Is there anything else you would like to say to the Commission in respect to the oyster fisheries? Try and give us a little protection, we have none at the present time, A man can get on my lease, and I have to catch him before I can prosecute him. I must catch him on the lease.

THURSDAY, 30 MAY, 1895.

[The Commission met at the Offices, Bligh-street, at 10.30 a.m.]

Present:—

FRANK FARNELL, Esq., M.P., PRESIDENT.

L. G. THOMPSON, Esq., J.P.

Mr. Henry Woodward, oyster merchant, Sydney, sworn and examined:—

6450. *President.*] Your name is Henry Woodward? Yes.

6451. You are a resident of Sydney? Yes.

6452. And have been for some considerable time? For forty years.

6453. How long have you been engaged in connection with the oyster business? For thirty-five years.

6454. For how long a period have you held leases? For about twenty-four years.

6455. Do you hold any leases at the present time? Yes.

6456. Where are they situated? At the Manning, Cape Hawke, Port Stephens, and the Clyde. I hope this Royal Commission will go and see Cape Hawke.

6457. What area do you hold at the Manning? I think about 8,000 yards.

6458. What extent do you hold at Cape Hawke? My rent for that place amounts to £130, that would be for 13,000 yards.

6459. What extent at Port Stephens? I have only got 2,700 yards there.

6460. What extent on the Clyde? I have a great deal there, the rental is £140—that would be for 14,000 yards.

6461. Have you held the lease on the Manning for any length of time? Oh, yes! ever since they were granted under the last Act. I took up many leases which were cancelled on account of the non-payment of rent, and as fast as they were cancelled I used to apply and take them up.

6462. Where did you direct your attention to first in regard to leasing? I was in a large way of business as a merchant when the Act was first passed to give leases, and could see the benefit to be gained, and with two others immediately applied and got five rivers.

6463. Was that under the old leasing system? Yes.

6464. In connection with the present system of leasing, to what river did you direct your operations first? I made applications on nearly all the rivers simultaneously before the Act was actually passed.

6465. So that in connection with all these leases, the Manning River, Cape Hawke, Port Stephens, and the Clyde they were simultaneously applied for? Yes; not in the areas I have now, but for large portions of them.

6466. Do you visit them personally? Oh, yes! I was for thirteen months at one time at Cape Hawke straight off.

6467. Which waters have proved, to your mind, the best for the growth of oysters? Cape Hawke for the growth, but not for the quality.

6468. Where are the best quality grown? At the Manning River—there is a difference of 5s. a bag in the value.

Mr.
P.J. Baalman.
22 May, 1895.

Mr. H.
Woodward.
30 May, 1895.

Mr. H.
Woodward.
30 May, 1895.

6469. I suppose you brought all the oysters from your own beds into consumption through the agency of your shops? Well, I supply the other shops in Sydney, and have been doing so all along. I have no shops of my own.

6470. In connection with the lease on the Manning, have you had any difficulties to cope with in the way of disease? Yes.

6471. What was the nature of it? In a lease I have, No. 1521, two or three years ago I noticed that there were a number of the oysters full of the disease. I at once telegraphed to my manager to strip that bed completely naked, and the manager, after searching everywhere, found the disease was confined to one end of the bed. It was only to be found on the north-east corner of the bed, and from that day to this we keep that portion of the bed stripped of oysters, and also a little way outside of it, and the disease has never spread at all since adopting that course. I have acted exactly in the same manner as if treating diseased cattle, and this has kept the disease down.

6472. Do you think the disease was brought about by natural circumstances, or was it conveyed there? By natural circumstances. The disease is in all the oyster fisheries in the world. It is attributed to a worm, and it is to be found everywhere little or much.

6473. There is a worm, is there not? It is my opinion that the worm is not the cause, but that it is the consequence of the disease. Professor Haswell tells you, in regard to Sydney Harbour, that in piles and beds of shell, or anywhere where mud accumulates, is the home of this worm. It is all over the world. The worm lives in this foul mud, and it is my opinion they enter the foul mud in the oyster shell as they do on the piles and stones which is their home.

6474. You do not agree with Mr. Whitelegge's opinion that the worm enters the oyster and exudes the mud? I do not believe it. When the disease was bad we could get thousands of oysters with no worm in them. It was only in rare cases you would get the worm. You would have to search amongst a great many diseased oysters to get it. I have experienced every stage of the disease, from the beginning to the very height of the disease.

6475. You favour the idea suggested by Sir Henry Thompson, which Professor Huxley speaks about, that "the leucodore drives burrows into the shell, and lives in them without any evil intent towards the oyster, but the burrows fill with fine mud, and this, spreading into the vacuities of the shell, gives rise to inky patches, which look unpleasant when the oyster is opened, and damage its commercial value, though, as I can testify, the flavour of the oyster is no wise impaired;"—is that your view? Yes; of course it is.

6476. Have you been visited with any other disease or agency by which your beds have become destroyed or injured? Yes; by floods. The last few months we have suffered at the Manning. We have lost the bulk of the oysters down to 4 feet of water. It is only a question of time, if the rain falls long enough, the oysters cannot live in fresh water, and as the water gets fresh lower and lower down it kills the oysters as it settles on them. It takes a long while for the fresh water to get to the bottom. Even after heavy floods we can get oysters salt. When they were talking about damming the George's River I was reading an account of how many years it would take, with all the rain that fell, to make the water above the dam perfectly fresh. It was a good many years. No matter how bad the floods, you can get the oysters as salt as ever they were, which proves the water has not penetrated down below as yet. At Cape Hawke you will see 20,000 sacks of oysters, and I shall be very pleased to hear of the Commission going there.

6477. Taking your experience of the Manning River oyster-beds, you appear to have coped successfully with the disease? I have done so at Cape Hawke and in the Clyde also.

6478. Have you any disease in Port Stephens? It has killed the fisheries right out. I have attempted to cultivate again, but they all died. The condition of the water is not suitable for oyster life, and the worst of it is that it is the only winter fishery we have in New South Wales. Of course, this is with reference to the deep-water beds, not the foreshores—they are only bankers.

6479. What is the yield you had for the year 1894 from the Manning and other fisheries? About 1,300 from the Manning, 1,900 odd from Cape Hawke; I really cannot tell you how many from the Clyde;—I should say about 500, and a very heavy crop is expected from that river next season.

6480. You have not had any from Port Stephens for the last eighteen months? No; not for seven or eight years.

6481. In connection with the leases at Port Stephens, have you asked for them to be surrendered? I have surrendered a good many. I paid the rent for years, but could get nothing from them, and the Commission have accepted the surrender of a good few of them.

6482. Have you tried the experiment of laying down New Zealand oysters? Largely.

6483. How did they succeed? They were no good at all. I have paid as much as 14s. a bag for New Zealand oysters. I sent 2,000 or 3,000 sacks to my fisheries when I was first trying to stock them.

6484. Can you account for their failure in reproducing? Well, the waters would not produce anything themselves, not even natural oysters in the river; see the years we were without oysters from the Manning and Cape Hawke.

6485. It was not by reason of the unsuitableness of New South Wales waters for a New Zealand oyster? The water was not suitable for oyster life during that time.

6486. When the water is suitable, do you think a New Zealand oyster would grow and propagate? I sent 30 or 40 sacks to my manager, Mr. Guyler, last year, and lost them all this season.

6487. You think that the New South Wales waters are not suitable for New Zealand oysters? I do not think they are suitable for any oysters that are imported; you can get authority for that from many works. If you want an oyster to live you must put it back in the water within a few hours; if they are out of water too long they get weak, and it is only a question of how long it will be before they all die. In England it is just the same;—they must get the spawn in the water as quickly as possible.

6488. Have you suffered at all from pilfering on your beds? I have; but I never take any notice of it. I have got the best bed for rearing a good quality of oyster that there is in Australia, and I doubt if there are any better in England. I have paid rent for it for twelve years, and have never had any returns from it. It is the Bar bed at the Manning. It produces the finest oysters, but it was destroyed by successive floods twenty-two years ago, and it has taken the whole of that time for the mud, trees, and stones that settled on it to be washed away again. There were 150 yards of oysters last year set in along the shore, but the settlers took them all away. We got another lot this season, but I expect they will all disappear again; the bottom is of clean jap stone. They used to smuggle oysters there at one time; five or six men would fill a ketch up in the night; there are now 150 yards of it stocked, but who is to look after it.

6489. As to the system of leasing at present in vogue, do you approve of the way in which people are allowed to take up these small areas? No; they cannot do any good with them.

6490. By their taking up the 100-yard leases it is like a practice of indiscriminate selection? If a man gets these small leases he will keep on shipping oysters from years end to years end, but they never come off his ground, but who is to stop him; it is quite a common thing.

6491. And it is not alone the leases that suffer from the depredations of the men that take up these small areas, but also the Crown lands? Yes; they live off them, either off the Crown lands or the leases; they have none of their own. Down at Moruya a man we all knew was supposed to live on stealing oysters for years; the Crown lands suffer just the same as the lessees.

6492. Will you give us an idea of what you think would be a good system to have enacted? There can be no system without supervision that I can see.

6493. Would you propose any departure in the manner of leasing, and as to areas, &c.? Yes; the areas leased are too small. I made suggestions to Sir Alexander Stuart, and submitted a map on which I had marked off large blocks in the Manning River, which I considered would be suitable areas, but he considered he could do better by letting leases along the shore to twenty or thirty people, where, in reality, there should be only one; if a boat were caught then on a block it would be no good for the man to say he was getting oysters off Crown lands; it would be a certain case that he was robbing you if he had oysters in his boat. I think there could be no better system than that of having large blocks.

6494. Would you do away with the present system of paying so much per 100 yards, and prefer to have a royalty? Not so far as I am concerned. I think if you let it in large blocks it would be a very good system to let at a nominal rent, and take a royalty for what those lands produced, no man could grumble at that. I would take up such places myself, and expend money so long as nobody could get in; if unsuccessful you have nothing to pay, and it is to your benefit to endeavour to make it successful, and if you can produce 500 bags off your lease you can afford to pay a reasonable royalty, as it would be to your own benefit to do so. I think it would be a very good plan.

6495. Supposing that were done would fishermen hauling on foreshores damage the oyster-beds? Yes; they drag the oysters right up. I have seen them dragged up in heaps on the Clarence River; the nets sink right on the bottom, and when the men haul them in from the shore they haul oysters as well as fish.

6496. I mean on the foreshores? The outer distance from the shore, the nets go down and they haul their nets and take the oysters along with the fish.

6497. How would you propose, in case we leased in the way suggested, to meet the difficulty between the fishermen and the oyster lessee? Why not reserve as now, where there are no oyster layings; the fisherman wants protecting as well as the oysterman. There is plenty of room for fishermen without hurting the oyster leases.

6498. You think it could be fairly arranged without interfering either with the fisherman or oysterman? Yes; look at the sandy and muddy shores we have which are no good for oysters, but are all right for the fishermen. You must have reserves.

6499. We have received the information, but I do not know if it is in evidence, that if nets are allowed to work amongst the diseased oyster-beds it would have the effect of destroying the worm disease in a measure? I have read so from Massington, but it is a lot of rot; it is like Whitelegge's opinion about taking them out, and washing them, and putting them back, and expecting them to live—taking them out for ten days, and, after washing them clean and drying them under a shed, then take them and put them on to clean beds;—but where are the clean beds to begin with, and how could you take them off and wash them; what becomes of the water which goes back into the river; are not the oysters put back into the diseased water. I never heard of such a parcel of nonsense in all my days.

6500. Have you tried to carry out oyster culture in the true sense of the term? I have indeed; I have laid out thousands of pounds upon oyster culture.

6501. Have you been rewarded for your patience and perseverance? Not so far. You may remember the pamphlet I published. I had eight or nine men at work at that time laying oysters collected off the shores, and I made those men lay them on good fattening beds, and they grew into magnificent oysters, and on another shore they all died. It was in the time of the drought. My opinions to-day are exactly the same as when first published in my pamphlet, and those opinions are confirmed since writing the pamphlet seven years ago. You will find in the pamphlet what was done at Cape Hawke. I should like to call your attention to the following statement in the pamphlet:—

A question that has always agitated the minds of the whole of the oyster people of this country is—how has it occurred that on several of our river banks oysters have appeared as the oysters on the lower beds disappeared? This is the reason—that, although the lower water had become too salt for oyster life, the top water was still at its proper percentage of saltness, so that on the shores the oyster could still exist.

About four years ago I leased the oyster-beds at Wallis Lake. The oysters on the beds had become very scarce, but my men told me there was an immense quantity of oysters on a bank, which, if laid down on the beds, would grow into good oysters.

I went there, and this is a description of the place:—You enter through the heads, and are at once in the lake, which is studded with islands. Oysters begin to show from the very entrance, but run small, as they do at most places near the sea. The good part of the fishery begins at about 2 miles from the entrance from the sea, and extends about 2 miles up. About 3 miles from the entrance is the mouth of the river Wollomba, which empties itself in the lake. Now, at the mouth of this river, a great bank of sand, shells, &c., ran right across, which blocked the salt water from running up and the fresh water from running down, except at the top of high water.

It was on the top of this bank the great quantity of oysters lay, but owing to the short time water covered them they grew very slowly and were always poor in quality. These were the oysters I now began to operate on, by removing them off the high beds and placing them in beds upon which they would always be in water. I had one portion of them carried up the river and laid upon an old bed situated well out in the river, and over which there was always from 9 inches to 15 inches of water; the remainder were carried down into the lake and laid on a bed that had been a famous one for breeding and fattening purposes.

In about six months' time the result began to show. The oysters that had been laid up the river grew into first-class oysters; those that had been laid in the lake died. 2,000 sacks of oysters were laid on that lake bed, and they were literally all lost. I could name the whole of the men that were engaged in the work. They are all at work on our rivers; many of them work for me at the present time.

Not one of us engaged in this work could at that time give any feasible reason why one portion of the oysters laid down had all died and the others did well, for at that time we never thought of salt as a factor in the matter; but now how easy to account for the loss of one portion and the improvement of the other. Those oysters laid up the river had water suitable to their life, owing to the fresh water flowing on top of the salt, and they lying so near to the top of the tide; and those oysters laid down on the lake bed died because the water they were put in was too salt, being very little different from the pure salt water of the ocean. Here is a remarkable European proof that the life and propagation of the

Mr. H.
Woodward.
30 May, 1895.

oyster

Mr. H. Woodward. oyster is entirely dependent upon the salinity of the water. In that portion of the north of Jutland that abuts on the North Sea are a series of lakes named Lim Fiord. This fiord, up to the year 1825, consisted of a number of connected brackish water lakes, with a flow out towards the Kattegat. During the last century many attempts were made to establish oyster-beds on the open sea flats, and likewise on the lakes. All attempts, however, failed, the water in the open sea being too salt and in the lakes too fresh.

30 May, 1895.

But in 1825 a great storm broke through the dam which separated these lakes from the open sea. In consequence of this the water of the lakes became gradually saltier. The brackish water-plants and animals disappeared. In 1851 oysters were observed, and year by year they extended over a larger area. In 1860 only 150,000 oysters were taken. At present there are ninety-eight beds, and in 1871-1872, 7,000,000 of full-grown oysters were exported, and to the present day this fishery is yielding great quantities of oysters.

We have here one of the plainest possible proofs that oysters cannot grow in waters too salt or too fresh, and there can be no doubt that if the breach made in the dam at Lim Fiord in 1825 was made good, so as to hold in the brackish waters of the lakes, and keep the ocean waters out, the whole of the oysters would die, and the fishery become extinct.

6502. In your evidence given before the Select Committee in 1889, I notice you stated that you held leases at the Clarence and Shoalhaven, as well as the other places you have mentioned? I have since got rid of them.

6503. You stated in your evidence also that Wallis' Lake was about the best oyster fishery you had? So I do now for production; Wallis' Lake and Cape Hawke are identical.

6504. In regard to the present Act, which allows of people going on Crown lands and obtaining supplies of oysters for consumption,—do you think that that should be amended? I think it should never have been in the Act at all; it is the worst thing that could have happened; it was the worst thing ever done to have this inserted in the Act, and you have only yourselves to thank for it.

6505. Do you think that is the reason the Parramatta has become denuded of oysters? No; it is the general public who take them. You could not keep the public off.

6506. Would you mind giving the Commission your idea in regard to the matter of the administration generally of the fisheries of the Colony? I cannot do that.

6507. Do you think the present administrative authority should be continued? I can only speak so far as the oyster fisheries are concerned. I think it would be wise to do away with the Commission—and this was my opinion years ago—and put it all under one head, a Secretary of Fisheries, and let it be in one of the departments, the same as the other departments—that is my idea—one man that can be appealed to, and decide on the spot to do this, that, and the other thing, and let him be answerable to the Minister as to what action he takes. I have written on that subject and published my opinions years and years ago. I think it would be much better under one head.

6508. You would favour the appointment of a person thoroughly acquainted with our fisheries? Yes; certainly. No foreigner should be appointed, as they know nothing about our fisheries. There was an idea of getting an expert from England or France to superintend our fisheries, but this would not be wise, as their fisheries are not constituted in any way like ours in the mouths of our rivers, and they know nothing about the subject.

6509. *Mr. Thompson.*] Do you believe that oysters originate in the open sea? I firmly believe it. I am sure the spawn comes in from the ocean.

6510. From the open sea to the inlets? Yes; Wollongong Harbour and Kiama Basin all go to prove this. If the bars close up, where are your oysters then;—there are none. Look at the main fishery on the Manning River—that bar was closed up for a number of years and there were no oysters at all, but when the bank of sand was washed away they all set in again.

6511. Can you account for the spread of the disease in oysters in the different rivers? No.

6512. Has it been done by taking oysters from one place and putting them in another? No.

6513. How do you account for the occurrence of oysters on deep beds? Spawn comes in from the ocean with the flood-tide and goes up the river and floats; then, in a short time, it solidifies and becomes heavier than the water and sinks; if it sinks on a hard substance it stops there and grows into an oyster; if it sinks on mud or sand it perishes, so that all hard bottoms up to a certain distance up a river, if the spawn goes on it will stay on naturally, and, likewise, if it goes on to the places barren of oysters they cannot live there.

6514. On account of the too great salinity of the water? No; it is the mud, it cannot live if it settles on mud or sand, and in times of droughts the bottoms of our rivers get full of marine matter, grasses, and all else that grows on the bottom, and the reason we have no oysters is because it falls on this vegetable matter and perishes. It wants the clean hard bottom.

6515. And not too great a salinity of water? Oh, no!

6516. Can you tell me the difference between the rock and the drift oyster? They are one and the same in my opinion. You can take an oyster off the top and call them rock oysters, and if you put them down a little way below low-water line they will gradually assume the shape of the deep-water oysters down below, as they widen and thicken. I believe the spawn falls indiscriminately everywhere.

6517. You do not favour the idea expressed by some about the spat of the drift-oyster being heavy, and that of the rock-oyster light? No; I believe the same spawn stocks both deep beds and banks.

6518. The difference between a foreshore and deep-bed oyster is, you think, that one is the spat from the deep-bed which escapes—? No; I think they come from the same inflow of spawn from the ocean.

6519. You do not think the beds in inlets are resuscitated from the spat emanating from oysters in the inlets? I do not think so.

6520. Would you refuse a lease of an oyster-bed to an alien until he had been naturalised? Require him to be naturalised undoubtedly.

6521. You have stated that it would be better to fix the payment of rents by results rather than by an annual sum? I think so; so few are in a position to pay it.

6522. What do you think would be a fair charge to make as a royalty? I think 3s. would not be too much as they would pay no rent and are under no risk, standing all to win and nothing to lose. They might lose a bit of labour, but if there were no oysters, there would be no royalty to pay, and I think that would be fair enough.

MARKET ACCOMMODATION.

FRIDAY, 17 MAY, 1895.

[The Commission met at the Offices, Bligh-street, at 11 a.m.]

Present:—

FRANK FARNELL, Esq., M.P., PRESIDENT.

L. G. THOMPSON, Esq., J.P.

Samuel Edward Lees, Esq., M.P., Mayor of Sydney, sworn and examined:—

6523. *President.*] Your name is Samuel Edward Lees? Yes.

6524. You are Mayor of Sydney, and a Member of the Legislative Assembly? Yes.

6525. This Commission has been for some time making inquiries with a view to the development of our fisheries, and they can see as well as anyone else who has devoted any study to the question, that in order to make their proposals a success, it will be necessary to have important alterations made in regard to the arrangements at present in vogue at the Woolloomooloo Markets. So far the evidence tends in the direction of censure on the authorities in respect to the manner in which the Fish Market has been conducted, and the neglect which has been allowed to exist for so long a time. The Commission would like to know whether an advertisement was inserted by you in the morning papers of the 22nd March, 1895, inviting all those who desired to give evidence respecting the Fish Market at Woolloomooloo to come forward and furnish their names, so that they might be examined by you? It was.

6526. Have the committee of the City Council appointed to inquire into the working and general management of the Fish Market held any meetings? Yes.

6527. Have you taken evidence on the subject? Yes.

6528. From what sources? From every available source. We have had a plethora of names sent in of persons who were willing to give evidence representing all branches of the trade—the private citizen, the catcher, the salesmen and agents, the auctioneers, and others.

6529. How long have you been engaged in your inquiry? Since the date of that advertisement—in fact I think before that. I believe that was the second advertisement; we have had, speaking from memory, quite a dozen meetings. We have had a meeting every week since the date that was first announced.

6530. Does the evidence already adduced prove there is a necessity for some reform? The inquiry has shown that grievances exist, and have existed for a long time, which were commonly known and understood.

6531. Are you aware of the publication of the evidence in the case of “Augustus v. McElhone?” I am only cognizant of the *Herald* report.

6532. Augustus was an agent, and McElhone was one of the public who visited the market one morning, and he took upon himself to inform people as to the condition of certain heaps of fish. The defence he set up in this case was that he was doing so in the interest of the public. Have you seen the result of that action? Yes.

6533. Would it not strike you as natural to believe that the Judge was satisfied that what Mr. McElhone stated was correct? I believe the Judge said that rotten fish was sold—had been sold—and that it was sometimes unavoidable, and he gave a verdict for the defendant.

6534. In connection with the display of fish, you being an alderman, and having taken great interest in the market accommodation, do you think there is room for improvement in the manner in which the fish are displayed—that is, instead of having them thrown on the floor, as they are at the present time, might not they be displayed on raised tables, or might not better arrangements be carried out? I am afraid you will be anticipating my committee by these questions. I may say, in a general way, the whole matter has had our full consideration. The evidence we have taken bears upon this point, upon the desirability of having tables or raised tables. The scope of our inquiry takes in the whole question as far as a committee can grasp it, and, speaking for myself, I am satisfied that reform is not only desirable, but also I believe that it is coming about.

6535. Have you considered the question of having an extra sale per day, or having the market open all day? I may say the committee has not decided upon anything, but evidence has been given upon this question.

6536. Have you considered the question of the establishment of auxiliary markets in any other parts of the city? We have not considered anything in the sense of considering what means should be adopted to meet the various complaints. Evidence has come out bearing upon such a point. When the evidence is closed then the deliberations of the committee will be directed to the general improvement of all matters in connection with the subject that require attention. The committee have taken evidence upon every subject and branch of the subject that come within the functions of such a committee in respect to all matters in connection with market accommodation. I beg to point out that owing to my position as Chairman of the Committee of the City Council, it would be unfair to enter fully into the matters which are under their consideration, as it would be giving the committee away, and I shall be glad if you will be satisfied by my saying generally that, in my opinion, there will be a large reform, and that great good will result from it.

S. E. Lees,
Esq., M.P.

17 May, 1895.

ROYAL COMMISSION ON FISHERIES.

APPENDIX.

A.

STATEMENT BY MR. H. ROUSE RESPECTING THE LEASING OF PORTIONS OF LAKE MACQUARIE FOR FISHING PURPOSES.

The Royal Commission on Fisheries,—
Gentlemen,

Dudley, near Newcastle, 9 April, 1895.

Having had a great deal of experience in fishing of all kinds on Lake Macquarie, I beg to submit that the present way fishing operations are carried on is most injurious to fishing and a great loss to the Colony, from the fact that there are so many fish being destroyed. I would suggest that one or two more breeding grounds be added to the lake, and that the lake be leased in mile frontages; by so doing every person would have a chance of leasing and erecting his fish-pots to preserve fish, which would be the means of having fresh fish for the market at any time required, instead of which the fishermen now pot their fish after each haul, and in the summer time especially when they come to pick them up again they find half the fish dead in the pots. It will not only be fishermen that would go into this, but there would also be private enterprise as well, as every man holding land would select the piece lying in front of him, leaving hundreds of miles open in the lake for net-fishing. I would suggest that the Commissioners should make a special visit to the place before carrying this into operation. I have spoken to several of the old fishermen on the same point, and they agree with me that this would be the best thing that could happen to them. If this was done it would be the means of doing away with the licensing of boats and men, if they had their own grounds, and should anyone be seen fishing on closed waters, I should suggest that a very heavy fine should be imposed.

I am, &c.,

H. ROUSE.

P.S.—Dr. Cox, the President of the Fisheries Commission, suggested to people on the lake that it would be very wise on the part of the Government to lease the lake out in blocks, the same as I have already suggested.—H.R.

GENERAL INDEX TO EVIDENCE.

- Acclimatisation..... 1337-1343, 1533-5, 5808-11, 5946-51, 6087, 6281-4.
- Acts, Fisheries 6-15, 46-51, 104-5, 1584-1604, 1970-80, 2108, 2241, 2909-10, 3678, 3904-5, 4001, 4394-5, 4614, 4943, 4947, 5103-6, 4716-8, 4731-2, 5744, 5830-1, 5972-6, 6019, 6096, 6100, 6246-7, 6262-6, 6300-2, 6504-5.
- Administration 82-5, 687-700, 1005, 1595, 1736-7, 2006-12, 2146, 2687-9, 2827-33, 3158-63, 3242-44, 3246-7, 3269, 3348, 3556-8, 3640-2, 3814-20, 3844-51, 4141-5, 4394-5, 4408-9, 4603, 4710-12, 4727-30, 4734, 4742, 4746-56, 4819-21, 4828-31, 4833-5, 4897, 4915, 4979, 4992-3, 5116-7, 5184-90, 5199, 5201, 5280-1, 5472-8, 5503, 5650-3, 5663-5, 5693, 5716-18, 5750-3, 5800-6, 5835-42, 5873-8, 5980-4, 6018, 6126-33, 6135, 6148, 6193-4, 6197, 6234, 6277-80, 6388-91, 6506-8.
- Aliens..... 600-1, 1782, 1837-40, 1843-5, 1871, 1922, 2300, 2532, 2743, 2873, 3199, 3249, 3328-9, 3442, 3581, 3781, 3834, 4172-3, 4276, 4378, 4461-4, 4555-6, 4676, 4792-3, 4855-6, 4941, 5376, 5524, 5699-5700, 5914-5, 6014, 6399, 6520.
- Amateur Fishermen..... 228, 282-6, 2531, 2742, 2955, 3097-3102, 3166, 3196, 3228, 3248, 3259-65, 3330-34, 3443, 3578-80, 4174-5, 4689-91, 4702, 4707, 4725-6, 4735-6, 4762-3, 4784, 4812-6, 4851-4, 4878-9, 4886, 4891-2, 4893-8, 4948-50, 5082, 5094-8, 5100, 5110, 5118-9, 5131-9, 5175-7, 5216-22, 5377, 5694-6, 5891-2, 6090-1, 6155-7.
- Anchovies 5296-8.
- Anglers, Protection of..... 16-17.
- Auxiliary Markets. (*See* Markets.)
- Banks, Fishing discoveries of..... 3, 1122.
- Baskets and Boxes (Fish) 379, 474, 976-7, 1030-2, 1157, 1171-2, 1240, 1467, 1949-50, 2059, 2096-8, 2171-2, 2227-33, 2596-2601, 2734-5, 2782-3, 2878, 3204-5, 3448, 3582-3, 3651-2, 3755, 4169-71, 4340, 5606.
- Boards, Fisheries 6-15, 45, 48-51, 83-5, 159, 189-198, 233-4, 700, 905-8, 1601-4, 1742-4, 3849-51, 3954-6, 4035-9, 4146-51, 4251-7, 4368-9, 4547-8, 4621-2, 4777, 4983-4, 4990, 5070, 5074, 5502-5, 5690-2, 5807.

1894.

(SECOND SESSION.)

NEW SOUTH WALES.

FISHERIES ACT, 1881.

(REGULATIONS UNDER.)

Presented to Parliament pursuant to Act 44 Vic. No. 26, sec. 9.

Chief Secretary's Office, Sydney, 7th June, 1894.

HIS Excellency the Governor, with the advice of the Executive Council, has been pleased to repeal the following Regulations under the "Fisheries Act, 1881," viz. :—

Regulation No. 16, published in a Supplementary *Government Gazette* of the 30th June, 1881, headed "Priority among Netters," and the Regulation published in the *Government Gazette* of the 16th March, 1894, on the same subject.

GEORGE R. DIBBS.

Chief Secretary's Office, Sydney, 7th June, 1894.

HIS Excellency the Governor, with the advice of the Executive Council, has been pleased to make the subjoined Regulation under the provisions of the "Fisheries Act, 1881."

GEORGE R. DIBBS.

PRIORITY AMONG NETTERS.

THE right of first shooting and hauling a net on any fishing ground shall belong to the licensed fisherman who first arrived on the ground with his licensed boat, marked in accordance with the Regulations, and who shall remain in charge thereof with his net ready for shooting and one end of its hauling line ashore, and the next turn shall belong to the licensed fisherman who arrived next after such first-mentioned person, and so on in order of arrival.

An unlicensed fisherman, or a licensed fisherman in an unlicensed boat or in a licensed boat not marked as aforesaid, shall not be entitled to shoot a net on any fishing ground until every licensed fisherman, then being on the ground with his licensed boat and gear ready for shooting, shall have had his turn.

Two or more turns may be taken at the same time, if the water to be fished permits of double-banking, but no net shall be shot round an inner net within a boat's length of the cork line of such net. It shall be unlawful to wilfully disturb or frighten fish on or in the vicinity of a haul so occupied.

The occupancy of a haul as aforesaid shall cover a space of not more than 300 yards, measured along the shore from the point where the boat in possession is moored, in the direction in which the net is laid for shooting.

Chief Secretary's Office, Sydney, 25th June, 1894.

HIS Excellency the Governor, with the advice of the Executive Council, has been pleased to repeal Regulation No. 52, published in a Supplementary *Government Gazette* of the 30th June, 1881, prescribing Penalties on breach of Regulations under the "Fisheries Act, 1881."

GEORGE R. DIBBS.

Chief Secretary's Office, Sydney, 25th June, 1894.

HIS Excellency the Governor, with the advice of the Executive Council, has been pleased to make the subjoined Regulation under the provisions of the "Fisheries Act, 1881."

GEORGE R. DIBBS.

PENALTIES ON BREACH OF REGULATIONS.

ANY person who shall commit any act in breach of, or be guilty of any default or non-compliance with, the requirements or prohibitions of any Regulation made under the "Fisheries Act, 1881," or under any Act amending the same, shall, in every case where no penalty or forfeiture has been in such case provided, be liable to a penalty not exceeding £10.

1894.

(SECOND SESSION.)

NEW SOUTH WALES.

FISHERIES ACT AMENDMENT ACT, 1883.

(REGULATION.)

Presented to Parliament pursuant to Act 44 Vic. No. 26, sec. 9.

Chief Secretary's Office,
Sydney, 7th June, 1894.

HIS Excellency the Governor, with the advice of the Executive Council, has been pleased to repeal the Regulation published in a Supplementary *Government Gazette* of the 22nd June, 1883, relating to the size of mesh in the bunt of a garfish net.

GEORGE R. DIBBS.

Chief Secretary's Office,
Sydney, 7th June, 1894.

HIS Excellency the Governor, with the advice of the Executive Council, has been pleased to make the subjoined Regulation under the provisions of section 1 of the "Fisheries Act Amendment Act of 1883."

GEORGE R. DIBBS.

REGULATION.

The size of the mesh in the bunt of a garfish net shall not be less than 1 inch and one-eighth of an inch measured in length on the diagonal between knot and knot of opposite corners.

1894-5.

LEGISLATIVE ASSEMBLY.

NEW SOUTH WALES.

GOVERNMENT LABOUR BUREAU.

(THIRD ANNUAL REPORT.)

Ordered by the Legislative Assembly to be printed, 28 March, 1895.

The Superintendent, Labour Bureau, to The Minister for Labour and Industry.

Sir,

I have the honor to present the third annual report of the Labour Bureau, from the 18th February, 1894, to 17th February, 1895.

I regret to have to report that the depressed state of the labour market, and want of employment, has been severely felt during the year, both in the city and throughout this and the other Colonies.

The large number of unemployed from the country districts registering at the Bureau, particularly during the last six months of the year, is an evidence that work of all kinds is scarce in the country.

While the productions from farming generally have been during the year above the average, the prices paid to the producer have been so low that the farmers do not employ the labour they would do if prices ruled higher. Still there has been a fair demand for farm hands, dairymen, and boys, as well as bushmen generally, during the year, the Bureau having assisted and sent to work no less than 990 of this class of labour. No doubt the large amount of surplus labour and the low prices at which this class of work is done has had a good deal to do with so many finding employment at this particular work.

Large areas of new land have been cleared and placed under cultivation during the year, which has given employment to hundreds of bushmen and farm hands from the Bureau.

The building trade, which is, as a rule, a correct index of the labour market generally, has been for some years and still is very much depressed in Sydney and throughout the Colony, and, as a consequence, a large number of mechanics in that particular trade are compelled to take work of any kind offering in order to support their families.

537	carpenters registered as unemployed.		
133	stonemasons	"	"
123	bricklayers	"	"
196	painters	"	"
81	plasterers	"	"
86	plumbers	"	"

During the year the coal trade in the Newcastle, Greta, Wollongong, and Lithgow districts has also been very slack, causing thousands of miners to be out of work, and swelling the ranks of the unemployed. The number of miners registered during the year was 2,116.

There are a very large number of compositors, clerks, accountants, architects, and other professional men who cannot find anything to do at their professions and are glad to adapt themselves to existing circumstances in order to try and support their families. During the year no less than 430 of clerical and professional men have been registered here as unemployed.

The largest number of any calling registered for work during the year is general labourers, viz., 4,548.

A large number of clerks and professional men, mechanics, and others have registered themselves as labourers, believing that by so doing they could get work more readily, knowing well the difficulty of finding anything to do at their particular callings.

On reference to the comparative table which has been prepared, showing the results of the three years' existence of the Bureau, it will be seen that the totals for the past year have been very large. Thus, the number registered for the year is 13,575, being an increase of 1,430 on the previous year, and making a total of 44,320 since opening. The number assisted and sent to work for that period is 16,380, as against 10,349 for the previous year, and 8,154 for the first year, giving an increase of 6,031 over the year 1893-4, and being more than double those sent out during the first year 1892-3. This gives a total of 34,883 for the three years. The amount refunded for passes during the past year is £2,477 15s. 8d., as against £2,676 10s., and £1,135 6s. 1d. for the two previous years respectively, being a total from this source of £6,290 1s. 9d.

The large total above referred to as having been assisted and sent to work has been principally swelled by the fossickers, who have been sent away from Sydney, Newcastle, Goulburn, and other places, to fields where they know or think they can make at least a living for themselves.

In all, 10,718 have been assisted as fossickers this year, as compared with 4,516 the previous year, making a total of 15,234 sent out in this way.

That a large proportion of these have done fairly well is evidenced by the number of families sent for to join their relatives, and by the numbers of letters from mates who are on the fields making at least sufficient to warrant them in advising their relatives and friends to come up and join them. The large increase in value of gold discovered for the year referred to is ample testimony in the same direction. Apart from the number of fossickers sent out, 5,662 others of various trades and callings have been so assisted, as against 5,833 of the previous year.

In addition to the ordinary mode of engagement through the Bureau, numbers of men find employment indirectly by persons coming and engaging them, and taking them away without giving any information or leaving any record on the subject.

Any estimate of the number of unemployed in the country at the present time would be unreliable, but when the agencies contemplated by the Minister are established, better and more reliable information can be supplied.

Fossickers.

The large number of men assisted and sent fossicking during the year is an evidence that this mode of endeavouring to make a living is appreciated by the unemployed generally, many of whom have done fairly well, while others have been able to earn tucker, or enough to live on. A large number of these men have settled down in the country, making a living by this means, farming, or other work, and some 600 families have been sent to join their husbands, making their homes in different parts, where the opportunity of doing so is easier and better than in the city. Of course, a number of men have been sent out who have done little or no good. Want of means with some, and want of experience with determination and perseverance with others, have been the chief cause of failure.

Fossicking was commenced in July, 1893, and the increase of gold for that year and 1894, compared with that of 1892 (previous to the commencement of the fossicking system), as published by the Sydney Mint authorities, is £263,086, and is the best evidence that the system has been somewhat successful in providing profitable employment to a large number out of work.

It may be also mentioned that the months of January and February, 1895, show an increase of gold yield over the corresponding period of last year of 7,000 oz. = £28,000.

During the year 2,320 rations have been given to destitute fossickers to assist them in reaching their destination, at a cost of £232.

Agencies.

I would recommend, with a view to testing the value of agencies, that (say) five be opened in connection with the Bureau—one at Newcastle and one at Tamworth, for the north; one at Bathurst or Orange, and one at Bourke, for the west; and one at Goulburn for the south—to be conducted under the supervision of the Sergeant or Officer-in-charge of Police in each town, whose duty should be to register the unemployed in each district, and supply employers with labour out of those locally unemployed, and, in the event of not being able to supply such labour as may be required, to communicate with the Superintendent.

Should this suggestion be adopted matters of detail can be arranged between the agents and the Superintendent.

Wages.

It is difficult to say what the rate of wages is in any calling at the present time. There are so many unemployed looking for whatever work there is offering, and glad to take any reasonable wages that no regular rate can be fixed. The Bureau does not interfere in the matter; it simply brings employer and employee together, leaving them to arrange wages and terms.

However, from the large number of letters received daily from employers in all parts of the Colony who require men, and stating the wages they will give, it is evident that the rate generally for the past year has shown a reduced tendency all round, though, in some branches, it is more noticeable than in others.

The annexed Schedules give the number in each calling sent out, and the wages given.

Refunds.

The refund of fares by rail and steamer shows a decrease on the amount received during the previous year.

The total amount received for the year was £2,477 15s. 8d., and that for the previous year, £2,676 10s.

The system of refund of fares came into operation in July, 1892, and the total amount received is £6,290 1s. 9d.

There is a large amount still owing—(say) £12,000—principally by men sent fossicking, and who, in addition, owe for their rights.

The amount received for miners' rights for the year, and included in the above total, is £65 12s. 6d.

Labour Settlements.

Under the Act of 1893 three of these settlements have now been in existence for some eighteen months, and I do not think their most sanguine supporters will say they are a success.

Pitt Town, with which I have been connected since its inauguration, has still about ninety families resident there. Mr. Taylor and myself visited the settlement a few weeks since, and, although the Government has assisted with over £6,300, it does not seem likely to ever become self-supporting. It may be able to support forty or fifty families, but not more. The experience of labour settlements on the principle of co-operation or commonwealth is not very favourable.

Registry Offices.

With respect to these, I cannot do better than repeat what I said in my report for 1893:—"During the existence of the Bureau numbers of persons engaged through registry offices for employment in the country have applied to me for railway passes, to enable them to reach their destination; and in all cases which I believe to be genuine I have granted such passes, at the same time taking an order on the employer in each case for a refund."

My experience, however, of these registry offices during the existence of the Bureau leads me to the conclusion that a great many abuses exist in connection with them which might and should be remedied.

In the interest of the unemployed themselves, I would strongly recommend that these offices should be licensed, and placed under Government supervision. The principal reason that prompts me to bring this matter specially under notice is, that I am satisfied that several of those professing to have obtained employment through registry offices have been victimised. After reaching their destinations by means of the railway pass obtained from the Bureau some of these find that they are "not wanted"; in some cases that no authority was given for their engagement, whilst in others there has been absolutely no employment. After spending, perhaps, all they possessed in registry fees, the result is that they have found themselves stranded in a strange place, without employment, and without the means for existence whilst they looked for it. When a person applies for a railway pass the original letter from the employer must be produced, and when this is not forthcoming a pass is rarely granted.

In some cases several persons, I am certain, are engaged for one and the same place; in others, the offices are established simply to obtain fees from the highest bidder. It also happens, from information I have obtained, the fare in some cases has been paid in advance by the employer, and retained by the registry office, and then the person engaged has been sent to the Bureau to obtain a pass. Several parties have had to sell almost everything they possessed to raise the registry office fees—in some cases as much as £5—and in these instances, if the Bureau did not come to the relief, the applicants—perhaps a married couple—would be left destitute.

In the interest of all those seeking employment through these offices, I would recommend that they all be licensed, in order to prevent fraud, and placed under the supervision of the Government, and so prevent poor people from being victimised.

This would result, not only as a benefit to the unemployed, but as a source of revenue to the State.

Relief.

Judging from the number of applicants for relief and number of rations issued for the year 1894, the distress has not been so great as for the previous year. The average number of families in receipt of weekly relief last year, 1894-5, was 368.3; the previous year it was 379. The total number of rations issued for 1894 was 41,884½, costing £3,097, the total for 1893 being 52,525, costing £3,840 6s. 0½d., being a decrease in the number of rations of 10,641 and £742 15s. 6½d. less in cost. This, with the relief given by several other charitable institutions and relief committees, gives some idea of the distress and poverty in and around Sydney.

Shelter.

During the year 53,582 tickets have been issued to the homeless. These, at 1d. each per night, make the total cost of shelter £233 5s. 2d.

Country Relief.

The amount expended for relief in different parts of the country for 1894 was £705 12s. 10d., made up of the following items:—

Name of Place.	Amount.	Name of Place.	Amount.
	£ s. d.		£ s. d.
Teralba	4 1 6	Wickham	65 0 0
Greta	260 8 7	Charlestown	30 0 0
Dudley	50 0 0	Katoomba	29 10 2
Adamstown	50 0 0	Bathurst	23 7 4
Hamilton	53 5 3	Wauchope	50 0 0
New Lambton	50 0 0	Merewether	40 0 0

Most of the country relief has been given as a subsidy of £ for £ voted by the Municipal Council (or raised by the public), and expended in giving work on the roads and streets to the destitute unemployed instead of giving gratuitous rations.

General.

The average daily attendance of the unemployed at the Bureau is from 500 to 600. They come and go all day, and if nothing turns up to suit them, they go elsewhere looking for work.

There is an increase of the unemployed from the other colonies this year compared with last. The number registered in 1894-5 was 1,101, the number for the previous year, 1893-4, being 1,057, showing an increase of 44. All those residing in the Colony over six months are registered as citizens of New South Wales. It is probable that a number of those from other colonies on our books do not give us correct information on this point.

The conduct of the men on the whole is good and orderly, and they give very little trouble, except when a few larrikins come among them, and who have to be dealt with firmly.

The police returns for the year are less than last, the convictions for this year being 153, as against 195 for the previous year, and 399 for the year 1892-3, showing a decrease of 42 this year.

The work at the Bureau has doubled during the year 1894, in consequence of the large number going fossicking on the old gold-fields daily, and the great increase of applicants for relief in the city and suburbs. Each application has to be inspected, reported on, checked, and marked by the Superintendent for

for rations, if correct. There is also the superintending the administration of relief in the country districts, the thinning of forests, and registering and reporting on applications for admission on to the labour settlements, together with a very large increase in correspondence from all parts of the Colony, which has to be attended to and answered the same day, and frequently necessitating the whole of the staff remaining back after office hours to keep pace with the work.

I am pleased to be able to report that notwithstanding the increased duties the whole of the officers of the Bureau do their work cheerfully and well, conscientiously keeping in view the object for which it was established by the Government.

Appended are statements in detail of the work and operations of the Bureau for the year ending 17th February, 1895.

JOSEPH CREER,
Superintendent.

CLASSIFICATION of Trades and Occupations registered during the year ending 17th February, 1895, and a comparison of same with the previous year:—

Occupations.	1893-94.	1894-95.	Occupations.	1893-94.	1894-95.

Females—The large majority of these are women sent to join husbands. With these have been sent 437 children for the year ending February 17, 1895.

General Usefals.—There has been an increased demand for lads from 14 years.

Labourers.—1,150 of these have been put on at Shea's Creek. About same number waiting.

Fossickers.—This large difference is accounted for by the system of sending fossickers away only having been in force for six months of the year 1894.

(SECOND SESSION.)

LEGISLATIVE ASSEMBLY.

NEW SOUTH WALES.

GOVERNMENT LABOUR BUREAU.

(RETURN RESPECTING.)

*Ordered by the Legislative Assembly to be printed, 11 October, 1894.**[Laid upon the Table of this House in answer to Question No. 5 of 11th October, 1894.]*

Question.

5. MR. WOOD asked THE COLONIAL SECRETARY,—Will he have any objection to lay upon the Table of this House a return showing the annual cost of the Government Labour Bureau since its establishment, with the names of all present employees at the Bureau, the nature of their duties, and their yearly salaries?

Answer.

The Government grant for the expense and maintenance of the Bureau since establishment in February, 1892, has been the sum of £1,400 per annum.

The following are the names of the present employees at the Bureau proper, with their salaries and duties:—

Name.	Duties.	Salary per annum.
Joseph Creer ...	Superintendent	£ s. d. 380 0 0
F. E. Bloxham ...	Secretary	290 0 0
W. R. Sterling ...	Accountant	133 0 6
C. E. Ramage ...	Chief Clerk	133 0 6
G. Eaton* ...	Clerk	133 0 6
J. Eldridge ...	Registration Clerk	109 0 11
T. Ireland* ...	Assistant Registration Clerk	109 0 11
G. R. Barton ...	Messenger	91 5 10
Thos. Waring ...	Caretaker	109 0 11

* To be retrenched at end of present month.

The following are the names of the employees in the Relief Department in connection with the Bureau:—

RELIEF DEPARTMENT.

Name.	Duties.	Salary per annum.
Joseph Creer ...	Superintendent; allowance for supervision and distribution of relief in city, suburbs, and country, and for receiving and reporting on applications under Labour Settlement Act, £10 per month ...	£ s. d. 120 0 0
A. M. Hagerty ...	Relieving Officer ..	109 0 11
J. K. Abbott ...	Assistant	52 0 0
J. M'Indoe ...	Inspector	130 8 4
J. M. Clark ...	Inspector	130 8 4
G. D. Ramage ...	Inspector	130 8 4
P. O'Gorman ...	Inspector	109 0 11

The cost of inspection was, prior to October, 1893, borne by the State Children's Relief Department, whose inspectors officiated.

(SECOND SESSION.)

NEW SOUTH WALES.

LABOUR SETTLEMENTS ACT.

(AMENDED REGULATION No. 6.)

Presented to Parliament, pursuant to Act 56 Vic. No. 34.

Department of Lands, Sydney, 14 August, 1894.

It is hereby notified for public information, that His Excellency the Governor, with the advice of the Executive Council, has approved of the alteration of No. 6 of the Regulations made in pursuance of the Labour Settlements Act by the Board of Control of the Labour Settlement at Pitt Town, by the substitution of the words "*month*" for "*week*" and "*three*" for "*five*," so that such Regulation in its amended form shall read as follows:—

"There shall be an ordinary meeting of the Board at least once in every month, at the office of the Board, at such hour as the Board may determine; and an extraordinary meeting of the Board may be summoned at any time by the authority of the Chairman or of any three members of the Board, not less than twelve hours' notice of the time and place of such meeting to be given."

"At every such meeting three members shall form a quorum."

J. H. CARRUTHERS.

[L.S.L. 94-195]

1894-5.

NEW SOUTH WALES.

LABOUR SETTLEMENTS ACT.

(REGULATIONS FOR THE SETTLEMENT AT WILBERFORCE.)

Presented to Parliament, pursuant to Act 56 Vic. No. 34.

Department of Lands,
Sydney, 20th December, 1894.

REGULATIONS UNDER THE LABOUR SETTLEMENTS ACT.

It is hereby notified, for public information, that the following Regulations, made in pursuance of the Labour Settlements Act by the Board of Control of the Labour Settlement at Wilberforce, have been approved by His Excellency the Governor, with the advice of the Executive Council, to apply to such Labour Settlement, in lieu of the Regulations published as a Supplement to the Government Gazette of the 10th May last, which are hereby cancelled.

[94-361 L.S. Leases]

J. H. CARRUTHERS.

REGULATIONS made in pursuance of the Labour Settlements Act by the Board of Control of the Labour Settlement at Wilberforce.

1. The Board shall, not later than at its fourth meeting, and thereafter annually during the month of January, and also from time to time as necessity shall arise, elect from among its own members a Chairman, Treasurer, and Secretary.

2. The retiring Chairman, Treasurer, and Secretary shall be eligible for re-election, and shall continue in office until their successors are elected.

3. The Chairman shall preside at all meetings of the Board at which he may be present, and he shall have a deliberative as well as a casting vote.

4. During the temporary absence of the Chairman, the members of the Board assembled at any meeting may elect any one of their number to act as Chairman. An acting Chairman shall do all such things as the Chairman is required to do by these Regulations during the absence or inability of the Chairman.

5. The Chairman and the Treasurer shall sign all cheques authorised by the Board; but in the absence of one or more of them, the signatures of such member or members as may be duly authorised by the Board to sign in their stead shall be sufficient.

6. The Secretary shall keep minutes of all meetings of the Board, receive and conduct the Board's correspondence, subject to the general supervision and directions of the Board, and act generally as the Board's agent in all such matters as the Board shall require.

7. In addition to the ordinary meeting of the Board, to be held at least once in every month, an extraordinary meeting of the Board may be summoned at any time by authority of the Chairman, or upon the requisition of three members of the Board. At every meeting five members shall form a quorum. Not less than twelve hours' notice in writing of the time and place of any Board meeting shall be given; but no such notice shall be necessary for any regular Board meeting which the Board may have arranged to hold at certain stated intervals.

8. The Treasurer shall keep all the accounts of the Board and pay and receive all moneys on the Board's behalf. No money shall be paid or expended without the authority of the Board being first had and obtained, and a receipt in writing shall in every case be taken, which receipt shall be filed as part of the records of the Board.

9. The Board shall annually appoint two auditors who shall from time to time, but not less than once in each period of six months, examine the Board's accounts and certify to the accuracy and general correctness of the statements prepared by the Treasurer, and of any abstract or balance sheet professing to represent the same. They shall also report upon the manner in which such accounts have been kept and make any suggestions which they may think necessary.

10. All orders of the Board for provisions, goods, or otherwise, shall be signed by the Chairman, or by the Secretary and Treasurer, on forms provided for the purpose, butts of which forms shall be kept as part of the records of the Board.

11. The Board shall not be responsible for any debt incurred by, or on behalf of, any individual member of the Settlement, nor for any debt incurred without the order of the Board.

12. The Board may from time to time appoint one of the enrolled members of the settlement as overseer of the Settlement, and such overseer shall see that any directions of the Board are carried out, and shall supply, in writing at least once in each month to the Board, a statement of the progress and condition of the Settlement, the work done, and such other particulars as may be necessary.

13. The Board may from time to time appoint one of the settlers to act as storekeeper, and it shall be the duty of the storekeeper to keep an accurate account of all the property of the Board including tents, tools, implements, and vehicles, live stock, and stock in trade, and property or goods of every kind. He shall also keep a record of all changes in the said property and of the incomings, outgoings, and balance, in such a form as shall be required by the Board, and he shall embody

she same in a report to the Treasurer whenever such report shall be called for by the Board. The Board shall require such a report at least once every three months.

14. The Board may, whenever it shall deem it expedient, call upon the overseer or storekeeper to resign, or may remove them from office and appoint successors in their stead.

15. No work for private emolument outside the Settlement shall be undertaken by any person resident in the Settlement, unless he shall obtain permission from the Board to undertake the same.

16. The Treasurer shall, on such day or days as the Board may direct, issue to each enrolled member of the Settlement a supply of provisions, or either orders or cash for the purchase of the same, for himself and the members of his family resident upon the Settlement, in accordance with a scale to be from time to time approved by the Board.

17. Such clothing and materials as in the opinion of the Board shall be necessary, and as the available funds will admit of, may be advanced by the Board to the members of the Settlement for the use of such members or their families.

18. The maintenance of each member of the Settlement and of his family shall be charged as a whole upon the funds of the Board until the result of the labours of any settler shall produce the amount necessary for his subsistence, when the cost of maintenance of such settler and his family shall cease to be a charge upon the funds of the Board; but in such a case the whole of his earnings shall be exclusively his own, subject to the payment to the Board of the rent of the land sublet to him and to his repayment of any portion of the loan with which he shall have been debited.

19. After the expiration of three months from the date of the approval of these Regulations the Board may cause an inspection to be made of the land granted or proposed to be granted to any enrolled member by way of sub-lease, and may cause an appraisal to be made of the value of the improvements effected thereon, and in the event of such improvements not being of a satisfactory character the Board may suspend or discontinue the granting of any allowances whatsoever to such enrolled member pending an enquiry into the circumstances connected therewith.

20. Any enrolled member shall when called upon by notice so to do assist in the erection of any necessary fence on the boundary of the land granted or proposed to be granted to him under sub-lease, and in the event of such fence not being erected within three months from the date of such notice the Board may call upon such member to show cause why he should not be disenrolled.

21. No enrolled member shall absent himself from the Settlement for a period in excess of twelve hours, without having first obtained the consent of two members of the Board; and it shall be the duty of the members of the Board granting such permission to report the fact at the next meeting of the Board, when the circumstances connected with it shall be duly considered, and a record made of the leave of absence granted to any enrolled member of the Settlement.

22. All live stock, working plant, tools, implements, vehicles, &c., purchased by the Board and allotted for the use of any enrolled member of the Settlement shall remain the property of the Board; and it shall be the duty of any member in temporary possession of any of the said property to render an account thereof, or to return the same to the Board when called upon so to do.

23. The Board may require each enrolled member, when in health, to do eight hours' work in each week in effecting improvements upon any portion of the Labour Settlement area, or in carrying out works which are deemed to be necessary in the interests of the whole community, or for such other purpose as the Board may think fit.

24. Any person enrolled as a member of the Settlement after the approval of these Regulations, if not a transferee as provided by Regulation 25, shall be debited with whatever may appear to the Board an equitable sum, having regard to the improvements on the land and the then value of the Board's property thereon.

25. Any member may transfer his interest, providing only such transfer shall be approved by the Board, and the transferee enrolled by the Board. If the Board approve of the transfer, the transferee shall succeed to all the rights and liabilities of the transferor, and such transferor shall be disenrolled on the day on which the transferee shall be enrolled.

26. If any member shall retire from or abandon the Settlement, or shall at any time be disenrolled, he shall, except as provided in Regulation 27, forfeit to the Board all his interest in such Settlement and all share of any distribution to which he might otherwise have been entitled. But where such retirement is caused by sickness or other sufficient cause, the Board may, out of any moneys at its disposal, assist such retiring member by payment to him of such sum as they may think he is, under the circumstances, entitled to.

27. Should any member of the Settlement die or be declared a lunatic, his interest as such member may be disposed of by his legal representatives to any person who shall be competent to become and shall become an enrolled member; and such person shall, when enrolled by the Board, succeed to all the rights and liabilities of his predecessor. Failing disposal as aforesaid within six calendar months from the date of death or declaration of lunacy, as the case may be, the Board may dispose of the interest of the deceased or lunatic member either for cash or upon terms, and pay the same to his legal representatives: Provided always that the Board may, but shall not be legally compellable, to pay to the representatives of any deceased or lunatic member such sum of money as, in the opinion of the Board, shall represent the interest of such member at the time of his death or declaration of lunacy.

28. A widow of a deceased member may hold a share in the Settlement, upon enrolment, provided that the conditions of labour prescribed by the Rules and Regulations governing the Settlement are complied with on her behalf.

29. Every member is expected to do his utmost to promote the interest and well-being of the Settlement.

30. Every member must keep the land sub-let to him in good order, and attend to the sanitary arrangements necessary for the well-being of the Settlement.

31. All complaints and propositions shall be given in writing to the Board at least twenty-four hours before the time of meeting.

32. No intoxicating liquors shall be sold within the limits of the Settlement, and any member selling or purchasing the same within such limits shall be liable to disenrolment.

33. No gambling shall be permitted within the limits of the Settlement.

34. Any enrolled member disobeying any direction, rule, or order of the Board, shall be liable to a penalty not exceeding £2 for every such offence; and obstinate and continued disobedience of any such rule or direction shall render any member guilty of the same liable to be disenrolled.

NEW SOUTH WALES.

LABOUR SETTLEMENTS ACT.

(CANCELLATION OF REGULATIONS NOS. 20 AND 21, AND OF AMENDED REGULATIONS NOS. 10, 12, 19, AND 42, OF THE PITT TOWN SETTLEMENT.)

Presented to Parliament, pursuant to Act 56 Vic. No. 34.

Department of Lands,
Sydney, 5 February, 1895.

It is hereby notified, for public information, that His Excellency the Governor, with the advice of the Executive Council, has approved of the cancellation of Nos. 20 and 21 of the Regulations made in pursuance of the Labour Settlements Act by the Board of Control of the Labour Settlement at Pitt Town, and of the alteration of Nos. 10, 12, 19, and 42, which in their amended form will read as follows :—

10. The Superintendent shall be the responsible Executive Officer of the Board for the organising of the settlement, the direction of the works undertaken, and the control and management of the settlers in relation to their employments. It shall be his duty to oversee and direct the Storekeeper, Steward, and other local officers of the Board, and to report in writing, at least once in each week, to the Board, which report shall contain a statement of the condition and progress of the settlement, the work done, and any other particulars necessary to enable the Board fully to understand the position of the undertaking.

12. Should any question arise as to the duties or functions of any local officer of the Board, the decision shall rest with the Superintendent, and his decision shall have immediate effect; but any officer or settler who is aggrieved at the action or decision of the Superintendent may appeal to the Board within one week after the date of the act or decision complained of.

19. There may be appointed from time to time from among the settlers, if the Board so determine, a resident Committee, which shall consist of five members, who may either be nominated by the Board or may be elected by ballot by the settlers themselves, according as the Board may determine; and it shall be the duty of the Committee so appointed to act as a Committee of Advice to the Superintendent on all questions on which he may from time to time consult them, and also to report to the Board upon any matter referred by the Board for their consideration, or upon any matter of extreme urgency affecting the well-being of the settlement which may or may not have been so referred: Provided that the Board may at any time dissolve any Committee of Advice, or disrate any member thereof.

42. The Committee of Advice may make recommendations to the Board through the Superintendent for the purpose of ensuring the efficiency of the regulations from a sanitary point of view, the lighting of the settlement, traffic regulations, police, and any other matter affecting the good order, government, social improvement, comfort, or recreation of the settlement.

NEW SOUTH WALES.

LABOUR SETTLEMENTS ACT.

(NOTIFICATION OF AMENDMENT OF SUB-SECTION (a) OF REGULATION No. 1.)

Presented to Parliament, pursuant to Act 56 Vic. No. 34.

Department of Lands, Sydney, 18th December, 1894.

REGULATIONS UNDER THE LABOUR SETTLEMENTS ACT.

It is hereby notified, for public information, that His Excellency the Governor, with the advice of the Executive Council, has approved of Sub-section (a) of No. 1 of the existing Regulations under the Labour Settlements Act being amended by the addition of the following words:—

“ Provided that, whenever the Minister shall deem it expedient, such Board may be composed of persons all or more than two-thirds of whom shall be nominated by the Minister.”

So that the Sub-section shall then read as follows:—

“ If the enrolled members of the Labour Settlement require monetary assistance at the commencement of the Settlement, the Board of Control shall be composed of persons of whom two-thirds shall be nominated by the Minister and one-third by the enrolled members of the Settlement: Provided that, whenever the Minister shall deem it expedient, such Board may be composed of persons all or more than two-thirds of whom shall be nominated by the Minister.”

CENTENNIAL PARK RELIEF WORKS.

(RETURN SHOWING SCALE OF RATIONS ISSUED TO MEN EMPLOYED AT.)

*Ordered by the Legislative Assembly to be printed, 9 May, 1895.**[Laid upon the Table of this House in answer to Question No. 1, of 9th May, 1895.]*

Question.

- (1.) CENTENNIAL PARK WORKS:—MR. SCHEY *asked* THE MINISTER OF PUBLIC INSTRUCTION:—
- (1.) Has he yet settled the scale of rations and amount of work to be performed therefor in connection with the Centennial Park work?
 - (2.) If so, will he please lay a copy of the scale upon the Table?
 - (3.) What amount does Contractor Kidman receive from the Department—(a) per ration; (b) per tin of milk; (c) per pound of extras, specifying articles and price respectively?
 - (4.) Have any arrangements yet been made by which men may receive ration tickets on the completion of their work, without having to return to the Bureau for such tickets?
 - (5.) If not, when will such be made?

Answer.

Centennial Park Relief Works—Ration Scale.

Workmen	Allowance.	Value of Allowance.		Hours to be worked per day of 8 hours.	
		s.	d.		
Single man	1 ration and extra	Rations. viz., 4lb. bread, 3lb. meat, 2lb. sugar, $\frac{1}{4}$ lb. tea.	Extras. and 1 tin milk	1 10 $\frac{1}{2}$	3 hours.
Married man with wife only.	2 rations and extras	viz., 8lb. bread, 6lb. meat, 4lb. sugar, $\frac{1}{2}$ lb. tea.	1 tin milk, and 2lb. rice, sago, or oatmeal.	3 5 $\frac{1}{2}$	6 „
Married man with wife and 1 child.	3 rations and extras	viz., 12lb. bread, 9lb. meat, 6lb. sugar, $\frac{3}{4}$ lb. tea.	1 tin milk, and 4lb. rice, sago, or oatmeal.	5 0 $\frac{1}{2}$	8 „
Married man with wife and 2 children	3 rations and extras	viz., 12lb. bread, 9lb. meat, 6lb. sugar, $\frac{3}{4}$ lb. tea.	1 tin milk, and 6lb. rice, sago, or oatmeal.	5 3 $\frac{1}{2}$	9 „
Married man with wife and 3 or 4 children.	4 rations and extras	viz., 16lb. bread, 12lb. meat, 8lb. sugar, 1lb. tea.	1 tin milk, and 7lb. rice, sago, or oatmeal.	6 9	11 „
Married man with wife and 5 or 6 children.	5 rations and extras	viz., 20lb. bread, 15lb. meat, 10lb. sugar, 1 $\frac{1}{4}$ lb. tea.	2 tins milk, and 7lb. rice, sago, or oatmeal.	8 7 $\frac{1}{2}$	14 „
Married man with wife and 7 or 8 children.	6 rations and extras	viz., 24lb. bread, 18lb. meat, 12lb. sugar, 1 $\frac{1}{2}$ lb. tea.	2 tins milk, and 7lb. rice, sago, or oatmeal.	9 11 $\frac{1}{2}$	16 „

LEGISLATIVE ASSEMBLY.
NEW SOUTH WALES.

VESSELS CARRYING COAL TO PORTS BEYOND
AUSTRALIA OR NEW ZEALAND.

(RETURN RESPECTING.)

Ordered by the Legislative Assembly to be printed, 13 June, 1895.

RETURN to an *Order* made by the Honorable the Legislative Assembly of New South Wales, dated 4th June, 1895, That there be laid upon the Table of this House,—

“ A Return of vessels coal-laden or mainly coal-laden which have sailed from Newcastle, N. S. W., or Sydney, for ports beyond Australia or New Zealand, between 1st May, 1880, and 1st May, 1895, and which have been reported missing, wrecked or otherwise lost, or on fire, or put into or returned to port in distress, together with a Return of the approximate number of lives known or concluded to have been lost in consequence.”

(*Mr. Joseph Abbott.*)

RETURN of vessels coal-laden which have sailed from Newcastle, New South Wales, for Ports beyond Australia or New Zealand, between the 1st May, 1880, and the 1st May, 1895, reported missing, wrecked or otherwise lost, or on fire, with the number of crew.

Year.	Name of Ship.	Cause of Loss.	Number of Men.
1880.....
1881.....
1882.....	Sirocco	Supposed foundered	20
1884.....	Indid	Foundered	18
1887.....	Lizzie Tredale	Supposed lost	15
1889.....	Niagara.....	do	7
1889.....	Lucknow	Missing	17
1889.....	Suakim	Supposed lost	24
1889.....	County of Carnarvon	do	22
1890.....	Harwarden Castle	Missing	23
1890.....	Ferndale	do	22
1890.....	Theaphane	do	27
1892.....	Osman Pasha	do	12
1892.....	Friars Craig	do	24
1892.....	Minnie Young	do	6
1892.....	Colwyn	do	19
1892.....	King James	Burnt; crew saved	32
1893.....	Lamorna	Missing	21
1893.....	Gowanburn	Supposed wrecked, New Zealand	31
1893.....	Girvan	Foundered; all hands saved	21
1893.....	Woolton	Missing	26
1894.....	Colintrave	do	27
1894.....	Nicoya	Wrecked; crew saved	12
1895.....	Cambrac	Missing	23

As regards Sydney, the only vessel known to have sailed coal-laden and reported missing is the “Santa Cruz,” she left on the 20th October, 1888, for San Francisco. The “Argo,” German barque, was ready for sea on the 29th July, 1893, coal-laden, but an explosion occurred on board which so damaged her that she had to be laid up.

By order,
GEO. S. LINDEMAN,
31/5/95.

1894-5.

LEGISLATIVE ASSEMBLY.
NEW SOUTH WALES.

VESSELS ARRIVING AT AND LEAVING PORTS OF
NEW SOUTH WALES.

(RETURNS RESPECTING, FOR 1894.)

Ordered by the Legislative Assembly to be printed, 26 February, 1895.

The Secretary of the Board of Health to The Under Secretary for Finance and Trade.

Sir, Board of Health Offices, 127, Macquarie-street, Sydney, 9 February, 1895.
I have the honor to forward you herewith the following returns respecting action taken by this Department with regard to vessels arriving at and leaving the ports of New South Wales during the year 1894:—

- (A) Return of vessels boarded and examined under the provisions of the Quarantine Acts, by the Health Officers, showing an increase for the year of 49 vessels, and a decrease of 6,407 passengers, and 8,465 crew examined;
- (B) Return of vessels quarantined and specially dealt with at Port Jackson, showing a decrease for the year of 56 vessels;
- (C) Return of vessels quarantined and specially dealt with at Newcastle, showing an increase for the year of 56 vessels;
- (D) Proclamations in force under the Quarantine Acts;
- (E) Bills of health issued to outward-bound vessels at Port Jackson and Newcastle, showing a decrease for the year of 129; and
- (F) Vessels cleared under the Imperial Passenger Acts.

I have, &c.,
EDMUND SAGER,
Secretary.

A.

RETURN of Vessels boarded and examined under the provisions of the Quarantine Acts, by the Assistant Health Officer at Port Jackson and the Health Officer at Newcastle, during the year 1894.

Port.	Number of Vessels.	Number of Passengers.	Number of Crew.	Number of Vessels detained for special action.
Port Jackson	362	5,218	20,169	65
Newcastle	227	127	5,340	127
Total.....	589	5,345	25,509	*192

* Full particulars respecting these vessels are given in Returns B and C.

NOTE.—Dr. J. C. Sibley performed the duties of Assistant Health Officer for Port Jackson until the 4th June, 1894, when Dr. W. Peirce succeeded him. The duties of Health Officer for Newcastle were carried out during the year by Dr. Chisholm Ross.

(SECOND SESSION.)

LEGISLATIVE ASSEMBLY.

NEW SOUTH WALES.

SEAWORTHINESS OF STEAMERS "LASS O' GOWRIE" AND "RESOLUTE."

(REPORT ON.)

Ordered by the Legislative Assembly to be printed, 22 November, 1894.

[Laid upon the Table of the House in answer to Question No. 13, of 3rd October, 1894.]

Question.

(13.) SEAWORTHINESS OF STEAMERS "LASS O' GOWRIE" AND "RESOLUTE":—MR. ELLIS *asked* THE COLONIAL TREASURER,—

(1.) Has his attention been called to certain correspondence in the Press, signed by Mr. Sam. Smith, Secretary of the Seamen's Union, in which he alleges that "it was commonly known that the 'Lass o' Gowrie' and 'Resolute' were unsafe for many months prior to their narrow escape from foundering, and that the crews of these vessels could get no one to interfere on their behalf, as "they carried no passengers"; also "that the administration of the Navigation Act by the Marine Board is defective"?

(2.) As this is a direct charge of neglect on the part of the President and the officials of the Marine Board, will he cause an official inquiry to be made to ascertain the truth or otherwise of these allegations?

Answer.

The published statements relating to the "Lass o' Gowrie" and "Resolute" are exaggerations. The vessels have both been employed on the coast, and never depart more than a mile or two from the land, moreover they have ample boat accommodation. The "Resolute" is reputed to be a good vessel, and she is still running. The "Lass o' Gowrie" has been laid up since she returned to port some months ago in consequence of a leak in her boiler. Constant complaints are made to the Board by seamen, but none have ever been made by the crews of these vessels.

(SECOND SESSION.)

LEGISLATIVE ASSEMBLY.

NEW SOUTH WALES.

COLLISION BETWEEN THE STEAMERS "SOL" AND
"ALATHEA."

(PARTICULARS OF THE ACTION IN THE SUPREME COURT RESPECTING.)

Ordered by the Legislative Assembly to be printed, 27 September, 1894.

The Secretary, Marine Board, to The Under Secretary for Finance and Trade.

25 September, 1894.

THIS case arose from the collision which took place some months ago between the "Sol" and the Parramatta steamer "Alathea."

The collision was to a great extent the result of accident, and the Board endeavoured to settle it amicably; but the demands of the "Alathea" party were so outrageous that it was thought better to meet an action in the Supreme Court than to yield to them.

The Board did not, however, wish to plead non-liability, and only sanctioned the action of their counsel with the view of protecting the public interest against the excessive demands of their opponents. With the point conceded by the jury of the non-liability of the Board, better terms will now be made with the owners of the "Alathea," and something like a fair settlement will be arrived at.

By order,

GEO. S. LINDEMAN.

LEGISLATIVE ASSEMBLY.

NEW SOUTH WALES.

NAVIGATION OF THE RIVERS DARLING AND MURRAY.

(PETITION FROM OWNERS AND CAPTAINS OF THE STEAMSHIPS PLYING ON THE MURRAY AND DARLING RIVERS, IN FAVOUR OF.)

Received by the Legislative Assembly, 30 August, 1894.

To the Honorable the Speaker and the Members of the Legislative Assembly.

The humble Petition of the undersigned owners and captains of the steamships plying on the Murray and Darling Rivers, and other the residents of the Murray and Darling District,—

SHOWETH :—

That the residents of the Lower Darling River District, and back country, are solely dependent on the river for obtaining supplies or forwarding produce to market, in the absence of railway communication. That the flood in the Darling River in the season of 1890 has caused many dangerous trees to be washed into the river, thereby endangering the life and property of those who have to navigate its waters, besides being the cause of navigation closing earlier than it would otherwise if these dangerous trees and snags were removed.

The recent floods have also made scours or "cuttings" across the bends, and as a result the ordinary channel has become silted up and unnavigable, while the "cuttings," being much narrower and shallower than the river bed, these "cuttings" form a serious impediment to navigation.

The South Australian Government have, by a series of fences in the Lower Murray, done much to prolong navigation in that part of the river, but these efforts are rendered nugatory so long as nothing is done to improve the New South Wales portion of its waters.

No effort has been made to improve the navigation of the Darling for about ten years past, and as may be naturally supposed, the river has become very bad in consequence, and at no time has anything been done by the Government of this Colony to improve the navigation of the Lower Murray.

Your Petitioners respectfully desire to express their high appreciation of the value of the locks proposed to be erected on the Darling River, believing that thereby not only will water be conserved for settlement, but the navigation of the Darling extended, if not made permanent.

Your Petitioners, therefore, humbly pray that you will be pleased to take immediate action to give effect to the wish of your Petitioners as expressed in this our Petition.

And your Petitioners, as in duty bound, will ever pray, &c.

[Here follow 225 signatures.]

REPORT of the Honorable SIR ARTHUR RENWICK, Executive Commissioner to the World's Columbian Exposition at Chicago, U.S., 1893, to His Excellency the Right Honorable SIR ROBERT WILLIAM DUFF, Knight Grand Cross of the Most Distinguished Order of St. Michael and St. George, Member of Her Majesty's Most Honorable Privy Council, Governor and Commander-in-Chief of the Colony of New South Wales and its Dependencies.

MAY IT PLEASE YOUR EXCELLENCY :—

Having now completed the various duties which devolved on me, in virtue of the Commission which your Excellency's predecessor, The Right Honorable the Earl of Jersey, G.C.M.G., P.C., was pleased in Her Majesty's name and under the Great Seal to issue to me as Executive Commissioner for New South Wales at the World's Columbian Exposition, held at Chicago, United States of America, I have now the honor to present for your Excellency's consideration and approval my Report on the said Exposition, and more particularly on the representation of our country thereat, as well as on various matters which seemed to me of importance in connection with the performance of the duties of my office as Executive Commissioner.

PLAN TO BE ADOPTED IN THIS REPORT.

The magnitude and importance of the World's Columbian Exposition; the very complete representation it afforded of the natural products, manufactures, scientific applications, artistic representations, ethnological and social conditions of nearly every country in the world; the important and interesting facts connected with its initiation, its representation of the leading features and characteristics of ancient and modern civilization, its World's Congresses, and many other matters, render my task no easy one. To convey even a general idea of the whole is one which would tax the powers and the ability of the most gifted. It will be my endeavour simply to bring under the attention of your Excellency such salient features of the Exhibition as may be condensed in the space at my command. To accomplish this purpose I believe my best plan will be to follow the course of the events which have occurred in connection with the performance of the responsible duties of my official position, and to portray in concise form some of the more important features of this World's Fair, the circumstances more directly connected with its history, its site, its architecture, its exhibits, and, in fine, its general nature, as well as to describe the very important and representative position which our country occupied in connection with the Exhibition.

ABSENCE OF EXPERTS FROM OUR COUNTRY.

I consider it my duty to state at the outset that it has been a constant source of regret to me that our country did not send to this wonderful exhibition of the latest advances of science and art a few specially skilled experts to report on such of the exhibits of the various nations as would be of value to our people. Other countries have invariably adopted this course. At the last Melbourne Exhibition the United States Government sent three experts for this purpose; and from the Report of the Commissioner for the United States at the last Paris Exhibition, I find that a number of such experts were sent by the American Government, and their reports—a mine of useful information to the various scientists, artists, and mechanics, as well as to the people at large of the United States—filled five large octavo volumes. Germany, France, and other countries invariably take advantage of the opportunities presented at great Exhibitions, and even Japan on this occasion sent over a large number of learned men for this purpose. The oversight of New South Wales on this occasion was especially to be deplored in view of the extensive and far-reaching character of this Exhibition. I could scarcely examine the contents of any one of the great departments of this World's Fair without having this serious omission impressed on my mind. Notwithstanding the very critical financial condition of the country at the time of the Exhibition, I am of opinion that the money which might have been expended for this purpose would have been infinitely repaid in the valuable information which would thus have been supplied for the information of all classes of the public. In the performance of the various and continuous duties of my office my time as Executive Commissioner was as fully occupied as it possibly could be; but, with an anxious desire that the lessons of this Exhibition should not be wholly lost to us, I have endeavoured, to the best of my ability, to provide, to some extent, this kind of information, and in my efforts I have been greatly assisted by the particulars generously and cordially supplied to me by exhibitors, by the Press and by the officials of the Exposition. I have also obtained and embodied in this report the views of special experts on several matters which seemed to me of importance to certain classes of our people with regard to the most recent improvements in regard to machinery, and advances in science and the like, as exhibited in this Exposition. In the remarks which I have made regarding exhibits, it will be found that I have dealt but briefly with those from our own country, my object being rather to furnish information in connection with the exhibits of other countries than to enter upon a prolonged description of our own.

INITIAL PROCEEDINGS.

Appointment of Commission and Executive Commissioner.

In the instrument appointing the Commissioners upon whom was to devolve the duty of collecting and transmitting the exhibits to the World's Columbian Exposition at Chicago, dated 28th September, 1891, my name was included, and consequently I had the opportunity of taking part in the proceedings of the Commission from its commencement. Subsequently, on 16th October, 1891, I received my Commission as Executive Commissioner (*See Appendix A*); and in that special capacity, recognising that on me would ultimately devolve the responsibility of providing for the proper display at Chicago of the various representative exhibits collected, I took every opportunity, by attending the various meetings of the committees appointed for the collection of special classes of exhibits, and by examining from time to time the various articles themselves, to make myself thoroughly acquainted with the character of our representation. Subsequently, when the President of the Commission left New South Wales for a time,

time, and the necessity for an Executive Officer to the Commission became apparent, the following resolution was passed at a meeting of the Commission held on February 5th, 1892:—"That during the absence of the President, the Secretary confer with the Executive Commissioner on all matters of importance outside all meetings of the Executive Committee and of the Commission." I had still further opportunity of gaining invaluable information for my future work, and of rendering advice and assistance to the Commission.

Departure on Duty.

The more important portion of its work having been completed by the Commission, and a general idea of the scope and character of the exhibits to be forwarded having been obtained, I considered it advisable to leave New South Wales to undertake my special work at Chicago. I considered it my duty, in the continued absence of the President, and in view of the necessity for an executive head, to recommend to the Commission the appointment of an Executive Vice-President.

Appointment of Executive Vice-President.

The two Vice-Presidents who had been appointed in the original instrument, the Hon. Sir Joseph Abbott, M.P., Speaker of the Legislative Assembly, and His Worship the Mayor of Sydney (Sir W. Manning), I was aware were too fully occupied with their important public functions to devote the time and attention, which I knew from practical experience was necessary for the purpose. After consultation with these gentlemen, I wrote a letter to the Hon. the Colonial Secretary, calling his attention to the necessity and importance of such an appointment, and having had the approval of the Government I suggested at a meeting of the Commission held on June 17th, 1892, that J. F. Burns, Esq., who had been created a Vice-President, should be appointed to fulfil the duties I had up to that time performed, until the return of the President, having previously obtained the consent of that gentleman to act in that capacity.

Insurance on Exhibits effected in London.

On June 28th I left Sydney, and arrived in London on the 16th August. In accordance with arrangements made with the Commissioners in Sydney, I immediately made inquiries as to insurance rates and a number of matters of detail. I cabled to Sydney on this subject, and eventually arranged, in accordance with the advice of the Commission, for the insurance of our exhibits to the amount of £25,000 with some of the best insurance companies in England. When this matter was completed I immediately left London for America (on October 11th), in order to be present at the dedication ceremonies of the Exposition. I arrived in New York on October 19th and left next day for Chicago, reaching that city on October 21st.

THE DEDICATION CEREMONIES OF THE EXPOSITION.

The ceremonies in connection with the Dedication of the buildings of the World's Columbian Exposition, celebrating the 400th anniversary of the discovery of America by Columbus, occupied three days. They began on the night of October 19th with a brilliant ball in the Auditorium, at which the Vice-President of the United States, the members of the Cabinet, the Speaker of the House of Representatives, the Chief Justice of the United States, the Associated Justices, the Diplomatic Corps, the Governors of the States and Territories, the Officers of the Exposition, and many other distinguished persons were present. A civil parade was held next day, at which very large numbers

numbers of people were present. On Friday, October 21st, the Dedication ceremonies proper of the Columbian week reached their culmination in the Dedicatory Exercises at Jackson Park.

Under the noble roof of the Manufactures Building the all-but completed Columbian Buildings were formally tendered by the local corporation to the National Commission, and then to the Vice-President of the United States (acting for the President), who then dedicated them in impressive terms to the memory of the great Genoese and the honor and glory of the Republic.

In the language of an able writer who has described the wonderful scene presented on this occasion :—

No circumstance, save only the lamentable absence of the President of the United States, was wanting to contribute to the solemnity and impressiveness of these ceremonies. On the rostrum sat eminent persons from every quarter of the globe. The Vice-President was supported by members of the Cabinet of his Chief, gathered for the first time in the history of the Government at a point a thousand miles distant from the capital. For the first time, also, since the Republic was born, the Chief Justice and his Associates of the Supreme Federal Bench came together outside of their Court. The Senate and the Representative House of Congress sat together almost *en masse*. The chief officer of the Army and Navy were present, surrounded by the flower of their respective staffs. One of the two living ex-Presidents of the United States held a seat of honour. The Governors of thirty States, Officers of the Philadelphia Centennial Exhibition, Members of former Cabinets, the Mayor of Chicago, great divines, orators, merchants, scholars and lawyers, came to sit beside the officers of the Exposition in their hour of final triumph.

Nor were the other nations of the earth absent from the scene. The heir of Catherine of Arragon sent his Deputy to sit beside the venerable minister of that nation, which, if it did not give aid to the Columbian venture gave birth to Columbus himself. From that far-away Cathay which Columbus thought to find, came ministers still fixed in the laws and customs which never change, though new worlds are found and new nations born. The new Republics of South America, whose heritage is the very soil touched by the foot of Columbus, sent messengers to bear their greetings to their older sisters of the North. Ministers, Consuls, and Commissioners, in a word, of all the nations who were to partake in the Great Exposition, were present to share in the glory of its inauguration.

It was a scene of unique splendour upon which these dignitaries looked. They sat upon an inclined platform against the centre of the east wall of the Manufactures Hall, within sound of the unending music of the lake upon the beach. Above their heads was a mass of patriotic colour. Against the background of the Stars and Stripes hung the ancient standard of Spain with its castles and rampant lions on brown and gold, and the gonfalon of Ferdinand and Isabella with their crowned initials flanking the nether arm of the green cross. On either side of these were the white and pale blue flag of the Exposition with its device of the linked crescents and the laurel crown, and the white and terra-cotta flag which a Danish artist has given to Chicago. Pendent from the roof were the flags of all nations. In the unending arches of the great building the American Flag or "Old Glory" was repeated again and again, mingled with the flags of the friendly nations.

The decorations, though simple, were upon a scale which it is difficult to conceive, unless one were present to observe the large spaces and the immense iron arches almost wholly concealed beneath the graceful folds of bunting streamers. The Speaker's stand and the great inclined platform reserved for the dignitaries was at the centre of the east side of the building. In front of it were the Press seats, hemmed in behind a pretty hedge of blossoming plants. In the centre of the platform was a raised platform in the shape of a semi-circle, extending out towards the audience portion, for the Vice-President, the Speakers, and high officers of the Exhibition, and others. Over the Speaker's table was draped a silken banner of the stars and stripes. Behind the table extended a magnificently carpeted broad aisle which separated the distinguished spectators portion, and over all was a grand festoon of American flags with the American eagle spreading his wings out from the centre. Along the galleries were groups of palms waving their tops among the suspended points of hanging streamers, and from the centre of the ceiling along its full length hung great silken American flags. The great windows at the west side of the building were covered over with cloths of white bunting to subdue the light. The floral decorations in the Manufactures Building were remarkable in design and rare and beautiful in appearance, the immense tree ferns from New South Wales being well to the front, and adding in no small degree to the harmony and beauty of the memorable scene. The decorations of the great building, while not at all diffuse, were sufficient to hide the immense trusses of the structure, break the distances, and make the building look like a grand musical palace. At the south end of the great hall was the stand for the orchestras and choruses, in which about 5,000 people were congregated. About 125 to 150,000 people were assembled in the great building, perhaps the largest number of persons ever congregated under one roof at one time.

In Appendix C will be found a full description of the proceedings at these ceremonies.

Illuminations

Illuminations at Night.

There was a variety of gorgeous illuminations at night in the Exposition grounds, and in fact a special feature of the three days exercises was the striking spectacle of the "Procession of Centuries" given on the Fair Grounds on the nights of October 20th, 21st, and 22nd.

Inauguration of the World's Congresses.

On the evening of the 22nd October, a large meeting, representative of American and foreign distinguished men and women, and consisting of diplomatists and Governors, statesmen and eminent jurists, scientists and artists, Church celebrities and society leaders, took place at the Auditorium to inaugurate the World's Congress Auxiliary. The motto of the Auxiliary was "Mind not Matter," and its object was to consider by means of its various meetings and discussions the present position and future development of all subjects outside of mere material progress. As the Exhibition represented the countless forms of material wealth, and resources, so the Congress was expected to unfold the mental, moral, and spiritual outcome and expectation of humanity, and thus it was anticipated that the humanities would not be overlooked by the necessary, the beautiful, by the useful, or the religious, by the practical everyday forms of life. The various meetings of these Congresses were subsequently held in the Art Institute of Chicago, a large building recently erected on the Lake Shore, near Van Buren-street. The cost of this building was defrayed by the Exposition authorities in part, on condition that the large rooms of the building should be at the disposal of the meetings of the various Congresses and their Committees during the currency of the Exposition. In Appendix D will be found a summary of the proceedings as well as the eloquent speech of Archbishop Ireland on the occasion, and at a later stage of this report further reference will be made to this subject.

ARRANGEMENTS AS TO SPACE FOR OUR EXHIBITS.

Object of my visit to Chicago on this occasion.

The principal object of my visit to Chicago at this time was to examine the various departmental buildings of the Exposition, and to obtain reliable information as to the allotment and location of space reserved for New South Wales. To determine these matters I found it necessary to visit the Exhibition buildings, at Jackson Park, almost daily, and, eventually, to attend on the chiefs of departments in their temporary offices in the Rand-McNally Building in Chicago. I found, to my surprise that, although most of the great nations represented had already been allotted their space in the several buildings, nothing of a definite character had been settled as regarded our country. It is true that our Premier, Sir George Richard Dibbs, had been informed by cable, while in England, that 50,000 feet had been reserved for us; but I found that the principal portion of this space was contained in the stock annexes and other out-of-the-way departments. The space for our valuable and representative mining exhibit had been fixed at about 4,000 feet only, and in many other matters the importance of our representation had been altogether overlooked. Endless interviews and negotiations followed, and at one time I thought that it would be necessary for me to withdraw altogether from representation on this account. But ultimately, through the kindness and unswerving assistance of Director-General Davis and the chiefs of the departments, this important matter was settled almost to my satisfaction. To show the difficulties that surrounded this question of allotment I may instance one case only, that of the space for our mineral display.

In

In order to obtain anything like the space required, several great countries had to be removed. Belgium was removed to another part of the Mines Building, and the boundary of France was modified; and Cape Colony was removed from the location determined for its exhibit. All this had to be done in the face of the fact that official notification had been given to these countries of their allotment; and had it not been for the constant use of the telegraph, and the friendly support of the officers of the Exposition, the matter could not have been satisfactorily determined.

In regard to two of our departmental exhibits I did not obtain a satisfactory settlement. In the Woman's Building only a limited space was granted. In regard to this matter there must have been originally some misunderstanding. This building was erected, not primarily as a building to receive exhibits of woman's work but rather for official purposes; and the exhibits it was to contain were only to be of such a nature as to represent special exhibits of woman's work of a peculiarly characteristic and national nature. In the Fine Arts Building I found that no space whatever had been allotted to us, and that there was none that remained for allotment. In this matter I was advised to apply to Great Britain for space for our purposes, as I subsequently did.

Question of Offices in the Exposition.

Amongst other matters brought under my attention when in London was the question of offices; and in conversation with members of the British Royal Commission, some of whom had already visited Chicago, it was suggested to me that it would be well to obtain a portion of the British Government Building (Victoria House), then being erected for that purpose. A definite offer in this matter was tendered to me by Sir Henry Trueman Wood, Secretary to the British Royal Commission; and an upper wing, containing three or four rooms, was offered to me for the sum of £1,000 for the season of the Exhibition. At the time I deferred acceptance of the offer until I had the opportunity of visiting Chicago. I examined Victoria House when in Chicago, and found that for many reasons it would be undesirable to accept the kind offer of the British Commission. It appeared to me that it would be a most important matter that New South Wales should possess a State House, as it is termed, of its own, where we could always receive our own visitors, fly our own flag, and transact all our business, if this great purpose could be accomplished at any reasonable rate. On this occasion I applied for the necessary grant of land for the purpose from the Exposition authorities, and obtained plans and estimates for the proposed building. The site I selected seemed very suitable, adjoining that granted to the Dominion of Canada, very near that of Great Britain, having Spain and Germany at the rear. The estimates for the building were reasonable, very little more than the amount asked for the apartments in Victoria House. The plan and elevation were settled at once, and I adopted as the most useful and inexpensive form of building a general representation of the old Sydney Post Office. For the sum of about £1,000 we obtained a building, erected of staff and wood only, but very commodious and very imposing, which, as I shall hereafter relate, formed eventually a most useful and conspicuous centre of reception for Australian visitors, a necessary suite of offices, and a Fine Art hall for our pictures.

Arrival of Mr. General Superintendent Hudson.

Having completed all these matters, just before leaving Chicago I received a telegram announcing the arrival of Mr. Robert Hudson, our General Superintendent, at San Francisco. Mr. Hudson's telegram informed me that he had come over thus early to settle the route and
the

the rates for the carriage of our exhibits from Sydney. I was surprised at this information, as I had definitely informed the Commission in Sydney, before leaving, that this was a matter which I should inquire into and report on to the Commission. As a matter of fact I had already seen most of the great railway companies running between Chicago and New York and other Atlantic Ports on the subject with a view to obtain the easiest possible terms. Mr. Hudson, subsequently, showed me an offer he had obtained while in San Francisco, and this offer was so much below that ordinarily quoted, that I could scarcely believe that his information was correct. As I had already arranged for my departure for London, I stated my opinion that if such an offer could be obtained it would be a very fortunate matter for the Commission. Mr. Hudson, after I left Chicago, found that the offer referred to had been confirmed by the railway and steamship companies. It was unfortunate that Mr. Hudson did not refer this matter to the Commission for final settlement, but I am sure that his great anxiety to obtain what then seemed, and since then has proved, most reasonable and satisfactory terms for the conveyance of our exhibits, made him overlook his official duty in this matter.

Departure for London—General Superintendent left in charge.

Leaving Mr. Hudson in charge, so that our representation should have a responsible person at headquarters to attend to a number of matters of detail, I left Chicago on November 10th, 1892. Before doing so I left written and explicit directions with the General Superintendent as to his course of action and plan of conduct during my absence.

REPRESENTATIVE WORK IN LONDON.

Request for Space in Fine Arts Palace and in Mines Building refused by British Commission.

Immediately after my arrival in London on November 20th several matters of importance engaged my attention. Knowing the desirableness of having adequate space in the Fine Arts Palace of the Exposition I had many interviews with the Secretary of the British Royal Commission (Sir Henry Trueman Wood) for that purpose, and Sir Saul Samuel, our Agent-General, gave me special assistance in the matter. As I was well aware that Great Britain did not propose to have a very large exhibit in the Mines and Mining Building I also asked the British Commission for some arrangement whereby my desires in this respect could be complied with. With regard to both these matters I was unsuccessful. While the British Commission expressed the desire to assist us in every possible way it was stated that they were unable to grant my request. At this time, also, I finally dealt with the terms and conditions of the policies of insurance of our exhibits in the English offices in conjunction with Sir Saul Samuel, who afforded me on this and on many other occasions very valuable assistance.

R.M.S. Orient Company's Exhibit.

Another subject which engaged my attention was that of the exhibit of the Orient Steam Navigation Company. This exhibit had been requested in Sydney, and correspondence with the head office had taken place, but no definite result had been arrived at. After several interviews at the head office of the Company I agreed to accept as an exhibit, under the usual conditions, the beautiful model of the R.M.S. "Austral," at that time an exhibit in the Imperial Institute, together with certain photographs of the R.M.S. "Ophir," &c.

Decorations

Decorations supplied by Pain & Co., of London and New York.

At this time, also, I entered into general negotiations with the well known firm of Pain & Co. (who had been engaged by the British Commission), for the supply of flags, trophies, and other decorations for our various courts; my orders to reach them, and to be provided at schedule rate for their supplies, after I had made the necessary arrangements in Chicago.

Return to Chicago.

As soon as the exhibits from Sydney were announced as having arrived in America, I left London on January 21, 1893, and arrived in New York on January 30, and left next day for Chicago, where I arrived on February 1, and at once entered fully upon my arduous and responsible duties as Executive Commissioner.

Weather, &c., in Chicago.

The weather at that time was very severe; the lake was frozen for several miles from the coast line; the temperature rarely rose at mid-day above 16 degrees Fahrenheit, and frequently fell from 10 to 15 degrees, and even 20 degrees below zero. The streets were a mass of snow, and footways were covered with a thick slippery coating of ice, causing accidents, often of a very serious nature, to be quite a common occurrence.

Loss by Freezing of all our Light Wines, Beer, &c.

The first news I received on my arrival was that all our light wines and our ale and porter had been destroyed by the cold, and I was compelled at once to cable to Sydney for duplicate exhibits and to obtain from the local authorities extension of time for their admission, which was at once granted, on my application. The state of the grounds at the Exhibition was simply frightful. To give an illustration of these difficulties, I may mention that in the offices in which we were temporarily located in the Mines building, although there was an immense stove to heat the room, the ink was frozen in the bottles, and correspondence was carried on under great difficulty. Officers in the Administration Building were frequently during this period unable to carry on their work. As if these circumstances were not enough to discourage, I found additional cause of trouble and anxiety in the fact that no catalogue had come with the exhibits. This circumstance, as was explained in correspondence from the Commission in Sydney, occurred in consequence of the overworked state of the Government Printing Office staff at this particular time. I further found when the cases were opened to identify the contents that the labelling intended for the direction as to which department the cases belonged to was in a considerable number of instances wrongly done according to official classification, and thus the expense of removal, on account of the great distance between the buildings, was vastly increased, and all the troublesome processes (permits, official notification, &c.) required in a great custom-house, such as the Exposition was in reality, had to be gone over again and again.

Spaces in the various Buildings marked out.

As soon as I had compared our various goods, as received by the first shipment, with the manifest forwarded by the Commission, I requested the authorities to mark out our various spaces in order that I might prepare our courts for the reception of their exhibits. I soon discovered that I had not only an arduous but also a most expensive task to perform. The vastness of the buildings of the Exposition necessitated the erection of screen walls of timber on all sides; rarely were wall spaces available, and the large number of enlarged photographs which had been prepared for our purposes added to this expense. The floors of the buildings were not strong enough to sustain many of our

our structures, especially in the Mining and Agricultural Courts, and I was compelled to make foundations for this purpose. There was some delay and considerable difficulty in obtaining skilled persons to stuff and mount the several hundred specimens of natural history sent from Sydney. And, lastly, the cases and tables required by all the Departments (except Mines) had to be prepared. Not an inconsiderable item of expense was entailed in connection with the framing of the very large number of enlarged photographs sent, and as the regulation for the admission of exhibits to the Fine Art Palace required all oil paintings to be suitably framed, this item of expense would run into a much larger sum than I had originally anticipated. For several weeks after my arrival the snow fell so heavily that the roofs of several of the great buildings were broken by its weight, and leaks innumerable added to the difficulties connected with the carrying out of our work.

Rearrangement of duties of Officers for purposes of installation.

In consequence of these difficulties, and the great distances between the buildings and other matters, I saw clearly that if our work of installation was to be completed with due economy before the date of opening (the 1st May), it would be necessary for me to adopt a system quite different from that employed in former Exhibitions, and from that which I had originally intended. I therefore determined to divide the onerous duties of preparing and placing the exhibits in the following way:—To Mr. Hudson I allotted the task of placing the exhibits in the Forestry, Agricultural, Machinery, and Transportation Buildings; to Mr. Pugh those in Horticulture, Fisheries, Fine Arts, and Ethnology; to Mr. Carne, with Mr. Ford, Mines; to Mr. Terry, Liberal Arts and Manufactures; whilst I personally supervised all, and guarded with the greatest care the necessary expenditure.

Grand principle of installation.

From this time forward till the opening of the Exhibition, on the 1st May, I was busily occupied from day to day with the various arrangements connected with the display of our exhibits as the various shipments arrived from Sydney by way of San Francisco. The great principle that I continually impressed upon my Superintendents was to produce a conspicuous display, in massive form, as far as possible, in each building, so that the attention of the most careless and casual visitor should at once be attracted to our representation; and I am glad to report that by the arrangements which I made in this respect with the exhibits of our country, I fully accomplished this very important purpose, as will be shown in a latter part of this Report. As showing the appreciation by other countries of my mode of displaying exhibits, I have been informed that the Canadian authorities have given instructions that the Dominion exhibits at the Antwerp Exhibition are to be arranged in accordance therewith.

Extension of space in Liberal Arts Department granted by British Commission and in Fine Art Palace by American Authorities.

I am glad to report that, although the British Commission refused to grant us any space in their Fine Arts Courts for our pictures, I received from that Commission an extension of our space in the Liberal Arts Building (adjoining the British exhibits), and shortly before the opening of the Exhibition in May, by the courtesy of the Director-General and Chief Ives, of the Fine Arts Palace, I received the concession of a bay for twenty of our pictures in the gallery of that building, over the British space. A further privilege was granted to me by the authorities of the Exposition. I was allowed to employ the wall space of our State Building (Australia House) as a branch of the Fine Art Palace, the pictures placed there to be subject to all the rules and regulations affecting those placed in the Palace.

Space

Space in New South Wales Courts.

It may be well to state in this place the exact amount of space our country occupied in the several departments of the Great Exhibition. The exact position of the spaces will be found on Plan, marked in blue colour :—

	Floor.		Wall.	
	sq. feet.	sq. feet.	sq. feet.	sq. feet.
1. Agriculture— Three Courts	8,693	...	13,600
2. Forestry— Main Building Block Road Cedar Block	2,400 594 104	3,098
3. Machinery	1,425	...	1,700
4. Transportation— Main Building Annex	1,071 702	1,773	...	2,056
5. Fine Arts— Main Building A. House	270 3,600	3,870	444 5,000	5,444
6. Fisheries	1,656	...	600
7. Liberal Arts— Three Courts	6,247	6,247	...	10,164
8. Manufactures	5,090	...	9,858
9. Mines and Mining	8,300	...	1,478
10. Ethnology— Bark Hut Main Building	300 4,366	4,666	...	6,702
11. Horticulture— Fern Court Fresh Fruit Pressed Wine Court Photos	3,780 400 364 765 440	5,749	100 1,250 1,100	2,450
12. Woman's Work	384	...	1,200
13. Space round Australia House, Asphalt, Tiles, &c.	6,200
Total, Floor Space	57,151	...	55,252

Summary of Goods forwarded from Sydney.

The various shipments of goods received by me at Chicago for exhibition purposes, as stated in the various manifests, was as follows:—

Ship.	Date of manifest.	No. of packages.	Measurement.		Weight.			Value.			
			ft.	in.	t.	c.	q. lb.	£	s.	d.

WHY CHICAGO WAS SELECTED AS THE SITE OF THE WORLD'S
COLUMBIAN EXPOSITION.

It will be of interest at this stage to refer to the question, so frequently agitated in connection with this Columbian Exposition; why the city of Chicago was selected by the American Congress as its site.

In the selection of a location for the Columbian Exposition the Congress of the United States encountered a difficulty such as no legislative body had ever experienced when considering such a subject. In older countries the capital ranks so far ahead of other cities that the mere suggestion of an International Exposition carried with it the understanding that the seat of such Exposition should be the national capital. Thus London, Paris, Berlin, Vienna, and other European capitals have been acknowledged to possess an unchallenged right to an International Exhibition whenever their respective countries have decided to hold such a celebration. In the United States, however, the spirit of democracy is carried even to the extent of rivalry between the great cities of the country in these matters. Thus it happened that there were at least five cities of such metropolitan character that any one of them could have adequately provided for the needs of an International Exposition. New York, Chicago, Philadelphia, Boston, and St. Louis were all of the rank of Exposition cities. At any one of these the Columbian Exposition might have been held with fair assurance of success as soon as the announcement of the World's Columbian Exposition had been definitely settled. Between three of these—New York, Chicago, and St. Louis—ensued a friendly contest, as to which should have the honor of entertaining the visitors of the Exposition. The result of this contest was the selection of Chicago, and the more or less graceful acceptance of that selection by the country at large.

History of the Exposition.

The history of the World's Columbian Exposition is a tale of modern miracles; of the achievements of great results in a marvelously short space of time. It is a string of cold facts that surpass fiction in their strangeness, and that will stand for ever as a mighty monument of the admirable enterprise and indomitable spirit of Chicago and its people.

Little more than three years had passed since the first suggestion for an American International Exposition, to mark the four-hundredth anniversary of the discovery of the continent, was made. The Paris Exposition was in full blast when the suggestion reached Chicago, and that city promptly took action in the matter. Very little consideration of the proposition was needed to convince the average Chicagoan that if a Columbian Exposition was to be held at all it must be held in the great Metropolis of the West—his own beloved city, which stands to him for all that is most enterprising and public spirited in American civilisation.

First Public Procedure.

It was on the evening of July 23rd, 1889, that the first public step was taken in regard to securing the World's Fair for Chicago, and then began the memorable struggle between New York and Chicago. The City Council of Chicago, on the date named, formally resolved that it would be good policy to make every effort to secure the Fair, and took the initiative by authorising Mayor Cregier to appoint a Committee of two hundred and fifty citizens to superintend the preliminary work. This Committee was appointed by the Mayor on July 30th, 1889, and held its first meeting in the council chamber at the City Hall on August 2nd. The best known, the wealthiest, and the most truly representative citizens of Chicago attended that meeting. Before the meeting adjourned a Stock Company, with a capital of \$5,000,000,
was

was established, and its affairs were placed in the hands of a small Executive Committee. Next day the work of the Committee of two hundred and fifty was divided among numerous Sub-committees, and popular enthusiasm in the work began to develop.

Further Stages.

On August 5th, 1889, an offer was made by George M. Pullman of a site for the proposed Exhibition near the town of Pullman. This site was so large that the entire Paris Exposition might have been put in one corner of it. The offer, while it was not ultimately accepted, served to open the eyes of the people of Chicago to the magnificent possibilities of their city as a World's Fair Site; and on the same day the Trades Assembly, representing all the organised labour of Chicago, unanimously resolved to put forth every possible effort to secure the Fair. Every trade, profession, and branch of business began to organise separately to attain the common object, and the advantages of Chicago were duly set forth in a formal address, issued August 13th, to Congress and the United States. On August 16th the Finance Committee perfected its plans for raising funds, and twelve days later it was announced that half the capital stock of the new Exposition Company had been subscribed. From that time money rolled in rapidly, and on September 20th came the cheering news that the entire \$5,000,000 of stock had been taken up. Among the large subscribers were Charles T. Yerkes, George M. Pullman, and Marshall Field, all of whom have been steadfast friends of the Fair from its earliest inception down to the present time. No sooner had the public announcement been made that the \$5,000,000 was raised than New York's opposition to Chicago developed. The news that the eastern city was a candidate for the Fair was made public on September 25th, and it was said that she would raise the sum of \$10,000,000 as a guarantee for the proper performance of her contract if given the Fair. From September, 1889, to February, 1890, the battle between the rival cities was waged without ceasing, in and out of Congress, and there are few who have not heard of the immense amount of wirepulling and political manœuvring that marked the struggle. All the forces of the East were arrayed against the influences of the West, but the men of Chicago stuck fast to their colours and won the victory.

First Congress reports favourable to Chicago.

The first Congressional reports, made in the last week of October, 1889, were favourable to Chicago, but its representatives relaxed no effort until the great struggle finally ended in victory on February 24th, 1890. On that date Congress passed the Act creating the World's Columbian Commission under the title of "An Act to provide for celebrating the four-hundredth anniversary of the discovery of America by Columbus, by holding an International Exhibition of arts, industries, manufactures, and the products of the mine, soil, and sea, in the city of Chicago, in the State of Illinois." [*The Act will be found in Appendix E.*]

Monetary Difficulties.

Chicago had won its victory, but the difficulties of its representatives were only then beginning. New York had agreed to raise \$10,000,000 as a starting fund for the Fair, and among the conditions imposed on Chicago by Congress was one to the effect that she must do as New York had promised to do. Consequently the next few months were spent in work among the aldermen of Chicago and the State legislators at Springfield, the capital of Illinois, in an effort to secure the appropriation of the second \$5,000,000. Some internal jealousies and dissensions had developed among the stockholders during the winter of 1889-90, even while the fate of the World's Fair was pending in Congress, and for a while these troubles looked dangerous.

All

All such feelings had to be nipped in the bud in the case of the Exposition Company or its glorious object would have been endangered. The necessary remedy was applied on April 4th, 1890, at a meeting of the stockholders for final organization. Chicago had already been selected by Congress as the place for holding the Fair, and the eyes of the world were turned upon this city with eager watchfulness. There was tumult over the election of directors at the meeting, and things looked dark and threatening indeed, when the Hon. Thomas B. Bryan, in a ringing speech, warned the stockholders that they were being watched by the entire world, and that it behoved them to act in harmony or throw up their undertaking. The warning was timely, and had immediate effect. Petty jealousies were laid aside, and everybody began to work for the general interest of the Exposition, regardless of personal or individual interests. This policy has happily characterized the management of the Exposition ever since, and to it is largely due the immense effectiveness of the work already done. After some months of weary work among the State legislators, authority was finally secured to bond the city of Chicago for the second \$5,000,000 needed for the Fair, and then the Directors of the Company began to breathe more freely.

Jackson Park as Site of the Exposition first mooted.

From February to September, 1890, the site of the Exposition occupied the attention of Chicago. At an early stage the suggestion to use the lake front near the busy portion of the city was greatly favoured by public opinion, but the difficulties in the way of the acceptance of this locality seemed almost insuperable, and this proposal, like that of Garfield Park in the west side of the city and others, was finally abandoned. The Jackson Park plan of the site, prepared by John P. Root, which formed the basis of those ultimately adopted, was made public on the 5th March, 1890, and, after a controversy extending over several months, the advantages of Jackson Park and the Midway Plaisance became so apparent that this site was finally adopted.

Early Proceedings of Directors.

The first meeting of the Directors of the Exposition Company was held on 13th April, 1890, and the first officers were elected on 1st May. Standing Committees were appointed and official salaries fixed on 7th May.

Increase of Capital Stock.

On 13th June, 1890, the Directors resolved to increase the capital stock of the Exposition Company to \$10,000,000, and this was accordingly done. Subscriptions for the additional stock were received, and it soon became evident that Chicago meant to distinguish itself by liberal treatment of the Fair. The Hon. Thomas W. Palmer was elected President, and Colonel John T. Dickinson Secretary, of the National Commission, 28th June, 1890. These gentlemen retained these positions till the close of the Exposition, and, in common with all other National Commissioners, have done yeoman service for its welfare.

Colonel Davis appointed Director-General.

The foundation of the permanent organisation of the Exposition was laid on 20th September, 1890, when George R. Davis was elected Director-General by the National Commissioners and Local Directors. Colonel Davis immediately set about the work of organising departments, and soon evolved a plan which was adopted after some weeks of disputations, argument, and controversy as to the powers of his office in relation to those of the Local Directorate. It gradually became recognised that the Exposition, to be thoroughly successful

successful from the start, must have an administrative head, and the Director-General was finally left in the enjoyment of supreme power over all the Exhibition departments. Subsequently to Colonel Davis' appointment the work of preparing for the Exhibition progressed steadily, and Jackson Park was surely transformed from a dismal morass into a city of white palaces, exemplifying the most perfect architecture, and conveying to the mind of the visitor profound admiration for the aggregated genius that had achieved so much in so short a time. The appearance of the Exposition Buildings at Jackson Park, and of the charming landscape that surrounds them, has become familiar to visitors, and all that need be added at this stage is that the *tout ensemble* has evoked the wonder of the millions who have had the opportunity of visiting it.

Co-operation of Women.

From the outset of the Exposition undertaking the women of America exhibited the liveliest interest in it, and their co-operation was early invited. On the day after the election of Colonel Davis as Director-General a Board of lady managers was appointed, which, under the presidency of Mrs. Potter Palmer, has laboured without ceasing for the general good of the enterprise, as well as in the specific direction of securing a complete representation of woman's work. In every State of the Union and in every country of the civilised world the influence of the lady managers has been exerted, and, as a consequence, one of the most interesting of all the buildings at Jackson Park was the Woman's Building.

Progress of the Work.

The winter of 1890-1 was a very busy one for the Director-General and his coadjutors. A Board of Architects was appointed, consisting of eminent men, selected generally from the United States. When the work of construction commenced in the spring of 1891 the gigantic and expensive nature of the undertaking was fully recognised, but the indomitable spirits of the chief movers in this great enterprise were not daunted at the prospect. As a consequence, there have arisen from the swamps and the sandhills of the erstwhile dreary "Jackson Park" the most magnificent Exhibition Buildings the world ever saw, set in a framework of picturesque scenic beauty.

State Boards of Managements.

The year 1891 also witnessed the appointment of many of the State Boards of Managements. Nearly all the States provided appropriations for their exhibits, and took an active interest in the success of the Exposition. These appropriations amounted to several millions of dollars, and betokened the sisterhood of the States in a very tangible way. Most of the States making appropriations had separate official buildings at Jackson Park.

Internal Management.

There were comparatively few changes in the internal management of the Exposition. During most of the time there were two governing bodies—the Local Directorate and the Board of Control of the National Commission. As might have been expected, frequently there was friction between these two authorities, and in order to obviate the difficulty, and at the same time simplify matters, a compromise agreement was reached in the month of August, 1892, whereby a Council of Administration, composed of two members from each of the old governing Boards, was placed in supreme control of everything, including the finances. This Council worked with comparatively little friction and gave fairly good satisfaction till nearly the close of the Exposition.

Director-

Director-General Davis' plan for dividing the work of the Exposition into a number of departments was adopted late in November, 1890, and worked well throughout the whole course of the Exposition. The following are the departments, with the names of their respective chiefs:—

- A. Agriculture, Food and Food Products, Farming Machinery, and Appliances—Chief Buchanan.
- B. Viticulture, Horticulture, and Floriculture—Chief Samuels.
- C. Live Stock, Domestic and Wild Animals—Chief Buchanan.
- D. Fish, Fisheries, Fish Products, and Apparatus of Fishing—Chief Collins.
- E. Mines, Mining, and Metallurgy—Chief Skiff.
- F. Machinery—Chief Robinson.
- G. Transportation Exhibits: Railways, Vessels, Vehicles—Chief Smith.
- H. Manufactures—Chief Allison.
- J. Electricity and Electrical Appliances—Chief Barrett.
- K. Fine Arts: Pictorial, Plastic, and Decorative—Chief Ives.
- L. Liberal Arts, Education, Engineering, Public Works, Architecture, Music, and the Drama—Chief Peabody.
- M. Ethnology, Archæology, Progress of Labour and Invention: Isolated and Collective Exhibits—Chief Putnam.
- N. Forestry and Forest Products—Chief Buchanan.
- O. Publicity and Promotion—Chief Handy.
- P. Foreign Affairs—Chief Fearn.

Space in Building.

The total space in the official Exposition Buildings was about 3,500,000 square feet, allowing space for the necessary aisles and pathways. This space proved altogether inadequate to meet the demands made by intending exhibitors, and it was affirmed by the authorities that if everybody had been granted the space asked for, the Exposition Building might have been filled twice over with exhibits.

Terms and Conditions of the Act.

At this stage I may be permitted to refer to the legal and official procedure founded on the Act of Congress. The Act of Congress was passed and approved by the President of the United States on April 25th, 1890, and, as I have said, its full text will be found in Appendix E. The Act declared that it was fit and appropriate that the four-hundredth anniversary of the Discovery of America be commemorated by an exhibition of the resources of the United States of America, their development, and of the progress of civilization in the New World. The Act further declared that such an exhibition should be of a national and international character, so that not only the people of the Union and this Continent, but those of all nations as well, could participate, and should, therefore, have the sanction of the Congress of the United States. To carry out this purpose the Act provided that an Exhibition of Arts, Industries, Manufactures, and Products of the Soil, Mine and Sea, should be inaugurated in the year 1892, in the City of Chicago, in the State of Illinois; a Commission was provided for, consisting of two Commissioners and two alternates for each State and Territory in the district of Columbia, and eight Commissioners and eight alternates at large, all of whom were afterwards commissioned by the President of the United States. This Commission and a Corporation organized under the State of Illinois, under the title of the "World's Columbian Exposition," were jointly charged with the task of making all needful preparations for the Exposition, and conducting it to a successful termination.

The

The Commission was composed of representative citizens of the various States and Territories comprising the United States, while the Directory of the Illinois corporation contained some of the wealthiest, best known, and most successful business and professional men in the City of Chicago.

Proclamation of President Harrison.

As the next important public step in connection with this matter the President of the United States issued a proclamation notifying the world that the Exposition would be held at the time and place named in the Act of Congress, and inviting all Foreign Countries to take part in the same.

The Proclamation was as follows :—

BY THE PRESIDENT OF THE UNITED STATES OF AMERICA.

A Proclamation.

WHEREAS satisfactory proof has been presented to me that provision has been made for adequate grounds and buildings for the uses of the World's Columbian Exposition, and that a sum not less than \$10,000,000, to be used and expended for the purposes of said Exposition, has been provided in accordance with the conditions and requirements of section 10 of an Act entitled "An Act to provide for celebrating the four-hundredth anniversary of the discovery of America, by Christopher Columbus, by holding an International Exhibition of Arts, Industries, Manufactures, and the Products of the Soil, Mine, and Sea, in the City of Chicago, in the State of Illinois"; approved, April 25th, 1890: Now, therefore, I, Benjamin Harrison, President of the United States, by virtue of the authority vested in me by said Act, do hereby declare and proclaim that such International Exhibition will be opened on the first day of May, in the year eighteen hundred and ninety-three, in the City of Chicago, in the State of Illinois, and will not be closed before the last Thursday in October of the same year:

And in the name of the Government and the People of the United States I do hereby invite all the Nations of the earth to take part in the commemoration of an event that is pre-eminent in human history, and of lasting interest to mankind, by appointing representatives thereto, and sending such exhibits to the World's Columbian Exposition as will most fitly and fully illustrate their resources, their industries, and their progress in civilization.

In testimony whereof I have herewith set my hand, and caused the Seal of the United States to be affixed. Done at the City of Washington, this twenty-fourth day of December, in the year of our Lord, one thousand eight hundred and ninety, and the Independence of the United States the one hundred and fifteenth.

By the President,

BENJ. HARRISON.

JAMES G. BLAINE, Secretary of State.

Formal invitations to Foreign Governments to participate in the exposition, and to appoint representatives thereto, were issued by the State Department at Washington, together with the regulations adopted by the Commission, the letters of which were transmitted to the diplomatic representatives of Foreign Nations for publication in their respective countries. The following Foreign Countries accepted the invitation of the Government of the United States, and were represented at the Columbian Exhibition, having made the financial provision for the more or less adequate representation of their products and resources:—Argentine Republic, Austria, Barbadoes, Belgium, Bolivia, Brazil, British Guiana, British Honduras, Canada, Cape Colony, Ceylon, Costa Rica, Denmark, Danish West Indies, Ecuador, France, Germany, Great Britain, Jamaica, New South Wales, Norway, Trinidad, Greece, Guatemala, Hayti, Honduras, Japan, Liberia, Mexico, Netherlands, Dutch Colonies, Nicaragua, Paraguay, Peru, Russia, Spain, Sweden, Uruguay, and others. Several countries were represented quasi-officially, such as India, and special representations were made of the customs, the products, and the antiquities of various other countries. The day for the dedication of the buildings was fixed for 19th October, 1892, and it was decided that the opening of the Exposition should take place on 1st May, 1893, and that the Exposition should close not later than the 30th day of October of the same year.

As

As regards foreign exhibits, section 11 of the Act of Congress provided that all articles which shall be imported from Foreign Countries for the sole purpose of exhibition at the said Exposition, upon what then shall be a tariff or customs duty, shall be admitted free of payment of duty, customs fees, or charges, under such regulations as the Secretary of the Treasury shall prescribe; but it shall be lawful at any time during the Exhibition to sell for delivery at the close of the Exposition any goods or property imported for and actually on exhibition in the Exposition Buildings or on its grounds, subject to such regulations for the security of the revenue and for the collection of the import duties as the Secretary of the Treasury shall prescribe: "Provided that all such articles, when sold or withdrawn for consumption in the United States, shall be subject to the duty, if any, imposed on such articles by the revenue laws in force at the date of importation, and all penalties prescribed by law shall be applied and enforced against such articles and against the persons who may be guilty of any illegal sale or withdrawal."

Copies of the Customs rules and regulations, prepared by the Secretary of the Treasury, 5th November, 1891, with reference to the admission of foreign goods, will be found in Appendix F, and the general regulations for foreign exhibitors, issued by the Director-General of the Exposition, in Appendix G.

It was also determined that awards designed to indicate some independent and essential excellence in the article exhibited, and as an evidence of advancement in the state of the art represented by it, should be granted, upon specific points of excellence or advancement, formulated in words by a board of examiners or judges, who will be competent experts; and the evidence of such awards should be parchment certificates, accompanied by bronze medals. It was expected that such awards would constitute an enduring historical record of development and progress, and at the same time afford exhibitors lasting mementoes of their success. I shall again advert to this subject at a later stage of this Report.

Board of Lady Managers.

Section 6 of the Act of Congress creating the World's Columbian Commission authorised and required said Commission to appoint "a Board of Lady Managers, of such number and to perform such duties as may be prescribed by said Commission." In pursuance of this authority the World's Columbian Commission authorised the appointment of two Lady Managers from each State and Territory and the District of Columbia, eight managers at large, and nine from the City of Chicago, with alternates respectively—said Board to be convened at such time and place as the Executive Committee of the World's Columbian Exposition should direct, and when so convened to organise by the election of a Chairman and Secretary.

Description of Jackson Park at an early stage, by Miss Harriet Monroe.

In connection with the practical outcome of all these provisions a beautiful and suitable site was selected ultimately for the Exposition, containing about 600 acres, charmingly situated on the shore of Lake Michigan.

A plan of the grounds as they appeared is shown in one of the illustrations, and as an aid to the better comprehension of the outward scene, I avail myself of the description written by an American lady (Miss Harriet Monroe), gifted with artistic instinct, but writing under the

the cold restraint of architectural realities, at a very early stage of the history of the Exposition, as quoted by the President of the Exposition at its first annual meeting :—

The South Park system consists of two great parks, connected by the Midway Plaisance, a strip of land a mile long and 600 feet wide, and united by boulevards with the heart of the city and with the west side and north side parks. Both Washington and Jackson Parks, and the Midway Plaisance as well, embracing 974 acres, were placed at the disposal of the Columbian Exposition. The south side system of cable cars connects with the two parks, and the Illinois Central Railway passes near the western boundary of Jackson Park and with other roads, was directly connected with the Fair during its continuance.

By reason of the greater picturesqueness of a lake shore site, and the greater accessibility of Jackson Park, both by water and land, and for the additional reason that, being for the most part unimproved, it was more readily adaptable to our purposes, Jackson Park was chosen as the principal site of the Fair. The 80 acres at the north which were laid out and under cultivation formed but a small fraction of the entire area of this park, which extends a mile further south, broadening constantly along the curving shore of the lake. In this unimproved portion, much of which was thickly-wooded with native trees, the ground was prepared for a system of lagoons and canals from 100 to 300 feet wide, which, with the broad grassy terraces leading down to them, passed the principal buildings, enclosed a wooded island 1,800 feet long, and formed a circuit of 3 miles, navigable by pleasure boats.

These canals, which have been crossed by many bridges, connect with the lake at two points—one at the southern limit of the improved portion of the park, and more than half a mile further south, at the great main court of the Exposition. At this point, extending eastward into the lake 1,200 feet, are piers which afford a landing-place for the lake steamers, and enclose a harbour for the picturesque little pleasure boats of all epochs and nations, which carry passengers along the canals, stopping at numerous landing places.

This harbour is bounded on the east, far out in the lake, by the long-columned façade of the Casino, in whose free spaces crowds of men and women, protected by its ceiling of gay awnings, look east to the lake and west to the long vista between the main edifices, as far as the gilded dome of the Administration Building. The first notable object in this vista is the Colossal Statue of Liberty rising out of the lagoon, at the point where it enters the land, protected by moles. Beyond this, beyond the first of many bridges, lies a broad basin, from which grassy terraces and broad walks lead, on the north to the south elevation of the enormous main building, and on the south to the structure dedicated to Agriculture.

The main building, extending north-westward a third of a mile, is devoted to manufactures and liberal arts, and received from all nations the rich products of modern workmanship. Recalling architecturally the period of the classic revival, it has the vivacity, the emphatic joyousness of that awakening epoch. The long low lines of its sloping roof, supported by rows of arches, is relieved by a central dome over the great main entrance, and emblematic statuary and floating banners add to its festive character. The north elevation of the classic edifice devoted to agriculture shows a long arcade behind Corinthian columns supporting a series of triple arches and three low graceful domes. Liberally adorned with sculpture and enriched with colour, this building, by its simplicity, refinement, and grace, is idyllically expressive of pastoral serenity and peace. At its noble entrance a statue of Ceres offers hospitality to the fruits of the earth. Beyond it, at the south, 63 acres of land are reserved for the live stock exhibit.

The lofty octagonal dome of the Administration Building forms the central point of the architectural scheme. Rising from the columned stories of its square base 250 feet into the air, it stands in the centre of a spacious open plaza, adorned with statuary and fountains, with flower beds and terraces, sloping at the east down to the main lagoon. North of the plaza are the two buildings devoted to mines and electricity, the latter bristling with points and pinnacles, as if to entrap from the air the intangible element whose achievements it displays.

South of the plaza is the Machinery Hall, with its power house at its south-east corner. A subway at the west passes under the terminal railway loop of the Illinois Central Road to the circular machinery annex within. North of this railway loop, and along the western limit of the park, is the Transportation Building. Still further north, lying west of the north branch of the lagoon, at the point where it encloses the wooded island, extend the long, shining surfaces and the gracefully curving roof of the crystal palace of Horticulture. Following the lagoon northward, one passes the Women's Building, and eastward reaches the island devoted to the novel and interesting Fisheries Exhibit, shown in an effective, low-roofed, Romanesque structure, flanked by two vast circular aquaria, in which the spectator looks upward through clear waters and studies the creatures of ocean and river. This building is directly west of the northern opening of the system of lagoons into Lake Michigan, and in a straight line with the Government Building and the Main Building, which extend along the lake shore to the south-east.

General

GROUP ON SOUTH CANAL.

LOOKING NORTH ON THE SOUTH CANAL.

CENTRAL ARCH OF COLONNADE.

General remarks on the Architecture and appearance of the "White City."

The architecture of the buildings was an imitation of Rome, with occasional borrowings from mediæval Italy or Germany. The great Administration Building, which recalls the splendid central dome of the Paris Exhibition of 1889, was built with the express purpose of being a mighty porch to the World's Fair. The Gate Beautiful of this temple was an appropriate introduction for visitors to the old world of art as here represented. The skill with which the device of men was used in constructing an inner dome, which rose 275 feet in height, as the monumental feature of the World's Fair, was very noticeable. This dome was the largest in the world, except that of St. Peter's at Rome, Michael Angelo's dome being 20 feet wider. Courts of space were situated between the classic and conventional buildings, but the sense of proportion was not marred;—terraces bright with flowers and verdure; the great basin an arm of the lake; long arcades of buildings; great fountains round the bronze gallery of Columbia; at the end of the basin a colossal statue of the Republic.

On the subject of the general appearance of the Exposition grounds, I may state that, in the recorded opinion of competent judges, who have been eye-witnesses of previous Exhibitions, none of the great expositions of the world which have preceded it can be compared with it. The extent of the grounds, the number of the buildings and the beauty of their architectural designs, the wonderful effectiveness of the entrance from the lake, and the charm of the lagoons, running by all the great structures, and bearing upon their glistening waters a perpetual procession of gondolas from Venice, and American electric launches, made it impossible to judge of this Exhibition by comparison with the panorama of any other the world has known.

Viewed from the lake, the White City was a glorious sight; with its domes, its white palaces, statuary fountains, and electric fountains. When the reception of the caravels—Santa Maria, Nina and Pinta, or the Viking ship—took place, the beach was crowded with sightseers; and one was not disenchanted by a nearer view of the city of white palaces. The effect of the great limitless expanse of the ocean-like lake was to give the Exposition an appearance entirely different from that of all former world's Exhibitions.

Scene at night.

While the visitor to the Exhibition was always impressed by the grandeur of the buildings and scenery during the day-time, it was at night that language failed to express the sense of admiration for the picture that dwelt in his mind after viewing the beautiful spectacle. The illumination of the grounds and buildings, with the electric lights running like elfin lamps along the lagoons and under the arches of the bridges, the electric fountains displaying their fantastic and beautiful figures in all the hues of the rainbow, the launches and gondolas floating over the shimmering water, the music and the fireworks, presented a fairy scene of unapproachable, never-to-be-forgotten, and indescribable beauty. On this subject I may be excused if I quote the poetic prose of a distinguished European writer:—

To parody a much-tortured distich, "If thou would'st view the World's Fair aright, go visit it by the pale arc light." Illuminated, the grounds and buildings become an enchanted world. You stand in a region preternatural. The material seems wholly transformed into the ideal. A Platonist might imagine that he saw no longer the gross palpable structures, but beheld their archetypal ideas as they glowed in the mind of the Eternal. The Administration building was but a framework of beaded fire inclosing spaces of erubescant snow. Its dome shone out as a colossal diadem, gemmed with jets of flame upon a ground of gold. Similar rosaries of incandescent wire ran round the colonnade at the foot of the great basin, and lit up the architraves of the intervening buildings. Search lights of various colours flashed about the grounds, flinging by turns every object of special prominence into bold relief. But, though the incandescent burners wreathed
the

the palaces with rare splendour, it was the arc light which gave to the illumination its peculiar unearthly semblance. Everywhere within and without the buildings it shed its rays, soft, mysterious, and benignant as of the harvest moon. It was as though the light which never was on sea and shore had at last been made visible to other than poet eyes. It gave the grass an eerie tinge; it lent an intenser whiteness to the masonry; it changed the waters into sheets of pallid flame. The greatest building in the world, with the electric radiance streaming through its miles of glass, seemed to be the very home of the starlight, and its shining sides called to mind Lucretius' *LUCIDA MÆNIA MUNDI*. But fairest of all the fair creations which night and light together formed within the grounds was the effect produced by the exterior of the Agricultural Building. Even in the daylight it is a fairy structure, but seen by the tamed lightning it is a vision of almost heavenly beauty. Viewed from the north side of the basin, with the foreground of gleaming water, its pure white columns standing out against the rich rose-colouring of the inner wall, glowing within and without with the clear, calm light that recalls the luminousness of perfect moral insight, it fills the mind with a positive fervour of spiritual joy. I have seen no picture of the abodes of the blest which comes so near to it in its serenity, its suggestion of the invisible holiness, its atmosphere of bliss. 'This would have given points to the writer of revelations had he seen it!' was a remark which hardly seemed profane in the presence of that mystic spectacle. Precious stones do not appeal to us Westerners as they do to Orientals, and for my part I prefer the white glory of the Hellenic architecture, transfigured by the electric light, to the blaze of all the jewels with which the gorgeous imagination of the East could deck the battlements or pave the streets of Paradise. 'Until I see the walls of the New Jerusalem itself I never expect to see a dream of more exquisite loveliness than this!' So I heard a man say to his friend; and the pure splendour of the scene before him made the enthusiasm of his words seem at least pardonable."

Those who were most ready to depreciate the Fair, and to cavil at the glowing language used over it, had to reckon with the fact that it had the power to turn the heads, to use a common phrase, of an extraordinarily large number of speakers and writers usually sane. There must have been some strange witchery about a spot which tempted so many differently constituted beholders to exhaust the resources of eulogy in the effort to transcribe the impressions it gave them. Yet all this wonderworld was in Chicago; it was the historic achievement of the Lake City.

Before proceeding further a short reference to the principal factor in the creation of this the greatest of all Exhibitions, the City of Chicago itself will form I trust a not uninteresting chapter of this report.

CHICAGO—THE EXPOSITION CITY.

While undoubtedly the World's Fair at Chicago has been the most wonderful exhibition of all time, perhaps the city itself and its characteristics are no less remarkable than the Exposition. Chicago is a typical American metropolis, whether we consider its age, its extent, or its development. Other great cities, such as London and Paris, where great Exhibitions have hitherto been held, are familiar to the people of Australia, but Chicago, if known at all, is vaguely known only as the site of one of the greatest fires in the world, or as a western American city having immense stock-yards and granaries. But the careful observer will find that Chicago itself was truly the greatest exhibit at the World's Fair. It is a supreme monument of American enterprise, and its marvellous history is one of the most extraordinary that has ever been narrated.

Its Wonderful Growth.

Sixty years ago the population of Chicago, according to the Government report, consisted of three families, occupying log cabins; to-day it is the second city in the United States, having a population of

NOTE.—The chief authorities consulted in this description are:—

 Publications of the Department of Publicity and Promotion.
 Various publications and pamphlets issued by exhibitors at the Fair.

of rather more than one and a quarter millions, a fact which entitles it to the rank of seventh among the great cities of the world. The three log cabins mentioned in the Government report of sixty years ago have now multiplied into a city possessing over 2,000 miles of street frontage, a river frontage of nearly 50 miles, and a lake frontage of nearly 20 miles. Condemned half a century ago as an unhealthy swamp, the Chicago of to-day boasts an exceptional sanitary record, its average rate of mortality, 17·49 to 21·00 per 1,000, comparing favourably with any centre of population of equal dimensions in the world. A little over fifty years ago Chicago was barely deemed of sufficient area to be admitted to the dignity of a city. To-day it comprises upwards of 170 square miles within its municipal limits. Twenty years ago the city was devastated by a disaster unequalled in modern history, a conflagration which destroyed nearly twenty thousand buildings, resulting in a loss of \$190,000,000, of which loss, however, not a trace remains in the city of to-day.

Value of Property.

The original founder is reported to have bought the site of the city and 300 miles round for the sum of 5s., two hundred years ago. Within the memory of men now living the whole ground-rent of Chicago could have been bought in open market for \$1,000. It would hardly have brought that sum in 1812, the day after the garrison of Fort Dearborn was massacred by the redskins. Corner lots that went for \$15,000 in 1845 are worth \$200,000 to-day. The Union Block, sold for \$2,000 in 1841, is now worth a million. Customhouse Block was bought, in 1833, for \$500,—it is valued to-day at \$750,000. In the Michigan Avenue, forty years ago, land sold at a dollar a foot which now would be snapped up at \$400.

The city adds to its population, under ordinary circumstances, at the rate of about 50,000 per annum, and a motley population it is, as I shall presently show, consisting chiefly of Germans, who, however, gradually become American citizens, and speak the English language eventually. Such a city, the mother city of the world's greatest Exhibition, deserves something more than a mere passing notice.

Names applied to City.

Chicago is variously named "The Phoenix City of the West," "The Garden City," "The Windy City," for reasons which will be obvious when this report has more fully described its characteristics.

Its Site and Area.

It is situated on the south-west shore of Lake Michigan, in lat. 41° 53' 6·2", long. 87° 38' 1·2" west, being 854 miles distance from Baltimore, Md., the nearest point on the Atlantic coast-line, 911 miles from New York, and 2,417 miles from the Pacific Ocean. It has, as mentioned before, a frontage on the lake of about 20 miles, inclusive of the parks at either extremity of the city, and this, with a river frontage of 41 miles, affords both dockage and harbourage. The area of the city is 181·5 square miles. It is 24 miles long and 10 miles wide. Its mean elevation is 25 feet above Lake Michigan and 582 feet above mean sea-level. That it should be but 60 years old and yet second city of the United States in point of population, and seventh in the same respect in the entire world, exhibits wonderful progress. Even the earliest residents of the place never dreamed that Chicago would attain commercial importance, and the time is within memory when the inhabitants feared the ruin of their town by canals and railways. To-day, however, it is the centre of fully one-third of the railway mileage of the United States and the most rapidly prospering city on the continent.

Three

Three Divisions of the City—North, South, and West Sides.

From the lake at Water-street, the Chicago River extends west about half a mile to Canal-street, where it divides into two branches, one extending in a north-westerly direction through that portion of the city, and the other southward for about $1\frac{1}{2}$ miles to 14th-street, when it makes a sweep to the westward as far as Bridgeport, among the lumber-yards. Here it again divides into two unimportant secondary branches, reaching, one west, the other south, and then empties itself into the Illinois and Michigan Canal, through which it is united with the Des Plaines River. Thus the main stream of the Chicago River divides the eastern portion of the city into two parts, one of which is known in common parlance as the "South Side," and the other as the "North Side." These two branches again separate the north and south sides from the west side, all that portion of the city lying west of those branches being known by that title.

Swing Bridges.

Communication between these different portions is kept up by means of fifty-three swing bridges, situated at the most important street crossings. These are further supplemented by three tunnels, one connecting the south with the west side at Washington-street, the second forming a similar link between the north and south sides at La Salle-street, and the third is located at Van Buren-street.

Summary of History.

The summary of its extraordinary history may be briefly stated. In 1801 a swamp; in 1811 a small military post (Fort Dearborn), soon to be abandoned, and to be the scene of a terrible Indian massacre; in 1821 again an insignificant military station; in 1831 a village of twelve houses, without mail-routes, post-roads, or post-office; in 1841 an incorporated city with 5,752 inhabitants, and an export trade amounting to \$328,635; in 1851 rapidly assuming commercial importance, on the eve of possessing railway communication with New York, its grain shipments increased to 4,646,831 bushels, its population numbering 34,437; in 1861 its grain, pork, and lumber interests all enormously developed, its population almost quadrupled, and its shipments of bread-stuffs increased tenfold within a single decade; in 1871 rich, proud, and magnificent, bidding fair to outstrip the most famous commercial cities of either the Old or New World; but suddenly, on one memorable October night, almost swept out of existence by the Great Fire, only to rise triumphantly from its ashes in more than its former splendour, a monument of indomitable spirit and energy; in 1893 the greatest railroad centre, live-stock market, and primary grain port in the world. Such, in brief, is the history of this wonderful city, the capital of the wealth-producing west.

The Great Fire.

It is but twenty-one years ago since this central business centre was a heap of smoking ruins, the net loss of property being \$200,000,000. The story may be shortly stated: At 9 o'clock on the 9th October, 1871, Mrs. O'Leary's cow kicked over a paraffin lamp in a shanty in De Koven-street. There was a high wind, the weather was dry, and the flames simply ate up everything covering a broad territory $3\frac{1}{2}$ miles along the lake front and a mile back into the city. The population of this tract was 100,000, and 18,000 buildings were burnt, including eight bridges, yet only 200 persons perished in the fire. The entire loss was estimated at \$190,000,000, of which only \$44,000,000 were covered by insurance.

Population.

Population.

The population of Chicago is very cosmopolitan, as the following statistics for last year will show:—

NATIONALITIES COMPRISING THE POPULATION OF THE CITY OF CHICAGO (1892).

American	292,463	Hungarians	4,827
German	384,958	Swiss	2,735
Irish	215,534	Roumanians	4,350
Bohemian	54,209	Canadians	6,989
Polish	52,756	Belgians	682
Swedish	45,877	Greeks	698
Norwegian	44,615	Spanish	297
English	33,785	Portuguese... ..	34
French	12,963	East Indians	28
Scotch	11,927	West Indians	37
Welsh	2,966	Sandwich Islanders	31
Russian	9,977	Mongolians	1,217
Danes	9,891		
Italians	9,921		1,208,679
Hollanders	4,912		

The estimates for 1893 show an increase on this number of about a quarter of a million, due, doubtless, to a large extent to the Exhibition. The negroes are said to number 13,000.

Municipal Government.

The Municipal Government of Chicago, like that of most American cities, consists of a Mayor and Common Council, with Departments of Health, Law, Police, Fire, Education, Public Works, Building, and Finance, and the City Clerk's, Treasurer's and Collector's Departments. The Mayor, City Clerk, Treasurer, Attorney, and Aldermen are elected by the people for a term of two years, the other officers and employees being appointed by the Mayor or by the heads of the various Departments. The Mayor's power is supervisory over the various Departments, controlling the police, and with a right of veto of any ordinance passed by the Council. His salary is \$7,000 per annum. The Common Council or Board of Aldermen meets every Monday evening, and is composed of sixty-eight Aldermen, two from each of the thirty-four wards into which the city is divided. The Mayor is *ex officio* the Presiding Officer of the Common Council, in his absence an alderman being chosen to fill his place. To pass an ordinance over the Mayor's veto requires a two-thirds majority of the Council.

Finance.

The revenue of the city and its expenditure are about the same, amounting to \$25,000,000. The bonded debt of the city amounts to \$13,545,400, bearing interest at $3\frac{1}{2}$ to 7 per cent. The bonded debt has been increased by the issue of 4 per cent. bonds \$5,000,000, as authorised by the State Legislature for the expenses of the World's Fair, which will make the city debt a little more than \$18,500,000, which is a much smaller debt than that of any other city of a similar size. The revenue covers cost of maintenance of Police, the Fire Department, Education, Water Supply, Sewerage, and many other matters.

Drainage.

Chicago deriving its water supply from Lake Michigan,* the disposal of its drainage was a serious and perplexing problem until, by a triumph of engineering skill, the current of the Chicago River was reversed, and the stream made to run out of Lake Michigan into the

* Lake Michigan, the second in size of the five great fresh-water lakes of North America, and the only one lying wholly within the United States, is 320 miles long, 70 miles in mean breadth, and 1,000 feet in mean depth. It is 578 feet above sea-level, and has been found by careful and accurate observation to have a lunar tidal wave of 3 inches. With an area of 22,000 square miles, Lake Michigan is the third largest body of fresh water on the face of the globe. Its principal harbours are Chicago, Milwaukee, and Grand Haven. With the lower lakes and the St. Lawrence River it forms a natural outlet for one of the richest grain-growing regions in the world.

the Illinois and Michigan Canal, and thence through the Illinois River to the Mississippi. The drainage system is very thorough (except when the pumping system gets out of gear, and at the close of winter, from the overflow of melted ice and snow, there is difficulty, as well as in the height of summer). There are over 888 miles of sewer, with more than 30,468 catch-basins and 33,726 manhole openings, and engineers are always busy with plans for improving the sewerage.

Water Supply of the City—"The Cribs."

Foremost among the public works of Chicago is the costly and unique contrivance by which it derives its supply of water from the lake. Two miles from the shore there is fixed a very substantial structure, termed, for want of a better name, "The Crib," within which is an iron cylinder, 9 feet in diameter, going down 31 feet below the bottom of the lake, and connecting with two distinct tunnels leading to separate pumping-works on shore. The first tunnel constructed, communicating with the pumping-works at the foot of Chicago Avenue, is 5 feet in diameter; this was commenced March 17th, 1864, and finished March 25th, 1867, costing \$457,844.95. The second tunnel, conveying water to the west side works, at the corner of Blue Island Avenue and Twenty-second Street, is 7 feet diameter and 6 miles in length. At the shore end of each tunnel the water is forced by enormous engines through the city. The total outlay for the whole system was about \$17,000,000. There are over 1,346 miles of main and distributing pipes, and the daily capacity of all the plants is 250 million gallons. In 1887 a contract was entered into for the construction of a new tunnel from the foot of Peck Court, to be 8 feet diameter, and to extend 21,441 feet (4 miles) out into the lake, connecting there in 45 feet of water with a new crib. This work is now nearly completed (1893). The capacity of this tunnel will be 130 million gallons per day, and it is now about to be put into active use.

Fire Department.

Chicago is most complete in its Fire Department, which has its head-quarters in the basement of the City Hall. It possesses 72 steam fire-engines, 22 chemical engines, 28 hook-and-ladder trucks, 2 river fire-boats, 1 stand-pipe and water-tower, 421 horses, and a staff of 970 men. By the fire-alarm telegraph system, established at a cost of nearly a million dollars, an alarm can be instantaneously flashed to the nearest station from any part of the city. The Department has an adjunct of considerable importance in the Fire Insurance Patrol, established in 1871 by the underwriters of the city, an organisation admirably equipped and highly efficient.

Water Traffic.

To a stranger the system of water traffic is peculiar, inasmuch as it neither possesses nor requires dock accommodation. The river, entering the city from the lake, crosses the business quarter at right angles, and then, dividing to right and left, gives the city a river frontage, of a kind, of 22 navigable miles. All along the banks of the river and its branches you see the huge elevators or great timber-yards where the ships discharge and load their cargo. To cause as little inconvenience as possible to street traffic there are fifty bridges in Chicago, most of which are worked by steam-power, and swing open to allow ships to pass. Delay is, of course, considerable, but the convenience of water transit to the warehouses is very great.

Shipping Returns.

Half a century ago the arrival of such a squadron as Columbus commanded 400 years ago would have been an event of importance in Chicago. To-day it is the second port in the United States in respect to

to tonnage, and the first in number of vessels arriving and clearing. Three hundred and thirty-nine vessels, of 71,260 tons aggregate burden, and of a total value of \$3,088,350, are owned and registered in the port of Chicago. In 1890, 21,054 vessels, aggregating to 10,288,688 tons, entered or left for the great lakes, a daily average of 57 vessels; in 1891 the arrivals were 10,354 coasting-vessels and 153 vessels engaged in foreign trade—a total of 10,507, with a tonnage of 5,138,253. The clearances numbered 10,235 coasting-vessels and 312 vessels engaged in foreign trade, a total of 10,547, with an aggregate tonnage of 5,150,615. In the month of August the arrivals averaged 56 per day, and the clearances 56. The duties collected on foreign imports amounted to \$5,182,476.

Lake-patrol.

The lake is patrolled by six steamships of the United States navy, antique in type, and valuable more as surveying-vessels than anything else. One or more of the fleet are often at anchor off Chicago.

Grain-elevators.

In other countries grain is conveyed in sacks or bags, but this mode of handling the immense quantities brought to and sent from Chicago would be useless. Instead of treating the grain as a solid, it is in bulk treated as a liquid in the Chicago elevators. These elevators are gigantic grain-pumps built like dredgers. A great leg, like an elephant's trunk, filled inside with an endless belt carrying buckets, each holding 18 lb. of grain, is thrust down into the ship's hold, where the grain is lying loose; the belt revolves, the buckets fill themselves, and are whisked up to the top of the building at the rate of 10,000 bushels an hour. It then works down by gravitation, weighing itself, and delivering itself just as it is wanted.

Buildings.

The mammoth buildings of Chicago, or rather its so-called "skyscrapers," are well known. Within the city limits there are about 180 square miles, but the business centre of the city is concentrated in the space of about half a mile square, and this is the occasion of the growth of the gigantic buildings found within this locality. The provision of the elevator or lift in every possible direction in these buildings alone makes them possible. Some of the buildings have no fewer than fifteen or sixteen elevators constantly running, so that no time is lost in getting up from one storey to another. Some of the buildings have restaurants and gardens on the top. In consequence of the loose alluvial soil upon which this city is built, considerable difficulty was experienced in connection with the foundations of these large buildings, and the great weight which must necessarily rest upon them. As a matter of fact, the soft soil in many places is not less than 30 or 40 feet deep. In order to make a solid base, on which to rest some hundreds of thousand tons (the weight of some of these buildings), steel girders and cement grouting are used. Pads, 18 inches thick and 18 feet square, made of alternating courses of steel beams, laid crossways, then filled in and solidified with cement, form the sub-structure on which these immense buildings are erected. The construction of the walls is also peculiar. The outside shell of the building has nothing whatever to do with the internal structure, and could be taken down without injuring the solidity of the main building, which is made of steel girders bolted together. The outside wall is often filled in with terra cotta and similar ornamental material. It would be impossible to refer at length to this very interesting matter, and therefore I shall only mention a few particulars in connection with some of the more striking buildings.

Masonic

Masonic Temple.

The Masonic Temple building has nineteen full storeys, or twenty-one, including the attic and promenade deck. Its height is 302 feet. Compared with its neighbour, the Auditorium, which is 270 feet, it looks much more towering. The building contains 7,000 electric lights, 1,328 radiators, 11 miles of steam piping, 24 miles of gas and water pipes, 4,700 tons of steel beams, and 17 elevators, with a daily carrying capacity of 50,000 persons. It has 170 feet frontage to State-street, and 114 to Randolph-street. The cost was \$4,500,000. It has a complete power plant, including two 500 horse-power Corliss engines, eight 125 horse-power Scotch marine steel boilers, 8 feet diameter, weighing 17 tons each, and all the necessary line shafts, friction clutches, flues, piping, belting, tanks, reservoirs, foundations and pipe cover. The total weight of the machinery furnished was 325 tons. It has a drill room on the eighteenth storey, large enough to hold 1,500 people, and a garden on the roof, in which an orchestra plays while refreshments are served.

Monadnock Block.

In the Monadnock Block, another immense building, the fact that everything connected with the establishment is under one roof, greatly facilitates the transaction of business. It is the largest business block in the world, sixteen storeys high, has 1,000 feet frontage to the street, and can accommodate 6,000 business persons. It has twenty elevators. It was in this block that aluminium elevators were first used. The Board of Trade building has a tower 300 feet from the pavement. Here the prices of the breadstuffs of the world are fixed.

The Auditorium.

The Auditorium is one of the great sights of Chicago amongst her mammoth houses. It contains a grand opera house, a fine hotel, a public hall, and a large number of offices, stores, shops, a Government weather station, &c. Our illustration gives a good idea of the exterior, by which it will be seen that the style of architecture is severely simple, the designers not having erred in regard to over-ornamentation. It is built on Michigan-avenue, and overlooks the Lake Front Park and Lake Michigan itself. The architects are Messrs. Adler and Sullivan, of Chicago; and though decoration has been no more sought by means extraneous to the necessities of construction than in the Forth Bridge itself, yet, like the latter structure, it impresses the beholder by the grandeur of its proportions and the overwhelming effect of its stupendous mass. On the other hand, rich, bold, and original ornament enriches the interior. The total street frontage on Wabash-avenue, Michigan-avenue, and Congress-street is 710 feet. There are ten storeys in the main building, the height being 145 feet. The height of the observatory tower above the main building is 95 feet, and the lantern above the tower extends another 30 feet. This gives a total height of 270 feet. The area occupied by the main tower measures 70 feet by 41 feet; the foundations cover about two and a half times a greater area. The entire weight of the building is 100,000 tons, the tower weighing 15,000 tons. The exterior is largely of granite, the interior being of steel, brick, terra-cotta, marble, and wood.

The drainage levels and all sewage in this, as in many others of the great buildings, has to be lifted by a special pumping plant situated in the basement, and delivered into the sewers. The foundations were a matter of great difficulty, as they are for the most part below the level of the Lake, less than 300 yards distance. To support the great superincumbent mass of this building, the foundations were spread
over

THE MASONIC TEMPLE, CHICAGO.

THE AUDITORIUM, CHICAGO.

over a species of platform or raft, the structure being made up of timber covered by concrete enclosing heavy steel rails and I beams. A level of 17 feet was adopted as a standard depth of the foundations, but the foundations of the tower were taken to 18 feet below surface. As the bottom of the foundations is 3 feet below the level of the lake, the water often reaches them, and therefore arrangements are made to admit water to the timbers at the base, or to flood them, if necessary, by artificial means if the water level in the lake falls. The volume of earth excavated in the foundations of the Auditorium was 28,860 cubic yards. The quantities of materials used were as follows:—1,000,000 feet of timber, 231 tons of steel rails, 77 tons of steel I beams, 2,565 cubic yards of broken stone, 2,921 cubic yards of sand, 2,650 barrels of cement, 933 cords of rubble stone, 4,296 cubic feet of dimension stone, and 1,280,000 bricks. In the whole building the number of bricks is said to be 17,000,000. There are 50,000 square feet of Italian marble and mosaic, 800,000 square feet of terra-cotta, 60,000 square feet of plate-glass, 25 miles of pipes, and 230 miles of electric wires. There are 10,000 electric lights, and 13 electric motors for ventilating apparatus, besides four hydraulic motors. There are 21 pumping engines, 13 elevators, and 26 hydraulic lifts for moving stage platforms in the theatre.

The theatre occupies the centre of the block, and has seating capacity for 4,000 persons for theatrical performances, but if it be used as a meeting hall, and the stage space is occupied, it will hold double that number. The theatre is so large that its full dimensions are not required on ordinary occasions, and arrangements are made to shut off a part of the galleries and reduce the size of the proscenium by a rising and falling screen. The total cost of the Auditorium building was £640,000, which appears small considering what has been obtained for it.

As a matter of curiosity, an estimate was once made of the number of persons present at one time in one of these mammoth buildings, and it was found to be over 20,000.

Meat and Grain Industries.

The markets of the city, and the stockyards deserve notice. The World's Fair City is more widely known to-day than any other American commercial centre, not excepting the Capital, or the great Atlantic seaports, as that of a great grain and live stock market only, the importance of its lumber trade, and the extent of its manufacturing industries being, for obvious reasons, less widely known. Meat packing is the oldest of Chicago's industries. The single butcher's shop which represented the meat trade of early Chicago has given place to an industry which annually receives upwards of 10,000,000 head of live stock, valued at \$200,000,000, and exports upwards of 1,000,000,000lb. of dressed meats, beside 1,000,000 cases of canned meats and barrels of pork. The human family further looks to Chicago as the food dispensary for an annual supply of nearly 100,000,000 bushels of wheat, corn, oats, rye, and barley, in addition to nearly 2,000,000 barrels of flour. The Union Stock-yards, in which the enormous business of the cattle trade centres, covers not less than 400 acres of ground, with 3,300 pens—1,800 covered, and 1,500 open. Provision is made for handling at one time 25,000 head of cattle, 14,000 sheep, and 150,000 hogs. The yards contain 20 miles of streets, 20 miles of water troughs, 50 miles of feeding troughs, and 75 miles of water and drainage pipes. Artesian wells, having an average depth of 1,230 feet, afford an abundant supply of water, and there are also 87 miles of railroad tracks, all the great roads having access to this vast market, the entire cost of which was \$4,000,000. About 1,200 men are employed at the stockyards proper.

Meat.

Meat-packing Industry.

The meat-packing industry is carried on in immediate proximity to the stockyards. As an example of the extent of the business, it may be stated that that controlled by Messrs. Armour and Co. occupies 70 acres of floor space, and employs about 4,000 men. Some 18,000 to 25,000 men are daily employed in the various packing houses, which number varies according to the season of the year. It is in these places that a visitor can see the rapidity of machinery, which caused a noted European writer sarcastically to remark that "a live pig went in at one end of a machine, and in a moment emerged from the other end of the machine as sausages." As witnessed at any of the great slaughter-houses, the process of killing may be thus shortly described: The drove of pigs marked for slaughter were driven up an inclined plane towards the chamber of death, and entered a pen in the landing where the killing was going on. At the door a running noose was slipped round the leg of the nearest pig; in an instant the rope was pulled tight, and the pig was jerked head downwards and swung on a long iron runner, dipping downwards towards the other end of the room, where stood the vat over which they bled to death. Standing ready to receive his prey was the slaughterer, with a long, sharp knife in his right hand. Seizing the pig by one ear, with his left hand he plunged the knife into its throat, gave it a murderous twist, and drew it out. The warm blood spurted over his hand, but the pig had already begun to slide towards the vat; another pig was swinging, ready for sticking, and so the procession went on. A dozen or more pigs, in progressive stages of inanition, were bleeding to death; those further down were almost motionless, the last stuck were struggling horribly. It is stated that one man can kill 5,000 pigs a day. At Swift's establishment I found that the capacity was—Cattle, 5,000 per day; sheep, 7,000 per day; hogs, 10,000 per day. Number of visitors to this establishment (Swift's) from middle of June to 23rd September, 75,642; week ending 23rd September, 10,700; largest number on one day, 22nd September, 2,596. In the Union stockyards 8,000,000 pigs, 3,500,000 cattle, and 1,000,000 sheep are handled every year. Of these, 6,000,000 pigs and 2,000,000 cattle are slaughtered in Chicago.

Chicago as a Grain Centre.

Chicago, from its admirable geographical situation, is the natural depôt for the exchange of the commodities of the east and west. Into her grain elevators, to which I have already referred, pour the harvests from the vast fields of the north-west, and in her markets they are exchanged for the products of the east, and the importations from foreign countries. The first shipment of wheat from Chicago took place in 1839; in 1842 the exports were 586,907 bushels; in 1855, after the opening of railroads to the east, they increased to 21,583,221 bushels of grain, about two-thirds of which consisted of wheat. In the year 1891 the total receipts of breadstuffs were not less than 231,821,529 bushels, valued at about \$136,040,000, and the exports 207,988,862 bushels. There are 27 registered grain elevators, with an aggregate capacity of 30,075,000 bushels.

The lumber receipts in 1891 were 2,045,418,000 feet, and the exports 865,949,000 feet.

Manufactories.

At the close of 1891 there were in the city 3,250 manufacturing establishments, excluding those of food products. The number of employees was 177,000, and wages amounted to \$96,200,000. The capital employed was \$109,000,000, and the value of their products was estimated at \$555,000,000. Besides these there were 6 rolling mills, 28 foundries, 89 machinery and boiler works, and 70 galvanized iron, tin, and roof slating works. There are no fewer than 2,000 factory chimneys in this city.

The

The Board of Trade manages the principal portion of the business connected with farm products, and is, of course, largely speculative, the visible supplies of the country being sold many times over in a season. The Board of Trade Clearing House statement of 1891 showed clearings of \$104,083,529.67. Transactions are permitted in lots of not less than 1,000 bushels of grain, or 250 barrels of pork. It is quite an exciting scene to visit this building (where strangers are permitted free in the gallery during business hours), and the excitement which prevails during crises quite rivals that seen in any of the similar centres of commerce in other great cities.

The Boulevards.

In a former part of this report I have stated that Chicago is sometimes called "The Garden City." This appellation is derived from the beautiful and artistic parks and boulevards which it possesses. The boulevards is the Chicago substitute for the London "square," and has much of the privacy of that peculiar institution. By municipal arrangement a certain proportion of property holders, along any residential street, when they wish to exclude business traffic from the roadway, can do so by a simple formality, provided the street does not lie next to any similar street used for traffic. The Park Commissioners of Chicago for that district, after due notice, take the matter in hand, improve the roadway, and put up notices stating "For Pleasure Driving." No traffic team is allowed to pass over the street so marked, and its inhabitants sleep in peace, and dream in comfort. The parks and driveways aggregate 3,290 acres, while the boulevards of Chicago, already completed, are nearly 100 miles in total length. The boulevard system connects the parks by a continuous chain of magnificent driveways, circling the city with a band of excellent roads, bordered with trees, metalled to the highest excellence for driving, and edged with cool green lawns on either side. The park system, with the adjacent boulevards, are under the control of three sets of Commissioners, one for each of the three divisions of the city.

The Parks.

The parks themselves are very similar to those in other great cities, and are adorned with artificial lakes, statuary, fountains, and similar ornamentation. One of the most attractive sights to be seen in Chicago is the immense number of vehicles of all kinds on Sundays in summer, driving along the boulevards and through the parks, and in winter the effect is equally remarkable, when, instead of carriages, sleighs are substituted. The celebrated lecturer, Max O'Rell, once had the opportunity of viewing the beauties of these boulevards during the leafy season of summer, and expressed his opinion that no drive in the world was equal to that which he had seen in the Chicago boulevards.

Telegraphs, Telephones, and Messenger Service.

It is needless to say that the system of telegraphy and of telephones is very perfect in every respect in Chicago, and so perfect, in fact, is the telephone system, that nothing can happen in any part of the city but it is immediately telephoned to police headquarters and other centres, and one of the most common sights in Chicago is to see the patrol waggons, the ambulances, and the fire-engines driving along the streets, summoned perhaps from different quarters of the city by messages thus received. One company alone in Chicago has no fewer than 8,500 telephones (generally abbreviated into "phones" in that city) and 1,800 miles of wire. In many of the leading hotels, drug stores, and other similar places, the use of a telephone can be had free or for a small fee.

Educational.

Educational Institutions.

I have had the opportunity of visiting some of the educational institutions of Chicago, and I must say that it is greatly to the credit of this city (the distinguishing characteristic of which is, undoubtedly, the pursuit of wealth, with an energy and singleness of purpose almost unexampled) to have made such splendid provision as it has for educational and literary purposes. Two hundred and fifty-three public, primary, grammar, and high schools; fifteen colleges of law, medicine, and theology; half a dozen academies of art and science; and two universities, are provided for by the liberality of the public of this city. It would be invidious on my part to enter into a discussion, or even into a consideration, of the peculiarities of the educational system of the State of Illinois, and of Chicago in particular, but the details above furnished show that the people are at any rate desirous that abundant provision should be made for educational purposes generally.

Public Libraries.

The public libraries of the city are: the Chicago Public Library, the Newberry, and the Crerar Libraries, all important institutions with large numbers of volumes, not only for reference but also for circulation. The two latter have been provided by private individuals, are amply endowed, and largely made use of. In the Public Library there are over 177,000 volumes, although the institution is less than twenty years old. It increases at the rate of thirty volumes per day, so that every year a good-sized library of some 10,000 books is stowed away on its shelves. Nearly one hundred persons are employed in connection with the care of these books. There is a daily average output of 3,654 volumes, which either leave the library in the delivery-waggons supplying the branch reading-rooms, or are carried out by individual members. Out of the care of these thousands of books that are daily put in circulation there was developed a complete system of book-keeping by which the whereabouts of any one of them, however widely scattered, can be learnt at a moment's notice. Distribution by station is increasing every year, at the expense of the home circulation given out individually at the main library, so that it now requires the entire time of twelve attendants and four waggons making two trips daily. There are thirty reading-rooms and distributing stations throughout the city of Chicago. The main reading and reference rooms are not neglected; 62,000 people visited the reading-room during one month, and in the same period 10,000 availed themselves of the privileges of the reference-room. The system adopted seemed to me almost as perfect as that in the public library of Dundee, Scotland, where the arrangements are very perfect indeed.

Post-office.

The Chicago Post-office furnishes statistics which perhaps show the metropolitan character of the city better than any other data which may be quoted. Thus it appeared that during a single year over 500,000,000 mail packages passed through the office, in addition to 27,000 tons of mail matter transferred from incoming to outgoing trains. The present post-office building, which was erected twenty years ago, at a cost of about \$4,000,000, has already been found inadequate to the wants of the department, and an agitation is now in progress to rebuild it on a scale that will make the Chicago Post-office exceed in cubic measurement even the great mail distributing centre at St. Martin's, London. In addition to receiving and dispatching local mails, the post-office at Chicago is the headquarters for the Sixth Division Railway Mail Service, which employs 856 railway clerks in the distribution of mails on cars throughout Illinois, Iowa, Nebraska, and Wyoming. The Inspector in charge at the Chicago Post-office has under his jurisdiction 10,000 postmasters and their employces, dispersed through the States of Illinois, Iowa, Wisconsin, Michigan, Minnesota, and the Dakotas. *The*

The Press of Chicago.

There are 531 newspapers published in Chicago, and the extent of their circulation may be gauged from the statement that 20,000,000 lb. of serial matter finds its way through the Chicago Post-office annually. The character of the Press is very different from that of the English or Australian, but this is too large a subject to enter upon in this report.

Chicago as a Railway Centre.

Chicago is perhaps the greatest railway centre in the world. Eighty thousand miles of line centre in this city, a number the largeness of which will come more forcibly home to the mind, when it is remembered that in all Great Britain, the original home of railroads, there are only 20,000 miles. For the clearance of the enormous volume of traffic thirty-five distinct railway lines terminate here, with seven handsome and commodious central terminal depôts, and over 100 other stations. The railroad lines reach from Chicago to the Atlantic and Pacific Oceans, Lake Superior, Gulf of Mexico, and all the great cities of the United States and Canada, as well as the borders of Manitoba and Mexico. These lines vary in length from 50 to 7,000 miles. One thousand three hundred and sixty trains arrive and depart each twenty-four hours, 260 of which are through expresses. A passenger may enter at Chicago a luxuriously furnished sleeping-car, and without leaving it reach any of the principal seaboard cities of the United States, as well as railway lines leading into Canada in the north and Mexico in the south. Nor is the accommodation in regard to street railways less abundant, cable and electric cars are seen everywhere. It is stated that there are 396 miles of street railways in the city of Chicago, running to all parts of the city, and furnishing accommodation to nearly 600,000 persons each day.

Illumination.

There are now in the city 2,335 miles of illuminated streets, mainly lighted with gas, the lamps of this description numbering over 37,000, but there are in addition 1,100 electric arc lights, the wires for which are principally carried in the subways—a system of iron tubes laid underneath the pavements of the streets—thus abolishing to a certain extent the objectionable feature of overhead wires.

Hotel System.

The hotels are very numerous, and some of them very large. With regard to their excellence of service and splendour of appointments some of them are unequalled anywhere. Some of these hotels are on what is called the "European plan," that is, the rooms are rented with gas, bath, &c., at so much per day, the meals being taken at the restaurant of the hotel or elsewhere at pleasure; others are on the "American plan," where a fixed price per day covers all expenses. Some hotels are on the combination plan, which includes both systems.

Hospitals, &c.

There is a very well regulated system of hospital and dispensary service, and the buildings provided for such purposes, while not remarkable either in extent or in superior excellence of administration, are sufficient. The charities generally are of two classes, public and private. The former, as is the case in most of the States, are under the control of county commissioners, removable, with other civil servants, on change of government. Applicants for admission to hospitals, &c., as well as applicants for relief, are dealt with by the county agent, who is the executive officer of the board. There is also a Charity Organisation Society, exercising a general watchfulness over philanthropic work. All the usual forms of assistance to the poor and the afflicted seem to be amply provided.

Sanitary

Sanitary Statistics.

I have already referred to the intense cold of the winter. In summer the temperature is very high during July and August, reaching 95° Fah. in the shade, and occasioning many cases of sunstroke. Notwithstanding these great extremes, and other unfavourable circumstances, such as the original insanitary site of the city, its rapid growth, and the crowded condition of some of its districts, tenanted by foreigners, the general health of the city is remarkably good. It is worthy of record that while in May, 1892, the death rates of the larger cities of the United States were as follows :—

New York	25·73	per thousand persons.
Boston	23·70	„ „
Philadelphia	22·21	„ „
Brooklyn	20·55	„ „

that of Chicago was only 20·25 per thousand—a remarkably low rate for a city of its size, and one reflecting great credit on the management of the health department of this city.

Religions.

In a cosmopolitan city like Chicago, every form and variety of religion, or no religion, is represented. Churches are to be found everywhere, and are well attended and well supported. But on Sunday theatres are open, games are indulged in, picnics are made, and all the forms of the so-called Continental Sunday indulged in. In fact one of the great sights of Chicago is the extraordinary procession of vehicles of every kind to be seen in the boulevards on Sunday, as I have already stated.

Results of the Exhibition to Chicago.

It would require more space than I have at my disposal to refer to all the peculiarities of this wonderful city; but as I have said before, undoubtedly one of the reasons which entitled Chicago to occupy the distinguished position of host, on behalf of the United States, at the World's Columbian Exposition, was not only its importance and energy but also its truly representative character as an American city.

The effect of the Columbian Exposition on Chicago will be well worth the large sums she has lavishly expended. Hitherto, a great commercial centre—and that only; a great cosmopolitan city, from the mixed races which formed her population, as a result of this Columbian Exposition she will be recognised throughout the world, not only as a great inland metropolis, but as a truly American city which has passed beyond the mere commercial stage, and has become possessed of a society reflecting culture, refinement, and artistic taste. For the promotion of this latter characteristic the Exposition, through its superb educational and artistic facilities and the example of the learned and distinguished guests from all parts of the world, must give an impetus to intellectual development which will be felt through all its subsequent history. Hitherto the reputation of Chicago has certainly not been that of an æsthetic city, but the subtle influence of this great Exhibition, reacting on a people proud of their city and its wealth, have created and will continue to create, that element of culture and tact which alone is required to enable Chicago to even surpass its rivals, and stand before the world as one of its highest types of civilization.

OPENING CEREMONIES, 1ST MAY, 1893.

The opening ceremony of the Exposition took place, as appointed, on the 1st May, 1893. The day, like many preceding it, was at first cloudy and wet, but before the hour of noon the sun shone forth and gladdened the multitude who attended the ceremony. Although most of the buildings were in an unfinished state as regarded the reception and arrangement of the exhibits, yet much had been done during the previous week to make the roadways and exterior arrangements of the grounds and waterways ready for the reception of the public. An immense amount of work had been effected in the interior decorations of the buildings, and as regarded the completion of the various courts of the countries represented; still, here, as has been the case in nearly every previous Exhibition, much required to be done. It was our proud boast that the country we represented, with its various courts and exhibits in every building but one, was fully prepared on the 1st of May. The exception was the Anthropological Building, which was not sufficiently complete until a month later to receive its exhibits. Even here we had raised the walls of our courts, and only waited the completion of the building to arrange our exhibits. Just as New South Wales had the credit and honour of being the first country to place its exhibits in the World's Exposition, so, now, it was the most complete on opening day. Of course many small details requiring after consideration and management were subsequently attended to, but as a whole the New South Wales exhibits stood out as a well-arranged and complete section of this great Exposition.

President Cleveland was received with great enthusiasm. He appeared in simple morning dress of an ordinary citizen, without a ribbon, a badge, or a medal, a striking contrast to the brilliantly uniformed representatives of royalties and of military powers who were present. It was impossible for those at a distance to hear the utterances of those who took part in the ceremony, and to the vast multitude the proceedings must have been entirely spectacular. The Chaplain of the United States Congress offered the invocatory prayer, but only a word here and there could be caught even by those in his vicinity. I was glad to hear the reverend gentleman in his supplication refer to Her Most Gracious Majesty immediately after the head of the Republic and before the rulers of other powers.

Then followed the recitation of W. D. Croffut's "Prophecy," a poem descriptive of Columbus' vision of the wonders to be wrought by his hoped-for discovery of the New World, but this was even less audible than the prayer. Its real significance was the fact that a woman (Miss Jessie Couthoun, who recited it) was seen by the vast multitude to take a prominent and lengthy part in the inaugural programme.

President Cleveland made only a short speech; in fact it would have been an act of vanity on such an occasion to address at length so vast a multitude. His voice was the only one of all the speakers on the occasion which reached any considerable portion of the great audience. His closing words were:—"Let us hold fast to the meaning that underlies this ceremony, and let us not lose the impressiveness of this moment. As by a touch, the machinery that gives life to this vast Exposition is now set in motion; so, at the same instant, let our hopes and aspirations awaken forces which in all time to come shall influence the welfare, the dignity, and the freedom of mankind."

As was stated by one present on the occasion, the scene which followed on the President's hand touching the magical button was probably as impressive a combination of sight and sound as any person in that great spectatorium had ever experienced. Down fell the veil from the face of the gilded statue of the Republic. Up rose the enormous jets of water which make the sea of fountains. Salvos of artillery

artillery boomed from the great guns on lake and shore; and cheers from the great multitude, and so ended the ceremony. In Appendix H will be found the text of the speeches of President Cleveland and of Director-General Davis on the occasion, and the poem of Croffut.

I may here mention that the mechanical device with which President Cleveland started the big Allis engine was a very simple machine. The name of the device is the Electro-automatic Engine, and it was contained in a handsome silver-trimmed oak case, about a foot square, and was surmounted by a 10-inch silver-plated gong. The case was firmly secured to the platform about two feet from the stem of the auxiliary valve. Projecting from one side of the case was a small sprocket wheel, connected by a brass drive-chain with a similar sprocket wheel on the stem of the engine's throttle valve. By closing the throttle valve, the motive power of the device, a powerful spring was wound up and the power thus created was held ready for action. Wires were run to the grandstand, and when President Cleveland touched the button the circuit was closed. The spring being freed, the sprocket wheels turned, the gong rang, the valve opened, and the big engine moved.

Later in the day President Cleveland walked through the Columbian Avenue, the main avenue of the Manufactures Building, and there met the representatives of the various nations, and in front of their courts and buildings was introduced to the Executive Commissioners and the members of their staffs. He was accompanied by the Vice-President (Ad. Stephenson), Members of the Cabinet, the Chiefs of the Exhibition, and other distinguished public men.

It was with great pleasure that I was able to cable to the Chief Secretary of our Government and the President of our Commission in Sydney that our courts were complete on opening day, 1st May. It would be superfluous for me now to refer to all the difficulties we had to surmount to accomplish the desired object. The congratulations we received on the occasion, not only from Australia but also from the representatives of foreign countries and the officials of the Exposition, not to speak of the sense of satisfaction we ourselves enjoyed from the accomplishment of one of the principal objects of our absence from our beloved country, amply rewarded us for all our arduous endeavours.

The Staff.

It will be advantageous at this stage to refer to the arrangement I considered it prudent to make in connection with the future working of our representation. In order to economise our further expenditure, and to maintain due efficiency, I, at this time permanently, fixed the staff to be retained in the various courts, determined the salaries to be paid, and the course of daily routine to be followed, and a number of other details. I may here state that all the gentlemen on the staff were Australians, with the exception of one assistant in the Mines court, who was retained on account of his usefulness in matters of repairs and practical work generally; and further, the assistants were for the most part the persons who had been promised appointments by me in Sydney before leaving, and had at their own expense come over to Chicago.

JURY AWARDS.

Considerable discussion took place in the early history of the Exhibition with regard to the method of making the jury awards. The system adopted previously at European Exhibitions, generally known as the jury system, was brought in contrast with that proposed by the Exhibition authorities, and known as the "One-Judge System." It was contended that while the former system awakened interest, cultivated a spirit of emulation, stimulated rivalry, and gave judges an opportunity to shut off the multitude of merely ordinary exhibits, it had

had serious faults, making, on the one hand, but an approach to justice and teaching nothing of the elements of declared merit ; while, on the other hand, it fostered the least generous sentiments, and opened wide the door to corrupt schemes and practices of every conceivable kind. It was stated that the system now proposed was in the main an inheritance from the Philadelphian Centennial Exhibition of 1876, and had all the merits of the older system without its faults. Under it the competency of the judges became more of a necessity, and was more certain to be secured, while integrity was subject to feebler assaults. It dealt not with a case in which if one wins all others must lose, but with one in which the fullest possible justice may be done to each and all. Under this system the report of the judge, revised and confirmed by the Departmental Committee, is the real award ; and that committee, having once put the stamp of its final approval of the proposition of a judge, gave to the award the full weight of its authoritative judgment. I may add that unquestionably this system was the one initiated and endorsed by the Act of Congress providing for the Exposition.

At the various meetings of the Foreign Commissioners, held from time to time at the early stages of the Exhibition, this subject was fully and warmly discussed, and eventually Austria, Belgium, France, Great Britain, Italy, Russia, Sweden, and certain other countries placed their exhibits *hors concours*. On the other hand the Executive Commissioners representing those countries, whose most important exhibits were natural products, thought that the proposed system would not be disadvantageous to them, and declined to sign the protest. It was apparent to me that the countries exhibiting fine arts and the results of their manufactures, the skill of ages and the highest scientific products of the world, were in quite a different category from ourselves, whose most important exhibits were in the shape of natural products ; and hence I acted with those who declined to sign. At a subsequent stage, Great Britain, under instruction from the Commission in London, as well as other countries, withdrew from the signatories and joined us. At this stage it was proposed that a conference by committee should meet the Awards Committee, and finally, by concessions on both sides, the principles of award contained in Appendix I were adopted, and rule 3, giving awards, was modified thus, the changes being contained in the proviso :—

Rule 3. The individual members of the said thirteen committees shall be, so far as possible, competent experts, and shall perform such duties and examine such exhibits as shall be assigned them by the Executive Committee on Awards. Provided, however, that it shall be the right and duty of the Departmental Committee of each department in every case where the character of the exhibit or the general interests involved be such as in the judgment of a majority to warrant and justify it, to notify the Executive Committee on Awards that there ought to be a special committee appointed to assist the individual judge in conducting the preliminary examination of a particular exhibit, and also indicating the number whereof such special committee shall consist; and thereupon the said Executive Committee on Awards shall in every case promptly appoint such special committee. And in case the said assisting special committee, or a majority thereof, shall be in accord with the conclusion of the individual judge, they shall indorse their approval on his report over their signatures on the result of their examination of such exhibit, and transmit the same to the Department Committee on Awards. There shall be a foreign representation upon each one of these thirteen committees, and the number of foreign judges will be fixed when the character and extent of the participation of the various foreign nations shall have been ascertained.

Notwithstanding these and other amendments, France continued throughout obstinate and remained *hors concours*. To New South Wales four judges in the ordinary male section and one woman judge were allotted ; and as there were no Commissioners present from our country, and I considered it very advisable for many reasons that we should be represented in Mines, Horticulture, Manufactures, Liberal Arts, Forestry, Transportation, I nominated the superintendents of our courts for the position—Mr. Hudson in Forestry (temporarily in Transportation), Mr. Pugh in Wines and Horticulture, Mr. Carne in Mines, Mr. Bruce in Wool (Agriculture), Mr. Terry in Liberal Arts (temporarily).
Mr.

Mr. Pugh's special department, Wines, not being ready for jury purposes at the commencement of the work, I arranged that Mr. Superintendent Terry should act in the interim as a judge in Liberal Arts till the judging in the Wines section should commence. Miss Margaret Windeyer was also nominated by me as a judge under the provision for Women Judges, and was appointed to Manufactures (Artistic Section). All these nominations were confirmed by the National Commission. I may state in this connection that Mr. Bruce afforded much valuable assistance, the result of his long experience, in arranging the wool classes and similar matters for the Exposition Authorities, and his selected points were generally approved by the exhibitors.

SUNDAY OPENING.

The propriety of opening the Exposition on Sunday was a much discussed subject, and from a very early period in the history of the Exposition the press of the United States teemed with articles on the subject. Eventually it was decided by the local authorities that the opening should take place, and action was at once proceeded with by legal process on the part of those opposed to Sunday opening to decide the lawfulness of the course of action thus adopted. The decision of the United States Circuit Court of Appeals, after ruling in favour of opening had been given by the Circuit Court, was rendered on June 18th, 1893, by Chief Justice Fuller pronouncing the unanimous decision of the Bench in favour of Sunday opening. Under the provisions made with the Foreign countries represented at the Exposition there was no compulsion in regard to the opening of the Government and State buildings or of individual exhibits, and consequently a large proportion of these were closed. Our State Building and our exhibits, like those of Canada and Great Britain, France, and many other countries, were closed on Sunday, notwithstanding the general opening of the Exhibition.

The Exhibition remained open on Sundays till Sunday, July 16th. In consequence of the small attendance, especially of the working classes, for whose special benefit the opening had been provided, the authorities determined that the Exhibition should be closed on Sundays. Appeal was made by Mr. Clingham against this procedure, and the matter was argued before the local Court, when the presiding judge (Goggin), after a very extraordinary deliverance, decided to grant a continuance for sixty days. Before this period elapsed the closing day of the Exhibition occurred, and the curious spectacle was afforded of an Exhibition legally open but practically closed to the public.

The decision of the United States Circuit Court of Appeals, as I have said, was delivered on Saturday, 18th June, by Chief Justice Fuller, with whom were Judge W. J. Allen, of the southern district of Illinois, and Judge Romanzo, of the western district of Wisconsin, and the decision was unanimous. The following statement comprises the chief points involved in the decision :—

The three judges determined that they had jurisdiction of the case. Directly, it did not involve the construction of any part of the constitution of the United States. The decision of the Circuit Court, from which the appeal had been taken (Judges Woods and Jenkins, Judge Grosseup dissenting), was based on other questions—as to the contract between the World's Fair Corporation and the United States Government, and on matters of policy relating to Sunday observance, not on the constitutional inquiry as to whether Congress could enact a law enjoining a closed Sunday. The constitutional question being eliminated the jurisdiction of the Court could not be doubted.

The decision held that the possession of Jackson Park was in the local directory, and not in the general government. The grounds are within the State of Illinois. Territorial jurisdiction had not been relinquished. The actual possession of the property, under State authority excluded the federal government from contest, except as to the powers delegated by law to the national Commissioners and as to the Government buildings and exhibits. These powers did not authorise Congress to order the gates closed regardless of State laws, and contrary to the directions of the Local Board.

The decision relating to the supposititious contract between the World's Fair authorities and the general government was explicit, clear, and emphatic. The Chief
Justice

BRITISH GOVERNMENT BUILDING, "VICTORIA HOUSE."

Justice said that the souvenir coin appropriation was not a mere donation; its terms constituted a contract with conditions attached; the Fair had not violated any of the conditions previous to their violation by the Government; by the action of the Government in withholding a part of the money the Fair was absolved from the Sunday-closing provision of the Souvenir Act; but, however this might be on further consideration of the rights in the case, the remedy of the Government was in an action at law for damages, not in an equity proceeding to close the Fair gates. All this, however, was technical. It was equity and common sense, but it was more.

The decision had a greater significance. It penetrated to the foundations on which the federal government rested. It vindicated and established the fundamental principle of State Home Rule. It contained the saving essence, the vital inspiration of the constitution of the United States, which reserves to the States and to the people all the powers not delegated to Congress. The delegated powers are few and simple. All personal rights and rights of property; all police powers except those exercised in the administration of federal laws; all the protections for the homes and firesides; all the laws and regulations relating to Sunday observances, at the World's Fair or elsewhere; all that relates to the well-being of the communities in the various States are subjects of State legislation and State police control. Congress cannot make a valid law determining how Sunday, or any other day of the week, shall be observed at Jackson Park, nor at any other public park, nor in the streets and highways, nor in the hotels and places of amusement, nor in houses of worship, nor in the homes of the people. In this respect the decision was a landmark on the road of human progress.

The decision was a welcome and priceless addition to the interpretations of law regarding the constitutional limits between State and Federal legislation. It recalled every thoughtful mind to the precepts of Jefferson, and of contemporary statesmen, by whom the lines of jurisdiction possessed by the Federal and State Courts and by the Federal and State legislative bodies respectively were bounded and defined.

THE OFFICIAL BUILDINGS OF THE NATIONS REPRESENTED AT THE EXPOSITION.

At no previous Exhibition have so many different nationalities been represented. The official list of the Exposition contained names of the representatives of no fewer than fifty foreign nations and thirty-seven colonies. Almost all of them contemplated, at one time or another, the erection of separate buildings. But the time was short, and space limited, and the consequence was that a large number eventually declined to build.

Foreign Buildings.

The seventeen foreign buildings which have been erected, and which no doubt proved one of the attractions of the Exhibition, were, with the exception of the Japanese building, which was located on the Wooded Island, grouped together in a small triangular space bounded roughly by the north inlet of the lagoon, the lake shore, and the north pond. This triangle lay directly across the park from the Women's Building and the Midway Plaisance. The location was the most retired and beautiful in the grounds, as all the buildings were close to the lake, and many of them looked out upon its water. The elevated railway wound between them, and the Illinois central railroad was easily accessible in the direction of 59th-street.

It would be impossible in this Report to find space for a full description of all these foreign buildings and the United States buildings, and, consequently, I shall describe, briefly, only the more important and imposing structures, selecting from the Foreign Government buildings those of Great Britain, Germany, Sweden, and Japan; and from the States buildings, those of Illinois, New Jersey, Pennsylvania, and California.

Victoria House.

A description of these buildings naturally begins with that of Great Britain, which was located on a little peninsula just north of the north inlet, and so close to the lake that it seemed as if a rough sea might fill its cellar with water. Just across the inlet from it, to the south, was the coast-line battleship, with its big guns pointed menacingly at the British head-quarters. The spot was destitute of shade, and being so close to the bridge over the inlet had more dust and noise than its neighbours. This building was called Victoria House, and at a distance looked rather insignificant, but as soon as one entered and inspected it

he

he found that it was quite English in its quiet but splendid elegance and comfort. For the erection of this building the English Government is reported to have appropriated £15,000, and private parties increased the amount to £25,000. From the outside one would wonder where the money was put; and so he might from the inside if he were a mere superficial observer. But a careful inspection easily accounted for the expenditure of that liberal sum. Victoria House was a good sample of an ordinary half-timber country-house in England of the Elizabethan period. The entire interior, including woodwork, ceilings, wall-paper, and carpets, was brought from England, and its different parts were copied after a number of famous English country-seats. The hall and staircase were after Haddon Hall, the residence of Lord Hardwicke, in Cheshire; the ceilings were after Queen Elizabeth's palace at Plas Mawe, in Wales; the reception-room was after Crewe Hall, in Staffordshire; the library was after Eaton Hall, near Chester; and the dining-room was after Campden House, Kensington, the residence of the Duke of Argyll. The plan of the buildings showed three sides of a quadrangle, with the open side facing the lake, and enclosed by a raised terrace, with iron rail fencing. The centre portion in front, or on the inland side, was recessed, with steps leading to the covered porticoes, which opened into the central hall. On one side of the hall was the library and reception-room, and on the other side the Commissioner's room. On the first floor were a number of rooms devoted chiefly to office purposes. The walls and ceiling of the principal rooms were panelled. Col. Edis, the architect, who designed the building, also furnished special designs for the internal fittings and furniture.

The German Government Building.

The great German building was the costliest, and, as was generally conceded, the finest foreign building in Jackson Park. The name given it and inscribed over its portals was simply "Das Deutsche Haus," and everything about it was obviously and intensely German. The plans of this handsome edifice were drawn by the Government architect, Johannes Radke, in Berlin. The building had an imposing frontage on the lake shore of about 150 feet with a depth of 78 feet. The tower which overtopped it like a kind of Byzantine minaret, with pillars and a dome, measured 150 feet from the ground. Over the main entrance, in gothic lettering, was a characteristic German motto, meaning:—

Fruitful and powerful,
Full of corn and wine,
Full of strength and iron,
Tuneful and thoughtful
I will praise thee,
Fatherland mine.

In the belfry were hung three huge bells which will ultimately be removed and placed in the church at Mercy, now in course of construction at Berlin, in memory of the late Empress Augusta. The building was a combination of several styles, but although thus somewhat contrasting in its several parts it was not lacking in harmony as regarded the total effect. The centre was in the form of a chapel, rich in decorations. Bay windows, projecting balconies, turrets, &c., gave the structure a most picturesque appearance, closely resembling that of an old German Rathhaus or city hall. The massive walls were decorated in fresco in South German style. The rather steep roof was covered with shining glazed tiles sent from Germany. The roof corners, water spouts, &c., down to the large lantern in front of the tower, were of shining brass or mellow hued bronze. The interior of the building was even finer and more impressive than the exterior. After passing through the magnificently decorated reception rotunda, to the left of which was the grand reception-room and the office of the Imperial German Commissioner, the second hall was reached. This inner hall, with the exception just noted, extended over the entire space in the building,

GERMAN GOVERNMENT BUILDING.

SWEDISH GOVERNMENT BUILDING.

building, covering an area of 2,000 square feet. The pillars everywhere were heavy, solid, and short throughout, and the arches semi-circular, the style being early German renaissance. Balconies rose in tiers on all four sides, the heavy timber and castings used in their construction being rich and decorative. Subdued colour effects were everywhere visible, and the niches and corners contained poetic paintings. The construction of the building cost \$250,000. This building contained a certain portion of the German exhibits to which I shall refer hereafter. More particularly the German publishers had arranged here a comprehensive general exhibit of their books, more especially of rare scientific and classical works, of which I subsequently shall give a fuller description. A reading-room for the public was provided. A second exhibit contained in the building comprised some very fine stained and painted windows and oriels, magnificent church vestments of silks, velvets, linens, brocades, &c., costly and artistic vessels for sacred use, handsome missals, Prayer-books and Bibles, and lastly, plastic church art such as statues and statuettes of saints, crucifixes, &c.; in fact the exhibits contained in this building were both numerous and valuable.

Swedish Building.

The Swedish building was certainly one of the most striking objects on the grounds. The design was mainly the product of the architect's fancy, but in working it out he had been inspired, in a general way, by the Swedish churches and houses of the sixteenth and seventeenth centuries. As far as possible the characteristics of the old Swedish architecture were illustrated.

In preparing the plans for this building a hexagon was inscribed between the sides of the triangular floor plan and the boundary of this figure decided the shape of the main hall of the building. The corner spaces of the structure formed each a separate room of considerable size, and galleries ran round the building, strikingly indicating its peculiar shape. The hexangular main hall was 60 feet square, and pitch of the cupola was 70 feet. On the top of the latter was a steeple, carrying a flagstaff from which the Swedish ensign floated, about 150 feet above the ground. The entire area of the floor was 11,000 square feet. The building was made in Sweden, where it was temporarily put together. It was afterwards taken to pieces, sent across the ocean, and erected on its three-cornered site at Jackson Park. Its entire cost was 40,000 dollars. The design of this pavilion was the product of the personal taste and fancy of the architect (Mr. Gustaf Wickman, Stockholm), guided by the style of the Swedish churches and gentlemen's country houses of the sixteenth and seventeenth centuries, and as far as possible the characteristics of the old Swedish architecture were retained. The lower part of the front wall of the pavilion consisted of modern brick, terra-cotta, and cement work. Except the part just mentioned, the entire structure was built of wood in accordance with the old Swedish fashion, the whole of the roof and walls were covered with shingles, the outside of the woodwork being impregnated with a preserving liquid to prevent decay. The huge crown on the top of the steeple as well as the framework around the bell were gilt, and the inside of the pavilion was painted in light colours, and richly decorated with bunting, coats of arms, crests, &c.

Within this building were arranged the principal exhibits of Sweden, consisting of a very complete exhibit of famous Swedish iron ores, and manufactured products of the same, as well as China goods and glass products, gold and silverware, wood pulp, and other manifold articles turned out by the numerous paper manufacturers in Sweden. There were some lovely embroideries and other needlework, but perhaps the greatest attraction of the pavilion was a representation of a genuine Swedish home, consisting of four rooms fully furnished and decorated
according

according to the custom of the country; beside pictures and panoramas and photographs and oil paintings there were in the galleries a number of exhibits illustrating the school system and the gymnastics of a Swedish institution.

Japan.

On the north end of the Wooded Island was the Hooden Palace of the Japanese Government. It was finished and dedicated with elaborate ceremonies on 31st March, 1893. It consisted of three low-pitched buildings connected by corridors; and representing three different epochs of architecture. It was designed by a native architect and erected entirely by native workmen. The work of the interior decoration was placed in the hands of the Tokyo Art Academy, and corresponded both in ornamentation and furniture with the three periods represented in the architecture. The material used was unpainted wood, which was worked up in an ingenious and effective way to display its colours, and on which had been put an exquisite polish. All of these showed in their exterior colouring the tint of sandalwood, except the sliding squares which served both as doors and windows, and which consisted of a lattice work of black, highly polished wood, over the inner surface of which was a white semi-transparent paper. The periods represented were the eleventh, fifteenth, and eighteenth centuries. The north wing, illustrating the eleventh century, showed the most prosperous area of the Fuji-wara period, while the south wing corresponded in date to our Columbian era, showing Japan as it emerged from the war of two dynasties into a clearer art life, whose key-note was purity and simplicity. The interior of this pavilion was furnished and decorated to represent the Ginkajura, the villa of an Ashikaga Shogun.

STATE BUILDINGS.

The northern portion of Jackson Park, although containing the great palace of Fine Arts and the foreign government buildings, was mainly devoted to the official buildings erected by the several American States and Territories. After the organisation of the National Commission, the World's Columbian Exposition, and the Board of Lady Managers; each in its own way, assisted by the Commissioners from the various States and Territories, commenced to ask each State for an appropriation for a special exhibit in the shape of a building which would represent the State. Some of the responses were prompt, and others held back for one reason or another. There were as many as some forty odd structures belonging to as many States and Territories. Strange as it may seem, the largest State in the American Union, Texas, was the only backslider; while the smallest, Rhode Island, had a beautiful little structure of Doric architecture. The Texas people commenced a handsome building, the plans of which were in keeping with the dignity of the "Lone Star State," but the Legislature refused an appropriation, and popular subscriptions ran low, and in consequence the undertaking was abandoned. Each State building was the especial pride of the people from the commonwealth that furnished the money for its successful completion. The State Buildings were a sort of headquarters for the different peoples, where members of the States could meet each other during the rush days of the exposition. Most of them had club rooms, banquet hall, and reception rooms, where their own people might feel at home some thousand miles from their home State.

Illinois.

The Illinois building was in the form of a Greek cross, one axis of which was 450 feet long by 160 feet wide; the other, 285 feet long and 98 feet wide. At the intersection of the arms of the cross the dome rose, having an internal diameter of 75 feet, and an inside height

NEW YORK STATE BUILDING.

height of 152 feet. Two galleries circled the interior of the dome, one 15 feet, the other 96 ft. 6 in. above the floor. On the entablature rose the drum, covered with galvanized iron. A round lantern, 12 feet in diameter and 35 feet high, crowned the whole, its height above the ground being 234 feet. At the east and west ends were large entrances. Within the building were rooms for the Governor of the State and his suite; others for the members of the State Board; a great exhibition hall, ante-rooms, and rooms for the accommodation of the Women's Board. There were rooms at the east end for school exhibition purposes, one being devoted to the purposes of a model kindergarten. In the northern end was a fire-proof room called the memorial hall, which contained historical objects usually kept in the State capital at Springfield.

New York.

The New York building was one of the most splendid on the grounds. It extended over an area of 14,538 feet, exclusive of terraces, porticos, or exedras, which covered an additional area of 3,676 feet, and was 214 feet in length, 142 feet in depth and 96 feet in height. The approach was from the south by a flight of fourteen steps, 46 feet wide, giving access to a terrace, 15 ft. x 80 ft., from which the loggia, 46 ft. x 17 ft. 6 in., was reached. At the entrances to the building were casts of the celebrated Barberini Lions, and the four pedestals lamps lighting the place were reproductions of the best examples in the museum of Naples. The porticos east and west of the building had a diameter of 50 feet, the open portion of which was covered, in the Italian fashion, by a coloured sail. On either side of the main entrance, in the niches outside the building, were placed the busts of George Clinton and Roswell P. Flower, the first and present Governors of the State. In the other niches in the facade of the second storey were two heroic-sized figures of Henry Hudson and Christopher Columbus—the four works of art being the production of Olim Warner. The exterior of the building was lighted by electricity. Above the arched entrance was the great seal of New York (10 feet high) illuminated by myriads of tiny lamps set close together. The main floor of the building consisted of a vestibule 17 ft. 6 in. x 46 ft. x 33 ft. 10 in. On either side of this vestibule were three niches in mosaic. The entrance hall, 46 x 84 feet and 20 feet high, was light in colour, the main mural decorations being on the grand staircase hall, 37 feet x 46 feet; the dome ceiling being 46 feet high. These paintings were adapted from Pompeian designs not previously used by any artist. In the well of the staircase was a room, 36 x 46 feet, in which was placed the relief map of the State on a scale of an inch to a mile. On the west of the entrance hall were the women's state apartments, consisting of three rooms, each 28 ft. 7 in. x 32 ft. 8 in., and 20 feet high. The walls of the suite of rooms were covered by a light silk of renaissance pattern, and the floors of hard oak were covered with Indian rugs. On the east of the entrance-hall was a similar suite of rooms, designed for the use of men, painted and furnished according to the general design. On the same floor were the lavatories, &c. The second floor consisted of a staircase hall, giving access through three double doorways to the reception hall, 84 x 46 feet and 45 feet high. The general scheme of the decoration was white and gold. On the west of this hall was the Women-manager's Board, 32 ft. 8 in. x 56 ft. 7 in. and 15 feet high. In the eastern wing was the museum, 32 ft. 8 in. x 56 ft. 7 in., and 14 feet high, which was filled with historical relics and documents relating to the history of the country and State. Adjoining was the general manager's board-room, 22 ft. 6 in. x 28 ft. 7 in. Two other rooms, 18 feet x 21 feet, completed the space on this floor. The roof formed a triple terrace garden enriched by terra-cotta pots, decorated with palms, bay-tree and flowering shrubs, and furnished with awnings, arbors, tables, and chairs.

Pennsylvania,

Pennsylvania.

This building was in colonial style, reproducing the historic clock-tower of Independence Hall, Philadelphia. The first and second storeys were of Philadelphia pressed brick, the floors of native marble and wood, and the walls ornamented with wainscot panellings from Pennsylvania Forest. The front entrance entered into a central rotunda 30 feet in diameter and 40 feet high. To the right and left were general reception, toilet, and dressing rooms. In the rear the exhibition room extended the entire width of the building, and its walls were ornamented with portraits of distinguished Pennsylvanians. Many rare documents and relics of historic interest were displayed, the most important of which perhaps was the old Liberty Bell, whose tocsin proclaimed to all the world the birth of the Republic. The crack in the bell was peculiar. The inscription on the bell was as follows:—

PROCLAIM LIBERTY

Throughout all the land unto all the inhabitants thereof.—Levit., xxv. 10.

By order of the Assembly of the Province of Penn'y for the State House, in the
City of Phila., 1752.

Broad staircases led to the second storey of the building, where the waiting-room and offices of the Executive Commissioner were located; also a room for the use of press correspondents, and another containing Pennsylvania newspaper files. The doors and windows of the second floor opened upon broad verandahs, and outside staircases led to the roof-garden. Historical maps, books, portraits of governors and other prominent citizens and relics, were exhibited. Surmounting the main façade of the building were several pieces of statuary, the Pennsylvania coat of arms, figures of William Penn and Benjamin Franklin, heroic in size (about 12 feet high), and the allegorical groups at the right and left angles of the building, which were indicative of mines and mining on the one hand, and of science, manufactures, and agriculture on the other, with the central figure in either case surrounded by sheltering and guiding spirits. The cost of the building was \$90,000.

California.

The California building was a reproduction of the typical mission that once was common in that State. Its length was 345 feet, the width 144 feet, height from the ground to the eaves 50 feet, to the roof-centre 65 feet, and to the top of the dome 113 feet. The walls were a close imitation of the adobe or sun-dried brick, used in the original structures; the roof was covered with tiles similar to those covering the Jesuit Mission-houses. The principal features of the building were copied from the beautiful old mission at Santa Barbara, the façades represented those of San Luis Rey and San Luis Obispo. The whole mass was relieved by a large central dome, around which was an open roof-garden filled with semi-tropical plants. The building was further embellished with the rich moulded windows over the arched entrances, and made musical by the old mission bells in its towers. Exhibits were arranged along the sides of the building on the ground floor, and consisted of minerals, petrified woods, wines, fruit, and a number of other matters. The offices were grouped on the second storey.

Some of the other State buildings were very characteristic, and all were more or less expensive. There can be no doubt that a very large sum was spent on the separate State buildings, the total amount having been estimated at about a third of a million sterling. The fact bears out what I have already said as to the strong local spirit and keen rivalry that exists between different cities and States in America. Some of the newer and the less thickly populated of them
collected

PENNSYLVANIA STATE BUILDING.

CALIFORNIA STATE BUILDING.

collected or appropriated very considerable sums for Exhibition purposes, a fact which shows how stimulating is a new country, and how energetic is a youthful community. These State buildings formed the most curious town ever built. Surely never before was gathered together a collection of houses so diverse in architectural character.

OFFICIAL BUILDINGS OF THE EXPOSITION.

Preliminary Remarks on Official Buildings.

In order to give a general idea of the magnificent structures provided for the exhibits of the world at the World's Columbian Exposition I have embodied, in the succeeding paragraphs, information obtained, not only from my own observation during many months, while the buildings were in course of construction, but what is much more to the purpose, from the best official records which have been freely placed at my disposal for the express purpose.

Grand Terminal Station.

On arrival at Jackson Park—while there were many entrances in the Stony Stony Avenue and other streets leading to the Exposition, as well as at the Lake front at the various piers, the proper official entrance was at the Grand Terminal Station, a handsome structure, situated west of the Administration Building and forming the west side of the Grand Plaza. It was of the Roman-Corinthian style of architecture, and in general plan was divided into three sections of which the central was 200 feet in length by the full depth of the building, while the east and west sections were three storeys in height, and contained the waiting-rooms, check-rooms, lunch counters, and the general railway offices. The gallery above was 25 feet wide and extended entirely round the central section, having a length of about 600 feet. Two broad stairways, built in the highest art known to moderns, led up to this gallery from the main floor. This gallery was both a waiting-room and a convenient place for the meeting of friends. In the upper part of the great hall there was a frieze of clock faces, 24 in number, and 5 feet in diameter, giving the time of the day or night at the principal cities of the world. On examination of these clock faces I found that the one representing Australia had the name of Melbourne with the time of the day at that city represented on it. I wrote at once to the authorities, pointing out that New South Wales was the only Australian Province officially represented at the Exposition, and that the Metropolis of Australia was the capital of New South Wales, and that its name was Sydney, and I requested that the necessary alterations of name and time might be effected. I am glad to report that my request was complied with, and the visitors to the Exposition had then the opportunity of knowing the exact time in Sydney corresponding with the hour of the day in the city of Chicago. The great hall, in its principal features and proportions, was adopted from the hall of the baths of Caracalla at Rome. The constructive material consisted of wood and iron, and the exterior and inner finish and decorations of "staff."* Rising above the station were two illuminated balls of metal and glass, 10 feet in diameter, showing clock-faces in every direction, giving local time. Here also was the "Lost
and

* *Staff*: This was the incombustible material with which the great buildings, the hundreds of columns, pediments, capitals, and all the profuse general ornamentation, as well as the gigantic statuary groups and allegorical pieces, were constructed. It was composed of a mixture of plaster of Paris and a small percentage of cement, in which were introduced frequent fibres of hemp, jute, or sisal grass, to give it toughness, so that it might be sawn, nailed, or bored at will. It was cast in moulds. The plaster and cement were first wet up to the consistency of treacle, and a layer was then spread on the well-lubricated wax moulds. Then followed a layer of the long, tough fibres; over this was poured another coating of liquid plaster, covering in the fibre and filling the mould to the required depth. In the case of statues and statuary groups the models were first fashioned in clay, and then coated in Staff. The workmen employed on this material and work were chiefly Italians, Frenchmen, and Germans, who are quite familiar with the art and practice of Staff-making.

and Found" Department, which was the receptacle for the innumerable articles left by visitors about the building. In connection with this matter a notice was sent to all the officials at the State, Government, and Official buildings, to send here such articles as inattentive visitors might accidentally leave behind them, and the necessity for this notice was recognised everywhere. The entire system of railroads was concentrated in this terminus upon thirty-five tracks. The cost of the main building was \$250,000, and of the landing-platforms connected with it \$50,000, making a total of \$310,000.

Whilst referring to this matter we cannot help admiring the sagacity which induced the organisers of the Exhibition to land their railway visitors just on the most imposing portion of the grounds. An excited and expectant railway passenger turned from the train into a long tunnel or dreary alley, when he expects something beautiful and surprising, is apt to become jaded and weary, so that when the view does gradually unfold itself it has lost half its charm.

First Glimpse of the Palaces.

The view that burst upon the delighted visitor to the Columbian Exposition, immediately he left the depôt within the grounds, far surpassed any effect achieved at previous Expositions, and it would be hard to find a parallel anywhere. The noted architectural spectacles of the world, which owe their charms to diversified surroundings, were, of course, out of the comparison, for the Chicago Exhibition had no aid from Nature beyond the magnificent setting afforded by the blue waters of Lake Michigan. Neither has Chicago historic associations by which the imagination can assist the eye. The architects of the Exhibition were dependent wholly on their own genius and noble precedents in architectural design, and they did their work well. Fortunately for Chicago she had not to depend for the success of a spectacle upon the vicissitudes of the weather to the same extent as in many other places, although she had to fight during the last six months of preparation with difficulties of climate of which Australians know nothing; so that a blue sky and a lake sparkling in the sunshine was a thing not to be despaired of, day after day, as it would have been in some less-constant climes. Before the summer had passed, visitors often longed for some veiling of the sunshine, but that was not a matter for the architects to consider. The task set them was to produce a holiday and festal impression, and to do this, as was done, without sacrifice of dignity, was, perhaps, as great a professional triumph as could have been achieved.

The names of the skilful architects who designed these glorious works of art were:—

Messrs. F. L. Olmsted & Co.—Landscape Architects of the Grounds, &c., &c.
 Mr. Richard M. Hunt, New York—Administration Building.
 Messrs. Adler & Co., Chicago—Transportation Building.
 Messrs. M'Kim, Mead, & Co., New York—Agricultural Building.
 Mr. W. L. B. Jenny—Horticultural Building.
 Mr. George B. Post, New York—Manufactures and Liberal Arts Building.
 Mr. Henry Ives Cobb, Chicago—Fisheries Building.
 Messrs. Peabody and Stearns, Boston—Machinery Hall.
 Messrs. Burling and Whitehouse—Choral Building.
 Messrs. Van Brunt and Howe, Kansas City—Electrical Building.
 Messrs. Holabird and Roche, Chicago—Stock Ring and Pavilion.
 Mr. S. S. Bemen, Chicago—Mines and Mining Building.
 Mr. Charles B. Attwood, Chicago—Fine Arts Building, Music Hall, Casino, Terminal Railway Station, Guards' Stations, Fire-stations, Balustrades, Bridges, &c.

The ironwork was in most cases designed by Mr. Shankland.

For the purpose of convenient record the following statement of the dimensions of the Great Exposition Buildings will be found useful, and at the same time will convey a more complete idea of their vast extent than could otherwise be easily given.

Dimensions

Dimensions of the Buildings.

Buildings.	Dimensions in feet.	Area in acres.
Manufactures and Liberal Arts	787 x 1,687	30.0
Administration	262 x 262	1.6
Mines	350 x 700	5.6
Electricity	345 x 690	5.5
Transportation	256 x 960	5.6

Illinois State	160 x 450	1.7
Illinois State Wings (2)	0.3
		158.8

The Exposition Buildings, not including those of the Government Building and the Illinois State Building, had also a total gallery area of 45.9 acres, thus making their total floor space 199.7 acres. The Fine Art Building had 7,885 lineal feet, or 145,852 square feet of wall space.

Destruction by Fire of Cold-Storage Building.

Happily the glories and success of the Columbian Exposition were not marred by more than one serious event throughout its duration; but this catastrophe, which took place on the 10th July, 1893, has to be recorded, as it was attended with great loss of life, and what was relatively of minor importance, the destruction of a large quantity of exhibits from participating countries, the loss, however, of this Colony being comparatively slight. This event was the destruction by fire of the cold-storage building, in which wines, beers, and perishable goods were stored on behalf of exhibitors. The fire broke out in broad daylight, while the grounds were crowded with visitors to the Fair. The flames first appeared on the top of the wooden cupola, which surmounted the smoke-stack, 191 feet high, and built of steel piping encased in wood. The flames spread with great rapidity, and within a very short time a large number of firemen belonging to various companies in the city of Chicago, with engines, arrived on the spot. In the discharge of their duties the firemen ascended the interior of the tower of the building, and so rapid was the spread of the flames that the escape of most of those who reached the upper portions of the tower was cut off, and twenty lives were lost, while many persons were dangerously injured. This unfortunate affair created an intense sensation not only in Chicago but in all parts of the world to which the information of the sad event was cabled. The building was 130 feet by 255 feet in area, with a tower reaching 220 feet from the ground. The structure was built by the Hercules Iron Co., at a cost, with machinery, of 200,000 dollars. Perishable articles were stored at

at the northern end of the building, and at the southern end were the ice freezing-tanks and the offices of the Company. The building was constructed with wood and iron, covered over with staff, the same material as that which was used generally throughout the World's Fair.

The Official Buildings.

I now propose to describe briefly the various official buildings, in order, referring to our own representation in them, as well as to the exhibits of leading character of other countries. It would be impossible for any one person to do justice to any single department of the exhibits, so extensive and so varied were these representations. All I hope to accomplish is to give a simple expression to the views and opinions I have formed of the more striking features of the various exhibits as they have occurred to me, whilst in daily observance of them, during the currency of the Exhibition, and to afford such information as may hereafter be of some value to those interested in the special subjects referred to.

ADMINISTRATION BUILDING.

Before proceeding to the various official buildings in order, a reference to the Administration Building is necessary.

Its grand and imposing appearance.

This building was one of the gems of the Exposition palaces, and stood in the most imposing position at the head of the great basin. Pictorial representation may give a general idea of the appearance of the building, but never can afford a standard by which its noble proportions may be judged. The design, which was the work of a New York architect (Mr. Rich Morris Hunt), was bold in general features and rich in ornamentation, the whole combining to form an impressive and pleasing structure in strict harmony with the purpose it was intended to serve. It was situated immediately south of the Mines and Electricity Buildings, north of Machinery Hall, east of the grand Terminal Railway Station, and west of the basin. The gilded dome of the lofty building was a most conspicuous object, and attracted the gaze of every visitor on reaching the grounds. In plan the building was rectangular, and measured 260 ft. 6 in. on each side; and consisted of four pavilions, 84 feet square, one at each side of the four angles of the square, and connected by a great central dome, 120 feet in diameter and 220 feet in height, leaving at the centre of each façade a recess 82 feet wide, within which were the grand entrances to the building. The roof which covered these pavilions was flat, and was made continuous by exterior galleries, which afforded a most delightful promenade for visitors. The first great storey was of the Doric order, of heroic proportion, surrounded by a lofty balustrade, and having the great tiers of the angle of each pavilion crowned with sculpture; the second storey, with its lofty and spacious colonnade, was of the Ionic order.

The Entrances.

The four great entrances, one on each side of the building, were 50 feet wide and 50 feet high, deeply recessed and covered by semi-circular arched vaults, richly coffered. In the rear of these arches were the entrance doors, and above them great screens of glass, giving light to the central rotunda. Across the face of these screens, at the level of the office floor, were galleries of communication between the different pavilions.

Interior Features.

The interior features of this great building even exceeded in beauty and splendour those of the exterior. Between every two of the grand entrances, and connecting the intervening pavilion with the great rotunda, was a hall or loggia, 30 feet square, giving access to the offices, and provided with broad circular stairways and swift-running elevators.

The

ADMINISTRATION BUILDING.

The Dome.

Above the balcony was the second storey, 50 feet in height. From the top of the cornice of this storey rose the interior dome, 200 feet from the floor, and in the centre was an opening 50 feet in diameter, transmitting a flow of light from the exterior dome overhead. The under side of the dome was enriched with deep panellings, richly moulded, and the panels were filled with sculpture in low relief, and immense paintings representing the Arts and Sciences. In size this rotunda rivalled, if it did not surpass, the most celebrated domes of a similar character in the world.

Pavilions.

The building was divided into four grand pavilions known as A, B, C, and D, occupied from the ground to and including the third floor by officials of the Exposition, express, telegraph, and telephone companies, bank, press headquarters, café, Columbian guard, &c. Above the third floor were four tunnel passages leading from one pavilion to another. The fourth floor was a circular colonnade for sight-seers, and from the fifth floor stairways led to the top colonnade.

In the building provision was made for the offices of the President of the United States Commission and of the Director-General; the Council of Administration; the President and the Secretary of the Exposition; the President of the Board of Lady Managers; the Secretary of Installation; Collector of Customs; National Commission; Postal and Telegraph Companies; Publicity and Promotion; the Official Publication; Press Association; Foreign Affairs; Express Companies and Bank.

The framework of the dome of the Administration Building was of steel; the foundation was on piles, driven down to the hard clay, and upon them were built up standards of continuous lattice work. The dome was framed of eight main ribs, one at each angle of the octagon, and in many ways each portion of framework was strengthened and stiffened to add to the general security of the work. Within the dome, round its walls in suitable panels were painted the names of all the great countries represented at the Columbian Exposition, and I was gratified to observe during the earlier stage of the Exposition the name of Australasia on one of the panels; some time later, however, in consequence of a supposed affront to some of the foreign nations, whose names were not recorded in this conspicuous manner, several of the panels had the names on them removed, and amongst these was that on which the name of Australasia had been placed. I immediately wrote the Director-General, calling his attention to the action which had now been taken, and pointing out that at great expense, and extraordinary toil and labour, our country had come to this distant land, and that it was only a matter of due and proper courtesy that our country's name should be distinctly recognised amongst the nations thus publicly represented. Soon afterwards I received a letter from the proper authorities, stating that the whole matter had been reconsidered and that in a few days the name of New South Wales as a represented country at the Exposition would be placed on one of the panels; which was accordingly done to my entire satisfaction; and in this and in many other matters I have been placed under great obligation to the Director-General of the Exposition.

Decorative Statuary.

I have already referred to the sixteen huge panels in which were inscribed in golden letters the names of the great countries of the earth represented at the Exposition. Extending around the dome, on top of the arches in which these panels were placed, was a strip of huge white moulding, handsomely carved and with its cuts and crevices

crevices worked in gold. Resting on this moulding were eight huge panels, one at each side of the octagon, each having a gilt slate supported by two winged female figures, and on each slate was the record of some great discovery or event in the history of the world's progress. Above these panels was a row of light terra-cotta coloured panels, through the top of which at regular intervals were let in small square latticed windows. Further up, on another stretch of moulding, were painted the names of men whose discoveries and inventions have been of great importance in the progress and development of the world. Beyond these was a row of plaster medallion showing the heads of the different types of women of the world, and still further up, at the summit of the great dome, were eight panels, each having a handsome plaster group. The central figure in each of these was a woman with outstretched arms and holding in each hand a wreath to crown some one of the figures bent before her. The central figure was the genius of the World's Columbian Exposition, the initial letters of these words, W.C.E., being inscribed over her head, and the kneeling figures in front representing Literature, Science, Arts, and Industries, upon which recognition and honour are being bestowed.

Upon the outer and upper dome Dodge painted his picture "The Glorification of the Arts and Sciences," the idea of which was the representation of Apollo sitting on a lofty throne and conferring honours on the victors in War and the leaders in Science and in Art. The form of a warrior was bent before him, and other favourites approached on the broad steps that lead to the throne. In the procession which extended around the dome were figures representing Music and Poetry, and the Arts, the Sciences, and Industries. There were also four winged horses drawing a model of the Parthenon, and over it were winged females drawing back the canopy from the amphitheatre in which all such gatherings were held by the ancients.

The external sculpture was the work of Karl Bitter, of New York. The building was decorated with twenty-eight groups and a number of single figures and relievos. Bas-reliefs of a larger size were especially used for adorning the interior of the dome. The most remarkable were those groups which were placed at the sides of the entrances; they were 34 feet high and represented the four elements, Fire, Water, Air, and Earth. At one side of an entrance the element was seen in its natural, unsubdued condition, and at the other side it was shown as in the service of man and subdued by him. Each of these groups was full of symbolical figures, and was placed in such a position with regard to the neighbouring great buildings as to be very characteristic. For example, opposite the Machinery Hall, Fire was symbolised, and opposite the lagoons, and looking out on the Lake, was the Water group. The Pavilions were decorated with twelve groups, each having three, allegorising the elements, their capacities, inclinations, and dispositions. Strength, patriotism, religious sentiment, charity, love of liberty, &c., &c., were thus symbolised. In the highest points, at the sides of the four smaller domes which surrounded the main dome, there were eight more groups allegorising the culminating points of human culture in Art and Science, Industry and Commerce, War and Peace, Theology and Justice. The leading motive of these groups, with their winged female figures, was to display a most charming interruption to the architectural masses.

The M'Monnies Fountain.

This fountain stood at the head of the basin immediately in front of the Administration Building. There were two electrical fountains, 50 ft. in diameter, to the right and left of the M'Monnies Fountain, two smaller fountains in front of the Fine Arts Building, and one in front of the Women's Building. Certainly no more striking and perhaps no more perfect a work of art could be found among the groups

groups and figures of sculpture which adorned the grounds than M'Monnies Fountain. It arrested attention even amongst the wealth of attractive objects which were visible in that portion of the park, and grew upon the imagination as one observed and comprehended the exquisite detail in which the artist executed a design of bold and large conception. Mr. M'Monnies was the sculptor, of whose fertility of imagination and skill in production this pæan was the creation. The idea presented by the work was that of Columbia, the genius and apotheosis of modern liberty. The ship of State floated in the centre of a circular basin or lake, and was idealised by a triumphal barge. In the prow was a winged figure of victory heralding the advance of freedom by blast of trumpet, and bestowing laurels on her champions with the disengaged hand. The barge was attended by eight sea-horses, each bestridden by the animated figure of a youth, who urges his steed forward. The rowers were eight female figures, representing Music, Architecture, Sculpture, Painting, Agriculture, Science, Industry, and Commerce. These stood on platforms, which rested on shields and mouldings of emblematic device; the forward poise of the bodies as they leant to the oars, and the tresses and drapery blown to the rear, conveyed the sense of rapid motion. At the helm was a hoary, omnipotent Time. Amidship, on a massive pedestal bearing the arms of the Republic, was throned Columbia, calm and erect in conscious strength, but pose and features expressing vigilance as became one who knew the price of liberty. Her feet rested on the globe in token of Freedom's triumph, her right hand rested lightly on the back of the chair around which her garlanded and happy children knelt; in the left hand she extended the torch that lights the world. Victory at the prow; Time at the helm; the Genius of Liberty sailing with serene confidence towards the Future. Such was the story of the sculpture. The proportions of the work were on a grand scale. The smallest figure was 12 feet in height.

Electric Fountains.

The culmination of brilliant effects was produced when the great electric fountains on either side of the M'Monnies Memorial were brought into play. They were much larger than anything of the kind attempted before, and were put in at a cost of \$50,000. The basins in which the apparatus was fixed were 60 feet in diameter. The floors were pierced for 304 jets altogether, by means of which the water was sent to a height of 150 feet. Like the rest of the display, the prettiest effects were produced by concealed lights, thus doing away with the marring by the glare of the exposed light while adding the charm of mystery to the source of the illumination.

The whole apparatus was controlled by electric signals from one of the domes of Machinery Hall. From there the different lights were turned on, and the transition from one form to another, and from one colour to another, controlled. A 36-inch main supplied the water. Illumination was by 38 arc lights of 100 amperes each, requiring nearly 1,000 horse-power in operation.

Mode of Production of the Colours in the Fountain.

The production of the lovely changing colours—the torrent of silver changing to mellow amber, then pale green, then cerulean, then opaline, iridescent, then like a Vesuvian cataract of fiery lava, then a cascade of molten silver—took place through the aid of coloured glass. In the floor of the fountains was a trap-door leading to the operating room, a great circular cellar about 35 feet in diameter and 8 feet high, filled with a wilderness of machinery, pipes, switch-boards, search-light reflectors, and electric wires; the water in the lagoon was nearly level with the ceiling, and a force-pump was used to keep out the soakage. The tops of the round rock-covered chimneys, through

through which the light streamed, were covered with heavy plate-glass laid in putty, and, of course, water-tight. Above this glass was the nozzle of the fountain. Below it, in the circular room, and directly underneath, were the search-light carbons burning in a reflector similar to the style of a locomotive head-light, which projected the powerful rays upwards against the sky. The changing colours were produced in a very simple manner. Between the electric light and the glass top of the low chimneys was a horizontal wheel about 6 feet in diameter. This wheel had six sections, divided somewhat in the shape of a six-cordate clover leaf. In each of the leaves or sections was a differently coloured glass, and the wheel when turned produced the effects desired. The question may be asked as to how the same light was cast upward through the dozen chimney holes of the fountain at the same time, and how the dozen glass wheels were turned simultaneously, one under each jet. The wheels were all connected with a simple system of shafting and bevelled cogs, so that the operator turned them all at once, bringing the same coloured glass between the search-light and the stream above it with the mechanical accuracy of machinery. In one of the sections of each wheel the glass was omitted, to give the white light or molten silver effect. The explanation of the mode in which the two widely separated fountains played the same colors and in the same manner simultaneously, although the operators could not see each other work, was as follows:—The operator in the tower of Machinery Hall commanded a view of both fountains, with which he had electric communication. By the simple turn of a switch he produced a white, green, blue, opalescent, or red light in front of the wheel turner, indicating thus the color of the glass next to be brought into play; and, in a similar manner, the style in which the fountains were to play. The water-head was furnished by the great pumps in the Worthington pumping station west of the Colonnade.

As the observer stood beside the MacMonnies Fountain in the Grand Court of Honour and gazed on each side of him he could not fail to admire the remarkable statuary encircling the main basin, and he would be particularly struck by the characteristic series of native American wild animals as well as a series of six rostral columns. Referring to these latter the sculptor, Mr. Johannes Gelert, stated that the principal idea intended to be conveyed was that of a great naval triumph such as the discovery of America truly was, and to serve this prime motive there was a sixfold repetition of the columns. On the pedestals were graven the names of great discoverers and the shafts were adorned with rostra or the prows of ships and emblems of triumph. On the double capitol stood the sailors' tutelary deity, Neptune or Poseidon, resting in his divine car, full of proud triumph and well pleased with the grand results of his sailors' great discovery. In addition to these triumphal columns there was a display of statuary characteristically American, and it was a happy inspiration which led the sculptors not to confine themselves to representations of inanimate forms and beautiful reproductions of inanimate ideas which have been elaborated to their utmost extent by the ancient Grecian and Roman masters, of which this noblest and most imperishable of the arts, while modern artists may hope to equal, it is utterly impossible for them to excel the ancient artists in the portrayal of the human figure, or in the evolution of graceful ideas as applied to columns, arches, and architectural ornamentation. The determination therefore to depart from conventional forms and to introduce into the landscape the figures of American animals was a happy one, especially when it is considered that the large majority of visitors to the Fair, American as well as Foreign, were more or less unacquainted with such representatives of the wild beasts of the country as the grizzly bear, the buffalo, and the panther. These conceptions likewise served another purpose, namely, to aid in the perpetuation of the forms of these animals long after they themselves are extinct species. It is a fact well known to naturalists
that

that many kinds of the marine and land animals of America are doomed in a short time to utter extinction; and prominent among them were the animals so ably represented by these sculptures. Most life-like and realistic were the animals surmounting the various bridges. Mr. Keney's thus described those for which he was responsible:—

“Old Ephraim,” at the north-east corner of the bridge, opposite the south-west corner of the Manufactures and Liberal Arts Building, was a male grizzly bear guarding the approach to his lair. He has been marching down the canyon, when his quick ear catches some note at discord with nature's harmonies. This rivets his footsteps in his tracks, suppresses his breathing almost, and so he stands with set ears, straining eyes, protruding lips, expanded nostrils, impressible to the next tone which shall rouse his nature into madness.

“As down the glen he strode along,
Vanished the blacktail's branching prong,
And even the finch's low sweet song
Stopped in the pine above him.”

“A Grizzly Grave-digger,” at the south-east corner of the bridge and opposite the south-west corner of Manufactures Building, represented a female grizzly which had dug up the head of a wild sheep she had buried and was pawing and playing with it, rolling it between her huge forepaws, each garnished with claws curved like reaping-hooks, set for some red harvest. All the varied nature of the bear was called into life; aroused by the proximity of the dead game she gloats over it in anticipation of the feast. Suddenly a magpie utters its cry of alarm—her play ceases.

“A Prairie King,” on the north-west corner of the bridge over the lagoon between Machinery Hall and Agricultural Building, was represented by a bull buffalo walking around the outskirts of his herd on the outlook for some danger which threatened. An imposing figure with shaggy, grim frontlet, and short, thick horns, the ponderous head, low swung to the rhythm of his walk, its sweeping beard almost touching the grass at his feet; a warrior of his tribe, whose towering front has stood guard when the savages of the desert have swarmed around.

“At sound of the Whoop,” on the south-west corner of the bridge, over lagoon between Machinery and Agricultural Buildings, was represented by a cow buffalo, which, hearing the whoop of the coming red men, stands with uncouth head high lifted, and shaggy fore-legs gathered beneath her. From her thin, nervous hindquarters to the tips of her sharp, curved horns, all was tense as a bow string, for there flashed in advance of those ringing screams a vision of the nude, brown horsemen of the plains, whose blotched mustangs are bearing them onwards, the old time destroyers of her race.

“The Still Hunt,” on the north-west corner of the bridge over the lagoon, opposite the west entrance to the Manufactures Building, consisted of a figure of an American panther, which represented, as did all the animals of the bridges executed by Keney's, that they were in some way watching the approaches. In fact, the gathering of the immense muscles, the limbs tremulous from restrained impulse, and the concentrated gaze all told their story, and left no doubt in the beholder's mind of the spring about to hurl the great cat upon his prey.

“At Bay,” on the south-west corner of the bridge, over the lagoon, opposite the west entrance to the Manufactures Building, was represented by a female American panther. Someone was approaching her fastness, and her first impulse was resistance. She had partly risen, and, with planted fore-feet, straining quarters, and swaying tail, displayed her fangs, while her down-drawn ears, wrinkled face, and passion-

passion-blinded eyes told at a glance that she thirsted even now in her savage feline breast for the wild grapple of the coming contest in all its fury, its blood, and its death.

Describing the statuary so ably executed by him, Mr. A. Phimister Proctor said:—"Two sullen moose, with shaggy manes, disproportionately long legs, short thick necks, and ugly noses stand one at each side of the bridge leading to the Agricultural Building. The animals' antlers are their only beauty, but the sculptor has given a faithful representation of them, and there are duplicates on the Colonnade. With heads raised, and nervous alertness and attention expressed in every graceful line, four elks stood in front of the Administration Building, while others were placed at intervals along the lagoon in attitudes as watchful as though they were gazing upon the purple heights of their familiar mountains. Two polar bears stood on the west end of the middle bridge, fronting the Administration Building. They gazed across an imaginary field of ice, and seemed to sniff the air for indications of seals or unfortunate Arctic explorers."

At the south end of south canal, immediately in front of the great Stock Pavilion arch, stood an accurate reproduction of the famous Egyptian obelisk known as Cleopatra's needle, the original of which, presented to the United States by the Khedive of Egypt, now stands in Central Park, New York. Its fellow was removed to London twenty years ago and set up on the Thames embankment. Hieroglyphics, representing the scenes from the history of Egypt occurring long before the historic era, contained upon the needle in the New York Park were omitted, although originally intended to be reproduced. At the base of the obelisk were four immense lions, to which the sculptor, Mr. M. A. Waagen, had given a very life-like appearance.

THE STATUE OF THE REPUBLIC.

An inscription to the following effect was written on the base, in English, Latin, and Greek:—

Annis quadringentis posteaquam Christophorus Columbus incognitum antea orbem terrarum Americam gentibus aperuit hunc in locum conveniunt homines omnium fere nationum quid quisque in artibus quid inventis rebus quid in agricultura præstiterit amico certamine inter se comparantes.

Four hundred years after the discovery of this continent by Christopher Columbus the nations of the world unite in this spot to compare in friendly emulation their achievements in Art, Science, Manufactures, and Agriculture.

This heroic statue was placed at the east end of the Grand Basin in the Grand Court of Honour. It was the work of Daniel Chester French. The form of the statue was clothed in a Grecian robe, but the head and features were distinctly modern and of the American type. It was a keen type of face, thoughtful, almost severe, but with great elements of beauty. Upon the head was a wreath of laurel leaves—the common emblem of victory—and around it a halo of electric lamps forming a semi-circle of light. The arms were lifted, but not imploringly, for one hand held a staff carrying the symbol of liberty (the Phrygian Cap), and the other a globe surmounted by an eagle. The bird of Freedom spread its protecting wings over the nations of the earth. The little finger of the statue measured just 2 feet 3 inches from knuckle to nail. A better idea of the dimensions of the work may be obtained when it is stated that the distance between the chin and the top of the head is 15 feet; the arms were 30 feet long; the nose was 30 inches long; the wedding-ring finger was 10½ inches round; the length of the forefinger was 45 inches. There was room on the hand to hold four men of ordinary size. Inside the statue was a stairway for the convenience and accommodation of the attendant. Without the plinth the statue measured

LOOKING WEST ON GRAND BASIN.

LOOKING EAST ON GRAND BASIN.

COLUMBUS ARCH IN CENTRE OF PERISTYLE.

A TYPICAL RESTAURANT, "CAFÉ DE LA MARINE."

65 feet; the total weight was 35 tons; the head alone weighed $1\frac{1}{2}$ tons. With characteristic and becoming modesty the able sculptor thus describes his grand creation: "My colossal statue of the Republic stands at the easterly end of the great lagoon facing the Administration Building. The statue is 65 feet in height to the top of the head, and rests upon a pedestal 35 feet in height. On account of the almost perfectly symmetrical arrangement of the architecture about it I have treated the statue in a formal and almost archaic manner. The figure stands firmly upon both feet; both arms are raised; in one hand she holds a staff with liberty cap and streamers, in the other a globe surmounted by an eagle. On her head is a laurel crown. Her heavy robe, which suggests a lawyer's gown, is open in front, and reveals a breastplate of scale armour and a sword half-hidden by the drapery. The statue is made of plaster and gilded." Mrs. Schuyler Van Rensselaer says that "its bulk impresses one much less than its beauty, for it is in scale with its surroundings and in harmony with their form and spirit. It is not an independent work of art; it is a piece of architectural sculpture as truly as though it had been designed for attachment to some building. It is an integral part of the splendid architectural panorama amid which it stands. In this place a statue of the more usual kind—a realistic figure in a natural attitude of repose or in vigorous action, or a graceful ideal figure with flowing outlines, contrasted gestures and varied masses, lights and shadows—would have been distinctly inharmonious. This figure, with its almost rigid outlines, the parallel gesture of the two uplifted hands, and its majestic movements so dignified as to be almost hieratic repose, is exactly what is wanted."

In the rear of the statue of the Republic, connecting with its classic columns the Casino and the Music Hall, was the artistic Peristyle, designed by C. B. Attwood, and resembling in the centre portion the Arc de Triomphe of the Place du Carrousel in Paris. On the Peristyle, on a panel beneath the far-famed Columbus Quadriga, was the following inscription:—

"But bolder they who first off-cast
Their moorings from the habitable Past,
And ventured chartless on the sea
Of storm-engendering Liberty."

The Peristyle was composed of forty-eight columns, twenty-four on either side, which symbolized the States and territories. On each column was a figure 14 feet high, and below were the names of the different States. This colonnade reached 234 feet from each corner building to the Columbus Portica. Over the water-gate, and surrounding the Columbian Arch in the Peristyle, immediately behind the statue of the Republic, was the quadriga representing "The Triumph of Columbus." Columbus stood in a chariot drawn by four horses, which were led by two women, and at either side of the chariot was a mounted herald bearing a banner. Mrs. Van Rensselaer, whom I have already quoted, has described the quadriga as embodying "An idea which seemed radically novel. No one remembers to have seen a quadriga designed as this one was. The four horses did stand simply abreast and by themselves, guided only by the Victory erect in her chariot. Between each pair advances a female figure, holding them to right and left by their bits. Thus those who face the quadriga see at each end a horse, then a woman's figure, and in the centre two horses. Even from words the interest of such a composition appears. We see one of the most original and one of the most delightful sculptured conceptions of modern times."

Heroic figures, 15 ft. in height, by the sculptor Theodore Baur, representing Eloquence, Music, Fisher Boy, Navigation, and an Indian Chief, many times duplicated, appeared on the Casino, Music Hall, and Peristyle. The conception of these figures was strong, and the sculptor's inspiration carefully carried out in their modelling.

On

On either side of the arch were groups representing the Genius of Navigation and Discovery, with supporting figures for each on the projecting prow of a vessel. These were the work of Bela L. Pratt, of New York.

The Music Hall, 200 feet long and 140 feet wide, was at the north end of the Peristyle, and contained an auditorium capable of seating 2,000 people, with room for an orchestra of 75 pieces, and a chorus of 300 people. The structure was three stories high, and was an architectural gem, both as to exterior and interior. The style was Roman Renaissance. The main entrance was between lofty Corinthian columns, through a broad loggia, and under arched doorways. On the main floor was the auditorium, oval in form, with the stage overlooking the lake at the east end. In front of the stage was a level space with a capacity for more than a thousand seats, while back of that rose tiers of seats. An orchestra of 300 could find seats on the stage, while the hall could seat 2,500. On the second floor was a recital hall, which could be turned into part of the main building by arranging the curtained intervening wall. A flattened glass dome furnished light for the main auditorium. The galleries on the third floor, running nearly the length of the building directly under the roof, could be used to increase the seating capacity of the house. Below the cornices of the Casino and Music Hall the names of the world's great musicians, composers, and singers. In the north-eastern angle of the landward side of the Peristyle was located the Lowney Pavilion, designed by Charles B. Attwood, which stood close to Music Hall. The design for the pavilion came from the Roman Temple of Vesta, and was quite artistically carried out.

East of the Peristyle and extending into the lake was the Main Columbian Pier which was one of the notable sights of the Exposition. Directly in front of the Casino it reached out 2,500 feet into Lake Michigan, and was 250 feet wide. The view to be obtained from the outer end of this pier was something that would be never forgotten by those who took it.

Extending from one end of the pier to the other up and down its centre was a movable side-walk of Multiple Speed Railway on which 5,610 persons could stand or sit and be carried along at different rates of speed, one-half of the walk moving at the rate of 3 miles per hour, and the other half just twice as fast. This walk was built on flat cars, 315 in number, and formed an endless train 4,300 feet long, and was propelled by ten ordinary street car electric motors. On the faster platforms were seats capable of holding four persons each, and just as easily as the passenger stepped on from the stationary platform to the slower moving walk can he step to this from the former swifter. The fare was 5s. a ride. This pier was one of the longest in the world.

The Exposition Pier had an area of $13\frac{1}{4}$ acres, and its general width was 250 feet. It was commenced 1st September, 1892, and finished by 15th December of that year. The pier was 12 ft. above the level of the lake while the depth of water along it varied from 8 to 18 feet.

UNITED STATES GOVERNMENT BUILDING.

The United States Government exhibit consisted of the Government building in which the various departments of the United States Government were represented; a naval exhibit represented by the battleship fully equipped and moored within the shelter of the mole which protected the northern entrance to the lagoon from the lake, built of brick and cement, as well as the actual materials employed in the construction of a real warship. In accordance with the Act of Congress, approved April 25th, 1890, the executive departments of the United States

U.S. GOVERNMENT BUILDING.

States Government made a very interesting and creditable display which was placed under the control of a special board of management in which the several departments were represented by some of their most important Government officials. For the display of these collective exhibits a large building was erected near the lake south of the main lagoon and of the area reserved for the foreign nations and the several States. This building was classical in style, and in its general character was said to resemble the National Museum and other Government buildings at Washington. It was constructed of iron, brick, and glass at a cost of 450,000 dollars, and covered an area of 350 feet by 420 feet. Its leading architectural feature was a central octagonal dome 120 feet in diameter and 150 feet high. The exhibits in this building were arranged in series according to departments. The south half of the building contained the exhibits of the Post-office Department, the Treasury Department, the War Department, and the Department of Agriculture, while the north half contained the exhibits of the Fisheries Commission, of the Smithsonian Institution, and the Department of the Interior. The State Department exhibit extended from the rotunda to the east end, and that of the Department of Justice from the rotunda to the west end of the building. The allotment of space for the different departmental exhibits was as follows:—War Department, 23,000 feet; Treasury Department, 10,500 square feet; Department of Agriculture, 23,250 square feet; Department of the Interior, 24,000 square feet; Post-office, 9,000 square feet; Fishery Department, 20,000 feet; and the Smithsonian Institution the balance of the space. Amongst the many important exhibits to be seen within the building were the mint presses at which medals in various metals (commemorative) were struck off of the Exposition. In the War Department there were representations of all the branches of the American service, including many interesting details. In the Post-office Department there was established a working post-office, so arranged that it afforded all the advantages of a post-office for the Exposition and at the same time enabled visitors to study the interior workings of a model city post-office. There was a display made of all the articles of postal equipment, postage stamps, stamped envelopes, and paper, to which was added a collection of curious articles of mail matter which had accumulated in the Dead Letter Office. A novel feature of the display was a collection of articles which had been sent during the past three years, in compliance with an invitation from the Postmaster-General, by postmasters and others, consisting of relics, curiosities, &c., pertaining to the postal service. Another feature of the departmental exhibits consisted of matters contributed or lent by foreign postal administrations, illustrating the postal service in the respective countries from which they were received.

The business of the post-office was conducted in the following manner:—From the post-office twenty-five carriers delivered letters, and there was a force of twenty-five clerks to handle the business. This, of course, did not include the railway post-office clerks, who threw letters and papers into the mail-car that stood just north of the post-office. More than 150 letter-boxes were placed around the grounds and in the plaisance, each State and Government building having a box. The post-office was a branch of the Chicago Post-office, and in it were exhibited the workings of a post-office of the first class, including the operations of the inquiry, stamp, money-order, registry, general, and carriers' delivery departments. The mailing division, where outgoing mail was handled, occupied the north half of the space, and the city division for incoming mail the south part. In the gallery were the offices for the third assistant postmaster-general and his superintendents. The outgoing mail collected by the carriers was brought through doors on the west side of the office and dumped on to the pick-up table in the north end of the mailing division. Six stamping machines grouped around cancelled the stamps, and the letters were put through a rough
separation

separation by States in a case that stood south of the pick-up table. Six clerks working before three double distributing cases south of the State case made up the mails for routes and placed it in pouches for the railway mail-cars. The opening table on which the incoming mail was back-stamped stood beneath the gallery. Carriers took it from this table to the tenant double case, where the mail was made up into routes for delivery through the different buildings. The furniture was so arranged that spectators looking through the glass screen could easily see every phase of post-office work. The screen was a handsome piece of cabinet-work, made of quartered oak panelled in deep squares, while the grill work was of bronze and the glass was of fine bevelled plate. A series of etched designs on the glass depicted the evolution of the mail service. An old-fashioned six-horse mail-coach and a post-boy represented the early days of the service, while well-executed pictures of an ocean greyhound, a modern railway mail-car, a sound steamer, a mail-waggon and a mail-carrier with his pouch bulging with letters, represented the mail-handling facilities of the present day. The railway mail-car, named Benjamin Harrison, stood just north of the post-office on a platform in the mailing division. The east side of the car contained plate glass, permitting the interior to be seen. It was manned with a full crew of railway mail clerks, who showed how papers and letters are handled at the rate of 60 miles an hour. It was a beautiful specimen of car building, 70 feet long, and equipped with the very latest appliances.

Not the least interesting exhibit, therefore, at the Exposition was the model post-office in the Government building, as the particulars I have already stated will demonstrate. It was one of the most useful of all the features that contributed to the convenience of visitors. Its work was begun 6th February, 1893, and not completed at the time of my departure from Chicago. James J. Hastings, superintendent, made a report to Postmaster Sexton on the work of the office during the period of the Exposition. It showed that during the six months 7,937,467 pieces of mail matter were dispatched, and 7,121,916 pieces were received.

This is as large a business as is done in a city like Detroit or New Orleans. Not only this, but the work usually done on trains by the postal clerks was performed by the clerks in the mail-car adjacent to the post-office. In this way the dispatch was aided and visitors were afforded an exemplification of the full working of the postal system. The office was organised for much less work than it has performed, but, owing to excellent management and the good fortune of having an exceptionally able corps of employés, the great volume of work was handled without delay and to the satisfaction of exhibitors and visitors.

The office was first established in the Administration Building, but shortly before the opening of the Fair was moved to quarters in the Government building, where it became a portion of the exhibit of the postal department. The corps included seventy-three men, thirty-one of whom were carriers.

As an Object Lesson.

Aside from its practical work in handling mails for the Exposition company, commissioners, exhibitors, and visitors, the model post-office was an excellent object lesson for the hundreds of post-masters of this country and other lands who examined its work. Not a day passed that from ten to forty men and women connected with various postal systems did not inspect the entire office when the attaches were at work. It was designed to be a model post-office, and the officials of the department affirm that it has performed its mission. To begin, the furniture and all the appointments of the office were
exceptionably

exceptionably fine, and the clerks were the best that could be obtained. Many foreigners who are connected with postal systems in their country examined the office and its methods and each one pronounced it to be very satisfactory.

The employés have had much to contend with in their work. They have had to deal with men and women from all countries accustomed to different systems and different methods of doing business. This fact made explanations necessary and frequent, but in few cases have unpleasant discussions arisen. Not only have the foreigners required some gentle handling by the employés, but some people from different portions of America itself were unable to understand why the postmaster could not tell if a letter had been sent to the New York State Building for Purity Jones, or if one had been received from Okemos for Samantha Smith.

The immense foreign business was the cause of much work, from the fact that packages were received which required the examination of custom-house officials. The delays caused some complaints from the foreigners, but in almost all cases the trouble was explained with patience and amicably arranged. The officials of the money order division were required also to keep a close watch on the payment of orders. Despite the big business done very little money was lost, although identification, in some cases, was incomplete.

Figures in the Report.

The report of Superintendent Hastings shows that the following pieces of mail matter were dispatched from the office:—

					May.	June.
Letters	520,455	927,588
Papers and parcels	35,660	69,530
Circulars	539,640	173,680
Foreign letters...	14,841	22,032
Foreign papers...	7,960	9,555
Total pieces	1,118,556	1,202,385
					July.	August.
Letters	1,104,864	1,144,848
Papers and parcels	91,045	101,920
Circulars	80,920	39,800
Foreign letters...	29,888	29,733
Foreign papers...	14,545	16,375
Total pieces	1,321,262	1,332,676
					September.	October.
Letters	1,287,597	1,260,057
Papers and parcels	117,640	119,930
Circulars	30,920	8,000

	1,130,191
Total	7,121,916

Record of Good Work.

In the Registry Department 12,081 pieces of mail matter were received and 17,409 pieces were forwarded. Of special delivery pieces, 5,044 were delivered; 15,867 letters were advertised, and all but 640 were delivered. This discrepancy is accounted for by the fact that the business of the office was wholly with transients. Receipts from sale of stamps, stamped envelopes, newspaper wrappers, and postal cards :—

Although

Although the Government building was closed, an entrance was made into the post-office and the room prepared for the cold of winter till the Exposition closed.

The Post-office Department of the United States is one of the most popular branches of the Government. Its operations extend throughout the length and breadth of the country, and it ministers to the business and social concerns of every citizen. The number of post-offices in operation is over 68,000; the length of the post routes is about 452,000 miles, and nearly 375,000,000 miles of mail service are now performed annually.

Exhibits in the Federal structure will be taken back to Washington, with the exception of some apparatus in the naval exhibit, which will be sent to San Francisco, and will become part of a new battle-ship that is being built there. The building will be sold to the highest bidder. Such a disposition of it is necessary according to the law that created it.

PATENT LAW CONGRESS.

In the Government Building there was an extensive display of patents of all kinds collected, to which it would be impossible to make detailed reference. At the Congress of Patents held in the Art Institute several suggestions were made for legislation to give inventors better protection. W. Lloyd Wise, of England, read a paper, entitled, "Some Suggestions for a Good Patent Law." The following are some of the suggestions he enumerated:—

1. The first applicant who complies with the prescribed requirements in any country should be entitled to a patent there, subject to international arrangements, provided he has not fraudulently obtained the invention from some other person or persons in the country.
2. Complete specification, with claims, should be lodged with the application for patent, but the applicant or patentee should be at liberty to apply from time to time for leave to amend his specification, claims, and drawings, by way of disclaimer, correction, explanation, or addition; and it should not be a ground of objection that the specification as amended would claim an invention substantially larger than, or substantially different from, the invention claimed in the specification as it stood before amendment.
3. The application for patent should be examined as to whether the application is in due form and the specification is clear; whether the invention is contrary to public morals; whether the invention appears to have been anticipated, regard being had to prior publications in the patent office of the country.
4. The preliminary examination should not extend to the utility of the invention.
5. The application should be advertised, and opposition be allowed on the following grounds:—Fraud, prior patent in the country for the same invention, prior publication in the country of a full description of the invention, prior public use of sale of the invention in the country.
6. The patent when granted should not be infeasible.
7. The validity and duration of the patent should not depend on any foreign patent.
8. The patent should be subject to moderate periodical payments.
9. There should be provision for compelling the owner of the patent to grant licenses on equitable terms, where needful to supply the reasonable requirements of the public, or where necessary to enable *bona fide* improvements to be utilised.
10. All patent agents or attorneys should be registered in the patent office of the country, should be required to annually obtain certificates of their right to practice, and should be liable for misconduct to be struck off the register and otherwise punished according to circumstances.

He was followed by Benjamin Butterworth, of Ohio, who delivered an able address upon "The Relation of our Patent System to Industrial Development and Progress." He said that the hostility of the labouring classes to every great invention interfering with their work should be greatly reduced because the United States owed its prosperity to inventions. William C. Dodge, chairman of the committee

committee on resolutions, presented the following resolutions as the work of the committee:—

Resolved,—That for the purpose of encouraging improvements in the useful arts, the development of new industries, and to make it an object for inventors or licensed manufacturers to practically put inventions into operation, a sufficient protection should be given to them to warrant such an undertaking.

Resolved,—That, as steam and electricity have brought all civilized nations near to each other, some practically uniform international system of granting patents should be adopted under which all the patents of the several nations may be issued.

Resolved,—That some international system for repatenting or registering patents should be adopted by the several nations granting them whereby patents granted in one country may be effective in each of the others without burdensome fees, taxes, or annuities.

Resolved,—That the requirements of working or of putting the invention into use within a stated time is an onerous condition which leads to the non-patenting and to a consequent non-using of inventions which required extensive plants of machinery, and that it is a condition which retards the introduction of inventions in the countries requiring them.

Resolved,—That all patents for their duration be independent of patents for the same invention in other countries, and be granted for the same term as that allowed by law for patents in the country granting them, and with no further restrictions than the applications therefor be limited to time fixed for application by citizens and the date of the grant antedating that of the oldest prior patent.

Resolved,—That a trade-mark valid in one country should be valid the world over to the first user, except only when antagonistic to local laws and to good morals.

Resolved,—That priority in the matter of trade-marks should be referred to the time of the commencement of a continuous user and not to the date of registration.

Resolved,—That a trade-mark connected with a false indication of origin should be considered contrary to good morals.

Resolved,—That a committee of five be appointed by the President of this Congress, charged with the duty of bringing these resolutions before the Congress of the United States and the Legislatures of other countries, as well as any future conference under the convention for the protection of industrial property concluded at Paris, 20th March, 1883, and to take such steps as they shall deem proper to perpetuate this gathering as a body for the amelioration of patent and trade-mark laws in their international relations.

The text of the American Patents Act for foreign exhibitors will be found in Appendix J.

EXHIBITS FROM OTHER UNITED STATES GOVERNMENT DEPARTMENTS.

The Smithsonian Institution and National Museum exhibits contained representations of all the various displays usually found in institutions of a similar character, and although very interesting and representative require no special remark.

The Department of Agriculture contained a representation not only of the literature but also of well selected collections of contributions from all the various sub-departments.

The United States fish exhibit was of a specially interesting character. According to the Act of Congress, creating the United States Government exhibit, the fish commission was divided into four special branches, viz. :—Inquiry respecting food fish, propagation of food fish, statistics relating to national fisheries and their methods, and the live fish exhibit in the aquaria. The special feature of this department consisted in the various illustrations of the science of fish farming, and it was most instructive to observe from day to day the collections of spawn and little fish in all the stages of development. The statistics relating to Government fisheries showed that at a single station on the Massachusetts coast the Government hatched 55,000,000 codfish and 20,000,000 lobsters in 1892. There are Government fishing stations and hatcheries in twenty-two different States, and these include the great fresh water fish hatcheries of the interior as well as the sea-coast hatcheries. The main idea of the Government fisheries exhibit was to illustrate not only the methods of catching fish as well as fish culture, but also the fisheries themselves and their management. In the

the department of fish culture there were tanks and troughs called "rearing troughs," showing the methods of hatching shad, pike, and perch. Actual spawn was used all through the currency of the Exhibition except during two months of midsummer when natural eggs could not be obtained, and instead of these artificial eggs were substituted for that period. The growth of the fish was shown by means of casts of yearlings, two-year-olds, three and four-year-olds, &c., and these casts were made of material the nature of which the Government keeps secret. Another interesting portion of this exhibit showed the method of taking the eggs from the fish, and there were fishermen's dorys, and full-sized lay figures, representing fishermen in the act of securing spawn. There was also an historical series of fishculture apparatus, models of complete fishing stations, and rigged vessels were shown, such as the trout station in Colorado, and the white fish station at Put-in Bay, Ohio, the shad station at Havre-de-Gras, Md., and the cod station at Woodshull, Mass. There was also a complete series of transportation apparatus showing the methods of transporting fish in cans or boxes. There was a valuable series of charts showing the effects of fish culture upon the different fisheries, and a complete series of photographs illustrating the operations of the U. S. Fish Commission. The Department of Scientific Inquiry included very valuable instruments for taking deep-sea soundings. Splendid models of the steamers "Albatross" and "Fish-hawk," the two principal Government steamers engaged in the fisheries were shown, as well as the nets which are used to bring fish to the surface from a depth of 3 miles or more, and intricate machinery for winding deep-sea nets, charts, and maps, a library of fish literature, models of vessels and boats, fish-traps, nets and seines, fish-eating birds, and angling apparatus.

The following tables, copied from records in the United States Fish Department, will afford some idea of the magnitude and importance of the Fish Cultivation question in the United States.

NUMBER of Adult Fishes, Yearlings, Fry, and Eggs, distributed by the United States Commission of Fish and Fisheries from 1872 to 1893.

Species.	Number distributed, 1872-82.	Number distributed, 1882-92.	Total Output.
Shad	200,946,350	767,697,000	968,643,350
Olewives	9,833,000	6,850,000	16,683,000

Str. Fish, Hank.	Shad and Spanish Mackerel	24,063,000

Appropriations have also been made by Congress for the establishment of additional stations in the States of Vermont, Texas, and Montana.

Naval Exhibit.

Outside the Government Building, on the lake near the pier, was a structure which to all outward appearance was a full-sized modern battle-ship, moored to a wharf. The structure had all the fittings belonging to an actual ship, such as guns, turrets, torpedo tubes, torpedo-nets, and booms, with boats, anchors, chain cables, davits, awnings, deck fittings, &c., together with all appliances for working the same. Officers, seamen, mechanics, and marines, were detailed by the Navy Department for service on board during the exhibition, and the discipline and mode of life on American ships of war were completely illustrated. The crew gave certain drills from time to time, especially boat, torpedo and gun drills, as shown in vessels of war. This exhibit was one of the most attractive shown, and was always crowded by visitors during the Exposition.

The dimensions of the structure were those of an actual battle-ship, viz. :—Length, 348 feet; width amidships, 69 feet 3 inches; and from the water-line to the top of the main deck, 12 feet; centrally placed on this deck was a superstructure 8 feet high with a hammock berthing on the same 7 feet high, and above these were the bridge, chart-house, and the boats. At the forward end of the superstructure there was a cone-shaped structure called the "Military Mast," near the top of which were placed two circular "Tops" as receptacles for sharpshooters, and rapid-firing guns were also mounted in each of these tops. The height from the water-line to the summit of this military mast was 76 feet, and above was placed a flagstaff for signalling. The battery mounted comprised four 13-inch breech-loading rifled cannon, eight 8-inch breech-loading rifled cannon, four 6-inch breech-loading rifled cannon, twenty 6-lb. rapid-firing guns, six 1-lb. rapid-firing guns, two gatling guns and six torpedo tubes or torpedo guns, and all of these were placed and mounted respectively as in the genuine

genuine battle-ship. On the starboard side of the ship was shown the torpedo protection net, stretching the entire length of the vessel. Steam launches and cutters rode at the booms, and all the outward appearance of a real ship of war was imitated. The superstructure showed the cabins, state-rooms, lavatories, latrines, mess-rooms, galley, and fittings, mess-table for crew, lockers, berthings, &c., also the manner in which officers and enlisted men live, according to the rules of the navy. On the superstructure deck and bridge was shown the manner in which the rapid-firing guns, search lights, boats, &c., were handled. The entrance to the conning tower was from the deck, in which were all the appurtenances the commander has at his disposal when taking the ship into battle and during the progress of a fight at sea. The electric light plant was installed, and provision made for heating with steam. On the berth deck were shown the various fittings pertaining to the hull, machinery, and ordnance; ordnance implements, including electrical devices, gun-carriage motors and range-finders; models showing typical ships of the past and present; samples of the provisions, clothing, stores, and supplies, bunting, flags, &c.; in short, the thousand and one things that go to make up the outfit of a man-of-war.

PRINCIPAL OFFICIAL BUILDINGS AND THEIR CONTENTS.

I now proceed to describe some of the more notable features of the principal official buildings, and the exhibits which they contained. For much of the special information contained in the descriptions I am indebted to the official publication of the Exposition, and to Press notices by experts, contained in the newspapers and periodicals of Chicago and other American cities.

Agricultural Building and its Exhibits.

Description of the Building.

THE building in which the agricultural exhibits were contained was one of the most magnificent structures of the Exposition. The style of architecture was Classic Renaissance. Placed at the continuation of the Grand Plaza, it served, on its side, to complete the splendid architectural effect of the grand and imposing structures which surrounded the Great Basin. The main architectural features were the great rotunda forming its main entrance, the four large corner pavilions, and the connecting colonnade. The building was 800 feet long, 500 feet deep, and at the back of the south side there was attached an annex 300 feet by 500 feet. The main plans of the building comprised two central galleries, each 85 feet in width, which intersected each other on the longer and shorter axes of the building. On either side of the main entrance were mammoth Corinthian pillars, 50 feet high and 5 feet in diameter. The main entrance led through an opening, 64 feet wide, into a vestibule, from which entrance was obtained to the rotunda, 100 feet in diameter. This was surmounted by a mammoth glass dome 130 feet high.

Decoration of the Building.

A great deal of the decorative work in the Agricultural Building had its motive, as was proper, in subjects native to America; for instance, there were representations of the maize, potato, tobacco, &c., and on the frieze the turkey. Each of the groups of statuary on the building represented some agricultural subject. The four corner pavilions had their domes surmounted with statuary—four grand female figures, typical of the four principal races of men, supporting a mammoth globe. The sculptor, Philip Martini, of Philadelphia, contributed the following subjects:—Twenty single "Signs of the Zodiac," twenty single figures of "Abundance," two groups of "Ceres," two groups of the "Four Seasons," four groups of the "Nations"—four figures in each group—and four pediments representing "Agriculture." Over the main entrance was a handsome pediment modelled by L. J. Mead, of Florence, Italy, representing Ceres, the Goddess of Agriculture.

The painted decorations of the Agricultural Building were the work of George W. Maynard, of New York, who chose the Pompeian style as most appropriate for the architecture, which was classic, but not purely so. The main entrance had something of the appearance of a temple devoted to the worship of the deities under whose protection the ancients believed Agriculture to be. On the right Cybele, the mother of Zeus and Demeter, or Ceres, was presented in her chariot drawn by young lions, and on the left was her special protege, King Triptolemus, to whom she gave a chariot drawn by winged dragons, with which he was sent forth to teach the peoples of the earth the art of agriculture. Between these were figures representing "Abundance" and "Fertility." Each of the corner entrances was decorated with figures on either side symbolical of the Seasons, and above them were friezes in which beasts of burden and other bucolic animals figured.

Connected with the Agricultural Building, and forming one end of the great colonnade leading from the Agricultural Building to the Machinery Hall, was the Assembly Hall. This was on the same level as the Intramural Station which formed the centre of the colonnade,

NEW SOUTH WALES COURT, AGRICULTURE BUILDING, SHOWING WOOL TROPHIES.

colonnade, and was reached from the second floor of the Agricultural Building also. It seated about 700 persons, and furnished facilities for lectures, delivered by gentlemen eminent in their special fields of work, embracing every interest connected with live stock, agriculture, and allied industries.

Dairy Building.

The Dairy Building, by reason of the exceptionably novel and interesting exhibits it contained, was regarded with great favour by World's Fair visitors in general, while by agriculturists it was considered one of the most useful and attractive features of the whole Exposition. It was designed to contain not only a complete exhibit of dairy products, in connection with which there was conducted a series of tests for determining the relative merits of different breeds of dairy cattle as milk, butter, and cheese producers, a matter to which I shall refer hereafter. The building stood near the lake shore in the south-eastern portion of the Park, and close by the general live stock exhibit. It covered approximately half an acre, measuring 95 x 200 feet, was two storeys high, and cost \$30,000. In design it was of quiet exterior. On the first floor, besides office headquarters, there was in front a large open space devoted to exhibits of butter, and farther back an operating-room, 25 x 100 feet, in which the model dairy was conducted. On two sides of this room were amphitheatre seats, capable of accommodating 400 spectators. Under these seats were refrigerators and cold-storage rooms for the care of the dairy products. The operating-room, which extended to the roof, had, on three sides, a gallery where the cheese exhibits were placed. The rest of the second storey was devoted to a café, which opened on a balcony overlooking the lake.

NEW SOUTH WALES COURT.

The representation of New South Wales in the Agricultural Department was large and characteristic. Our space was in an excellent position, with one of the main avenues of the building forming the frontage and another passing through its centre, and a secondary passage at right angles; thus dividing the space into three courts. The area for New South Wales in the Agricultural Building contained 8,693 square feet floor space, and 13,600 square feet of wall space, and is represented in the plan attached. I divided our exhibits in this department into three great classes, and in the space allotted to us three courts were made for their reception. The Wool and Grain courts faced the main avenue, and were separated by another wide passage. The back court contained meats and grain as well as beer, &c.

Our Wool Court.

The Wool Court was walled round with great arches, reaching to the galleries above, and was built up with the wool bales sent from Sydney. This was a work of great labour, but it had a most imposing effect. The bales were opened out, the exposed coverings being removed, so that a solid wall of wool about the height of the arches was presented to the view. Only the end cover of the bales was cut down and tucked under for this purpose, with a view, hereafter, to replace it, the under covering portion of the bale in the soffit of the arch being left exposed to view in the state in which it was received from Sydney with the owner's name, brand, mark of station, and other particulars on it. Pyramidal trophies of wool bales were made in the centre of the Court, and these were similarly exposed, the whole pyramid being enclosed with a kind of canopy with curtains, to protect from dust, &c. This canopy covered the whole pyramid when the court was closed. In making the arrangements just described we were assisted by a leading American expert in wool, engaged in accordance with a promise I made to the Commission in Sydney.

Under

Under his guidance and advice an exhibit of our wool was made such as had never before been seen in America. The display was very different from similar displays made heretofore, and in an admirable manner exhibited the commercial value and the abundant quantity of our staple, in a very artistic arrangement. The court, which was familiarly known throughout the building as the "Blue Room," was visited by all the leading wool-growers of America and elsewhere, and in all the leading papers dealing with wool commendations of the highest character were expressed at the value and interest of the exhibition. No other country had such a display, and it was universally acknowledged to be the finest and best arranged in the Agricultural Building.

Special cases were made for the fleeces—in fact everything connected with this display was original and adapted to the circumstances of the exhibition. The cases ran all along the front of the court in the main avenue, and through the court in various directions. Round the pillars were placed the selected exhibits of the Technological Museum's representation in suitable cases, and thus the character of the court was made complete as a very perfect representation of our staple industry from an artistic, an educational, and a commercial standpoint. The large wool-waggon of Goodwin was shown in this court, there being no room for it in our limited space in the Transportation Building. The waggon was loaded with wool after the Sydney commercial form, the coverings on the bales being retained, and it formed thus quite a remarkable contrast to our other wool exhibits. The large and beautiful photographs of the wool industry in its various stages, and the illustrations of work on the stations, and of station life generally, as well as of the scenery of the runs of the country, were hung on the pillars and walls of the court, the whole of which was very tastefully decorated with New South Wales flags and large blue and silver signboards labelled with the name of New South Wales. At the west entrance to this court a very large entablature, about 18 to 20 feet in height, was so placed as to attract the attention of every visitor, and on it were painted in large letters and figures the most important statistics of our wool industry. At a later stage of the report I will make reference to the action taken by me for free admission of wool into the United States.

Fronting the main avenue, the grain court was embellished with glass-covered cases containing the various samples of flours, with masonic blue ribbons in a knot as a decoration, this colour forming a very pretty contrast to the snow-white colour of the flour. The tobacco was placed in cases of similar character to those in which the wool fleeces were placed, but somewhat altered to suit the character of the exhibit, and each little bundle was tied with blue ribbon of our country's colour. The various grain exhibits were placed in glass-covered cases against the walls of this court, and on the screen wall above the cases were displayed the samples of grasses, &c., sent by the Agricultural Department of Sydney, the whole having a very interesting and instructive appearance.

The Great Maize Arched Trophy.

In the centre of the court were very large and handsome trophies in which were placed the exhibits of tinned meats, sauces, curry powders, honey, and preserves. In the avenue dividing the courts I caused an immense arched trophy of selected maize to be erected, and this was the best of this class of trophies in the building. Just as the wool arches in the neighbouring court reached to the full height of the court and to the galleries overhead, so this trophy of similar height covered all the wall space of this part of the court, and was a centre of attraction and of admiration whilst being erected, the agriculturists from all parts of the building representing this interest,
from

from all parts of the world, were critical inspectors of the work as it progressed, and still more critical examiners of the maize itself. This maize was a complete revelation to the American exhibitor, and in my judgment, as the result of a very careful examination of similar exhibits in every section of the great building, was unequalled by any other maize shown. The United States is generally and truly considered to be the greatest maize-producing country in the world, and after many forms of cultivation it is used in an endless number of ways as a daily article of food by millions of the people, as well as a food for horses, &c. So much so is this the case, that it is the "corn" of this country as with us, in popular language. It came, therefore, as a matter of unbounded surprise to the people here, living in the midst of the great prairie fields of America, that New South Wales not only exhibited such splendid samples, but showed them in such immense quantities, brought from such a great distance. The arched maize trophy was very prettily decorated, and was tasteful in all its details. The large photographs of racing and stud horses were distributed on the walls of this court, and so admired were they that many offers to purchase them were made by visitors interested in the subject. On the posts at the entrances to this court were placed the exhibits of sugar-cane tied up with our blue ribbon. They were much admired on account of their large internodular distances.

In the back court was a large central trophy of tinned meats. The grasses, bundles of oats, &c., were displayed on the walls of this court in neat order, somewhat similar in plan to that adopted in the French agricultural courts. The casks of porter and ale were painted blue, with gold for the hoop-irons (as a contrast to those of Great Britain in the adjoining Court) and were placed on suitable stands. The various essences, brandies, and aerated waters were located here, with a continuation of the photographs on the walls both inside and out. The photographic exhibit of the Rosehill Racecourse and others of a similar nature were here shown. One striking point of decoration must not be forgotten: In the centre of all the wool and in the great corn arch I placed the Australian Coat-of-Arms with the emu and kangaroo rampant, while above each floated the New South Wales flag, with the Southern Cross well displayed.

UNITED STATES EXHIBITS.

The grain exhibits of the United States, as might have been anticipated from the fact that they are the great grain suppliers of the world, were very numerous. Each of the represented States had a large booth, the walls and pillars of which were in many cases completely made up of maize and other cereals. Some of these booths were very handsome, but a large number seemed to me not only ineffective as a display but tawdry in appearance. In some cases the pillars of the booth were made of glass columns filled with differently-coloured grain, and the variegated appearance was very pretty. An agricultural show, to be really effective, ought to be massive and rather commercial in character than merely decorative in appearance. The varieties of the grain of all kinds, and of grasses exhibited in the various courts, were simply marvellous.

The exhibit of Wisconsin was contained in a very beautiful booth, and appeared to be one of the best of the State exhibits, both in regard to its neatness, its massiveness, and the excellent classification of its contents. That of Illinois contained nearly four thousand specimens of grain in glass jars. On the inscription in this Court it was recorded that in 1892 this State provided thirty million bushels of wheat and two hundred and thirty million bushels of maize. In the exhibit of this State there was an illustration of the mode of inspecting and grading maize adopted in Chicago. There were also shown the miniature standard cars adopted for this purpose officially by the Board of

of Trade. A most instructive exhibit was made by the United States Government. It was arranged by and under the supervision of the Federal Department of Agriculture, and, in the main, was a collective exhibition made by the 54 experimental stations and all the agricultural colleges in the United States, of which there is one at least in every State and territory except Alaska. The results of the different lines of experimental research, those attained by the chemical laboratories, those of the botanical, entomological, and bacteriological laboratories, were all embodied in this exhibit. In it also were shown the methods and results obtained from feeding, fertilisation, irrigation, and in the breeding of cattle and in dairy work. These various features of scientific work as applied to agriculture were all more or less brought home to the eye and the understanding by numerous series of photographs, by the contents of scores of show-cases, in which wax or papier-maché were reproductions of the living objects were on view, by a long string of technical instruments, and all sorts of apparatus.

I saw no maize of our yellow colour superior to that of New South Wales, and the majority of the exhibits of this class by other countries were undoubtedly inferior to ours. The wheat, especially that of Canada, was very excellent, but that shown by New South Wales, in the judgment of experienced visitors, and the building was daily thronged by such, from every State of America and nearly every European country, was a surprise, on account of its clean appearance, its large proportion of nutrient qualities, and its weight. There was a wonderful show of grain in the Iowa State Building, the walls and pillars of which were completely lined with maize and other grain of every form and colour. On every hand I discovered evidences of the anxious desire of the farmers of that country to push the export of maize into other markets, and it was highly amusing to hear foreigners who could hardly speak a word of the English language, endeavouring to explain the difficulties occasioned by the McKinley Tariff, reciprocity and the like to American farmers. Amongst the best of the States' exhibits of grain, in addition to those I have mentioned, were those shown by Ohio, Missouri, Nebraska, Indiana, and there was a fair exhibit also in the California State Building.

CANADIAN EXHIBIT.

Canada had a large space and exhibited many specimens of cereals, flour, and the products of the dairy; but the Ontario section was the most interesting. It contained the great cheese made at the Government experimental farm at Ontario, which weighed over 11 tons. The milk from 10,000 cows was used in its production, each cow giving one day's milking. The total weight of the milk used was 207,200 lb. The cheese was 6 feet high and 28 feet in circumference, and was valued at from four to five thousand dollars. Once every ten days it was carefully turned over. It was encased in a vat of riveted steel boiler plates which rode on a heavy wide-wheeled truck. Strong oak uprights securely bolted rested on this truck and between these the huge cheese box was suspended in wrought-iron stirrups. The revolution was accomplished by a series of screws. The turning was necessary because the cheese was young, and was still "curing."

CAPE COLONY.

Cape Colony had a small Court but one very well arranged adjoining our Wool Court on the east. Perhaps the most artistic exhibit it contained was that of the mohair, the hair of the Angora goat. In some respects the specimens shown almost rivalled the celebrated Turkish mohair; in lustre, however, it was not equal to the European variety.

OTHER

OTHER COUNTRIES.

India, Ceylon, and some other countries had numerous exhibits of tea and coffee and cocoa. Great Britain had several exhibits of beer, mineral waters, whiskey, &c., but its show was comparatively speaking not what one might have expected. Sugar, rum, coffee, fibres, and other similar exhibits, were shown in a very illustrative manner in the Jamaica, Trinidad, British Guiana, Spanish, Venezuelan, and other courts in this building.

BEER AND BREWING.

The exhibits representing the great brewing interests were very widely scattered throughout the building, and it was difficult to form an idea from them of either the magnitude of the brewing industry, and the development and present status of malting or those allied industries which depend, more or less, upon brewing, such as cooperage, the manufacture of waggons, refrigerators, glassware, ironware, and of the numerous machines, engines, and implements used in brewing. It was difficult to find to what extent agriculture is benefited by brewing in the production of barley, hops, oats, hay, and of the live stock used and employed in breweries. I could not find any exhibits which showed modern brewing as a science, based upon the discoveries, inventions, and researches of scientific chemists. Exhibits in abundance were contained in pavilions, triumphal arches, in pyramids, &c., but as to how beer was made or how the different kinds were produced, there was no hint. Hops from Bohemia; specimens of malt from Austria; fine beers and Bavarian hops from Germany; Great Britain, New South Wales, and Canada, with cask and bottled ale and beer from their principal manufactories were largely represented. Belgium, Norway, Spain, Switzerland, Mexico, Brazil, and Hungary, had similar exhibits, and even Japan exhibited beer made by the O'Kur Beer Brewing Co., in Sutta Mura, near Osaka, Japan, and also barley grown there. American exhibitors similarly showed only beer in the advertising form of bottles in trophies, &c., with one highly creditable exception in the display made by the Bartholomay Brewing Co., Rochester, N.Y. It consisted of a working model brewery, after the pattern of their actual plants on a scale of 1 to 1,728. This model was made of iron, copper, and brass, and measured 4 feet square and 6 feet in height. No detail was lacking to make it a complete brewery; it was operated by electricity. Its capacity was one barrel per day, but owing to the internal revenue regulations it was not brewing, although it was kept constantly in motion as if brewing. Even the ice machine could actually produce 75 lb. of ice every twenty-four hours. The model was not a toy, but was large enough to afford an opportunity for the study of the actual working of a modern brewery.

One novelty which struck my attention was the "champagne-beer" shown by a Newport, Ky., firm, which is said to be the only one in the United States manufacturing this so-called new kind of malt beverage. The process of making it is a secret one, known as the "Hagenbusch System" in Germany, where it is said to be extensively in use. The essential part of the process consists in strongly carbonating common lager beer while being bottled. As the effect of carbonic acid is antiseptic it is claimed for "champagne beer" that it retained all its sparkling qualities for a long time and in any clime. It cannot, however, justly be styled a new kind of malt beverage for any kind of beer, even at the stage of "ruh beer" may be used for the purpose, the process of brewing not being changed at all. As to the claim of retaining all its good qualities in any climate the same is said for Pasteurisation, by which method the bottled beer is sterilised so as to prevent a new fermentation, which spoils the beer. The process of Pasteurisation, however common, was not on exhibition, but a large number of bottles containing Pasteurised beer was shown, while a German

German export beer firm exhibited (on the main floor of the Agricultural Building) Pasteurised beer in metal barrels, with a certificate from the North German Lloyd steamship, testifying to the fact that beer in such barrels withstood all influences of temperature during various sea voyages and in different climates.

There was shown an exhibit of the Liquid Carbonic Acid Gas Manufacturing Company of Chicago, in Machinery Hall, showing an apparatus for carbonating beer, by the use of which the second fermentation or the "Krauesen" was dispensed with. The beer was saturated with carbonic acid at the stage when those undesirable substances resulting from its first fermentation have been eliminated. It was stated that this would do away with the necessity of the second fermentation, shorten the time of brewing by several weeks, reduce the expenses for keeping extensive storage cellars, and save a large percentage of malt and hops, but, as is well known, the same claim has been made for other processes, such as the vacuum process, &c.

While on this subject I may state that the exhibits of the appliances, the machinery, and the supplies which formed the requirements of the brewing trade, were placed in the Palace of Mechanic Arts, but for convenience may be referred to here. The ice machines, without which the manufacture of beer is nowadays considered to be an impossibility, may be first mentioned. The De la Vergne Refrigerating Machine Company of New York had a 150-ton refrigerating machine on exhibition. It was an excellent representation of the highest improvement in the compression system. Besides being an illustration of this system, the machine was characterised by its double-acting compressor. It exhibited the same pattern on which the De la Vergne Company lately made the 500-ton ice-machine, which is the largest refrigerating machine ever built in the United States. Various other companies showed variously-sized refrigerating machines, some in operation both in the building and in various places in the grounds.

In the line of apparatus for bottle-washing, cleansing, rinsing, wiring, corking, capping, foiling, &c., there were some ingenious and recently-invented machines. The Eick Bottle Cleansing Machine Company, of Philadelphia, exhibited the only machine which does the washing and rinsing in one combined operation and their device seemed to be very perfect.

It was a striking peculiarity of this class of exhibits (I mean that representing the brewing industry) that while hops, malt, and barley were largely represented, and these are the articles all honest brewers profess to use for malting purposes, there were no exhibits of the well-known malt substitute, so extensively used and advertised, made from maize. There were no "ceraline flakes," "brewers' grits," "frumentum," "quick malt," "zeamays," "dextrine corn malt," "maize malt," or any other "brewers' corn goods." Neither did I see the slightest visible evidence of the fact that rice is very often preferred as a malt substitute, and that syrups, saccharine, and other valued things are deemed necessary ingredients of beer.

TOBACCO.

There was a large and comprehensive exhibit of tobacco.

As regarded the quality and variety of leaf tobacco for cigars, the exhibits of Mexico appeared the best. The Mexican product greatly resembled Havanna tobacco, and it would have required a technical examination to distinguish its highest grades of wrapper from the best Cuban tobacco. Cuba had a very small display. Amid the rich and handsomely arranged cases of cigars in the Cuba section appears a huge sign reading: "Cuba produced in 1892, 27,000,000 kilogrammes"

kilogrammes of tobacco. Price per 1,000 cigars, weighing 13 lb., in a first-class factory, 45 dollars. The same goods in the United States, on account of the McKinley Bill, 110 dollars—an average of 168 per cent. on the production value. Small exhibits also were shown of leaf for cigar wrappers from Sumatra, Java, and Borneo. Greece and Turkey displayed tobacco of splendid quality for the production of cigarettes as well as smoking tobacco. The leaf was very small and could be completely utilised without being stemmed.

The United States Government exhibited in the Agricultural Department of its building a selected exhibit of tobaccos of commercial value grown in the various sections of the country. It would appear that tobacco is grown to a greater or less extent in forty-two States and territories. The entire crop of 1889 (latest report) was 488,255,896 lb.; exported in 1892, 255,431,675 lb.; imported in 1892, of Havannah tobacco, 18,332,323 lb.; of Sumatra, Java, and Borneo, 2,919,607 lb. There is very little Borneo tobacco brought to America and almost no Java tobacco of late years, so that it may be assumed that the imported article is all Sumatran. The Government returns show that there were manufactured in the United States in 1891 of cigarettes, 4,422,024,212; cigars, 3,137,318,596; plug, 166,177,915 lb.; fine cut, 166,968,870 lb.; smoking, 76,708,300 lb.; snuff, 10,674,241 lb. There were exported the following:—About 2,000,000 cigars; cigarettes, 320,000,000; plug and all manufactured tobacco, 15,136,711 lb. There were imported about 52,000,000 cigars, 2,802,125 cigarettes, and 395,957 lb. of manufactured tobacco, including snuff. In pipes there were so many varieties on exhibition that it would be impossible even to catalogue them in the space at my command. They reached from the primitive pipe used by the American Indian, as shown in the United States Government Building, to the wonderful meerschaum displayed by Vienna firms in the Manufactures Building. Of the latter I must mention amongst the beautiful designs in meerschaum a cigar-holder, representing the triumphal entry of Charles V into Antwerp, after the celebrated painting of Hans Makart. It was 12 inches in length. A pipe in the form of a dog's head, with the muzzle perfectly designed of meerschaum, and a collar of amber, was quite remarkable. The head was about the size of that of a fox-terrier, and it required one cubic foot of material for its production. In another pipe, representing a Spanish bull fight, all the figures were perfect to the smallest detail. This pipe was 18 inches long, 10 being of meerschaum, and 8 inches of amber, and its weight was less than 4 oz. No better idea could have been obtained of the uses to which tobacco is put than by taking a stroll during the currency of the Exhibition through the Midway Plaisance. There might be seen the aboriginal natives of the country smoking the pipes of their forefathers, the young bucks sucking a cigarette, the Missouri meerschaum (corn-cob), in the mouth of a gaping farmer, the young business man with his fragrant Havanna, made by the skilful union workman, the "weed" of the apprentice boy, while the chewing and snuffing were done either awkwardly or artistically by a score of different nationalities.

PACKING COMPANIES' DISPLAYS.

A remarkable exhibit was that of the Swift Refrigerator Co. It consisted of a number of specimens of the products obtained in the curing and preparation of pork and other meats on a framework surrounding an elegant freight car, the sides of which were made of plate glass set in white wood, and its wheels and trucks gilded. This apparatus represented the mode of conveyance of meat and other articles, such as those exhibited, at a sufficiently low temperature, to preserve them from decomposition. The car was loaded with carcasses and with fats, sausages, and other similar matters, and the temperature was

was shown by thermometers placed at different parts of the car, and seen through the glass walls. Near this exhibit was that of the North Packing and Provision Company, with two end towers and a central pagoda. The towers were surmounted by white stuffed pigs, and the pagoda was crowned with a golden star with a circle, in which swung a bronze boar. The exhibit consisted of all the forms of packed meats, preparations, and the like. Cudahy's exhibit, as well as that of Armour, were decorated in a characteristic manner, and were splendid exhibits of the packing industry.

MILL PRODUCTS.

In the Agricultural Building one entire gallery was devoted exclusively to exhibits of mill products. A conspicuous model was that of the largest mills in the north-western States. The model occupied a space of 35 x 30 feet, with the engine and boiler rooms, elevators and railroad tracks complete, constructed on a scale of 1 inch to 1 foot. The Company's large mill, "A," is the largest mill building in the world, and still has room for an increase in its capacity of 5,000 barrels a year daily. At the right of the general exhibit was an immense barrel, which, like the booth, was constructed of many little barrels; in fact, 10,500 barrels were used in the construction representing the daily output of the mills.

In the annex of this building there was a good exhibit of portable grinding mills, with both vertical and horizontal millstones, sent from Indianapolis, in which not a point of usefulness or detail was omitted.

WINDMILLS.

The windmills exhibited formed a perfect colony by themselves near the south pond at the rear of the Agricultural annex, and were of all sizes, all heights, constructed of all kinds of material, and with all kinds of names from the "Enterprise" to the "Eclipse," some face to wind, some stern to wind, others side to wind, and all showed by various results how the power of wind, as well as that of water, has been subjugated by man. As a matter of contrast, an old Dutch mill, with its hull and stage, the colours of tower, hull, and cap blending in peaceful harmony, was also shown.

AGRICULTURAL IMPLEMENTS.

In the machinery exhibit of Agricultural Hall there were machines in great variety which compete directly with hand labour. Ploughs for horse, ox, or steam power, cultivators, drills, planters and transplanters, rakes, automatic farm waggons and fertilisers, &c., some combining in one machine drill, hoe, cultivator, and plow; harvesters that cut the grain and bind it as they go along. Others there were which cut, thrashed, and measured into sacks ready to be hauled to market or granary. Mowers and reapers, hay-loaders, machine forks for unloading the hay from the wagon into the mow, are there also. There were also automatic stockfeeders, operated by a 99-cent clock, which could feed the horses and cattle while the attendant gets an extra hour or two of perhaps much-needed rest. Nearly every machine on exhibition had some automatic attachment to save labour to the operator and also labourers to the owner of the machine.

One machine was shown in this department which deserves special mention, as it is destined to do away with a great deal of hard and distasteful hand labour. It was called a "potato harvester." This machine was made to be drawn by a span of horses, though any
power

power of locomotion might be applied. It was rather rudely made, probably being the first of its kind in use. The construction was similar to that of the "sulky seeder." A cone-shaped contrivance hung under the framework, into the front end of which were set triangular spear-shaped knives or hoes, from which a 3-inch band protruded at right angles with the side of the cone and ran in spiral form to the rear end of it. This, when the machine is in operation, has a screw-like motion, boring along the surface deep enough to gather in the potatoes, carrying them back into a sack properly attached for that purpose, the loosened dirt falling through the open work of the cone, like flour through a rotary sieve, leaving the soil in condition for the next crop.

CLOTH-CUTTING MACHINES.

One machine in this department has special interest for the labour student, it was the Caldwell cloth-cutting machine, exhibited by the Electrical Machine Company in the north-west gallery. A framework of piping about 5 feet 6 inches above the table and standing on the floor, of any length, according to the table to be used. Attached to this frame were two tracks on which a bow-shaped truck ran; attached to this truck, subject to the will of the operator, was a sliding spring from which, by coil spring, the machine suspended, allowing the operator to move the machine freely in any direction, down one side of the table and back the other.

The machine was very small, not occupying much more than a cubic foot of space outside the track work, which from the nature of its construction was not inconvenient. The knife was vertical when in place, and when in action had two movements vertical, like a jig saw, and a horizontal or forward movement at the same time. It did not require a very strong current of electricity to run it, from 70 to 110 volts being quite sufficient. It cut any number of layers of cloth to the thickness of 2 or 3 inches. An expert operator with this machine can cut as many garments as twenty to thirty hand workers, and do the work much better.

WOOL EXHIBITS.

The exhibits of wool were very numerous, and were brought from Russia, China, Egypt, Thibet, Peru, Morocco, Turkey, Iceland, Spain, Bagdad, Cape Colony, New Zealand, Victoria, Canada, and the United States. As I have already stated, the exhibit from New South Wales, by its imposing and massive character, as well as by the well-arranged series of its fleeces and specimens of wool, was *facile princeps*, and eventually obtained the chief share of the awards in this department.

The Russian exhibit contained a number of photographs of the far-famed fat-tailed sheep of Central Asia, with their long staple wool, and a variety of other breeds, including the Merino, with crosses. European Russia has about the same number of sheep as the United States—47,000,000. Some of the wools exhibited were of excellent grade, but most of the samples appeared coarse. Uruguay had an excellent show of grade wool, chiefly of the Rambouillet Merino strain.

Some years ago, when Executive Commissioner to the Melbourne Exhibition of 1880, I reported on the Argentine wool to the effect that ultimately Argentina might become a rival to Australia as a wool-producing country.

I now find that the total exports of wool in 1891 were 300,000,000 lb., the clip of 80,000,000, of the Argentine Rambouillet strain, and for which the chief market is found in France. The wool exhibited was not shown to the best advantage, but appeared to be of fair staple and light in condition. As regards weight of fleece and fineness of staple, it cannot be considered equal to the Australian Merino, and if the numerous specimens exhibited were a fair sample of Argentine wool, as I believe they were, Australian wool, of the best clips, in the opinion of the experts, will hold its own in its own sphere in the comparison.

The United States Show was scattered, some of the exhibits being contained in the State buildings, and others were only too frequently quite masked by the elaborate shows of grain, wheat, &c., when they were exhibited. Ohio, which produces the best wools in the United States had, unquestionably, the best display, with its 300 fleeces. With this exception the United States wool exhibit but poorly represented the resources of the country in this respect. What wool was shown clearly indicated that the coarse character of the product was such as quite unfitted it for the manufacture of high class, finely textured cloths. Even the United States experts, when contrasting the Australian with their own wool, were compelled to admit that our wool was unapproachable for the qualities which the manufacturers desire, such as softness, silkiness, lustre, brightness, strength, trueness of fibre, elasticity, freeness, pliability, length of staple, evenness in the length and quality of the wool, lightness of waste in scouring and spinning quality.

In judging the wool the following points obtained :—

1. Weight of fleece.
2. Length of staple.
3. Density.
4. Evenness and fullness of covering.
5. Brightness, softness, and yolk.
6. Wave, freedom from kemp and fineness.
7. Freeness and elasticity.
8. Evenness and quality of wool all over.

Deductions and additions of points were also made for percentage over or under 50 per cent. loss in scouring, and for fractions of an inch under or over 3 inches in length. Samples were also taken from the fleeces and subjected to microscopic examination and dynamometric tests, the results of which were entered in the Report.

It would be superfluous to refer in detail to the various wool exhibits, with all their peculiar characteristics. The principal interest for our wool-growers will centre in the report of the expert judges on the subject, hereafter to be published. At the present time the various investigations by microscopists and others are being made in Washington and elsewhere, and the results of these examinations, to be published in the Official Report, must be both interesting and useful.

DAIRY EXHIBITS.

Elsewhere I have described the dairy building, and the general purposes to which it was applied. The experiments made in the building and the lectures delivered were of great interest. The experiments were carried on for several months in a very systematic and scientific manner, under the conduct of experienced men from the agricultural

agricultural colleges of America, who had at their disposal all the apparatus required for actual testing. The dairy cattle exhibited were of pure breed and ascertained pedigree, and represented the Shorthorn, the Jersey, and the Guernsey. About twenty-five selected cows of each breed were picked out from the cattle exhibited for the purpose of the experiments. The objects of this test, which the authorities considered one of decisive character, was to determine the best and most useful class for the production of milk, butter, and cheese, the observations being made in the course of the experiments as to the condition of the animal with reference to weight and other circumstances during its continuance.

The results of the milk and cheese contests of fifteen days in May between the breeds of cattle at the Fair were as follows:—

	<i>Jerseys.</i>	<i>Guernseys.</i>	<i>Shorthorns.</i>
	lb.	lb.	lb.
Milk	13,296 $\frac{4}{5}$	10,938 $\frac{6}{5}$	12,186 $\frac{7}{5}$
Cheese	1,451 $\frac{7}{5}$	1,130 $\frac{6}{5}$	1,077 $\frac{6}{5}$
	\$	\$	\$
Value of cheese	193.98	135.22	140.10
Value of whey	9.26	7.72	8.67
Increase live weight	14.72	21.60	31.91
Total value	217.96	164.55	180.72
Cost of feed	98.14	76.25	99.36
Net profit	119.82	88.30	81.36

The Jerseys, in the fifteen days, gave 1,109.7 lb. more milk than the Shorthorns, and 2,357.8 lb. more than the Guernseys, and the Shorthorns 1,248 lb. more than the Guernseys. The milk of the Jerseys, when made into cheese, produced 321.14 lb. more cheese than the Guernseys, and 374.16 lb. more than the Shorthorns. The Guernseys, though giving less milk, exceeded the Shorthorns in cheese by 53.02 lb. The increase in live weight is largely in favour of the Shorthorns over both the other breeds; the Guernseys gained over the Jerseys. The cost of feed and production showed that the Jerseys took care of and profitably assimilated a larger amount of feed than the Guernseys, and but little less than the Shorthorns.

The Guernseys produced cheese at less cost than the other breeds. The Jerseys have always occupied a high place as producers of butter, but have been considered generally a small milker of rich milk. That the Jerseys should have produced so much more milk and cheese than the other breeds was a general surprise to those who did not know their capacity in this direction, and showed that they are great milkers, and the champion dairy-cow of the world for both butter and cheese.

Each cow was credited with the quantity of milk given daily, the total solids in milk, and the whey. Each breed was credited with the total milk given and the quantity of cheese actually made at the dairy, and the whey. The cheese was scored by experts and valued. Each cow and each breed was debited with the food consumed. Increase in live weight was credited at 4 $\frac{1}{2}$ cents a lb. Each cow was milked in the presence of a representative of the testing committee. Each cow's feed was weighed by such representative twice daily. The feed was kept by such committee under seal. A daily analysis of the milk was made by skilled chemists. A regular ledger account was kept with each cow. This test was the most complete, the most carefully conducted, and the most thorough that has ever been made in the world, it is said, and twenty-five cows of each breed competed.

STOCK

STOCK EXHIBITS.

Just beyond the Agricultural Building, in a south-westerly direction, was the live-stock pavilion, which looked like a Roman amphitheatre, and still further south were the buildings containing the stalls where the live stock on exhibition were housed. The stock shows, for the most part, were held in the closing months of the Exhibition. At the end of August the exhibition of horses and cattle was held, lasting one month. The sheep and swine exhibits followed, from the end of September to the middle of October; and in the latter part of October the shows of fat stock and poultry were held simultaneously. The rules of the Exposition provided that none but registered stock would be admitted. The principal portion of the exhibits, for self-evident reasons, was of domestic origin. The quarantine regulations of the United States are stringent, and precluded the appearance of many exhibits from foreign countries. Canada was largely represented in each of the groups, and some of the animals of that country were splendid specimens. Kentucky showed some fine horses. Vermont and the New England States showed splendid specimens of their breed of sheep. The Canadian sheep were of Southdown and similar English-bred types. As I have already said, the arrangements for the animals were very good. The stalls and stables were so arranged that partitions could be altered to suit the special needs of each exhibit. The general public could not only witness the special pavilion exhibits without extra charge, but could pass through all the avenues between the barns and stables, an opportunity being thus afforded to see all classes of fine stock at close quarters. There was a hospital for sick animals, in charge of a veterinary surgeon. The accommodation in the stock pavilion itself, which I have said was built on the amphitheatre plan, and constructed of wood and staff, was very convenient for visitors. Tiers of seats rose to the roof for the accommodation of from six to eight thousand spectators, and thus everyone had ample and convenient opportunity to observe the various animals brought out for show purposes.

(Sig 293)

WORLD'S COLUMBIAN EXPOSITION.

HORTICULTURAL BUILDING.

Horticultural Building.

Exhibits of Horticulture, Floriculture, Arboriculture, Viticulture, and Pomology.

THIS building was the largest ever erected for the purposes of a horticultural exhibition, being 1,000 feet long, with an extreme width of 287 feet. It contained about 89,000 square feet more of exhibiting space than the combined floor areas of the buildings used for a similar purpose at the Centennial, New Orleans, and the Paris Expositions. It occupied an excellent situation, facing the Lagoon and the Wooded Island. The building was really a gigantic conservatory, with wings adapted for fruit and flower exhibitions, and with the space at its south end devoted to the exhibits of the wines of the world.

The varied classification of the Horticultural Department necessarily required a building adapted to divers uses. Its general plan was an imposing, central, glazed dome, 114 feet high on the inside and 187 feet in diameter, with a gallery extending around a well or open centre. Four parallelogram-shaped rooms, technically called curtains, each 270 feet long, connected the dome and central pavilion, forming two interior courts 90 feet wide by 270 feet long. Each end pavilion was two storeys high, with an area of 217 by 250 feet on each floor. The style was Venetian Renaissance, the order Ionic, with a broad frieze decorated with cupids and garlands.

The central feature of the Horticultural Building was a highly-ornamented pylon, forming the main entrance, with a recessed vestibule decorated with statuary. On the face of the pylon were groups, one on either side, representing the "Awakening and the Sleep of Flowers." Aside from the frieze the sculptural decorations of the Horticultural Building consisted of six single figures and two large groups. On the eastern front of each pavilion at the ends of the building were two figures placed on the level of the second storey. The one on the south was called the "Painting of the Lily," and consisted of the figure of a nymph holding a lily, and regarding it intently with her brush poised in the air. As is well known the ancients attributed to these spirits of wood and field the care of plant-life. The other figure was symbolical of the cultivation and use of the grape, and represented a fawn holding in one hand a brimming beaker, and in the other a bunch of grapes. The drapery of this figure was a tiger-skin, a favourite costume of Bacchus, the God of Wine. On the north pavilion was the draped figure of a woman personifying the study of botany, and holding in her hand a scroll on which was inscribed the lore of that science. The last figure, at the extreme north of the building, represented a gardener of the ancient type examining the bursting buds of a vine. Just inside the vestibule stood two figures, each 10 feet in height. The one on the right was a light airy personification of Flora, poised on tiptoe, and with outstretched arm a flowering branch, to which she turned, and smiling face. Around her feet were plants and blossoms profusely decking the earth in response to her glad presence. The motive of this figure was suggested by the well-known statue of "Hope" by Bodenhausen. On the opposite side was the figure of "Pomona," with four matronly forms struggling with the overflowing basket of fruit, which in spite of her

her development she seemed to be unable to lift. As regards the two main groups just outside the main entrance, the one on the south side was the artist's ideal of Autumn, a composition which was called "The Sleep of the Flowers." In it the figures of the two sitting figures suggested sleep, and even the standing figure seemed as if she also were soporifically inclined; the only touch of animation was the single belated Cupid who sat contentedly absorbing a bunch of grapes. This fruit was shown hanging in abundant clusters from the rocks on either side; at the feet of the figures was placed a branch of withered oak. On the other side was the Springtime group, sometimes called "The Battle of Flowers," in which the artist tried to express the vigor and push of awakening vegetation by means of broken and angular lines, making the composition as great a contrast as possible to the Autumn group. Figures of the three nymphs, a fawn and two Cupids, all laughing heartily, as they pelted each other with buds and blossoms, were shown. The figures in these various groups were about 8 feet high and the work occupied several months. In the frieze around the inside of the dome were festoons and wreaths of the passion vine; and in the wreaths were painted the names of men famous in horticulture and kindred arts.

Opposite the main entrance, and flanked on either side along the lagoon with long rows of mammoth vases, filled with flowers and trailing plants, was a succession of steps leading down to a broad landing, for picturesque gondolas and other water craft. The dome was sufficiently large to admit of the construction of a miniature tropical mountain and an extensive cave underneath. Several cascades were formed upon the side of the mountain, and the sparkling waters leaped from rock to rock under the foliage of the largest palms, tree-ferns, and other tropical plants that have ever been collected in a conservatory. New South Wales, many Central and South American countries, Africa, and every nation in Europe, the West Indies, China, and the largest conservatories in the United States have contributed to the collection of plants which were exhibited in the dome and east curtains. Japan, among many rare plants, furnished some dwarf trees more than 100 years old, and only a few feet in height. The entire cave was constructed of stalagmites, stalactites, and quartz crystals from a South Dakota cave, and the numerous electric lights placed within it produced a most dazzling and pleasing effect.

Near the Horticultural Building were auxiliary greenhouses, aggregating 25,000 square feet, for the purpose of developing plants to the highest degree of perfection before placing these on exhibition. There were also eight large propagating houses, covering a space of 20,000 square feet, part of which was assigned to exhibitors for the propagation of plants of merit which could not be transported from their distant homes. A large number of cold frames also occupied adjacent ground, and outdoor space to the extent of about 25 acres (including the greater part of the Wooded Island) was assigned to the department for the exhibit of trees, shrubs, and plants, which were hardy in the open ground during the time of the Exhibition. Every suitable provision was made for the supply of water and of regulated heat, more than 10 miles of 1½-inch steam pipe being used for the latter purpose. In addition, 5 acres at the western entrance to the Midway Plaisance were assigned for the nursery exhibit.

The dome gallery contained exhibits of herbariums, photographs, florists' supplies, fruit and flower plates, &c., and was used as a promenade from which to look down on the plant displays.

The west curtains, in which the pomological exhibit was installed, aggregated 692 feet in length, and were 46 feet wide. The 35,000 plates and jars of fruits were from every part of the world, and were represented either in fresh specimens, wax models, or varieties preserved in fluids. Every

NEW SOUTH WALES SECTION, FERN HOUSE, HORTICULTURAL BUILDING.

NEW SOUTH WALES SECTION, FERN HOUSE, HORTICULTURAL BUILDING.

Every country in which the grape is grown extensively made a display of wines on the first and second floors of the south pavilion. France, Spain, Portugal, Italy, New South Wales, Germany, and other foreign countries were in the competition for honours in the greatest viticultural exhibition that has ever taken place.

Each floor of the north pavilion was devoted to seeds, horticultural appliances, canned and dried fruits, jellies, marmalades, &c. The largest seed firms of Europe and America were well represented; improved horticultural machinery was extensively represented; the canned fruit displays were elaborate and tastefully arranged; and there was in this pavilion a miscellaneous list of exhibits interesting to all classes of visitors.

A bearing orchard of oranges, lemons, and other citrus fruits filled the entire North Court, while the opposite court on the south contained a typical wine cellar from the Rhine, in Germany, and several basins of artificially heated water, in which were grown the *Victoria Regia* with its enormous leaves, and other water plants.

Artistically arranged flower-beds occupied the space in front of the Horticultural Building, while on the area at the back there was a varied exhibit of greenhouses, constructed by leading firms, chiefly American, and filled with rare collections of plants.

The central feature in the landscape architecture of the entire grounds was the Island; from it the best view could be obtained of all the departmental buildings. The flower-beds and walks were designed with special reference to the exhibiting to good advantage semi-hardy rhododendrons, azaleas, kalmias, conifers, roses, &c. Foreign countries, especially France and Germany, were the most liberal contributors, and the exhibition of large and rare specimens was unequalled.

Five acres at the western end of the Midway Plaisance was assigned to a nursery exhibit. France made a very interesting display in fruit trees trained into every form and grafted in different ways, as well as a great variety of evergreen and deciduous shrubs. The State of Wisconsin illustrated, with bearing plants, improved methods of growing and flooding cranberry marshes. An acre in bearing orange trees and many exhibits of deciduous and evergreen trees and shrubs made very attractive displays in this locality.

New South Wales Court.

In this building our country was represented in no fewer than five sections. The space allotted for our wines was placed in the recess at the south-east corner of the building, between two important entrances and immediately at the end of the main avenue of that part of the building devoted to viticulture. The site was well placed. At first only one-half of this section was allotted to us and the other half to one of the South American republics, but on my representation that the space granted would be insufficient for our exhibits, after some correspondence and arrangement I had the pleasure to receive official notification from the authorities of the Exposition that the extra space I had demanded had been granted to us. The court then occupied the whole of the bay, and had a frontage of over 60 feet, the total floor space being 760 feet and wall space 1,250 feet. On consideration, I found that our best course with this space was to erect trophies and stands on which to display the numerous and valuable wine exhibits of our colony. The photograph of the court will give a general idea of the arrangement. There were no fewer than twelve of these trophies, some of them 14 feet high, painted black and gold, cream and gold, and blue and gold, shelved to carry the wine bottles and surmounted with a flower-pot with plants. Along the top of the court were vine-leaves in a trellis, and this added much to the beauty of the appearance.

I regret to state that many of our wines forwarded were improperly labelled. In some cases a name representing certain well recognised characteristics was applied to a wine of quite a different nature. These eccentricities, as a rule, find little sympathy from jurors.

The following suggestions were made to me by one of the most experienced experts in wine and may be found useful:—In bottling, the wine should be filled quite up to the cork, and no interval should be allowed. Casks, in wine production, should be small, not larger than 40 gallons. New wine should be put into small casks. These will ultimately be found cheaper than large ones, and they are more easily handled. In large casks the wine is found to be of different character at different parts of the cask, according as it is drawn off from the top, the middle, or the bottom of the cask. The best temperature for wine is 46° Fahr.

In the pomological section, and from the peculiarity of the position and its surroundings, I found that arched-wall screens, with central tables covered with shelving to carry the fruit exhibits, would best answer the requirements of the situation. Over this Court, as in the case of the Wine Court, in neat design were painted the words "New South Wales," and the walls were hung with the enlarged photographs of fruit scenes. I regret to state that I cannot report favourably of the manner in which the preserved fruits were prepared for exhibition; neither those from our Agricultural Department nor those from private exhibitors could for one moment be compared with the foreign and American exhibits of the same kind as regards the "get up." To add to my dissatisfaction, I found when unpacking the case in which these fruits were sent that some onions had been packed in the same case, and that these had decomposed on the voyage, producing a disagreeable flavour in the whole of the contents, which required care and time to get entirely rid of. Many of the visitors experienced in the packing of fruit examined these exhibits, and expressed surprise at the want of skill displayed in the packing, while they admired the excellent fruits presented. Our fruit-growers have much to learn before they can equal the excellent and beautiful methods adopted by other countries in respect to the preparing and packing of our excellent fruit.

In the main gallery of the central rotunda of the building I obtained a splendid position for our beautiful photographs of the parks and gardens of New South Wales, through the kindness of Chief Samuels; and these photographs were a constant source of attraction to the great number of persons who from the galleries rested, or surveyed the magnificent horticultural displays below. This space was wall space, with a narrow floor space to keep off the visitors.

One of the great attractions of the horticultural building was our Fern Court, containing our great ferns, the macrozamia, and bird's-nest ferns. For these a space of 3,780 feet was provided, and I may state that during the whole course of the Exhibition this part of the horticultural display attracted increasing attention. Mr. Thorpe, the chief of this department, lent us his valuable advice and assistance in the arrangement and disposal of these exhibits, and to the great care and the labour bestowed by him and the gardeners under him much of the fine effect produced by this arrangement was due. In the undergrowth of the ferns was placed an immense number of beautiful specimens of young gum-trees, pepper-trees, and other plants, and the whole was so arranged as to give quite a natural and exquisitely beautiful appearance. Banners, with the legend, "New South Wales, Australia," floated over the whole. Here we had Germany and France on one side, and Japan on the other; but the characteristic idea impressed on every visitor was that the scene was Australian. I am glad to report that, while the macrozamia did not seem to take kindly to the air of Chicago, the ferns appeared even
more

NEW SOUTH WALES WINE COURT, HORTICULTURAL BUILDING.

more full of foliage and more beautifully green in colour than even in their native habitat. The only losses that occurred in connection with this class of exhibit was the death of the principal branch of the great tree-fern and the four macrozamia, numbered 800 in our catalogue.

With regard to the various shipments of fruit sent from Sydney I forwarded from time to time brief information regarding each lot as it arrived in Chicago, in accordance with the cable code arranged for that purpose, and in various letters to the Commission I gave more detailed information on the subject.

First Shipment.—The first shipment of our fruit was brought by the "Mariposa," which left Sydney on 20th March, 1893, and arrived at the Exhibition on 10th May, having been fifty-two days in transit, of which time twenty-seven days were taken up by the carriage between San Francisco and the Exhibition. The shipment consisted of eleven cases of apples, three of pears, three of grapes, and one of passion-fruit. The apples comprised Golden Russet, New Hawthornden, Pomme de Neige, Cleargate Pearmain, Winter Pearmain, Northern Spy, Five Crown Pippin, Brown's Perfection, Kentucky Red Streak, and Triomphe de Luxembourg. The grapes consisted of white Muscat and Wantage. The pears comprised Gansel, Bergamot, and Butler pears. Nearly all the apples arrived in good condition; there was not one bad among the Golden Russet. The Five Crown Pippin, Pomme de Neige, Norman Spy, and Kentucky Red Streak were particularly noticeable for their excellent state of preservation. The juror who examined them officially expressed his high approval of them, and the public at large, as well as pomologists, expressed surprise at the excellent condition in which they had arrived. Out of the three cases of pears, only three or four pears in fair condition for examination were obtained the whole of the remainder were quite decayed. The grapes arrived in bad condition, but a few bunches were obtained from the lot, and were placed on exhibition; they were remarkable for their size and their excellent flavour after their long journey. The passion-fruit was wholly decayed. This shipment had been brought over under the condition of ordinary cargo, and without the advantage of cold storage or any particular care, and those portions—the apples and grapes—which were in good condition were pronounced to be as excellent of their kind as any similar fruit exhibited at the time.

Second Shipment.—The second shipment of fruit left Sydney in the R.M.S. "Oroya" on 25th March, *via* London and New York, and arrived at the World's Fair on 30th May, thus having been sixty-six days in transit. This shipment consisted of 17 cases, *viz.*:—10 cases of apples, 4 of grapes, and 3 of pears. The apples consisted of Bailey's Sweet, Seedling Pearmain, Kentucky Red Streak, and Scarlet Pearmain. The pears were all winter Nellies and the grapes Muscat of Alexandria. Although this shipment had been sent over under cold storage conditions the results were not as satisfactory as in the case of the first shipment. The actual state of several cases of apples was as follows:—

Case 2636	Bailey's Sweet	...	No. in case	126	...	bad	36
" 2370	Seedling Pearmain	...	"	114	...	"	100
" 2368	Kent Red Streak	...	"	111	...	"	61
" 2369	Scarlet Pearmain	...	"	152	...	"	37
" 2365	Kent Red Streak	...	"	106	...	"	56
" 2364	Bailey's Sweet	...	"	98	...	"	65
" 2361	" "	...	"	131	...	"	21
" 2362	" "	...	"	123	...	"	23
" 2367	" "	...	"	129	...	"	49
" 2366	Scarlet Pearmain	...	"	99	...	"	59

The contents of the three cases of winter Nellies pears all decayed; not a single presentable specimen could be obtained. The four cases
of

of grapes had suffered much; in fact only about one-third of the contents of each case was in fair condition. It would be difficult to say why there was such a serious difference between this shipment and the first, more especially when it is remembered that special precaution in regard to the use of cool chamber and the like had been arranged for in Sydney before the departure of the shipment. With regard to the grapes it was clear that the system of packing adopted was not a good one, and it struck me when examining them that sufficient care had not been taken after cutting the branches to remove all traces of moisture, &c. The cork shavings which had been used for packing material appeared to be too fine in structure, and great difficulty was experienced in removing the finer cork fragments out of the grape clusters. It was suggested to me that the system adopted in America of packing the fruit in small boxes, containing about 4 lb. each, not too tightly packed, and of placing these small cases in a larger one was a much more successful mode of conveyance.

Third Shipment.—The third shipment left Sydney by the “Monowai,” on 17th April, 1893, and arrived at the World’s Fair on 7th June, taking fifty-two days in transit. It consisted of three cases of apples and pears exhibited by the Pastoral Agricultural and Horticultural Association, Armidale. The results on opening the cases of this small shipment was as follows:—

Case 2410	Apples in case	19	...	good	9	...	bad	10
„ 2411	Pears and apples in case	...	13	...	„	7	...	„	6
„ 2412	Apples in case...	...	35	...	„	13	...	„	22

This shipment was not equal to either of the previous ones in general results, but such of the fruit as was in good condition on opening the cases looked remarkably well, and on exhibition lasted longer than any of the previous samples.

Fourth Shipment.—The fourth shipment of fruit by R.M.S. “Orient,” which sailed from Sydney 8th April, consisted of twenty cases apples, one of persimmons or date-plums, and one of oranges. The varieties of apples were: Canove Pearmain, Wagner, Nickajack, Gladneys Red, Buncombe, Romanite, Scarlet Pearmain, and Horn. Of these only a small portion was decayed, but the oranges and persimmons were totally destroyed.

Fifth Shipment.—The fifth and last shipment left Sydney per R.M.S. “Alameda,” on 15th May, and arrived at the World’s Fair on 27th June, being forty-three days in transit. It contained fifty-one cases, three of which had been sent by the New South Wales Commission and nineteen by private exhibitors.

The cases forwarded by the Commission contained oranges and lemons, and one case of passion-fruit for Sir Roderick Cameron, of New York, which, however, on being opened was found to be completely decayed. The oranges and lemons had not suffered much in transit; in fact the lemons in three or four of the cases were all perfectly sound. As I informed the Commission in my official letter on the subject, the oranges were of a very poor description, both small and sour, and quite unworthy of carriage. Our show-stands were in the immediate vicinity of the Californian exhibit of oranges and immediately adjoining the great tower, about 40 feet high, covered with oranges, the produce of that State, and the contrast between these miserable specimens and those of our neighbour occasioned no small amount of unfavourable criticism. Why these windfalls—as they appeared to be—or all too premature fruit should have been forwarded as specimens of the far-famed produce of the Parramatta River is to this present moment to me a matter of astonishment. The only course I could adopt with these specimens of what an orange ought not to be was to select only such specimens as appeared the best for submission to the judges with the hope of modifying their opinion of the whole. The

The private exhibits consisted of apples and a small quantity of oranges. W. Eyles, of Orange, exhibited Winter Pearmain, Luxembourg, Granny Smith, Majentin, Grasseys, and Five Crown apples. Of these the Winter Pearmain, Grasseys, and Granny Smiths arrived in good condition. Some of the Granny Smith apples were magnificent specimens, the size and colour being remarkable; in fact I saw no fruit at the time on exhibition among the immense number of exhibits of all kinds displayed in the large horticultural halls which surpassed them. The balance of the exhibit, consisting of Luxembourg, Majentins, and Five Crowns arrived in very bad condition. It was a remarkable circumstance that the Five Crown apples, which arrived in a completely decayed condition, in this shipment, were, as I have already reported, the apples which arrived in the very best condition in the first shipment, after being fifty-two days on the journey. The other private exhibits were all more or less completely decayed. These private exhibits were marked in the instructions of the manifest of the shipment as "For sale on behalf of exhibitors," and I caused all the necessary inquiries to be made with regard to the disposal of such of the fruit as was in good condition. I found that the sale would not be permitted within the grounds of the Exposition, except through some concessionaire, and further, that 25 per cent. of the gross proceeds would have to be paid to the World's Columbian Exposition authorities, and that the concessionaires required 50 per cent. of the balance. In addition to this, there were a number of formalities, such as passing the Customs, entry fees, and the like, so that ultimately very little money would be left for the exhibitor. Doubtless some of the apples could have been sold, as a novelty, at prices as high as 10 cents (5d.) each, but this would have been no criterion as to the real outside marketable value of the fruit. Good American apples were being sold at the time at 2 cents (1d.) each, or even less. In consequence of the difficulties to which I have already referred in connection with the sale of the fruit in question, I considered it advisable, under the circumstances, to place the sound fruit amongst our fruit exhibits, so as to add to the effectiveness of our display in this section.

After the arrival of the early shipments of our fruit I cabled instructions to Sydney to cease forwarding any further shipments. I took this course because I found on inquiry and examination of the markets here that at the time there was an abundant supply of all kinds of fruit from the different parts of the United States and South America. Communication by land and sea is so frequent and so reasonable in cost, especially in regard to railway carriage, and the art of packing fruit is so perfect in the United States, that no sooner is a market created than the supply is soon provided. When to this is added the fact that the cold storage provision on the railroads is, perhaps, the most perfect in the world, it will easily be seen that it will be a difficult thing to outbid the home fruit-growers of the United States. I am quite certain that greater care and skill must attend our mode of packing our fruits before we can hope for great success in this direction, and in regard to this matter the fruit-growers of Australia have a great deal to learn.

Before passing from the subject of our display in horticulture, I may here quote one of the numerous Press statements, although American in tone, made regarding our general display in this building:—"John Thorpe, Chief of the Horticultural Bureau, says the exhibit of New South Wales in this department is, without exception, the most effective made by any foreign country at this Exhibition. He greatly regrets the absence of an elevator in the building, from whose height the visitor might be able to look down upon the tropical forest of Australia. Praise from Sir Hubert is praise indeed, but every visitor to the Horticultural section will fully coincide

coincide with Chief Thorpe's views after inspecting the very artistic exhibit made by the Colony. With Uncle John it has been a labour of love to accentuate the beauties of the trees and plants sent from Australia, and one might easily fancy himself in an avenue of the famous Botanical Gardens in Sydney while viewing the delightful little forest laid out in the north wing of the main building. In the pomological section there is a good display of canned and dried fruits, including pears, peaches, plums, apricots, and apples. Of live fruits the exhibit of apples is particularly fine, a number of varieties being shown. In spite of the fact that the fruit was fifty-two days on the road from Sydney to Chicago, and has been on the shelves thirty days longer, there is a freshness still discernible on the apples that makes one long to pocket a few specimens when out of sight of the attendant. In Viticulture, New South Wales is represented by a good display of clarets, sauternes, tokays, and hocks; of the sweeter wines there are muscats, muscatelles, ports, and sherries. The Colony excels in light wines. New South Wales ships a considerable quantity of fruit, especially oranges and lemons, to the neighbouring colonies, and expects to do a good trade with Europe as soon as the difficulties connected with the transmission of fruit have been overcome."

It will be necessary also to have more direct and immediate communication with America to effect this purpose; and there must be preparation for immediate and combined action on both sides, so that on advice as to the requirements of any particular locality, shipments may be immediately effected. This last principle will be most satisfactorily accomplished only when we are in direct communication by telegraph with America. It is true that climatic conditions are different in New South Wales and America, and undoubtedly when the conditions I have already referred to are in operation, this will be an important factor in connection with trade relations between the countries. As I will show at a later portion of this report, there are other directions through which important commercial relations may be established between these countries.

The south-eastern curtain of the Horticulture building was radiant with flowers, Illinois occupying space at the extreme end, and showing a pretty collection. Near by was a cactus patch, representing some of the dreary spots that abound in New Mexico, and comprising many varieties of cacti, the creamy-flowered yucca, the Spanish bayonet, meschal, cholla, tuna, and some others. Massachusetts, directly opposite, contributed a number of fine ferns, one of which had remarkable spreading leaves. Missouri also made a creditable display, and California exhibited a few cactæaceous plants. The place of honor in the south-east curtain was held by Pitcher and Manda, of Short Hills, N.J., their collection, including the orchids, being valued at \$50,000. These occupied a large space running down the middle of the curtain; a large number of selected crotons of red and yellow, many varieties of dracenas, and some superb anthuriums in foliage and flower. The latter is a native of South America. Then there was a splendid collection of marantas, with their great luxuriant zebra-striped leaves. There were a great many varieties of ferns, among which was the golden fern, a native of Peru. This was unlike any other, and from its leaves impression may be made upon a coat sleeve or other cloths, such as cashmere and the like, which would be mistaken for engravings. There were also many other excellent ferns known only to a few, one of the rarest being the crested sword fern, a native of South America; golden maiden-hair fern, tongue fern, and adiantum Farleyense, a variegated sport of maiden-hair, very scarce. Among other rare plants in this collection were the heleconia aureo statua, with broad, sweeping leaves with golden stripes, an umbrageous plant standing 6 feet high. Aspidiastia, vivid in green and variegated colours; eighteen bigonia rex, and several varieties of selaginella or club moss,
natives

natives of the East Indies; collection of birds-nest and stag-horn ferns from New South Wales; more club-moss of a bluish metallic shade; *Davallia Mooreana*, a native of the South Pacific Islands; *Pteris Wallichianii*, a native of Japan, the largest fern on the collection, being 8 feet across, and which was set out in 3-inch pots three years ago; *Pteris Victoria*, named after the Queen of England, a native of the East Indies and Southern Africa.

This collection also included *Davala Fijiensis*, a native of the Fiji Islands; a superb fern known as harefoot; pyramids of fern asparagus of many varieties; flowering anthuriums in gaudy blossoms and rich foliage; a large collection of flowering genista; 100 azaleas in orange, red, and crimson flowers; the same number of hydrangeas, abundant of blossom. There were also 84 varieties of pine-apple plants; 150 varieties of palms—32 of sago palms, or cycads, the largest of which was presented by Don Pedro to Mr. Van Alen, of Newport, seventeen years ago, and which was secured by Mr. Manda for the Exposition. There were also 32 varieties of the Norfolk Island Pine, and more than a hundred cocoanut palms, 9 feet in height, growing the nuts, quite a novelty.

The south pavilion of the Horticultural Building contained the very large collection of wine exhibits. Germany erected a special pavilion outside the main court for its wine show. It was a costly but a beautiful structure. Panoramic views of its chief vineyards, with representations of the growing vine and the clustering grapes, made in some special material passing into painted continuations in the vista, made a very distinctive and intelligible picture of the Rhine vineyards and the scenery of the chief wine districts of Germany. Not only were the far-famed wines of the country shown in splendidly prepared and arranged cases, stands, and trophies, but the wine cellars and the processes of storing and manufacture were also exhibited. This exhibit was a most admirable one, the result of much planning and great skill, and I have no doubt was all prepared beforehand in Fatherland, and shipped, like so many of the German displays in other buildings, from Germany to Chicago, specially for the purposes of this exhibition.

France had a space adjoining ours containing about 2,000 feet, in which were exhibited all her far-famed wines. In the gallery there was the French exhibit of the leading champagnes, about 90 feet by 19 feet in area. Austria was well represented. Canada had about 100 square feet. Spain was assigned a space just adjoining the floriculture exhibit. The Spanish Government made a beautiful display of the wine-growing resources of that country. Individual Spanish exhibitors had gallery space, and made an important exhibit.

Portugal made a gallery display, and Italy also exhibited in the gallery, occupying the whole of the west end, 107 feet long. Both of the latter exhibits were marked by a prodigal display of the famous brands from those countries, and the methods of viticulture celebrated for centuries in song and story.

A special effort was made on this occasion by the American wine-growers with the object of exhibiting the wonderful development of the manufacture of their native wines of late years. All the great wine-growers of America were represented, and some of their pavilions were beautiful and striking in the extreme, the hand of the artist and the designer having been employed without regard to expense. Natural vineyard and scenery as well as the various processes in the manufacture of wine were shown. New York exhibitors made a collective display. A number of the most prominent wine-growers of that State erected a most artistic pavilion on the main floor. They exhibited dry, still wines, champagnes, and brandies. In the proper seasons they showed specimens of grapes from which certain wines
are

are made. The Brotherhood Wine Co., of New York, erected a very handsome pyramid of wine bottles filled with Empire State product, and the Boston Co., which makes excellent wines, was included in New York's collective exhibit.

Ohio wine-growers made a combined exhibit. A highly ornamental column was erected, around which were gathered the main portions of the exhibit.

California made the largest American exhibit. From the Stanford Wine-growing Co., and allied firms, came a most elaborate display from the great wine-cellar at Vina. Senator Stanford had the largest vineyards in the United States, containing more than 7,000 acres. His company also produces as much brandy as all the other American brandy-makers put together. The famous Vina cellar was reproduced in cycloramic form. A visitor passing down the main aisle obtained the same view as if looking into the real cellar. About 20 by 30 feet of space was required for this single exhibit, which was located under the gallery almost in the centre of the pavilion. Looking apparently into the cellar the visitor saw the cooperage, the storing of wines, and all the other appurtenances. In front of this exhibit were shown the bottled wines and brandies. Adjoining the Stanford exhibit was a large exhibit of the largest California wine-makers—The Napa Valley Wine Co., Arpad Haraszthy Co., J. Gundlach & Co., and C. Carpy & Co. The Haraszthy Co. make the principal California champagnes, and the Carpy Co. is one of the largest wine-makers and dealers in the State, producing between 1,000,000 and 2,000,000 gallons yearly. This collective exhibit contained a representation of the scenery of California. The growing vines were shown, the natural grapes and wine machines on a realistic scale. The centre of one of the big California trees was hollowed out, and in its centre were shown the climbing vines. On its walls were perfect duplications of vineyard scenes. In this exhibit there was a very fine showing of the bottled wines produced by the several companies.

The Italian-Swiss Colony, of Sonoma County, has about a thousand acres under cultivation. This colony combined with F. Korbelt Brothers, the famous cooperage firm and wine-growers, and made an elaborate display of the Sonoma County product. In this exhibit there was one of the immense fermenting tanks, 16 feet in diameter and 20 feet high, built of the California redwood, and had the appearance of a large vault with a door leading inside. It was the original intention to send this tank filled with wine, but ultimately the interior was used for exhibition purposes and was very attractive. The exterior of the tank was finished in a most ornamental way.

FRUIT.

The collections of ripe fruit from the American States and Canada were, undoubtedly, the largest and most complete ever collected. While the show from nearly all the States was very representative, that of California was unquestionably the largest and the best. Its immense trophy of oranges, about 30 feet high, and its large and extensive display of eight or nine varieties of the same fruit and fruit-bearing trees, as well as the continuously renewed collection of fruits in the State Building, attracted much attention, and induced the opinion that, not Florida but California was the chief orange-growing State in the Union. In addition to oranges, olives of excellent appearance, limes and lemons, walnuts, grapes, raisins, and other fruit were exhibited. In the transport of their grapes the vignerons of California exercise a care and attention unfortunately wanting amongst New South Wales growers. The grapes are carefully examined when removed from the vine, tenderly turned over and cautiously handled, they are then packed in paper-lined boxes containing five, ten, or fifteen pounds

pounds each, so that no undue pressure on the soft and pulpy fruit may occur. Various modes of preserving fruit for market were adopted by exhibitors, some preferring one plan and some another, but I am convinced that whilst there are exigencies in connection with most of the plans adopted, a perfect system has not yet been arrived at.

The Chenivert process is as follows :—

THE GREAT FRENCH PRESERVING PROCESS.

Directions.

Prepare a tight box or small room in which to burn the compound. Any common dry goods box, say about 3 feet square, will answer nicely for family use, and can be made sufficiently air tight by simply pasting in a lining of a few thicknesses of old newspapers.

Place in box or room earthen jars, crocks, or wooden pails containing a sufficient amount of clear cold water to cover the articles when placed in the receptacles in which they are to be kept after being processed, until used.

All fruits contain a percentage of acids, use no metallic vessels.

In an open dish place enough of the compound to consume the oxygen in the box or room; the amount required will depend upon the size of the box or room, say, two or three plates full, light the compound in the open air, and wait until the flame has spread well over the surface; then place in the box or room, close cover or door, calk tight around edges with strips of damp cloth, let it remain about two hours, then open the box or room and place on shelves, or suspend in open baskets, the fruits which you wish to process, relight the compound, following directions as above and process about two hours longer. It is essential that the water be more thoroughly processed than the fruit or vegetables. Should you desire to use your fruit within a short time simply treat the water and pour over the fruit, but for long keeping treat both. Rain water is preferable, but any pure water will answer.

If more of the compound is lighted than will be consumed it is not lost, as what is left may be used another time. Simply turn over the crust formed from burning, sprinkle on a little fresh compound, and burn again from time to time until all the virtue is consumed. Too much will not be used, and the process is not complete if too little is applied.

Place the articles processed in jars or receptacles in which they are to be kept, cover them with processed water, and set away in a cool place to keep.

With this process it is not necessary to use air-tight cans, but better to cover tight enough to prevent rapid evaporation.

Should any of the articles be inclined to float they should be weighted down and kept beneath the surface of the processed water.

All kinds of fruits and vegetables may be preserved whole and in their natural state for exhibition purposes, but for table use it is best to prepare your fruit by removing cores, pits, skins, or rind, before processing, and especially with such fruits as oranges and lemons, where the rind and seed are strongly flavoured, both should be removed. Green corn may be cut off or preserved on the cob, if cut off it should be scalded slightly to set the milky substance.

Peaches, pears, plums, apples, tomatoes, and other similar fruits or vegetables, may be preserved in their natural state or sliced.

Fresh meats or fish should be processed about four hours, lighting the compound twice, the same as in the treatment of water, after which pack in barrels or boxes with a very little salt, simply enough to produce moisture, and while not entirely essential it is best to remove the bone from meats.

Butter may be preserved by being packed solid in jars or tubs, on top of which place two or three inches of processed water.

Eggs should be processed the same as meat, after which put them away in a cool dry place to keep packed in cases or barrels.

Cider may be kept sweet by being processed the same as water, from two to four hours, depending upon quantity treated at a time.

Milk should have only slight treatment, say in quantities of five gallons in five gallon jars, process about two hours, lighting the compound only once. Treated in this manner the taste will not be affected and the milk will keep perfectly from five to ten days.

Before eating preserved fruit add desired amount of sugar, and cook a few minutes in some water in which fruit has been kept.

Select good fruit and not too ripe.

Should any of your fruit show signs of spoiling, simply pour off the liquid and renew with freshly processed water.

Exercise the same care with this process that you would with the old method and you will be more than pleased.

Formula :—Take of sulphur, 1½lb.; white sugar granulated, ¼lb.; charcoal, ¼lb.; wood ashes, 1 teaspoonful; fine salt, one-half teaspoonful. Grind fine, and mix by sifting through a sieve. For meats or fish add to the above one-quarter ounce of saltpetre.

Canadian Fruit.

The Canadian show was an excellent one; the apples, especially those of Ontario, were almost as fine as our own. The grapes exhibited were not to be compared with those of New South Wales either in regard to size or flavour; in fact, I saw no grapes in the Exhibition, extensive as it was, equal to those of New South Wales. The Province of Ontario exhibited over 100 varieties of apples, 60 of strawberries, 50 of plums, over 100 varieties of grapes, 70 of pears, a number of varieties of gooseberries, cherries, and peaches. This province was one of the most successful exhibitors in horticulture and agricultural produce of all kinds, due, doubtless, to the impulse originating in the well-organised experimental farms of the province.

A description of the method of packing fruit for export, as adopted in Canada, will be found in Appendix K.

Fruit Evaporators.

A number of fruit evaporators were exhibited in the pomological section.

The principle of all the fruit evaporators exhibited consisted in the presence of a hot-air chamber, containing hot-air at a regulated temperature. The practical difficulty to be solved in all these machines is to provide an equal distribution of the heat, so that the fruit on the shelves shall not be unequally dried. In most of the evaporators another difficulty is occasioned by the absence of sufficient provision for the escape of the heated air after it has become saturated with moisture. Several of these machines seemed, as far as construction was concerned, to meet the difficulties I have described, and many varieties are employed by fruit-growers in the different States.

FRUIT RESOURCES OF CALIFORNIA.

From a publication on the resources of California, prepared by authority of law, and under the auspices of Governor Markham, of that State, I have gleaned a number of particulars which, in view of the trade relations in fruit likely to be soon established between America and our country, will probably be of interest. As regards agricultural products the following general facts are significant and necessary in view of any future trade between Australia and America.

	When Sowed.	When Matures.
Wheat	October and November (summer-fallow)...	July.
Wheat	December and January (winter-sown) ...	July.
Barley	December and January	June and July.
Oats... ..	January and February	June and July.
Corn	February and March	June to August.
Beans	February and March	May to July.
Peas... ..	February and March	April to June.
Tomatoes	February and March	May to July.
	Bloom.	Mature.
Apricots	March	May to July.
Peaches	March	May to November.
Pears	April	June to October.
Apples	April	June to November.
Oranges	April	December to March.
Cherries	March and April	May to July.
Almonds	January to March	October.
Plums and prunes ...	March	June to October.

In many portions of Southern California and along the coast garden vegetables are grown throughout the year, and hardy vegetables are growing every month in all the interior valleys, except in the mountains.

The

The grain farmer, for summer-fallow crop, ploughs his land in the spring; it lies fallow till October or November, when he sows it; he next, after rain comes, ploughs for winter-sowed grain, which should be sowed by January, although we make good crops sometimes by sowing as late as March in good soil. Harvest season begins in May and June for hay, and in June and July for grain, and continues to August. The grain is cut and stacked, and afterwards threshed, or is threshed as it is cut. It may be left in the field without fear of rain.

The fruit-grower ploughs and plants trees soon after the rainy season—in December or January; he prunes his trees in November and December, or later; he ploughs his orchard in January or February, and reploughs and cultivates until June or July. His early fruits begin to come in by May, and are followed almost continuously by successive varieties of other fruits until November, when late pears are gathered.

In November and December olives are ready for the pickle and press, and in January, February, March, and April our oranges are marketed, thus making the round of the year, and every month yielding its return of some kinds of fruit. The orange ripens a month earlier in Northern California than in Southern California. The fruit-grower, it will be seen, has no day when work is not before him. The season between the last fruit picking and the work for the next year is scarcely long enough to repair tools, clean up packing houses, and prepare for the new year.

With regard to fruits, the apple is abundantly produced of excellent quality, and in a very large part of the State it is the principal fruit grown. There are at present 19,527 acres devoted to its culture, and of these 13,751 are in bearing. According to the report the apple crop finds its market not only in San Francisco and other countries of the State, but is also exported to the northern and eastern States and to Australia. The peach and nectarine are principally used for canning and drying purposes outside of the local markets, and are exported to the Eastern States and to foreign markets. At present there are 54,827 acres devoted to peach culture, of which 33,791 acres are in bearing, and 1,080 acres in nectarines. The fruit is purchased at the canneries and driers at from \$20 to \$40 per ton. The dry product sells, peeled, at from 10 to 20 cents per pound, and unpeeled, at from 7 to 12 cents. The peach is both the favourite and leading deciduous fruit in California. The fruit ripens earlier than any other State in the Union, is large in size, of superior flavour, and the tree begins to yield profitable returns as early as the second year after planting. The fruit is also reported to be exempt from many of the diseases to which it is subject elsewhere, and it is long-lived and produces phenomenally large and regular crops. Another great advantage in peach culture is the naturally dry climate during the ripening season, which is advantageous in fruit drying, and for this reason no artificial heat is required. The ripening season is longer in California than elsewhere, extending from May to December. Only a few years ago the shipment of ripe peaches to the east was deemed a hazardous undertaking; now the business of transporting green fruit east from California has increased to such an extent that more than 2,500 cart-loads were forwarded to the eastern States during 1892. Besides this, shipments were made of ripe fruit in refrigerator cars over 3,000 miles of land and 3,000 miles of sea to London and Liverpool. Over 400 tons, requiring nine special trains, reached foreign markets last year (1892). Inquiries from Germany, as well as from other European countries, are coming in, and there is now a reasonable probability that each following year these new markets will demand a larger line of California fruits.

The pear, the apricot, the quince, the cherry, and the fig, are all abundantly produced in this State, and large tracts of land are devoted to their cultivation.

The olive is very widely grown, and almost the entire State seems well adapted to its culture, the higher parts above 3,000 feet of the Sierra Range and the low lands near the ocean alone excepted. The industry as yet is only in the initial stage, and there is every prospect that it will soon become as important as many others.

There

There are now 8,000 acres devoted to olive culture, of which nearly 3,000 are in bearing. In 1891 there were 11,200 gallons of olive oil produced, which found a ready market at from \$10 to \$12 per case of one dozen quart bottles. About 50,000 gallons of ripe olives were made into pickles, and sold readily at from 60 cents to \$1.50 cents per gallon.

Prunes.—The report further says that the commercial value of California's prune crop is immense; and when it is taken into consideration that the prunes were not introduced until 1856, and that for twenty years but little progress was made, it gives some idea of what to expect in the future. The quantity of prunes now consumed in the United States is enormous, and it will be years before the demand on this side of the Atlantic can be supplied. There are at present 49,626 acres in this State planted with prunes, and of these 25,328 acres are in bearing. The plum is not so extensively grown, there being 5,014 acres planted, of which 3,725 are in bearing. The plum grows to perfection, and gives good return, both for export and for canning. The immense area devoted to prune culture testifies to the profound and well-founded confidence felt in the future of the industry by the people of California. Although but a comparatively new aspirant for public favour, the California prune has forced its way in advance of the imported article, and brings from 2 to 2½ cents per pound more than the French prune sold in competition with it. The proportion of pith and skin to meat in the California fruit is much less than in that of the French article, while the proportion of saccharine matter is much greater. The Californian prunes are more like dates than the French or Turkish prune, and, when cooked, have a most delicious flavour. Besides this, dealers have found out that the California prune keeps better and longer without sugaring than the imported goods. Prices for green fruit delivered at the buyers range from \$25 to \$40 per ton; the dried product brings from 5½ to 10 cents per pound. Plums for export sell at from 40 cents to \$1 per box of 20 lb. The prune is a prolific bearer, and can be relied on for annual crops. Unlike many fruits, it does not take an occasional season's rest, but will yield its average returns every season. If properly cultivated, some fruit may be gathered the third year, and the fourth year will yield a fairly profitable crop; the fifth year will give from 50 to 60 lb. to a tree, which the sixth year should double. From this time on, the tree can be considered as in full bearing, and will give from 150 to 300 lb. of green fruit annually. The production in California, for the year ending December 31st, 1892, was valued at \$25,000,000.

Citrus Fruits.—Perhaps of still greater interest will be the information in regard to these fruits. Still, quoting from the publication already referred to, I find that the area devoted to citrus culture in California has been largely increased during the past few years. In 1892 there were planted 1,976 acres of lemons and 7,950 of oranges; of the latter Los Angeles planted 3,352 and San Bernadino 3,050. The immense profits of this industry have attracted the attention of capitalists and several companies have been organized for the culture of citrus fruits on a large scale. The relative importance of citrus culture in the State will be appreciated, from the fact that while its growth as a commercial industry is confined to the last ten years, the crop of 1892-3 amounts to about 6,000 car-loads. Careful authorities place the present annual consumption of oranges in the United States at 5,500,000 boxes, or an approximate total of 825,000,000 oranges. A use of only one orange a day to each individual would require an annual supply of 23,725,000,000 oranges, and at an average of 500 to the tree it would require 678,000 acres to meet the demand, or more than ten times the acreage in California.

California

California oranges do not meet the competition people suppose, because the crop ripens after the Florida crop is gone, and oranges from Mexico, Panama, and Tahiti come in earlier than the California crop, leaving the latter practically without a competitor. An important feature in the citrus culture is the fact that the large yields are not secured at a sacrifice of quality or flavour. On the contrary, the quality cannot be surpassed and the strongest evidence of this is the fact that at the New Orleans Exposition gold medals were awarded to California for the best twenty varieties of oranges in competition with all other countries. At present there are 59,997 acres planted with the orange, 41,240 acres of which are in bearing.

The culture of the lemon in this State has of late years shown marked activity, and the acreage is annually increasing. The fruit when cured is worth at least \$2 per box, or \$600 per acre. The lemon crop is gathered from October to December and is then stored away for several months, until the market demands an acid fruit. Lemons in this way are kept as long as ten months without showing any deterioration in quality. The acreage of lemons is 10,062, of which there are 5,612 acres in bearing. The citron and the lime bear well although not very extensively grown.

Of nut-growing fruits the walnut yields large returns. The area of its culture is spreading rapidly over portions of the State where it finds a congenial home. There are at present 14,912 acres planted and of these 6,520 are in bearing. The almond does well in California, is a good bearer, and gives handsome returns, the crop being reliable and the nut very superior. The crop is gathered as early as August and September. There are 10,906 acres devoted to the almond, 4,386 now being in bearing. The product has sold at from ten to thirty cents per pound, and from 100 to 150 dols. net has been realized per acre, the orchards not being over five years old, and of course as they become older the profits will necessarily increase.

Grape culture.—Nearly every variety of grape is grown in California. It is also the only raisin-producing State in the Union, and this industry, which was the outgrowth of the past twenty years only, ranks to-day among the most important of the State. Its raisins are practically replacing the imported article, and in a short time the United States, instead of being an importer, will become an exporter of raisins. There are now 82,222 acres planted with raisin grapes, and 16,452 acres with table grapes and grapes for export.

The fruit picking, curing, and packing gives employment to a large number of women, boys, and girls. In the canneries and in cutting and packing the fruit for drying they are more deft than men, and in working by the piece can earn high wages. All the members of a family are called into action during the long fruit season in California.

The acreage devoted to the culture of different fruits in the State as enumerated in 1892 by the State Board of Horticulture, collected by special agents, amounted to 282,496 acres of bearing fruits and 118,918 of not bearing. The shipments of deciduous fruits increased from 1,832,310 lb. in 1871, to 336,184,986 in 1892. If we estimate that it takes 5 lb. of green fruits to make one of dried, and 3 lb. of grapes to make one of raisins, it will be seen that California produced in 1892, exclusive of home consumption, 677,355,546 lb. of fruit.

The trade in canned fruits is one of the most important industries in the State, and the export trade has developed by a steady and substantial growth. In 1876 the output was 270,833 cases, in 1892

it

it was 1,847,000 cases. The *California Fruit Grower* states that during the season of 1892 the thirty-three great canneries operating in California packed fruit as follows :—

		Cases.
Apricots	385,757
Peaches...	565,455
Pears	268,479
Plums	135,296
Other fruits, berries, grapes, cherries, &c.	247,409
Total pack...		1,602,396

Shipments of Citrus Fruits.

The following table shows the importance of citrus culture in the State, and also its rapid growth. The figures are given for the southern counties, where the bulk of the fruit is produced. About twelve car-loads were exported from the other counties in 1891, and twenty-two car-loads in 1892-3, which is a rapid increase for these new citrus belts :—

Counties.	1890.		1891.	
	Boxes.	Cars.	Boxes.	Cars.
Los Angeles	198,695	781	632,071	2,212
San Bernardino	487,000	1,705	487,882	1,708
Orange... ..	112,190	307	147,332	516
Ventura	9,460	33	19,475	68
San Diego	6,600	23	18,861	66
Santa Barbara	6,478	23
Totals	813,945	2,849	1,312,099	4,593

Figures of the output for crop of 1892 are not yet available, but it is estimated that it will reach over 6,000 car-loads, the highest yet produced.

FISHERIES BUILDING—SOUTH ENTRANCE.

FISH AND FISHERIES BUILDING.

Fisheries Building and Exhibits.

FISHERIES AND ANGLING EXHIBITS.

IN another part of this Report I have made reference to the Government fish exhibit in the United States Building, but the importance of this phase of the Exposition is so fully recognised in the United States that one of the most beautiful buildings on the grounds, specially adapted for its peculiar purpose, was erected for the full display of the fish exhibits of the world.

Description of the Building.

This beautiful structure was situated on the north side of the northern entrance from Lake Michigan to the Lagoon. It was close to the loop which formed the northern terminus of the Elevated Railway, and faced the Government Building, its picturesque design forming a contrast to the grandiose architectural display afforded by the latter structure, and it was a fortunate matter for both buildings that the water inlet formed a natural barrier marking the separation between them. The length of the main building was 364 feet, and the width 162 feet, but the projecting vestibules increased the maximum width to 200 feet. The extreme length of the building was 1,100 feet, and the width 200 feet. In addition to the vestibules there were two annexes connected with the main building on each side by arcades.

The architecture of the building was of the school of "Spanish Romanesque"; the design had much originality in it, and was undoubtedly of a most picturesque and pleasing kind, which was more than could be generally said of originality in architecture. The walls were made to imitate dark-brown stone, whilst the roof was of old Spanish tiles. Mr. H. Ives Cobb was the architect, and the cost of the building was estimated at \$350,000. One of the annexes was devoted to angling, and the other to an aquarium, which was partly underground, and on an unusually large scale. The annexes, it should be stated, were on a lower level than the main building, and were connected with the latter by curved arcades. The projecting vestibules in the centre of the main building, one being on each side, were flanked by circular towers 23 feet in diameter and 61 feet high. Inside these towers were winding-stairs, which gave access to galleries beneath the painted roof.

The total amount of floor area in the main building was 55,536 square feet. In addition, there was a gallery 30 feet wide, running the entire breadth and length of the structure, and on both sides. The gallery space amounted to 27,120 square feet. At the wall side of the gallery floor the gabled roof leaned somewhat, and, together with the roof-braces, afforded pretty little booths or bays. These bays were considered the most effective arrangement of space for exhibits, and therefore it was a matter for congratulation that the requirements of construction did not in any matter conflict with the needs of the exhibitor.

In the centre of the polygonal building was a rotunda 60 feet in diameter, in the middle of which was a basin or pool 26 feet wide, from which rose a towering mass of rocks covered with moss and lichens. From clefts and crevices in the rock crystal streams of water gushed and dropped to the masses of reeds, rushes, and ornamental semi-aquatic plants in the basin below. In this pool
gorgeous

gorgeous gold-fishes, golden ides, golden tench, and other fishes disported. From the rotunda one side of the larger series of aquaria might be viewed. These were ten in number, and had a capacity of from 7,000 to 27,000 gallons of water each. Passing out of the rotunda, a great corridor or arcade was reached, where, on one hand, could be viewed the opposite side of the series of tanks, and on the other a line of tanks somewhat smaller, ranging from 750 to 1,500 gallons each in capacity. The corridor or arcade was about 15 feet wide. The glass fronts of the aquaria were in length about 575 feet, and had 3,000 square feet of surface. The total water capacity of the aquaria, exclusive of reservoirs, was 18,725 cubic feet, or 140,000 gallons. This weighs 1,192,425 lb., or almost 600 tons, and of this amount about 40,000 gallons was devoted to the marine exhibit. In the entire saltwater circulation, including reservoirs, there were about 70,000 gallons. The pumping and distributing plant for the marine aquaria was constructed of vulcanite. The pumps were in duplicate, and each had a capacity of 3,000 gallons per hour.

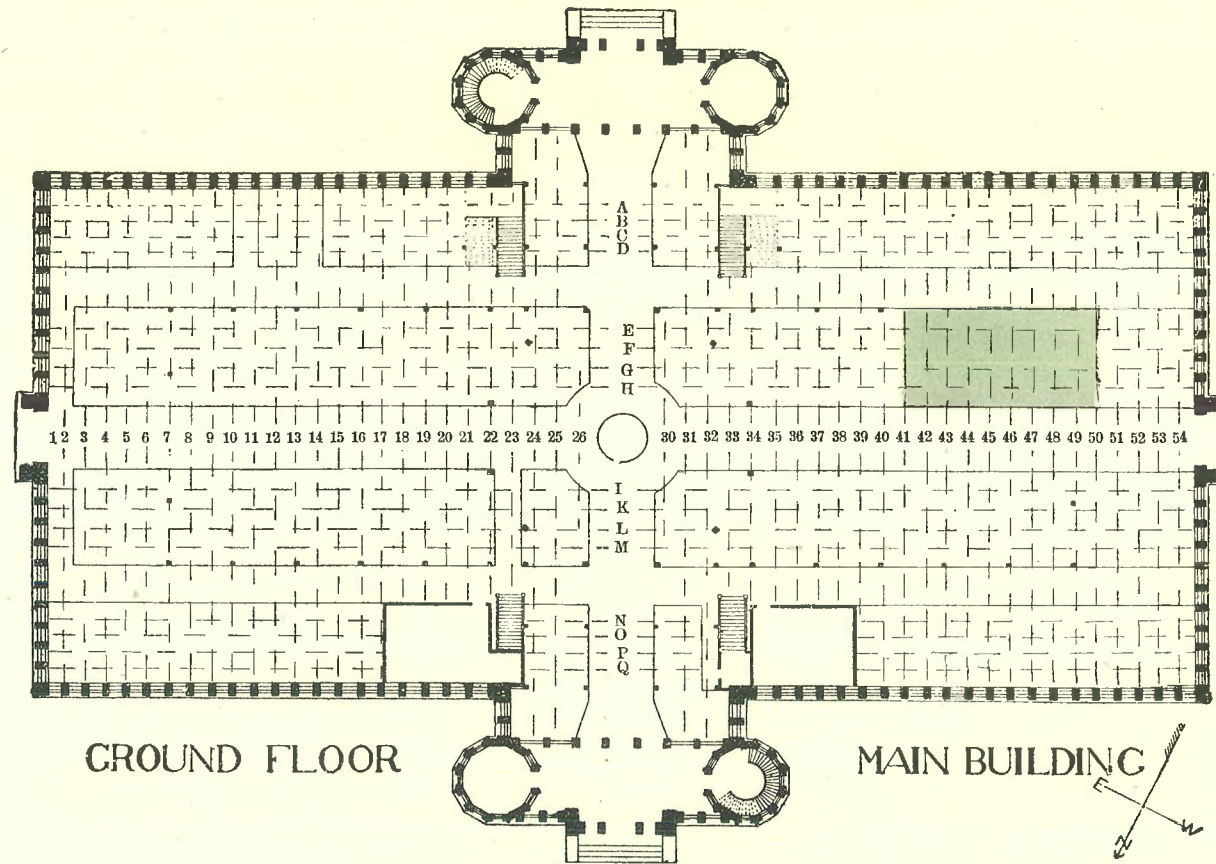

The Government aquaria, in the annex of the Fisheries Building, were converted into picturesque combinations of water and rock, where live fish were made to feel quite at home in congenial surroundings. In these aquaria, trout, carp, golden ides, and gold-fish disported. United States Fish Commissioner M'Donald, in speaking of the preparation of the saltwater for the tanks in which marine fish were placed, said of the Government exhibit:—

For three months we experimented with evaporating sea-water, and using the material for shipment to Chicago, in order to avoid sending water so far inland. For some mysterious reason the revamped sea-water we thus obtained would not do, and the fish died. We have found that by mixing a brine made from Turk's Island salt with natural sea-water, half and half, fish got along nicely in the combination. This is what we use in the aquaria. In all, we have about 70,000 gallons of sea-water for the saltwater fish. As it is something we cannot afford to waste, our arrangements for its purification are complete. It is conducted from the aquaria in rubber tubes to the filter, which is located in the cellar. This consists of stone, gravel, and sand made in strata, as in natural soil. The water comes from the aquaria into the top of the filter, and is drawn off from the bottom after it percolates through the sand and gravel. It then runs off into a cistern, with a capacity of 60,000 gallons. A duplicate set of pumps, run by electric dynamos, drives the water again to the reservoir in the top of the building. From there it runs back into the aquaria, entering through a jet just above the surface. The entering stream carries enough air with it to aerate the water and give the fish air. In the filter the top layer of sand will be changed frequently. With our fresh-water fish lake water will do fairly well. It is not clear enough, and must be filtered carefully. No attempt will be made to save it, as with sea-water."

The Government aquaria, as I have said, were in a circular building in this department, nearly 100 feet in diameter. A row of aquaria lined the outer walls with the space broken only at the doors, and the effect as one passed through the aisle was as if he were walking on the bottom of a lake, with the waters held back by a heavy plate-glass. The inner row of aquaria was 12 feet wide, and in the centre of the building a mound of aquatic and semi-aquatic plants. On this inner row was the large aquarium for the Mississippi River. It was 72 feet long, 12 feet wide, and 5 feet deep. A submerged bank, such as is so often seen in Western rivers, rose from the bottom of sand and gravel. Nearly every variety of fish found in the Mississippi Valley was there. Cat-fish, 80 lb. in weight, and 7 inches between the eyes, and sturgeon, 5, 6, and 7 feet long, were in the collection, with pickerel, outclassing the record, for company. The series of aquaria, showing all varieties of trout and salmon, extended along the south side of the building.

One peculiarity of the building was a remarkable odour, an odour such as one seldom meets with. It might be described as the concentrated essence of the odours from all the different kinds of fish in the various rivers, seas, lakes, and oceans of the world. To be able to get a scent of all the species of the finny tribe, both living and dead, in one breath, was an exceedingly rare experience, and it was found here.

NEW SOUTH WALES COURT. FISHERIES BUILDING--View 1.

NEW SOUTH WALES COURT, FISHERIES BUILDING. View II.

New South Wales Fisheries Court.

In this building New South Wales was allotted a space of about 3,000 feet, but I found, when placing the exhibits, that some I had expected, such as nets, boats, &c., had not been sent by the Commission, doubtless for good and sufficient reasons. Consequently I resigned the back portion of our space on the ground-floor, and, also, our allotted space in the gallery, to Canada. The space we occupied was bounded on the west by France, and on the east by Canada, the main avenue being north, and the minor passage south.

Within this space, with a splendid frontage to the main avenue, our exhibits presented a very striking and satisfactory appearance. Both our side enclosing-walls were covered with the very excellent representations of our fish by Mr. Podmore, and in the same place was the large photographic representation of the Sydney Fish Market, taken by electric light. Immediately in front of the court was a large model of the Sydney Lighthouse (Macquarie Light), of the following dimensions—base, diameter 3 ft. 6 in., height 12 feet—covered over with tins of preserved fish. The exhibit formed a very remarkable and attractive trophy of the Cape Hawke Fish Preserving Co., and the Clarence River Fresh Fish and Canning Co., as well as the exhibits of fish prepared with the assistance of the Chief Inspector of New South Wales Fisheries, were placed on pyramids raised on tables, and made an excellent appearance.

In the centre of the court I had constructed a large rock scene (9 feet in diameter and 11 feet high), on which, in a very natural attitude, were placed the seals from Seal Rocks, New South Wales. These exhibits had been forwarded over as skins; I had them carefully mounted by an expert, and the whole appearance of rocks and seals were remarkably effective. At the foot of the rocks a quantity of oyster exhibits were placed, giving an excellent finish to the whole scene. Other oysters and mussels were placed on appropriate tables. The collection of reptiles, prepared with the assistance of Dr. Ramsay, of the Australian Museum, placed in spirits in suitable jars obtained from Philadelphia, and as well as those of Mr. Holt, were a source of constant attraction to American visitors. The crustaceans also came in for a full share of attention. The model boat, with all its gear complete, built by George Barnett, was mounted on a stand, and beside it was the yacht gig by Fanner, which, on account of inadequacy of space, I was compelled to remove from Transportation Building. The *bêche-de-mer* and similar exhibits were placed on tables specially constructed for them, as were the fish oils and the tanned porpoise skins. A very attractive feature of the court were the pearl shells by Lichtner and Solomon, which were placed on pyramidal trophies. The fish-eating birds I had stuffed and mounted, and placed in two large cases which formed the extreme wings of the front of the court. On the tops of these cases were placed the large albatross and pelican, forming an excellent summit to the exhibits. The various pamphlets sent by the Commission were placed on tables for distribution, and were also handed to the officials in the courts of the various countries represented in the building.

The whole court was decorated with New South Wales flags and masonic blue banners, with "New South Wales" and "Australia," in silver letters, emblazoned on them, and the representation, as a whole, was very effective.

Of the other countries, Norway, Canada, and Massachusetts had by far the best displays, that of Norway being undoubtedly not only the most extensive but also the most characteristic and the most scientifically arranged.

Norway's

Norway's Exhibit.

In the north-west corner of the main building was the Norwegian exhibit. It was the most complete and attractive display in the Fisheries Department. Great skill was displayed in its arrangement, and every separate article was placed so as to be seen to the best advantage. Great economy was observed in the work of installation, and every available inch of space was occupied. The large posts extending from floor to ceiling were covered with artistic displays, and the walls on the north and west sides were hung with beautiful paintings and pictures executed by Norwegian artists. The complete exhibit was divided into five groups and represented over 100 individual exhibitors. In the first group were seen varieties of sea-weeds, mussel shells in endless varieties, casts of various species of Norwegian fishes and gaudy plumed aquatic birds. The next group contained paintings of herring fisheries and whale-fishing; also models of whaling steamers, maps, drawings, and literature illustrating fisheries; fishing gear and lines, nets, seines, weirs, lobster-traps, knives, gaffs, and models of fishing vessels. Maps showing statistics of Norwegian fisheries, foghorns, guns, harpoons, equipments for whales and porpoises, hooks with artificial bait, cod-fishing apparatus, boats, self-regulating line buoys, and winches for seines and sails were also to be seen in this group. In the third group fishermen's clothing outfits were displayed. It included skin and oil clothing and equipments such as boots and the regular fisherman's oilskin suits nicely made. The fourth Norwegian group was large enough to discount many of the exhibits in the building by itself. There were all kinds of fish cured and ready for food, and models of fish-curing and canning establishments were exhibited as well as models for drying, salting, curing, smoking, trimming, and cooking. There were also products prepared from fish, such as oils, roes, isinglass, and manures, and the methods and appliances for preparation were illustrated. There were sea and fresh-water pearl-shells, mother-of-pearl, sponges, corals, and other such products for purposes both useful and ornamental, and appliances for carrying fish and preserving them during transport, and models of fish-markets and connected appliances. In the last Norwegian group apparatus and implements for fish-culture were exhibited. Hatching, breeding, and rearing establishments, including oyster and other shell-fish grounds, were shown.

Canadian Exhibit.

Canada had the largest space of any country in the Fisheries Building. It was located just to the left of the main entrance on the south side of the building. The exhibits were neither so compactly nor so scientifically arranged as in the case of Norway. There was a good deal of the artificial look about Canada's display. The stuffed fish had an exceedingly dead look, as had also the aquatic birds and mammalia. The oyster, clam, and star-fish exhibit was excellent and met with hearty praise on every hand. The primitive Indian fishing gear was one of the most attractive features of the exhibit. Canada's display covered a wide range, there being an exhibit for each of the five groups into which the department was divided.

United States.

The different States of the Union were well represented in this building. Massachusetts made the best State showing, the Boston exhibit being very fine. Boston is without doubt the largest fish market in the world. In 1892, 90,000,000 lb. of fish were handled on the wharf alone. It is estimated that in 1892 208,000,000 lb. of fish products passed through the hands of wholesale dealers in that city, the value reaching the aggregate of \$11,000,000. Statistics show us that the United States lead all countries of the world for the amount in pounds and value of fish caught, England ranking second, and Norway ranking fifth, and yet praise for the finest exhibit of fish products must be accorded to Norway. The

The New England States made a very fine showing of the different appliances used in the fishing industry. They showed boats, pound-nets, trap-nets, weirs, seines, gill and purse nets, and lines. Mackerel and herring are caught in gill-nets. The cod is also caught in the same manner, but only in the three first months of the year, as the general mode of catching the cod is by line. The season's catch of mackerel for 1892 was very poor, as it has been for some time past. New England fishermen ascribe this to the use of the purse seine. A law was passed about six years ago prohibiting the catching of mackerel before 1st June. The object of this bill was to prevent the wholesale destruction of spawn fish when coming north in the spring. This law expired last year, but it certainly should have been continued. The fishery officials of the Canadian Government are very pronounced in their protest against the purse seine, as a destructive method of catching mackerel, and at the present time a proposition is before the United States Government to abolish the use of it. The purse seine can only be used of course when the fish school; but as they school in great numbers and always on the surface, it will be easy to show the variations. The difference between the gill-nets and the purse is as follows: The meshes of the gill nets are so made that the small fish, which are not good for market, can pass through, and in line fishing the smaller fish will not take the hook; but in purse fishing the net is so constructed that when it has been floated under the school of fish, the bottom is closed by means of lines and everything is thus brought on board the vessel. The smaller fish are then picked out and thrown overboard, and as it takes some time to do this, the fish are all dead or nearly so when they reach the water, and so great has been the slaughter that it has been stated that the coast from Boston Bay to Mantinicus Island, in Maine, during the month of August, from 5 to 30 miles off the shore, was covered with dead mackerel. This kind of work will of course drive the fish away, and as the fish have a tendency to come back to the place where they spawn, they do not appear in such great numbers as formerly. The modes of catching mackerel have varied. They used to be caught by seines and at night. The present method is by fishing by steam seine boats. Three of them were ready May 1st, 1893. A great feature of these boats is that the look-out man steers the boat from his post 25 feet above the deck, by means of wheel ropes, in the direction of the fish as soon as he sights them. It is estimated that these boats can make three sets against two of the old.

I have already made reference elsewhere to the fish exhibit in the United States Government Building, but I may here refer to some statistics which were published in that building showing the importance of the trade in that country. These statistics, it was explained, had been collected with considerable difficulty, as might naturally be inferred from their character. It was only by personal visits to those engaged in fishing, or kindred industries on the Atlantic, Pacific, and Gulf coasts, the great lakes, and the larger streams to tidewater, that it became possible to tabulate the figures for the year 1892. Of these the grand totals for all the States and Territories are as follows:—

Persons employed in fishing and fisheries	178,415
Number of vessels engaged in fishing	6,484
Net tonnage	172,319
Value of vessels, with outfits	\$14,137,075
Number of boats under 5 tons burden not registered in the Custom-houses	67,584
Value of these boats	\$4,419,087
Value of shore and other property directly tributary to the fishing industry	37,143,117
Total of investment in fisheries	55,699,279
Total value of product to fishermen	40,154,979

If half this total value is added as the amount of the profits of the wholesale and retail trade, subsequently—and this is said to be

be a reasonable allowance—the value of the trade will amount to \$60,000,000; and hence it is not surprising that the Government of the country is taking every possible means to assist this industry, by scientific research, for the purposes of increasing and cheapening this wholesome article of food. Further information on this subject will be found in the description of the fisheries exhibits in the United States Government Building.

ANGLING EXHIBITS.

The Western Rotunda Annex was chiefly devoted to a display of the various forms of angling apparatus, and a number of novel devices and improvements in angling goods were exhibited, chiefly by American houses.

Fishing Rods—Split Bamboo.

Perhaps the best display of fishing-rods was shown by A. G. Spalding and Brothers, of New York. The rods of this firm were of split bamboo—or as they are called in England—rent and glued. The improvements of the Spalding rod, known as the Kosmic Rod, in addition to the careful selection of materials and the first-class skilled workmanship employed in their construction, consisted chiefly in the peculiar character of the ferrule joints. The ferrules were short, but perfectly cylindrical and well fitted, requiring no locking device. In addition to the careful fitting of the ferrules, there was a collar of thin celluloid placed under the ends of the ferrules, thus materially strengthening the rod at the places where most rods are apt to give way. The collar was covered with a silk wrapping.

A novel feature in split bamboo rods was shown by A. B. Shipley, of Philadelphia. The rods were made of double enamel, that is, the inside as well as the outside of the rod was composed of six strips of the outer rind or enamelled surface of Calcutta bamboo, a plan which is said to add greatly to the strength of the rod. Two split bamboo rods, made by the inventor of this style of rod (the late Samuel Phillippe, of Eastern Pennsylvania), and which were made over fifty years ago and the first of their kind, formed an interesting exhibit.

Steel Rods.

The Horton Manufacturing Co., of Bristol, Conn., exhibited a new variety of fishing-rods, composed entirely of steel. These rods are made in three pieces, like other rods, and fitted with ferrules and guides or rings. They are formed of pieces of thin steel, bent around a mandril into a tube with the edges in opposition, but not braized. This arrangement allows not only a bending motion but a certain amount of twisting motion as well, and approaches very nearly the action of a wooden rod. The rods shown were very strong, and nearly as light as wooden rods of the same length.

Reels.

A number of improvements in reels, both multiplying and click, are shown in both the expensive and the low-priced article. In multiplying reels for bait-fishing, especially the large reels, some excellent reels were shown made with vulcanised rubber heads with aluminium spools and fittings, steel gearing, and jewelled bearings. Necessarily these reels are expensive—costing £10 and upwards, while some German silver reels, made in Kentucky, renowned for their fine workmanship and accurate adjustment, cost as much as a gold watch, and in many respects are quite as carefully made. They multiply four times, and are intended for making long casts from the reel. In fact I have seen them at the lagoon near the Izaak Walton cottage make casts of from 100 to 150 feet. These reels cost from £4 to £5 each. Some very fine and very light click reels for fly fishing were shown, weighing only an ounce or two, made of aluminium, while others for
salmon

salmon fishing were made of a combination of aluminium and vulcanised rubber. These reels are much less expensive than multiple reels having no gearing.

The automatic reels for fly fishing are quite a novelty. These reels were constructed on the plan of a spring tape measure, any slack being taken up by the strong coiled flat spring. The fish can take line from the reel, but any slack line is at once taken up, so that the angler has always a taut line. The reel is operated by a flat lever with the little finger, the lever lying along the grip of the rod. If it is thought desirable to reel the fish in, it can be done by pulling the line through the guide; when the spring takes it up.

One exhibit appears to be very excellent of its kind. It was shown by a Rochester firm. This automatic reel, the attendant stated to me, was an invention giving the angler perfect control of his line. With this appliance a slack line is an impossibility. It may be wound with the rapidity of lightning, or as slowly as desired. The beauty of it is that it winds on the barrel evenly without twisting or kinking. A manufacturing company of Bristol, Conn., showed fourteen styles of steel rods, which certainly seemed a vast improvement on the common jointed rods now in use.

A silk company had a working machine showing the silk fish-lines it makes in actual process of manufacture. In some beautiful samples of this work the heavier lines were about the thickness of a common thread of worsted, containing 576 threads of raw silk, the lighter lines containing 96 threads.

A Battle Creek, Mich., manufacturer showed his famous folding boat, the largest of these boats, which will carry four men, weighing with oars and complete outfit only 75 lb.

As a part of its exhibit the Chicago Fly-casting Club built on the banks of the North Pond and east of the Art Building a little staff-house which presented a complete reproduction of Izaak Walton's fishing-house on the Dove. The "Compleat Angler's House" still stands after two hundred years, a monument of one man's affection for the gentle art. The old house was built to accommodate Walton whenever the latter might come down from his city home, and this little building was a pretty representation of the original.

For the principal portion of the information herein contained I am indebted to Dr. Henshaw, in charge of the Angling Department, who kindly supplied me with a number of reports by the Expert Judges in this section.

Mines and Mining Building and Exhibits.

Description of the Building.

THE building devoted to Mines, Mining, and Metallurgy, although not having the same marvellous architectural beauty as some of the other structures, was, in my humble judgment, one of the best of the buildings in Jackson Park for exhibition purposes. With its large floor space, covering an area of $5\frac{1}{2}$ acres, and its extensive galleries, 60 feet wide and 25 feet from the floor, running round the whole building, well lighted on both sides by large windows, it was admirably adapted for the purpose it was intended to subserve. I think considerable credit was due to the architects for their avoidance of marked architectural features, which would necessarily be lost in consequence of the surroundings and the character of the exhibits placed within the building.

It was the first Exhibition Building that was distinctively devoted to the mining industry, and within its walls was gathered the first separate and comprehensive mineral and metallurgical collection of exhibits.

The building was rectangular, and embraced on the ground-floor spacious vestibules, restaurants, toilet-rooms, &c. On each of its four sides were placed the entrances, those on the north and south fronts being the most spacious and prominent. On the right and left of each entrance, inside the building, started broad flights of easy stairs leading to the galleries. These were 60 feet wide, and 25 feet high from the ground-floor, and were lighted on the outer sides by large windows. Above there was a high clerestory which extended entirely around the building. Between the main entrance and the building were decorated arcades forming an open loggia on the ground-floor, and a deeply-recessed promenade on the gallery-floor above. From this level there was a fine view of the lagoon, with its wooded island to the northward; whilst from the southern end the visitor looked out on the animated scene displayed by the great Central Court. These covered promenades were each 25 feet wide and 230 feet long, and from them access could be had to the building at numerous points.

The roof rested upon ten great cantilever trusses, so that the floor was practically unencumbered, there being only two rows of iron columns on either side. This was the first instance of the application of the cantilever system to building, and the result was a structure signally adapted to exhibition purposes, the gain in space being quite large.

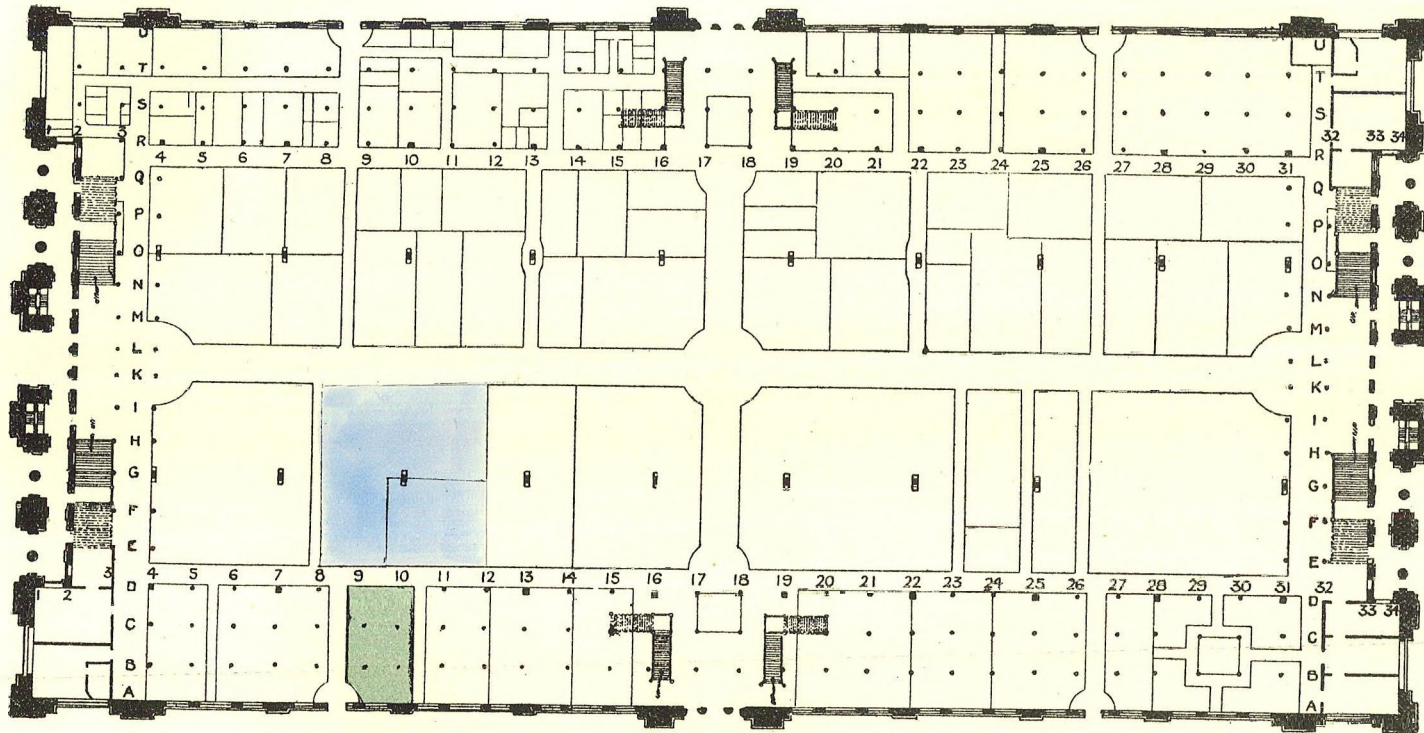

The cost of the building was \$250,000. It was commenced in July, 1891, and was the first building finished. In its construction there were employed 592,000 lb. of iron, 282 car-loads of lumber, and three car-loads of nails, while the glass in the skylight covered $1\frac{1}{2}$ acres.

Character of the Exhibits.

The exhibits seen within the walls of this great building were as varied as they were attractive and interesting. Here were presented all the precious minerals and gems, all the economic minerals and materials,

MINES AND MINING BUILDING.

(sig. 299)

—OFFICIAL ALLOTMENT OF SPACE— —MINES AND MINING BLDG.—
 —GROUND FLOOR PLAN— —WORLD'S COLUMBIAN EXPOSITION—

materials, all the metals in the crude as well as in the manufactured state, and all the machinery, implements, and appliances; in fact everything pertaining to the arts and sciences directly or indirectly involved in the mining and metallurgical industries. Of the official classification, twenty-seven groups and one hundred and twenty classes were required to cover the exhibits that were shown on the floor of this building. The exhibit space was laid off in regular sections so that the visitor could readily understand and follow out the installation.

Bullion Boulevard.

The wide central avenue, running the length of the building, and named "Bullion Boulevard," divided the foreign exhibits on the west from the domestic exhibits on the east. The boulevard was one of the most attractive and entertaining promenades on the grounds, and furnished a scene of striking beauty. The States and Foreign countries had here presented a large portion of their wealth of rare and representative mineral products, and built enclosing pavilions and pagodas of symmetrical design and graceful proportions.

Allotment of Space.

On the west side of this aisle were France, New South Wales, England, Canada, and Germany; Mexico and Brazil had large areas at the south end; as well as Cape Colony, whose exhibit of diamond washing, sorting, and polishing, was here a centre of attraction. Beyond these countries, Austria, Spain, Italy, Japan, Russia, and the South and Central American countries spread out their mineral treasures. Upon the east side of the boulevard, and facing it, were artistic façades of classic columns, capitals, and pediments, arched entrances and colonnades forming the structures erected by the United States of America. The north section was occupied with numerous exhibits of coal, iron, clays, building and ornamental stones, mined in the vast mineral belts of the Alleghanies and the central basin. In the south section predominated quartzose ores, the gold, silver, and precious metals, produced by the treasure States of the west.

Character of Exhibits.

Many features of unusual interest were to be found within the courts of the States, such, for instance, as the geological obelisk illustrating the geology of New York, the silver statue revealing the wonderful richness of Montana, the quarter-of-a-million-dollar collection of gold nuggets from Colorado, and the precious gems of North Carolina. All these, as well as other mineral products to be found within these structures, enabled the visitor to gain a comprehensive conception of the great mineral resources of the United States. Including some three or four displays in the gallery, thirty-two States in all were represented on the floor of the mining building. Beneath the gallery were in operation machines of every description used in and out of mines—all the usual methods and appliances for sinking, shafting, and driving levels; pumps and engines for driving and hoisting; trams and cars for loading and unloading; huge crushers for pulverising rock of adamant; ingenious apparatus for quarrying stone, and for turning and polishing into marketable shapes; roasting and chloridising furnaces; apparatus for refining precious metals, &c. A complete working plant in miniature illustrating the methods of placer and hydraulic mining was also shown. The outside exhibit of well-drilling machinery connected with this department was located south of Machinery Hall. Here were all the rarities of apparatus employed

employed for drilling for water, gas, and oil. The tramway connecting the outside ore-yard with the building was constructed to carry material for purposes of demonstration to the mouth of the tunnel, which ran across the south end of the building, but, owing to water, this tunnel was abandoned when constructed. The gallery was occupied with displays of a lighter and more technical character, which I may here briefly enumerate. At the north end one of the leading oil companies of the United States had an exhibit presenting the entire story of oil production, manufacture, and distribution. Near by were arranged a series of courts in which were grouped, according to affinity, all of the industrial economic mineral material, such as graphites, clays, asbestos, limestones, cement, salts, sulphurs, pigments, mineral waters, abrasives, &c. A national display of building-stones in cubes of uniform size was situated at the centre of the west gallery, and in connection therewith were to be seen very interesting enlarged microscopic slides of rock sections, &c. Next to this was a departmental coal display, consisting of samples of coal from all of the principal coal-mines of America, in uniform size, upon aluminium mounts, and arranged around a large plate-glass map, showing the geographic and topographic position of the contributing mines. An extensive coke-plant was reproduced in miniature. An operating assay laboratory was open to the inspection of visitors in the room at the south-east corner. In the western gallery, at its south end, the rooms which we originally occupied as offices before Australia House was erected, were devoted to a library for mining and metallurgy, with a very comfortable reading-room, in which the periodicals and other literature of mining were placed at the disposal of those interested in this subject. Here, also, the associated societies of mining and civil engineers had offices. Models of famous mines and of special mine-workings were exhibited in the north-east corner. Almost the entire west gallery was occupied by departmental collections in metallurgy and mineralogy, which were displayed in cases and cabinets of uniform size, and illustrated a valuable and scientific mineral series, while a sequential exhibit of metal-reduction samples exemplified the processes employed in the metallurgic arts. A low row of ground-glass transparencies hung before the windows, and showed pictorially the primitive appliances and methods used by the ancients both in mining and metallurgy.

New South Wales Court.

In arranging the space in this building to be allotted to our large and valuable mineral display, I found when I arrived in Chicago, in September, 1892, that an altogether inadequate allotment of about 4,000 feet had been made. The situation of the space was unobjectionable. I at once endeavoured to have the extent increased. The difficulty in connection with this matter arose from the fact that official notification of their location had already been made to the countries in the immediate vicinity of our space. I stated, as an ultimatum that all our exhibits would probably be withdrawn unless adequate provision were made for this most important department of our exhibits, and through the kind co-operation of Director-General Davis, after much communication with Belgium and the Latin Republics of South America, additional space occupied by Belgium and Cape Colony was granted to us, provision being made for those countries elsewhere. By this means we acquired a space of 13,920 feet, and I had hopes that, at a subsequent stage, I would obtain additional space from Canada; but in this latter anticipation I was disappointed. The consequence was that we were unable to make such a grand display as I had originally hoped; although our exhibits were well placed, the avenues through the courts were much narrower than I could have wished them to be. Notwithstanding this, I have no hesitation in stating that, taken as a whole, and regarded from an

NEW SOUTH WALES COURT, MINES BUILDING, CENTRAL AVENUE.

NEW SOUTH WALES COURT, MINES BUILDING, TRANSVERSE VIEW.

NEW SOUTH WALES COURT, MINES BUILDING, SHOWING TROPHIES OF BULK-ORES.

an exhibition standard or an educational standpoint, or as a display of the mineral resources of the country, our representation was unrivalled.

The following description of our courts in this building, as written by Mr. Carne, the Superintendent, will be found to be interesting:—

The New South Wales exhibit for the mines display at the World's Fair consisted of 2,550 packages, measuring 11,106 cubic feet, and weighing $275\frac{1}{4}$ tons. The contents of these packages were arranged on a floor space containing 8,301 square feet.

The court had a frontage of 87 feet on the Main Central Avenue, and a depth of 160 feet to the western wall of the building. A main divisional passage traversed the space at right angles to the frontage, the entrance to which was formed by two massive octagonal trophies of tin and copper ingots with bases of ores. Following this passage west, two raised platforms, one on either side, were met with; on these were advantageously placed four handsome upright show-cases with pyramidal plush-covered stands within, each containing rich exhibits of gold or precious stones, to be mentioned later on. The passage then passed under the centre span of a large triple archway, and through an avenue formed of full sections of coal-seams, ranging from 6 feet to 14 feet high; these sections were partially encased in panelled framings, which carried small archways, supporting trophies of flags and coats of arms. At about 60 feet from the western wall a cross-passage formed a good division between the metallic minerals and coal, and the non-metallic minerals and geological collections and maps. The entrance to the latter section was formed of large handsome marble slabs panelled into an archway frame; the main passage continued between large and massive pyramids of building-stones, trophies of cement, paint ochres, alumstone, &c., and terminated at the Superintendent's office. The whole court was decorated tastefully with trophies, formed of shields with the Australian arms and flags, which were advantageously placed at all convenient points. On the wall space and partitions excellent enlarged photographs of mining and cave views and geological and mining maps were arranged effectively.

The most striking objects in the court were the handsome silvered column erected by the Broken Hill Proprietary Company, and the massive triple archway which spanned a portion of the space not far from the frontage. The column will be described hereafter. The archways, having two clear spans of 11 ft. 6 in., and one of 15 feet, sprung from four massive pillars 12 ft. 6 in. high, and 4 ft. 6 in. square; two consisting of bituminous coal, and two of petroleum oil coal or boghead mineral. The bases of the pillars were formed of sandstone 1 foot in thickness, and capped by 6 inches of Sydney sandstone. The 11 feet of coal between the sandstone bases and caps of the two centre pillars represented about the average working thickness of the main (borehole) seam from which the coal was taken in the Newcastle coal-field. The sandstone bases represented the strata below the upper coal-seams, which are quarried in this district for building purposes, and the sandstone cap the upper beds of the coal measures at Sydney, and of which the principal public and private buildings of the capital are constructed. As before stated, the remaining pillars consisted of petroleum oil cannel coal, or kerosene shale as it is locally termed. The two principal mines in the Colony each contributed a pillar formed of rough blocks, and into which full sections of the seam were worked.

The superstructure of the archways, which rose about 28 feet from the floor, was covered with black cloth, and bore an inscription
on

on both sides in bold silver letters, giving statistical information of the quantities and values of the various metals and minerals produced in New South Wales from 1851 to end of 1891. The inscription is as follows:—

Total value of minerals raised in New South Wales from 1851 to end of 1891, \$453,353,378.

Mineral.	Value. \$
Gold	178,758,698
Silver, silver lead, and silver ore...	54,978,350
Tin	46,300,228
Copper	29,273,874
Antimony	562,778
Bismuth	178,075
Fluxes	511,701
Sundry minerals	844,648
Coal	124,195,672
Shale (petroleum oil coal)	6,885,269
Iron	1,864,115

It is worthy of note that a comparison of the *per capita* values of the production of the United States and of New South Wales respectively, for the ten years ending 1891, on an estimated population of 65 millions for the United States and one and a quarter for New South Wales, shows a result of \$149.5 to \$11.1 in favour of the latter. This calculation is based upon the return given in the 11th United States Census, and the Annual Report of the Department of Mines and Agriculture (N.S.W.) for 1891. Taking the total production of each country to the end of 1891 on the same *per capita* ratio, the result is also largely in favour of New South Wales. Though coal has taken, and is destined to hold, the premier position in the mineral productions of New South Wales as regards the value of its annual output, it is to the indigenous gold that the Colony owes its rapid advancement. Gold was first mined in Australia in 1851, though its existence was known and reported by several different persons at intervals antedating the above date by twenty-eight years; the first authentic record of its discovery was by a surveyor named McBrien in 1823. Recent researches, indeed, have been brought to light a record dating back four centuries. On an ancient Portuguese chart of the 14th century the north-west coast of Australia is depicted and marked Costa Dora, the gold coast.

At the present time the gold supply is chiefly drawn from reefs or veins, the easily worked shallow alluvials of the earlier discovered gold-fields having been worked out. Alluvial or "placer" gold-mining is, however, still carried on on a small scale in numerous localities, and in the New South Wales Court were exhibited samples illustrating the physical characteristics of the precious metal from all the principal workings, whilst neat labels afforded analytical information as to quality and value, from tests made in the Sydney Branch of the Royal Mint. Conspicuous among the gold specimens exhibited by the Department of Mines and Agriculture was a handsome nugget containing upwards of 313 oz. of gold, and a fine specimen of reef quartz with 258 oz. of gold. Mr. Isaacsohn, of Nundle, had a magnificent display of crystallised gold, as well as a large number of reef and alluvial gold specimens. In his exhibit was also included a number of large and handsome aggregates of quartz-crystals from "vugs" or cavities in the auriferous reefs in the Peel River District.

Professor Liversidge, of the Sydney University, in his collection of crystallised and other gold specimens illustrated some rare and specially interesting forms of occurrence.

The display of auriferous reef and lodestone in the New South Wales Court was as varied as it was extensive and massive. The exhibits ranged from carefully prepared general collections of hand specimens, illustrating the nature of the vein and lodestones and associated

associated minerals in nearly all of the principal mining districts of the Colony, to large blocks and pyramids of ores several tons each in weight. These massive displays arrested attention, and by the size of the blocks composing them, afforded some evidence of size as well as character of the deposits from which they were taken. In the arrangement of these pyramids, the position and transition of the ores from oxidised to sulphurised conditions was maintained in accordance with natural order; the sulphuret ores from beneath the level of the water forming the base of the trophies.

Gold-bearing reefs occur in New South Wales in sedimentary rocks of Silurian, Devonian, and Carboniferous ages, also in hornblende granite, porphyry, diorite, and serpentine. The auriferous alluvial drifts are of Permian, Tertiary, and Quaternary ages. Examples of gold-bearing veinstones, and of alluvial gold, from each of the above-mentioned formations were on exhibition.

In all the best known and proved mechanical appliances for separation and saving of gold from reef or limestones, a certain percentage of loss is inevitable even under the most kindly conditions of gangue, or association or refractory sulphides. Samples of veinstones possessing one or more of the above characteristics were also on exhibition. With a view of endeavouring to obtain some really practical results from the display at the World's Fair, large bulk samples of ores of a refractory character were brought to it for the express purpose of testing any new appliances or processes which it was confidently expected would be in full working order within the Fair grounds; and thus if a patentee should achieve results superior to any hitherto attainable, the mine-holder and the inventor would by this means be brought into touch to the mutual benefit of each and the good of the country at large. But it is a matter for regret that these expectations have not been realised. The mining machinery exhibits at the World's Fair fell far short of anticipation, little or nothing new was shown, and even the extremely limited display of well-known machinery was not fitted up on a working basis. Tests of ores on a reasonably large scale, such as would afford some indication of the value of the invention for the treatment of certain varieties of ore, were not possible owing to the almost total absence of adequate provision for sludge and other requirements.

Apart from the great practical and educational value of a display of mining machinery in active operation, the general attraction of the Fair to visitors would have been greatly enhanced by such a demonstration, as was evidenced by the daily-crowded condition of the South African space devoted to diamond-washing, cutting, and polishing.

Perhaps the most conspicuous object in the whole building was the silvered column of the Broken Hill Proprietary Company, which rose to a height of nearly 40 feet from the floor. The base of the trophy was formed of rough blocks of the native ores from the famous Broken Hill lode, 10 tons of which were used for this purpose. Over the rough ores were eight plate-glass compartments containing picked samples of the richer ores. From the top of the glass cases rose a handsome column supporting atlas and globe, the whole ornately figured, and covered with silver leaf. The complete column above the ores at base representing in bulk the average yearly production of silver from the Broken Hill Proprietary Mine during the first six years of its smelting operations. From May, 1886, to May, 1892, the total production during that period being over 36,500,000 ounces of silver, and in addition nearly 152,000 tons of lead.

In connection with this famous lode, which was fully represented by exhibits from all the mines along its course, a very important and critical problem presents itself, and one, too, which is more or less forcibly

forcibly obtruding itself upon the silver producers in almost every silver-field the world over, viz., the excessive percentage of zinc sulphide which makes in the material below water-level. In the lode in question this difficulty is still further intensified by the extremely intimate mixture, in almost equal proportions, of the zinc and lead sulphides, which renders mechanical separation impossible by any known methods. The ores at present operated are the easily worked oxidised masses above the water-level, and vast though the supply of such material undoubtedly is, yet at no distant date the refractory sulphide supplies must be drawn upon. The local conditions are, perhaps, the chief obstacles to the utilisation, with reasonable prospect of success, of any of the known processes for treatment of ores of the character indicated. Costly timber and fuel, owing to total absence of either within reasonable distance, and uncertain labour conditions, are the chief impediments.

It was hoped that by bringing a large quantity of the particular ore in question to the World's Fair, and thus affording practical evidence of new and abundant supplies of refractory material requiring an efficient economic process for successful utilisation, investigators and inventors gathered there from all countries would be stimulated to effort in that direction, the abundant supply in the New South Wales Court being at the disposal of such for experimental research and practical test.

Silver lodes occur in numerous localities over a large proportion of the area of the Colony, and the nature of the ores in them was fully illustrated by extensive collections of hand specimens and large bulk trophies.

Next in importance are the tin ores, of which an extensive display was made, embracing both lode and alluvial tin deposits. Tin ores were first mined in New South Wales in 1872 in the north-east portion of the Colony, known as New England. The tin production is a steady source of wealth, though the easily worked surface deposits and shallow alluvial leads first discovered have been, comparatively speaking, exhausted. As the "leads" or "gutters" were traced into deeper and wetter ground, generally covered by an extensive sheet of basalt, the annual yield decreased to its present stable condition. With the advent of more powerful machinery and a larger bases of operation the deep leads will be rendered more productive and remunerative. So far little has been done in the way of lode tin-mining. Several lodes have been worked to some extent in the New England field; but the irregular bunched character of the lodes deterred small parties from the continuous exploration necessary for proper and successful development. Near Broken Hill, in the north-western portion of the Colony, a number of tin lodes occur, some of which were partially opened a few years since during the mining boom in that district. The lodes occur as greisen dykes in schist country; the tin-stone being disseminated through the gangue in irregular bunches and scattered grains. The locality is naturally waterless, but no doubt in the near future present difficulties will be overcome, and this district will add tin to the list of its already great mineral productions.

Copper and copper ores formed a large feature in the display. A large trophy of ingots from the Nymagee Copper Mine surmounted a base of ores from all the chief mines, whilst in show-cases was a general collection illustrating the character of the ores in nearly all the known copper lodes in the Colony.

At the present time copper mining and smelting are practically at a standstill owing to the low price of copper; the conditions governing the production in Australia at the present time are such as to render profitable working impossible when the market price to the producer of copper falls below £45 per ton.

Bismuth

Bismuth ores occur in three localities in the Colony, but have been only exploited on a small scale in one locality; though a new find at present being opened at Pambula, from which a sample was shown, offers fair promise; at this locality it is associated with payable silver ore. At Kingsgate, near Glen Innes, bismuth mining was carried on for a short period. The lodestuff occurs here as "pipes" or bunches in granite near its junction with slate; nodules of bismuth up to 50 lb. weight were obtained. The ores consisted of carbonate, oxide with sulphide, the two former generally coating a nucleus of native metal. Under the method of working adopted considerable loss was occasioned owing to the fine powdery condition of the carbonate disseminated through the lodestuff. The ore and associated minerals at the localities mentioned are fully illustrated by specimens in the display.

Antimony in the form of star, granulated, crude, and artificial oxide, was exhibited by Lark and Sons, of Sydney, in the form of a massive trophy, about 16 feet high, facing the main avenue, formed of plates of star antimony, with show-case at the base containing the crude and oxide, and samples of the ores worked. A general collection of antimony ores was also exhibited by the Department of Mines and Agriculture. In the Macleay district, from which Lark and Sons exhibit was obtained, the lodes occur in Devonian rocks. In the Hillgrove gold-field antimony sulphide occurs as veins and bunches in the auriferous quartz-reefs. The antimony sulphide in this district contains up to 3 ounces of gold per ton, but owing to the difficulty and cost of extraction a large proportion of the gold is lost to the producer. The Garibaldi and Eleanora Companies on this field forwarded bulk exhibits for the purpose of having tests made of any new processes for separation which might be in operation at the World's Fair; but, as already pointed out, this purpose was defeated by the absence of any exhibits of the nature required.

Iron ores formed an important part of the New South Wales display, and much interest attaches to them, inasmuch as they form an important source of as yet undeveloped wealth. About twenty-five years ago iron smelting operations were begun, and were carried on for a short period on a limited scale in two localities, but were not financially successful owing to labour troubles, and the extremely low price of imported iron brought out as ballast. It is confidently anticipated, however, that at no distant date the iron-smelting industry will be established in one or more centres in the Colony. The most available deposits are close to railway carriage, and in proximity to both coal and limestone. The ores chiefly are brown hematites and magnetites. Large bulk samples of these ores from all the principal deposits were exhibited, as well as a large general collection of show-case specimens from all the known iron-bearing localities. Included amongst the bulk samples was an exhibit of magnetite from Port Stephens, near Newcastle, the great coal port. This ore was from the only extensively bedded deposit as yet discovered in New South Wales, and is close to water carriage and limestone. The presence of a high percentage of titanitic acid unfortunately renders this ore at the present time practically unworkable in its present condition, owing to the destructive action of the titanitic acid upon the furnace lining; but no doubt the difficulty will be overcome in the future, in view of the fact that titaniferous iron possesses special qualities which render it peculiarly adapted for certain manufacturers.

Chrome iron and manganese oxide are as yet practically unworked, though limited quantities of each have been shipped abroad, there being no local market for such ores. The conditions of land carriage and freight to a foreign market very materially bar the colonial article in view of the more cheaply won material of other countries. Chrome iron ore occurs in quantity in several localities, as also manganese oxide. Examples of these are exhibited.

Cobalt

Cobalt and nickel ores in the form of sesquioxide in manganese wad, and as arsenide with mispickel, were also shown in the New South Wales Court; an attempt to work the former by a leaching process was not brought to a successful issue. The arsenide of cobalt is likely to prove an important discovery. The lode occurs at the junction of intrusive diorite, along the contact of which with the slates it forms bunches; reliable assays of average samples have yielded 14 per cent. of metallic cobalt. A trial shipment of 30 tons of this ore has recently been dispatched to England.

Traces of nickel only have been discovered as yet in the Colony.

Platiniferous sand was exhibited from the North Coast, where it occurs in several localities, chiefly between the Richmond and Tweed Rivers. Fine gold occurs associated with it in the black beach sand, and for many years beach-working has been carried on for gold, especially after easterly gales. In the miners' ordinary cradles a small quantity of platinum collects on the blanketings, but no efficient means of saving this metal has yet been tried. The sand consists of ordinary quartz grains, titanite iron ore, zircons, and a little cassiterite. Platinum in limited quantity occurs also in small grains in the auriferous gold drifts of the Colony in several localities. Platiniferous lodestuff, with assay yields varying from a trace to 1 or 2 ounces per ton, has recently been discovered in the Broken Hill District; but so far, owing to the extremely fine state of division of the metal in the ore, no practical method of treatment has been suggested.

Mercury ore—cinnabar—has been discovered in three localities in the Colony, but not in payable quantity. At the first discovered locality it occurs as scattered grains in drift, in the other localities in serpentine and quartz veinstone respectively. Examples of the latter were shown in the display.

Lead ores are so intimately associated with the silver-bearing deposits of the Colony that no special mention need be made of them. As showing the importance of the Broken Hill Proprietary Mine as a lead-producer it may be mentioned that in six years the output of this metal reached a fraction less than 152,000 tons.

Zinc ores—the zinc blende—is also, unfortunately perhaps, associated in large measure with the silver lodes below water-level; but there is little doubt that when an economic process has been discovered for treatment of ores of this class, the large quantities of zinc, probably in the form of zinc oxide, will be produced in the Colony. An extensive display of the ores referred to was on exhibition.

Tungsten ores—wolfram and schleeite—were shown from several localities in New South Wales. These ores are not yet worked, but the recent great advance in their values will doubtless cause exploration of some of the known deposits.

Gemstones.—An interesting display of cut and uncut gemstones was made in the New South Wales Court by the Department of Mines, Professor Liversidge, and Mr. Isaacsohn. The occurrence and association of the diamond in the Colony was fully illustrated by a series of carefully prepared and excellently displayed samples of the diamond-bearing gravels, associated gems, minerals, &c., from a number of localities in which the diamond has been found. About 60,000 carats of diamonds have been obtained from the diamond workings of New South Wales; but mining for them has neither been extensive nor continuous. The stones exhibited were characteristic of the size and quality of the New South Wales diamonds, being small but brilliant. A recent discovery of emerald-bearing matrix was illustrated by a number of samples of the veinstone, and cut and uncut emeralds, from the New Emerald Proprietary Mine, Vegetable Creek, New England,
New

New South Wales. The colour of these gems is good, but the hardness of some of the matrix renders their extraction without injury very difficult. Beryl and topaz, of great beauty, were shown from the alluvial tin leads of New England in which they occur; together with sapphire, cairngorm, amethyst, &c. A small display of opals was made from White Cliffs, but these specimens are rather of mineralogical interest than economic value; opal of highest quality occurs in the fields and finds ready local sale; recently a rush has taken place to White Cliffs because of the quality and beauty of the later finds. Opal also occurs in a vesicular basalt at the Abercrombie River, samples of which were shown.

An interesting display was made of alumstone and alum crystals from a recently-discovered deposit in the Gloucester District. The Australian Alum Company, which made the exhibit, has commenced operations at Bulladelah, where the alumstone occurs as a massive outcrop resembling limestone. It is the intention of the Company to ship the stone as ballast to England and thus to treat it where sulphuric acid is obtained cheaply, for though very good results can be obtained locally by ordinary roasting and dissolving and evaporation, yet infinitely superior results can be obtained by the addition of sulphuric acid.

The western portion of the New South Wales space was devoted to non-metallic minerals, building stones, and fossils. The entrance was in the form of an archway, constructed of polished marble slabs and tiles. These marbles were of excellent quality and colour. So far little has been done in marble quarrying and working for building and ornamental purposes; and the finest slabs exhibited were from surface outcrops, being the first cut, and polished therefrom. Serpentine, of varying shades of colour and texture, was shown from Bingera and near Young, and a handsome verde antique porphyry from near Cowra.

Three large trophies, principally of sandstone, in 1-foot cubes, represented the building stones, which are chiefly used in the city of Sydney and in the Hunter River District. Sydney is situated on the Hawkesbury (triassic) sandstone formation, and many quarries are at work within the city limits. The stone is of excellent colour, grain, and of great durability; of high crushing stress, easily worked, and capable of receiving and retaining very fine edges.

The sandstone from the permo-carboniferous measures of the Hunter River District is usually of very fine grain, colour, and quality, and is extensively used in the city of Newcastle.

Granite from Moruya and Trial Bay was exhibited in the collection in large rough and smaller dressed blocks. The Moruya granite is a handsome grey stone, and is used for columns and pedestals. The tall polished pillars in the colonnade of the Sydney Post-office are from the Moruya Granite Quarry, also the pedestals of the principal statues erected within the city. Granite of excellent quality and great variety of colour abounds in the Colony, and will in the future be largely availed of for building and ornamental purposes.

A very durable stone from Bowral, syenite, was exhibited in rough-dressed blocks. From the compact texture, hardness, durability, and resistance to the ravages of seawater, this stone has been selected as the most suitable material for construction of piers, buttresses, sea-walls, &c.; it is also largely used for railway permanent-way construction, erection of public buildings, street curbing, and blocking.

Paint ochres of all shades, from light-yellow to rich red-yellow and purple, were shown by the Gordon Emery and Colour Company, J. Clabby, and the Kalsomine and Metallic Paint Company. The latter company also displayed a large exhibit of prepared kalsomines of

of exquisite shades of colour. The Gordon Emery and Colour Company have recently established works for the grinding and preparation of the ochres from their property.

The Cullen Bullen Lime and Cement Company made an important display of hydraulic cement, and illustrated its character and preparation by a series of samples of the raw material, and from the different stages of preparation to the finished article, and practically demonstrated its high character by a number of fine castings and printed reports of properly authenticated Government tests and uses. This cement, known as the "Kangaroo" brand, is largely coming into favour.

Amongst the numerous other economic minerals in the New South Wales Court which may be briefly mentioned were kaolin of high grade, barytes, limestone, calcite, tripolite, whetstone, &c. Six large geology show-cases were devoted to geological specimens, and these were arranged near the display of geological and mining maps of the Colony. The fossils consist of the characteristic forms from the principal sedimentary formations of New South Wales, and range in geological age from the upper Silurian (which is the oldest formation yet identified by organic evidence) to the Quaternary, each of the important divisions of the geological record within this range being represented. The whole were grouped, classified, and adequately labelled, and formed an interesting and valuable illustration of the geological formations depicted on the maps. Of the latter the most valuable was the geological map of the Colony brought up to date of the present year (1893). This map showed great advancement upon any previous issues in general artistic features, colouring, and elaboration of details. A striking feature in this portion of the display was the number of natural-size sections of the principal coal-seams of the Colony. These formed an important illustration of the massive sections of coal already mentioned.

The great value of the unique display which New South Wales made of her vast mineral resources was enhanced by a carefully prepared detail catalogue, which described minutely each and every exhibit from reliable reports; gave statistical information as to analyses, assays, and bulk yields wherever obtainable; and furnished a concise introductory account of the nature, occurrence, and associations, &c., of all the elements of her mineral wealth.

I may conclude this description by quoting the published opinion of a mining expert, who critically examined the Court and its contents:—"It was not a breach of courtesy to other exhibitors to state, what is generally conceded, that the best all round exhibit in this building of Mines and Mining is found in that court over which floats the light blue flag of New South Wales."

German Court.

The exhibits of Germany were very imposing, but, unfortunately, the most important of these, in the principal space, were not mining exhibits so much as representations of the manufacturing processes such as forging, casting, and welding, applied to steel and iron. These exhibits were truly grand, but quite out of place in a purely mining building. As a matter of fact the German Empire is the leading State on the European Continent as regards the quality and value of its mining productions, in which it is only excelled by England and the United States. The mining of precious metals, which predominated in former years, has lately found a rival in coal-digging, for in Germany and other European States just as much attention is paid to this branch of mining as to the others. The production of coal comprises three-fourths of the entire mining industry of Germany, and by it 800,000,000 merks (£40,000,000) were realised proper in the year 1891.

The

The main part of the exhibit was installed on the north gallery of the Mining Building, where an extensive exhibit of samples of minerals and a photographic display showing the geological formation of this source of Germany's industry in a scientific manner.

This exhibit was composed of five groups, formed according to the government districts in which the minerals are mined. The geological survey was illustrated by maps of the Kingdom of Prussia and the Thuringian States; samples of bituminous coal were shown from the Lower Rhine, the Ruhr District, and upper Silesia. Iron, zinc, and lead ores from the Siegerland, the Prussian Province of Saxony, and Upper Silesia were well represented. There were also specimens of gold and silver ore from the Kingdom of Saxony and the Hartz Mountains. The raw and unmanufactured salts of the potassium salt-mines of Stassfurt, and exhibits of the Royal saline at Schoenebeck gave some idea of this source of Germany's natural products.

The approximated value of iron production in the year 1881 (\$72,753,000) had increased to \$118,000,000 in 1890. Germany stands third among the iron-producing nations of the world.

Besides the exhibits mentioned, graphite and graphite manufactures, limestone and ornamental stone, quarry products, nickel and cobalt, were represented by individual exhibitors. The royal oberbergamt (assay office) at Halle made an exhibit of plans of the brown coal deposits and models of the brown coal-mines. The United Chemical Works at Halle, on the Saale, made an interesting exhibit of products extracted from brown coal, such as brown coal tar, illuminating oil, yellow oil, red oil, dark paraffine oil, paraffin, and candle materials.

Among the iron exhibits was a column of cast-iron pipe and sewer pipe, all artistically arranged, and a cold bent rail fifty-four metres long. Beams of ingot iron, twenty-four metres long, completed this most comprehensive exhibit.

The magnificent and imposing iron and steel trophy exhibit of Baron Stumm, a display made by the personal solicitation of the Emperor of Germany, erected at an outlay of nearly \$200,000, always arrested the attention of the visitor. Pyramids and branching columns of structural iron and steel were built up to a height of about 100 feet, and assumed figures as bewildering in ramification as they were graceful in outline. An entrance arch was surmounted with bronze allegorical figures, while within the space statuary groups of metal-workers and metal-working appliances formed an ornamental fountain. Lofty obelisks of polished beam and rail sections stood at the corners and on the rear wall. There was worked out, in mosaics of burnished blast-furnace slags, plans of the works and names of the products.

This German exhibit in the western gallery, in its central portion, contained a large number of most excellent models and specimens of metallurgical works, among which the model of a coal dust brick works was conspicuous. Specimens of the bricks as used for fuel were shown. There was also a model of the Royal salt works at Schoenebeck exhibited by the Huyssen firm, and various models of the processes of sinking shafts through quicksands. On one of these a pulsometer stood on a floating platform and pumped up a mixture of sand and water. Sections of the tubes used to form the water-tight wall of the shaft were linked together, as if in actual use, to form the wall of the exhibit. An interesting model was that of a man-engine in a shaft, showing the working of this process of vertical transportation. In addition to the models of the smelting works at Rorstag, Lautenthal, there were representations of those at Oker, Clausthal, and Gosler, and a great variety of models of the apparatus used in the various mining processes. In the court specially devoted to coal-

mining,

mining, there was a model showing the tipping of the coal trucks by means of a revolving steel circle, with catches to fit on the upper margin of the truck.

Austrian Exhibits.

In the Austrian exhibit there was a very interesting exhibit of crucible steel, termed "Poldihutte" (poldi-steel), from Kladno, Bohemia. Eighteen crucible-steel posts, in groups of three, formed a hexagonal booth. These posts were 18 feet long and were hammered from crucible-steel ingots which were 2 feet long by 1 foot square, leaving the base 1 foot by 1 foot, and the other or top end into first a hexagonal and then finishing into round steel $1\frac{1}{4}$ inches in diameter. The centre of the booth was formed of hammered steel in many shapes for commercial uses. The cases about this centre were filled with fractured steel, showing all degrees of hardness, from the mild to the hardest of tool steel. These fractures, under the magnifying glass, showed a perfect degree of homogeneity, a point in manufacture that has not hitherto been surpassed. An exhibit of scythes, hammered into exceeding lightness, was made. In another stand, files, hand and machine made, from the lightest for jewellers' use, to the largest, 16 inches, were shown. The latter were produced by the Steel and Iron Co., St. Egyd, Austria. At the front of the aisle, hanging up, was a rolled plate or sheet, 162 feet in length by 3 feet in width and $\frac{1}{12}$ of an inch in thickness, which is the largest plate ever rolled. It was made of iron and was rolled by a new process or arrangement of rolls, designed and patented by Herr Wittgenstein, of Vienna, and rolled at Rudolfshutte, Toplitz, Bohemia.

Cape Colony.

In the small but well arranged court of Cape Colony the exhibits from the celebrated Kimberley Mines of that country were shown. The original blue diamond-bearing earth, with the diamonds in the rough, were a constant source of attraction, especially on the days when the diamonds were washed out of the watery matter by the actual machines employed at Kimberley. A number of lapidarists from Tiffany's establishment cut the rough diamonds in a part of the space, and the various operations connected with the work were observed through the glass walls of the Court.

A most instructive opportunity was afforded the visitors at the Fair in the illustration of the processes employed to make a diamond ready to be placed in an ornament. First the clearing process, which consists in first making a nick in that part of the crystal below the part to be removed. The nick must always be parallel to an octagon, which forms the face of the stone. A quick blow is given a knife, which has been placed in this almost microscopic nick. If this blow has been successfully dealt the piece drops off and shows a smooth face on both sides. This clearing process is used only for gems containing flaws, and it is only necessary to a small percentage of gems.

The cutting of diamonds is most interesting. They are cut by the rubbing of two diamonds together. To do this they are cemented on the cutting stick with shellac. The dust obtained in the cutting is used afterwards in the polishing. When shaped for polishing, the gem is given to the setter. The setter secures the diamond in a cone-shaped, fusible metal, which has been fastened to the end of a stick. The point to be polished is always exposed, and points sharply outward. A diamond when brilliantly cut often requires to be set at least twenty, or thirty times. The process of polishing requires mathematical correctness, in order that it may, as nearly as possible, reflect the light that enters the centre of the stone. Diamonds are polished on horizontal circular disks or wheels of iron. The wheels are covered with oil and diamond dust. The light, life, brilliancy, and even colour of a diamond is almost entirely insured by its scientific polishing.

United

United States Exhibits.

Whilst foreign countries occupied the western side of the floor space, the American States exhibits, as I have said, were placed on the eastern side of Bullion Avenue, for the most part in separate pavilions of handsome and, in some cases, very elaborate structures. Classic pediments and columns, parapets, arches, and turreted battlements made a beautiful and interesting spectacle, each separate pavilion forming a fitting temporary habitation for the exhibits of the States. Every marble slab, the clay, brick, and tessellated pavement, was material selected for the purpose to represent the characteristic mineral of the State. In this way a monotonous repetition of mineral riches, either as heaps of ores or as carefully-arranged cabinets or cases, was avoided, and an ever-changing picture of mineral and metal wealth was afforded. A remarkable exhibit seen in the centre of the Avenue was an object of interest and wonder to every visitor. It was the column of coal, representing the famous 60-foot seam of anthracite, contributed by Pennsylvania. There was also another wonderful column arranged by the chief of the division of Mining Statistics and Technology. This column represented the mineral output of all kinds, for one second of time, in the United States. The base was formed of a block of bituminous coal 4 ft. 6 in. on every side; above was a smaller block of anthracite; then, in order of their volumes, limestone, natural gas, petroleum, iron ore, granite, salt, sandstone, phosphate rock, marble, gypsum, marl, mineral waters, copper, zinc, lead, and a number of other metals, the column being surmounted by blocks of the precious metals, and the summit being formed by a small group of gems. The quantities and values of the principal material composing the column, according to the latest Census reports, are as follows:—

Material.	Tons.	Dollars.
Bituminous coal	105,268,000	117,188,000
Anthracite	45,236,000	73,944,000
Limestone	5,000,000	2,300,000
Natural gas	15,000,000
Petroleum	54,291,000	32,575,000
Pig iron	8,000,000	128,337,000
Salt	9,000,000	4,716,000
Building stone	47,294,000
Phosphate rock	587,000	3,651,000
Marls	135,000	67,000
Mineral waters	2,996,000
Copper	38,455,000
Silver, troy oz.	58,330,000	75,416,000
Gold	1,604,840	33,175,000
Gems	235,000

The foregoing list does not, by any means, include all the minerals that made up the column nor the official Census list, but it comprises those which are the most important. To summarise the mineral wealth illustrated in this ingenious manner, and in the courts of all the pavilions of the different States in the Mines Building, I may here give the following figures:—

Metals	\$302,307,922
Non-metallic mineral substances	353,790,416
Value of miscellaneous minerals	10,000,000
Total	\$666,105,837

Remarkable Exhibits.

The most notable display in precious metals was the renowned Montana statue, "Justice," cast in solid silver, worth \$61,800, which rested on a plinth of solid gold representing \$230,000.

The

The largest and most complete exhibit of nickel ore made was that of Ontario. Upon a base of heavy masses of pyrrhotine and other nickel ores rested the cone-shaped concentrate or nickel matte, surmounted in turn by a huge ingot of pure nickel.

One of the most interesting collections of gems and semi-precious stones was that of New South Wales, by Kunz, the author of the standard work on "Gems and Precious Stones." This exhibit contained Amazon stones, noble opals, amethysts in glodes, hydrophanes or "mad" stones, sectionised and polished jades and agates, quartz, a tiger's eyeball 4 in. diameter, a collection of cones, flakes, and chips of obsidian, illustrating the ancient method of making spear and arrow points, and a great variety of gems, antiques, and curios, together with a set of illustrated works of ancient writers on gems.

In the Arizona section there was a magnificent show of variegated ores of copper, which vied in colour with the transformations of the kaleidoscope. Surrounding the massive piece of azurite streaked with green malachite, which formed the central trophy, were pictures and symphonies in blue, green, and silvered plush, and satin mineral surfaces. The polished sections of agatized wood, shown here as well as in the Manufacturing Building, were the largest and best specimens ever exhibited.

The singular but important use of asbestos as an incombustible fabric was exhibited by operating machines which took the crude rocky fibre through the processes of separation, carding, spinning, and weaving, and produced a theatre curtain or a suit of asbestos clothing. The exhibits of asbestos from Canada were very excellent and extensive.

Standard Oil Company's Exhibit.

A very remarkable exhibit in the north gallery was that of the Standard Oil Company, which displayed not only the results obtained by this company but also a summary of the natural oil resources of all the United States. In the centre of the exhibit was a large glass vessel, equal to the contents of a barrel, of crude oil, just as it is delivered from the pipe lines of Pennsylvania; in fact a mixed product of many wells, as pumped through the lines commercially. Shale cases, containing the leading products from the barrel, were displayed, such as naphtha and its results, burning oils and their different grades, and the residues used for lubricating purposes, the manufacture of paraffin oil, &c. The specimens in their different colours, about 200 in number, arranged in the order of their specific gravity, and other characteristics, were also shown. There was also a representation of the first refinery erected by this company, as well as one of a more modern refinery, in which all the stages of the various operations were shown by the collection of glass bottles filled with the various products from the different parts of the works. In another case were examples of the commercial uses to which paraffin is applied. A very interesting exhibit was the pyramid of barrels representing the oil-production of one day of the whole of the United States; and as it contained the equivalent of 142,000 barrels, the importance of the industry was at once forcibly conveyed by the exhibit. The pyramid was painted in various colours, which were intended to indicate the proportions of the various products—burning oil, naphtha, lubricants, &c. A large and curious collection of lamps, ancient and modern, was also shown, together with a large light-house lamp burning petroleum; and to complete this very remarkable exhibit there was a modelled geological section nearly the length of the gallery, explaining the different formations with which the occurrence of oil is associated.

The

The Galleries.

In the north end of the western gallery the mineralogical section was filled with cases containing hand specimens of American minerals of every kind, but the system of classification and examination was very crude. One interesting exhibit was a series of large prints on glass, or transparencies, showing the state of mining processes in the 16th century. Just beyond this part was the large and varied collection of phenomenal geology by the celebrated Ward, of Rochester, N.Y. There was in the north gallery a splendid map in relief of the Rocky Mountains (sea-level), and several of the Sacramento Valley, and others representing the State of New York, which were remarkably well executed. In the east gallery there were a number of remarkably good booths, highly decorated and very ornamental, from the different American States, containing representative exhibits of sulphur, salt, mineral waters, and other matters contained in the group 40 to 48 of the official classification. At the southeastern end of the east gallery were some rooms devoted to the chemical analysis of ores, &c., and containing the usual apparatus for this purpose. Here the chemist was enabled to make assays and similar tests, and experiments of a practical nature were carried on during the currency of the Exposition.

Coal-mining Machinery.

Amongst the mining machinery exhibits under the eastern gallery perhaps one of the most interesting and important to the coal operator was that of the Jeffrey Manufacturing Company, of Columbus, Ohio. Here were shown the latest improvements in coal-mining machinery, operated by air and electricity. The machines exhibited were the result of years of careful study and experiment, and have rapidly advanced in perfection since 1877, when the first successful coal-mining machine, operated by compressed air, was introduced by this company into the Hocking Valley. Since that time no fewer than 500 air-machines have been put out, and are working successfully in every coal-producing State in the United States, as well as in British Columbia.

The rapid advance of electricity as a means of conveying power was utilised by this company, and they now have over 100 machines so operated, while they turn the same agent to account in lighting the mines, as well as for running mining pumps, ventilating fans, and hauling the coal out by electrical locomotives. The extreme flexibility of the conductors, and the ease with which it can be subdivided and transmitted from place to place, makes it the best medium by far for power transmission in mines.

This mining machinery exhibit consisted of electric mining locomotives, electric and air mining pumps, electric and air drills, and electric and air under-cutting machines. The under-cutting machine is made substantially in the following manner:—A rotary cutter bar 3 feet long, into which steel cutters are inserted in such a manner as to present a cutting edge along its entire length when revolved on its axis, is held by means of bronze journals at one end of a sliding frame, having an electric motor or air engine at the other end. The speed of the motor or engine is reduced by suitable gearings, and connects through a shaft with the cutter-bar by means of an endless link chain belt, which drives the bar and drags back part of the cutting. Three small chains act as conveyors for the cuttings, and run in the same plane and parallel to the driving chain. The whole frame, with motor, bars, and chains, slide freely in a stationary frame, which is held securely in a horizontal plane by jacks placed at each end.

This

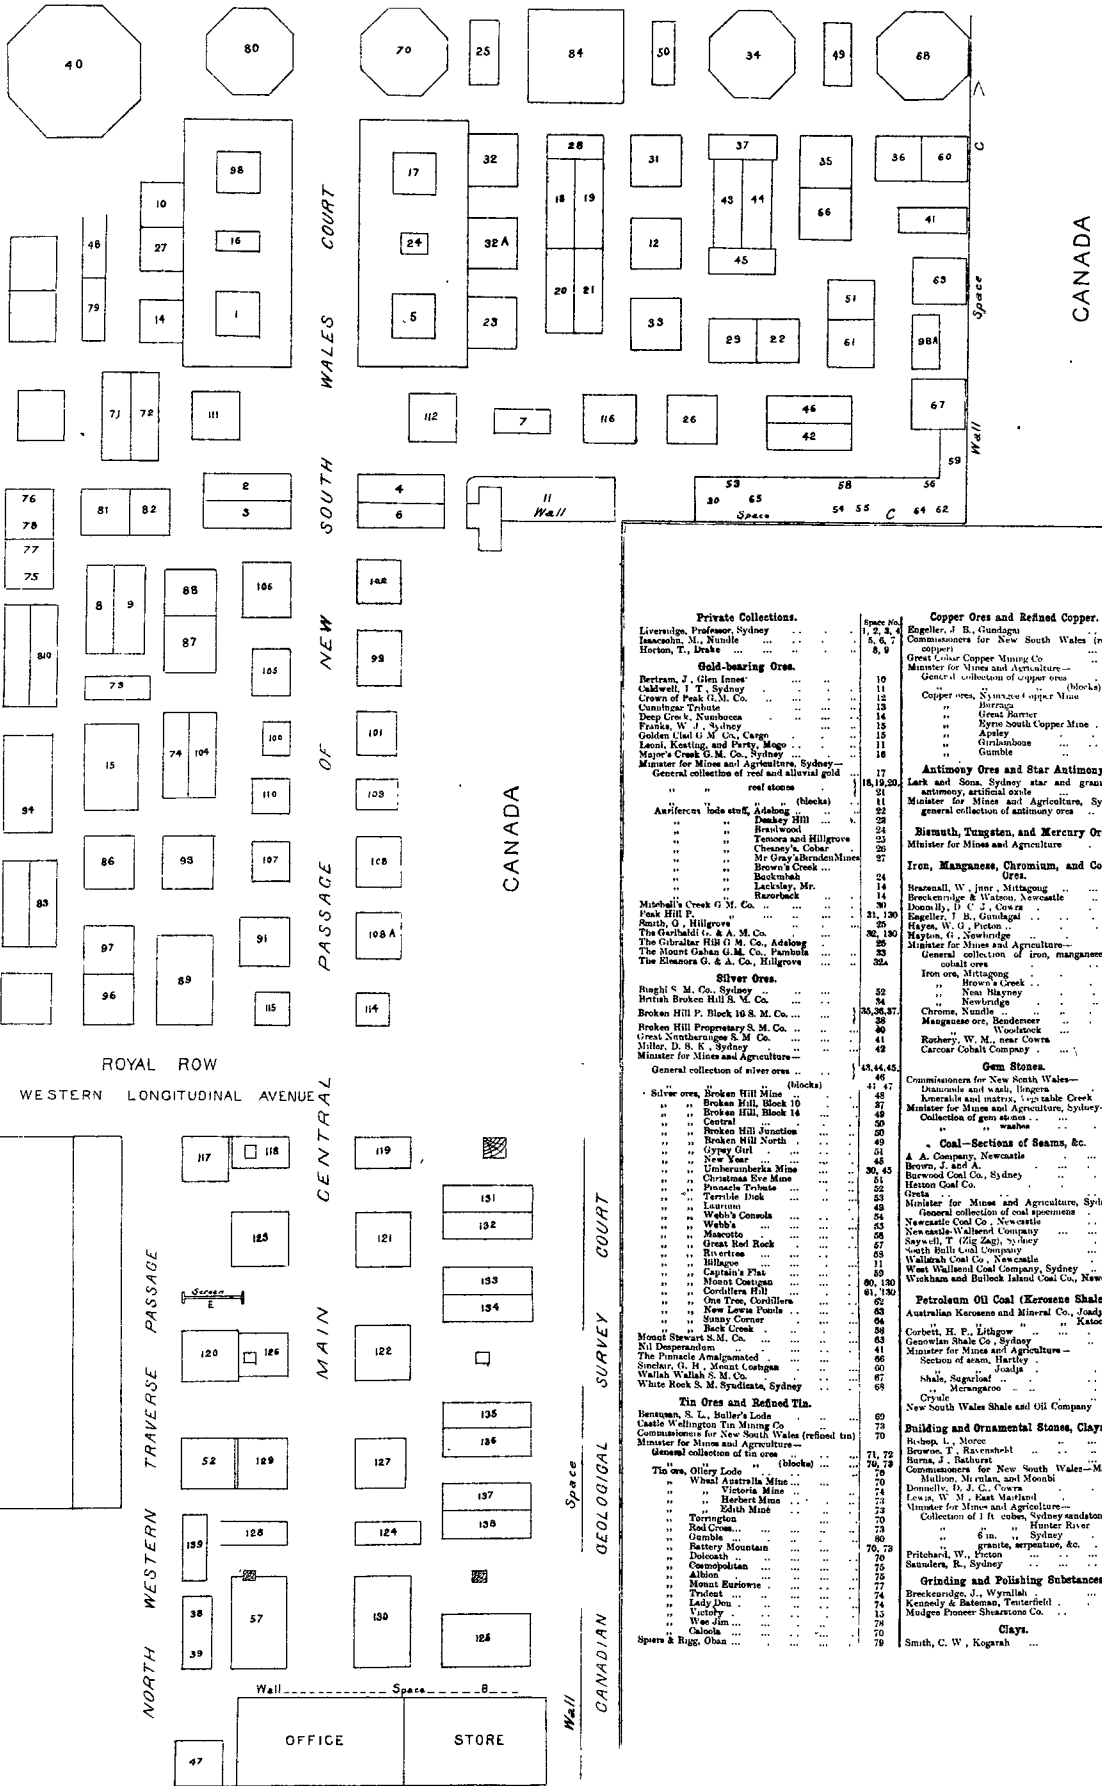

This frame acts as a guide to the cutter-bar frame, and is provided with two racks, into which two pinions, on the sliding frame, run in such manner as to feed the bar forward or backward as they are engaged into one of two worm wheels, which are driven by the motor in opposite directions, the one driving the bar ahead having a slow motion, the other running faster, thereby making a quick return. The method employed in mining coal is as follows :—

The machine is placed cutter bar end against the wall, at one end of the same, with the frame at right angles to the face. The machine is then clamped securely in position, started, and a cut made the required depth ; then the bar is withdrawn, the machine shifted to one side the length of the bar, and operated as before until the entire wall is undercut. Holes are then drilled near the roof, into which blasts are placed, and the coal is blown down, broken up, loaded, and hauled away. In this manner from 1,200 to 1,800 square feet of coal are easily undercut in ten hours, reducing the labour, waste of coal, and cost of mining the same to a minimum. The drilling is all done by air or electricity, the company making apparatus especially designed for that purpose, which is as compact and light as is possible. With these drills 6-foot holes, 2 inches in diameter, are drilled in one minute. They also exhibited coal-conveying, elevating, and screening machines, which they manufacture in endless variety.

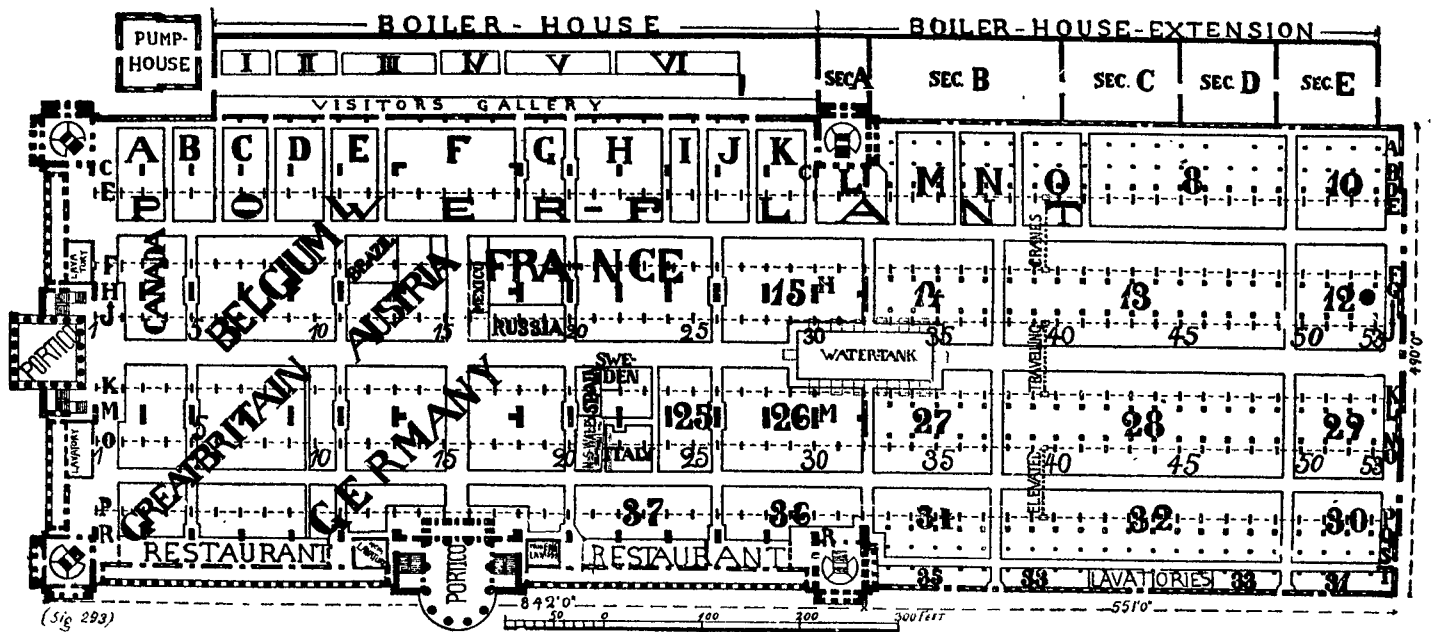

Their different classes of apparatus are carefully illustrated in descriptive catalogues, especially prepared for World's Fair distribution, and which they gladly mail, post paid, to interested parties desiring the same.

As has already been stated, I experienced great disappointment in consequence of the absence of machinery suitable for the treating of the large quantity of low grade and refractory ores which, at my suggestion, had been forwarded for practical testing, in order to discover, if possible, economical methods of reduction. In the absence of this information I obtained, on the recommendation of the Premier, the assistance of Mr. Jewell, who travelled over various parts of the United States in order to investigate the methods employed at various mines and smelting works. The information which Mr. Jewell has supplied (which I hope will be of value to our mining community) will be found in Appendix L.

GROUND FLOOR PLAN, MACHINERY HALL, WORLD'S COLUMBIAN EXPOSITION.

MACHINERY HALL.

Machinery Hall, or the Palace of Mechanic Arts, and its Exhibits.

ALTHOUGH this building was not of such vast proportions as the Manufactures Building, and had not the same enormous roof span, it was nevertheless an imposing piece of engineering work, as well as a beautiful architectural structure. In regard to site its chief façade fronted upon the great central basin; it lay south of the Administration Building and west of the Agricultural Building, from which it was separated by the north branch of the lagoon.

Description of the Buildings.

The main building was 850 feet long and 500 feet broad, and with the Machinery Annex and Power House cost about \$1,200,000. The building was spanned by three arched trusses, and the interior presented the appearance of three railroad train houses side by side. These iron trusses were about 50 feet on centres, and the spans about 125 feet each. The naves were lighted and aired from above by large monitor roofs; in the centre three domed roofs, each covering an open space 125 feet square, took the place of monitors. Outside of this immense three-naved room on the north-east and south ran a 50-foot wide two-storey building. This opened directly on the main hall; both on the first floor, and on the second floor on the north and east fronts, forming a great gallery.

There were two main entrances to Machinery Hall, one on the north facing Administration Building, and one on the east facing Agricultural Hall. In each of the four corners of the main building was a domed pavilion containing a grand staircase, and there were other staircases adjacent to the two grand staircases referred to. There were other entrances along the sides and ends of the main hall and annex, giving ample accommodation to the immense crowds.

The annex building contained three naves, and ran 550 feet to the westward, carrying out the long naves formed by the trusses in the main building.

On the south of the main building for its whole length was a one-storey structure, which contained the vast steam and electrical plant which supplied power and light to the whole of the Exposition buildings and grounds.

The area of Machinery Hall was $17\frac{1}{2}$ acres, of which 425,000 square feet were in the main hall, and 269,990 square feet were in the annex. This total was not quite as large as the space covered by the great Machinery Hall and its annexes at the Paris Exhibition of 1889, and the demands for space were far in excess of that at the disposal of the Exhibition authorities. The fact was much to be regretted. A large number of exhibitors had to curtail their space, much to their disappointment, while others determined not to exhibit. Their disappointment was shared by the visitors, especially those from abroad, as the United States could not organise any exhibition more popular than that devoted to machinery, America being par excellence the home of mechanical ingenuity.

Although more fully described elsewhere, I may here give a short account of the installation for the generation of electricity for power transmission and lighting, inasmuch as all the machinery for
that

that purpose was housed in this building. The heart of the Columbian Exposition was in Machinery Hall. From there its vital force leaped through a thousand channels to every part, infusing that light and life which made the White City the grandest achievement of man's achievements. The adoption of electricity on a very large scale for driving machinery in motion was one of the most interesting features of the Exposition; 25,000 indicated horse-power was provided, or 25 per cent. more than would be necessary to drive two of the largest British battle-ships of the Royal Sovereign class at ordinary full speed. This gigantic power-station formed an annex to the Machinery Hall. It was arranged along the south wall, a space being reserved 850 feet long by 150 feet wide for the purpose. This building contained the engines, dynamos, and boilers (themselves exhibits) for generating steam and electrical power, which are fully described in a subsequent part of this report. The conductors, after leaving the dynamos, were arranged in a suitable fire-proof rack under the main floor, about 150 feet from the south wall and running along the length of the building. From the rack five distinct groups of feeding wires started to supply various sections throughout the grounds and buildings. Starting from the generating station, a tunnel was provided and its passage was of sufficient capacity to accommodate 150 insulated cables of varying sizes up to 600,000 millimetres diameter. The tunnel leaving the generating station ran north under the Machinery Hall and across the space in front of the Administration Building to the Electricity Building. But a full description of this tunnel and its contents will be found in the report of the Electrical Building.

The whole of Machinery Hall throughout rested upon planking and trestle work foundations. Its frame was very largely of wood, but the main trusses spanning the building were of iron, and of such width that they will be serviceable in the future in the construction of railroad service. The main building and annex added together gave a perspective of nearly 1,400 feet in a straight line. In each of the naves an electric travelling crane moved from one end to the other. These were used for installing and moving the machinery exhibits. Platforms were built on these travelling cranes, and they were used to carry visitors.

The exterior of the building was covered with staff, which was used for the covering of all the other buildings at the Exposition. In the figure and ornamental work every attempt was made to indicate the purpose of the building, the statues representing mechanical force, or carrying portraits, or the names of inventors.

Running the entire length of the main building and the annexes were three avenues or aisles, the centre one 25 feet width, and the sides each 15 feet in width. At the western extremity of these aisles entered the tracks of the auxiliary railroads for the conveyance of heavy machines to the first cross aisle, from which the travelling cranes carried them.

The comprehensive character of the display to be seen in this branch of the Exposition was apparent from the classification. Eleven groups, comprising eighty-six classes, were devoted in the general classification to the Department of Machinery. Among these eighty-six classes were found almost every known mechanical device.

New South Wales Court.

In this department we had allotted us originally a space of almost 3,000 feet, but, in consequence of the paucity of our exhibits in this section, I resigned the back portion of our space to Germany, retaining 1,425 feet. The Court was walled round, as our chief exhibits were the large photos. of the water supply of Sydney and the hydraulic cranes

Exhibit of Sleepers and Steel Rails. Transportation.

cranes at Newcastle, for which screen space was required. This court also contained the fire-escape of Dr. Moir, the series of bellows by M'Nab, and the Austin perfect patent washer, as well as the patent grease interceptor of Mr. Griffiths, of Ashfield, and the patent rail switch of M'Creddie. In large and suitable glass-covered cases, on tables specially made, were exhibited the beautiful specimens of typographic electrotypes sent by Mr. Potter, and the specimens of heraldic and commercial embossing and chromolithography of Messrs. Turner and Henderson. To make the court attractive, and to fill up the space, I permitted Mr. Gregor, of Sydney, to erect a band-saw, with which articles of fancy, cut from the timbers obtained from our forestry exhibit, were made daily with the power placed free of cost at our disposal. There was also a stamping-machine, made by the Hoskins Engineering Co., with which medals marked as stamped in the New South Wales court, World's Columbian Exposition, were produced.

Classification.

The arrangement of the Machinery Department included eighty-six classes, collected in the following groups:—

GROUP 200.

69. Motors and apparatus for the generation and transmission of power, hydraulic and pneumatic apparatus.
70. Fire-engines, apparatus, and appliances for extinguishing fire.
71. Machine tools and machines for working metals.
72. Machinery for the manufacture of textile fabrics and clothing.
73. Machines for working wood.
74. Machines and apparatus for type-setting, printing, stamping, embossing, and for making books and paper working.
75. Lithography, zincography, and colour printing.
76. Photo-mechanical and other mechanical processes of illustrating, &c.
77. Miscellaneous hand-tools, machines, and apparatus used in various arts.
78. Machines for working stones, clay, and other minerals.
79. Machines used in the preparation of foods, &c.

The contents of Machinery Hall were the products of the tireless thought, labour, and experiment of millions of men, each having added his mite to the total sum of exact knowledge exhibited in the mechanical wonders which amazed and bewildered every beholder.

The constant demand for great steam power, combined with safety and economy, produced in the group of fifty-two boilers the highest type and perfect arrangement of steam generators. The old cylindrical shell and modern return flue boilers were completely discarded, each of those exhibited and used being of the water-tube type, a type as old as Watt's tea-kettle. Difficulties of construction and the simplicity and cheapness of the shell boiler checked its development and use until changed conditions and improved tools now make it the only type of boiler capable of supplying the power with the safety and cleanliness required by the needs of the Exposition. These boilers, working under a pressure of 125 lb. to the square inch, developed a combined force of from 25,000 to 30,000 horse-power. This great power being divided into some 11,000 tubes in the fifty-two boilers reduced the danger of an explosion to a minimum. This was illustrated by the fact that several of these tubes burst during the course of the Exposition without damage, except to the tubes actually ruptured.

ruptured. The fuel used was oil reinforced in heating power by a jet of steam, the flow being regulated by the simple movement of a valve. The absence of coal, ashes, dust, and customary smudge of the common boiler room permitted the firemen to wear white uniforms, and enabled some of the exhibitors to paint their boiler fronts a lily white. The steam supply operated eighty-three engines, which illustrated the methods of converting steam-power into motion. The great variety and complexity of the mechanism by which this transformation was effected furnished an interesting but perplexing sight, and yet amid all its intricacy the essential parts of each engine were but the more perfect mechanism of the Watts, Stephenson, and Fulton of the past. The cylinder, piston, crosshead, connecting rods and crank, and eccentric were in them all, more beautiful in form, perfect in fit, and effective in operation. The rotary engine, which a few years ago concentrated so much attention from machinists, and by which the more perfect and economical use of steam was to be effected without the use of the parts above mentioned, had no place in Machinery Hall, nor was there any form of engine exhibited in which these parts were absent.

Improvements in Modern Engines.

In Appendix M will be found a detailed statement of these various engines, but in this plan I desire to refer to the leading principles involved in their construction. The most conspicuous, because of its size, was the Allis engine. This machine represented the development of the general horizontal type.

The distinctive lines of the improvement illustrated in the engines exhibited apart from the scientific distribution of metal, combining strength with lightness and beauty of form, together with accuracy of fit and finish, were to be found (1) in the variety of valve motions designed to secure perfect control of the admission and exit of steam into and from the cylinder; (2) the utilisation of the expansive force of steam under high pressure; (3) high speed; (4) economy of space.

The prevailing type of valve was the Corliss, the name given to the 1,000 horse-power engine which furnished power at the Centennial Exposition at Philadelphia and now in use at Pullman. This valve was also used on the 2,000 horse-power engine in Machinery Hall. This valve motion is a combination of four cylindrical valves, one at each end of the upper side of the cylinder for the admission of steam, and one at each end of the lower side for its exit. Perfect and instantaneous regulation of these four valves is obtained by mechanism so complex and costly that machinists are stimulated to seek more simple and cheaper methods, many of which were illustrated in the engines exhibited.

The value of utilising all the expansive force of steam was shown by the fact that the expansion was the prevailing type, and the great Allis engine with its four cylinders showed the highest development. The application of the expansive use of steam was not confined to the stationary engines, but was also the prevailing type of the locomotives exhibited. Nor was its adoption limited to American engines. English, German, French and Belgian exhibits showed the universal recognition of its value. In this, as in the valve motion, the principle is the same yet the methods adopted were quite varied. The Allis engine had its four cylinders set at the four corners of a square, the course of the steam passing through these cylinders forming the letter "Z." Each cylinder increases in size proportionately with the decreasing force of the steam, its expansive force being exhausted in the fourth or low-pressure cylinder. The decreased pressure of the steam in this cylinder is assisted by the vacuum formed by the condensation of the steam

steam in the condenser, operated by a separate engine. Other engines had the cylinders in "tandem," one ahead of the other, some side by side, or one directly over the other.

For economy of space and high speed the vertical or marine type of engine seems destined to succeed the horizontal type. The Edison, Westinghouse, English and German exhibits showed splendid engines of this type.

In the English exhibit the Williams' high speed, central valve, vertical engine greatly attracted the attention of machinists employed by the Exposition Company to erect the various engines exhibited. One of these engines, a triple expansion of 360-horse power, ran the great search-lights, furnished by Schukert & Co., a German firm, on the Manufactures Building. This engine occupied a space of about 8 feet by 8 feet by 6 feet, and ran from 300 to 400 revolutions per minute. One end of the triple crank shaft connected directly with the dynamo. The governor fixed at the other end of the shaft operated a throttle-valve. The steam valves were in the piston-head, and exhausted directly into the air. The small size of the engine and its plain appearance caused it to be overlooked by many, but machinists did well to give it more than a passing glance. In order that the best information on this subject might be provided, I have had prepared a complete account of these engines, which will be found in Appendix as stated at the beginning of this article.

Having now referred to the great engines exhibited in Machinery Hall it will not be inappropriate as a contrast to mention the smallest engine in the building.

This engine, which, together with the boiler, could be covered with the bowl of an ordinary wine-glass, was a high-pressure beam engine, constructed principally of gold and silver, and was composed of over 150 pieces. The diameter of the cylinder was $\frac{1}{16}$ of an inch; length of stroke, $\frac{3}{16}$ of an inch; diameter of flywheel, $\frac{3}{8}$ of an inch. The cylinder, cross-head, and beam were made of gold, and the boiler of silver, in five separate sheets. The screws which held the several parts together were so small that they could scarcely be seen with the naked eye. The engine, boiler, stack, and plate, on which the whole rested, weighed 9 dwt. and 10 gr. (less than $\frac{1}{2}$ oz.)

In the tools used in the construction of the mighty machines just described was shown the same perfected growth which comes alone from patient industry and experiment. The musical dreams of a Mozart, or the artistic inspiration of a Michael Angelo have no parallel in the world of machinery. From the open blacksmith's forge and his simple tools to the furnace, steam-hammer, shears, punch, bulldozer, drop-hammer, and electric welding machines, the progress has been step by step. To-day the smithy has been transformed into a machine shop, and Longfellow's "Village Blacksmith" remains but a pleasant memory of the past. To sever a bar of iron 5 inches square or punch a 3-inch hole in a plate of iron 2 inches thick, when highly heated, was something of a job for a blacksmith and his helper. Some of the machines exhibited did this with cold iron as if it were so much cheese. From heavy connections for engines and other heavy machinery to the most delicate parts of the sewing-machine, a range of forging that would test the skill of the best blacksmith is now done with great rapidity and perfection by the drop forge. A fine exhibit of this work was shown by J. H. Williams in the model machine shop in Machinery Hall, and by the United States in the Government Building.

Another attack on the ancient blacksmith by the machinist and electrician was exhibited in the electric welding machines of the Thompson Electric Welding Co., in the Electricity Building. The principle

principle involved is that of causing currents of electricity to pass through the abutting ends of pieces of metal which are to be welded, thereby generating heat at the point of contact. The scope of this welding process is almost unlimited, passing entirely beyond the range of forge or furnace. The link of the lady's smallest watch-chain, or the anchor chain of a man-of-war can be welded with equal facility. Railroad frogs, crossings, or rail joints can be welded solid, or the boiler head of a locomotive can be sealed by this magic force.

The planers exhibited ranged from the small machine worked by hand to the giant of 30 foot bed and 12 foot all round clearances. The improvements secured increased accuracy and scope of work, with care and quickness of manipulation. A screw set at an angle of 30 degrees to the run of the bed was substituted for the rack and pinion. A friction clutch took the place of shifting-belts for reversing. The cross-head was raised or lowered by power, and all motions could be controlled from either side of the machine. On the giant in the Niles exhibit six tool heads were operated at once, covering the face, sides, and portions of the under sides of the work.

Lathes are being perfected on similar lines. The speed from cone to back gear can be changed instantly by a friction clutch between the cone and large gear. The tool can be raised or lowered by the double wedge rest. Micrometer attachments on the slide rest and tail block made the finest adjustment of cut practicable. Hollow lathe spindle and tapering attachments were the rule. One lathe had its set of screw-cutting gears fixed in a box in front of the lathe head, and with one change of gear on spindle and intermediate all the ordinary threads might be cut by the simple movement of a lever.

The milling machine, if not already so, bids fair to become the most valuable tool in the machine-shop, with the perfection attained in the manufacture of cutters. Its scope and power are wonderful. Hillis and Jones exhibited a vertical machine fitted with a compound slide rest and chuck in one, capable of doing all kinds of heavy machine or engine work. In addition to standard machines, Pratt and Whitney exhibited many specimens of milled work which illustrated the power and scope of these machines. One was part of a lathe bed 20 inches wide, with two ways for slide rest and tail block all finished, including the in and outside edges at one operation, the feed being one and one half inches per minute. The work moves with the run of the cutter instead of (as usual) against it. Milling machine-cutters, shown by Brown and Sharpe, Pratt and Whitney, and T. E. Reinecker, of Chemnitz, Germany, were among the most beautiful products of the machine-shop. Browne and Sharpe's representatives refused to explain the method of getting clearance on the teeth of their curved and spiral cutters, while Reinecker, the German machinist, showed the special tools made for that purpose in operation. The cutters after being turned and grooved are put in the lathe and made to revolve slowly. The lathe tool, which is operated by a cam underneath the slide rest, moves slowly in, taking the cut just back of the edge of each tooth, and moves out again rapidly to escape the face of the next tooth. The speed of the cam is regulated by suitable gearing.

The machines exhibited for drilling, boring, and tapping covered the whole field of this class of work, automatic movements, rapidity, and ease of adjustment being the lines of improvement.

A machine exhibited by Pratt and Whitney had a capacity of 2,500 globe valves bored and tapped in a day. The specimens of work exhibited showed that these machines had been brought to great perfection. The two and three cutter heads in common use have been discarded, and for all work under 6 inches the four-cutter head is used. For work of larger diameter more cutters are used, but always an

an even number. Powerful lead screws, the same pitch as the thread to be cut, feed the work into the cutters, which produce square and "V" thread screws for machine, "jack," vice, and bridge purposes, fully equal to the work so slowly done in the lathe.

The Acme Machine Co. exhibited a screw made of machinery steel, 26 inches long, $1\frac{1}{4}$ inch diameter, $\frac{3}{4}$ core, two threads to the inch, finished at one cut.

A non-breakable bolt machine was exhibited. The feature of this machine was a safety block, so fixed as to resist the force employed to forge the bolts, but whenever the machine becomes jammed from any cause the block is moved by the extra strain, thus preventing the slipping off of the belt or breaking the machine.

Among the nut-tapping machines was one rated at a speed of 30,000 $\frac{1}{4}$ -inch nuts per day. Its operation was entirely automatic.

The chain saw mortiser, exhibited by the Dubuque S. Speciality Machine Works, of Dubuque, Iowa, appeared to me to be one of very great utility. The machine has only been introduced to the wood-working trade during the last two years, and is stated to be the means of supplying a long felt want in the trade. It is intended to supplant the old style chisel or power mortiser. In stock work it is stated that the machine has great advantages over any other, and works much more accurately and rapidly. For blind mortising it is an excellent tool, as mortises of any depth to 6 inches can be made with it, and is always free from dust and chips. Its range is greater than that of any other machine, being adapted for all sizes of mortise from $\frac{1}{4}$ inch to 1 inch, and from an inch and a half in length upward. The proprietors state that some of its advantages are that:—

It mortises faster than other mortisers. In hard woods it will mortise from four to six times faster. Its work is always accurate. No boring is required in making a mortise in any wood, either hard or soft. No chips or shavings are left in the mortise to be removed, but the mortise is always clear of chips. No reversing of stock is required to make a thorough mortise, up to 6 inches. It makes blind mortises as easily as through mortises, and always leaves them clear of chips. A smooth-running machine, it requires no extra bracing of floors. Gives relief from the annoying jar of chisel machines. In yellow pine and cypress the machine is of special value, as the gum has no evil effect. By an arrangement of stops in stock doorwork, all mortises in a stile can be made with five movements of the table, and with no laying out of stile.

Beaman and Smith exhibited a safety drill and tap holder, constructed on the principle of the common union coupling used in gas and steam fitting. The male part is made with a taper shank to fit lathe or machine; its face was recessed, and a ring of vulcanized fibre inserted. A similar ring is fitted into the coupling-nut; the union is made as a socket for drill or tap.

One of the most novel and interesting exhibits were the machines of the Morton Manufacturing Co., of Muskegon Heights, Mich. To chip and file a key-seat, or fit a key with the file, is a slow, laborious, and unsatisfactory job for most machinists. The Morton machines dispense with these methods. The tool-bar was a square steel of any length, moved with rack and pinion, set perpendicularly, and marked from above or below, the machine being fixed or portable. A keyway, 3 inches wide, $1\frac{1}{2}$ inches deep, and 35 inches through the hub, has been cut by this machine in thirty-seven minutes. The tool takes the full width of the keyway at each cut, cast-iron shavings being exhibited $3\frac{1}{4}$ inches wide. The reverse motion, feed, chucks, and other adjustments were in keeping with the extraordinary effectiveness of these machines.

The

The exhibit of taps, dies, reamers, punches, gauges, scales, micrometers, and fine tools of all kinds was great beyond description. The subdivision of labour and the duplication of parts of machines has made accuracy of size and fit such a necessity that the microscope has been called into use to enable the machinist to read the measurement of standard tools. A measuring machine was exhibited by Brown and Sharp, with microscopic attachment, by which the 100,000th part of an inch could be measured.

The exhibits of Great Britain and of France, as a whole, were quite unworthy of those countries; what were shown, although good, were not at all representative. Canada's exhibit was better than I expected to find it, although not to be compared with the exhibits of America or Germany. This latter country was well represented, and I have elsewhere referred to several of its exhibits, especially to that of Krupp, who, in Machinery Hall, represented samples of mining machinery, powerful ore crushers and grinders, also improved assaying machinery.

A very interesting exhibit was made by a Berlin firm, which constructs machines for the manufacture of safety-matches and match-boxes. These matches can only be ignited on the surface of the box they are packed in. Both box and match are prepared with a certain chemical substance. The manufacture of the matches and boxes was shown here in a practical manner. One person can work a single machine, and in Germany this is done mostly by girls. The process for the manufacture of the boxes is started by a machine which does the shaving of a block of wood (cottonwood) into very thin sheets; then another machine does the cutting, folding, and labelling of the 36,000 boxes per day. Two peeling machines can cut 24,000,000 matches out of prepared blocks of wood per day. The dipping process—placing the chemical preparation on one end of the match—is also done by a very ingenious contrivance, whereby 2,200 matches are dipped. To prevent the matches sticking together they are placed in a frame with a holder for each one. Thus the process is facilitated, and one operator can dip almost 2,000,000 matches per day. Although poplar and cottonwood are used chiefly in Germany, the process at the exhibit was demonstrated with willow. Another interesting feature of the process of the manufacture of matches was the filling of the boxes. With the aid of automatic machines, a girl can fill 1,800 boxes per hour.

Another part of the German machinery exhibit was represented by kneading and mixing machines—machinery for the manufacture and working of paper by combined rolling and friction calenders, with from ten to twelve rollers 90 inches on surface, and a downward pressure of 50 tons on each end of the journals, these mammoth calenders being driven by two twin engines.

The electrotyping process for rotating printing presses was demonstrated by an Augsburg firm. Prominent German illustrated papers, such as the *Fleigende Blaetter* and *Leipziger Illustrirte Zeitung*, &c., use electrotypes for their rotating presses instead of stereotypes. The single and double page ruling machines, exhibited by a firm from Leipzig, were of interest to the representatives of the book-binding trade and to manufacturers of stationery goods.

The Austrian exhibits were very limited. The principal exhibit Austria made was that of Emil Ritter von Skoda, of Pilsen. Some remarkably fine open hearth steel castings and rapid firing guns were displayed by Mr. Skoda. A propeller screw, for the North German Lloyd steamship "Spree," was 22 feet in diameter, and weighed 25 tons. Several very large gears and a number of pinions, locomotive and car-wheel centres, car-wheels, air chamber for a pump, cylinder-head,

head, crank shaft, shrinkings, and miscellaneous castings, formed the balance of the cast-steel exhibit. Tests of steel from Mr. Skoda's foundry withstood projectiles discharged from the most powerful guns, and the Austrian Government is now using it for armour plates. The Siemens-Martin process is used, and the product is free from flaws or "blow holes." Tensile strength of the Skoda castings ranges from 60,000 to 100,000 lb. per square inch, with an elongation of 20 to 35 per cent., and a reduction of the area at fracture of 40 per cent., according to hardness and softness. What material such steel is for marine and for bridge work, where dead load is a too important factor, and in many other departments of engineering construction, where lightness, strength, longevity, or maintenance are of moment, and forgings too expensive to use. Small samples of cast-steel bent at right angles, and one doubled on itself, did not show visible fracture. Although the subject of ordnance is referred to under "Transportation," I may refer here to the Skoda rapid-firing guns, which attracted fully as much attention as the big propeller screw. The trio was 47 m.m., 37 m.m., and 8 m.m., in diameter. The latter, the mitrailleuse, automatically discharges itself when set in operation, by taking advantage of the recoil at a speed of 350 to 500 shots per minute. The other guns can be readily fired twenty-five times per minute.

To the military engineer these guns were very interesting, on account of the simplicity of their mechanism. The breech-lock contained only five parts. Another very important feature was the electric sight points, and in practice an entirely new one. Both sights in darkness are very distinct, enabling a gunner to aim as well at night as during daylight. According to official reports by the war departments of Austria-Hungary, in a test for ascertaining the longevity of the mitrailleuse, 30,000 rounds were continuously fired without exhibiting any deterioration of any of the parts, though, of course, theoretically there must have been some, especially in the barrel. It has been given severe trials in hot, cold, rainy, and dusty weather, and worked equally well under all conditions.

Printing Machines.

The display of printing presses at the World's Columbian Exposition was large and representative, comprising, as it did, not only the most recent advances but also the interesting relics of the mode of printing adopted many years ago. Immediately opposite our court was the exhibit of R. Hoe & Co., with two presses (in full operation) of the style known as the quadruple stereotype printing machine. The following description from the *Chicago Herald* by an expert (Geo. E. Smith) is interesting:—

This press prints and delivers folded four, six, or eight page papers at the running speed of 48,000 per hour; ten, twelve, fourteen, or sixteen page papers at the rate of 24,000 per hour, and twenty or twenty-four page papers at the rate of 12,000 per hour. It has the appearance of being a very intricate and complex piece of mechanism, yet a skilful pressman operates it with ease. There are many different sizes and varieties of these machines made, and they can now be seen running in nearly all the large cities of this country, as well as in Great Britain and her colonies. Their special features are speed, simplicity, durability, and completeness.

The latest achievement of the Hoe Company is the "sextuple" stereotype perfecting press, a monster machine of double the capacity of the "quadruple." A working brass model of this press, manufactured at the special request of the United States Government for its Patent Office exhibit, can be seen in the Government Building at the Exposition. The full-sized press costs a fortune, and there are only two of them in operation. Each press is composed of over 16,000 pieces, weighing together 130,000 lb. Its total length is 26 feet and 3 inches; width, 18 feet; height, 12 feet. It prints on both sides of three continuous webs of paper, supplied from three separate rolls, splits the web longitudinally, associates the narrow webs in one of several groups, severs the webs collected transversely into sheet lengths, unites the sheets together by pasting, folds them, and delivers a perfect newspaper composed of many sheets bound together, cut open at the head and counted. And the speed with which all this is done is

marvellous.

marvellous. Papers of from four to six pages are turned out at the rate of 96,000 per hour; eight-page papers, 72,000 per hour; ten or twelve page papers, 48,000 per hour; sixteen-page papers, 36,000 per hour; fourteen, twenty, or twenty-four page papers, at 24,000 per hour.

Passing on to the exhibit of the Goss Printing Press Company, an opportunity was afforded of studying three specimens of the presses patented and manufactured by that Company. The improved Goss newspaper perfecting press, with folder, prints papers of from four to eight pages, the width of which may be six, seven, or eight columns, and has a capacity of 10,000 papers per hour. Then there was the improved Goss book press, especially adapted for catalogue, novel, or pamphlet work, printing from a continuous roll of web, delivering the sheets folded in signatures of eight, sixteen, thirty-two, or sixty-four pages at a speed of from 4,000 to 16,000 per hour. This press, built on solid foundations, requires small space, and is easily managed. All the cylinders being very heavy, and having large solid journals, the machine is held rigid and firm, insuring a perfect and even impression. There are no grippers, and a perfect register is thereby insured. Every part of the press is accessible to the operator from the floor on which it stands, and while a high rate of speed is attained, the action is always easy and noiseless, and the quality of the work uniform. The object aimed at by the makers and patentees, the Goss Brothers (who have been practical printers for twenty years), has been to produce a simple, strong, and reliable machine, which can be worked with the greatest economy, and at the same time possesses every good feature that practical experience has shown to be valuable. But the principal feature of the Goss Brothers' exhibit is their straight-line press and folder, which has no angle bars, collector or tapes. It prints from four to sixteen pages, inclusive, and at a speed of 24,000 per hour. Its notable points are simplicity, durability, and ease of action, and its manufacturers claim that it can be operated at less expense than any other press of the kind. Its additional merits are perfect distribution and fine finish.

The next exhibit was that of the Potter Printing Press Company, whose quarto and folio web printing and folding machine has acquired great popularity since it was first introduced to the trade. This press takes paper from a roll, prints from stereotype plates, and cuts and pastes and folds as many as may be desired at the rate of from 10,000 to 12,000 per hour of eight-page papers, or 24,000 per hour of four-page papers. Among the many features which conduce to its popularity and success may be mentioned its compactness, simplicity, durability, maximum of result from minimum of time and labour, and absolute certainty of delivery and freedom from clogging. This last result is secured by using the smallest number of tapes, and by having the sheet under positive control at all times, so that it cannot stray from its course or choke the folder. In this machine the number of columns is fixed, but their lengths may be changed at will. The special features in which superiority is claimed for the Potter press are the character of work produced, economy of production, and the simplicity of the machinery. Its capacity can be doubled at any time by the use of a supplementary printing attachment, which enables it to produce the work of two machines. It was on this press that the *Daily Columbian*—that unique publication made up of the initial pages of the leading dailies—was printed, and the appearance of this beautiful paper spoke volumes for the character of the work done on the Potter. But a still better illustration of the excellence of the work turned out by this press is *The Chicago Herald* itself, which is conceded to be the handsomest daily paper in the United States. *The Herald* is printed entirely on the Potter press, its press-rooms being equipped with ten of these superior machines, and arrangements have recently been made, owing to the rapid growth of *The Herald's* circulation, to double the capacity of these machines.

The exhibit of Walter Scott & Co. included eight presses and a number of other devices belonging to the printing trade, the entire collection representing a value of not less than \$60,000. Press No. 1 in this exhibit was a rotary plate-printing, inseting, pasting, cutting, folding, and counting machine. It will work a different number of pages, inseting, pasting, cutting, and folding them in book form, and counting the copies in packs of fifty at a speed of 28,000 per hour—a greater speed than ever before attained by the use of two sets of plates on such a machine. No. 2 is a rotary plate-printing, cutting, pasting, and folding machine, which will work newspapers of four and eight pages, of six, seven, and eight columns, delivering them folded to a quarter-page size at a speed of 12,000 per hour. The columns are placed around the cylinder so as to work a different number or width of columns to the page. The third was a lithographic stop-cylinder machine, constructed with a view to efficiency, durability, and simplicity. The stone is adjustable in the bed-box in all directions, and the cylinder starting and stopping device is positive in its action, capable of working at great speed without jar or noise. A perfect register is ensured at all times. The sheets are delivered direct from the delivery-cylinder to the fly, and the fly-fingers are each mounted with steel star-wheels to prevent smut. Press No. 4 was a flat-bed perfecting, with table and roll-feed. It was constructed similar to the two-revolution press, but had two impression-cylinders and two sets of inking devices—one set for each form. The bed movement is new, dispensing with the universal joint so long in use, and gives a uniform motion, which ensures a perfect register. Automatic means are provided for preventing offset, allowing very fine printing to be done without inconvenience. No. 5 is a two-revolution four-roller press, with table and cam distribution and front delivery, very strongly built, and provided with the new bed motion and various other improvements. Air-cushioning cylinders with adjustable heads are used to assist in reversing the bed. The impression can be thrown off at the will of the
feeder

feeder without stopping the machine. No. 6 was a two-revolution two-roller press, constructed on a plan similar to No. 5. The next was a single large cylinder book and job press, with table, rack, and screw distribution and back delivery. The cylinder is geared to the bed during the impression, and the bed is unyielding. In addition to the various other improvements, it is fitted with a new safety gripper device to prevent accident, should the gripper be left in the wrong position. No. 8 was a two-revolution pony press, especially adapted for stationery, railroad, insurance, and job printing.

Next was an exhibit of lithographic presses, manufactured by the Potter Printing Press Company. These presses were among the first introduced in this country, and have been improved from time to time, until to-day there is probably no more popular machine than Potter's patent lithographic cylinder press. It was equipped with heavy side-frames, girders, ribs, bed-plate, &c., which, when bolted together, form a super-structure that so immovably sustains every working part of the machine that absolute precision of movement is assured. The cylinder was rigidly held in position at perfect rest until the bed begins its return movement, affording ample time for the deliberate feeding of the sheet to the guides and for closing the grippers. The patent feed-guide tongues were located in the cylinder-opening, a marked improvement on the common plan of attaching them to the underside of the feed-board. This admirable arrangement has a twofold office—the first being to support the sheet as it is seized by the impression-cylinder grippers without wrinkling it; the second to prevent the possibility of the thin paper curling away from the delivery-cylinder grippers. The stone-bed is provided with vertical bolts properly located, by which stones of various thickness may be readily adjusted and accurately levelled. An automatic system, put in operation by moving a single lever, causes two or three rollers to be given to each impression, while by a trip-at-will the impression-cylinder is under the control of the feeder at all times. Fine specimens of the work done upon this press were on exhibition.

Passing on to the display of McIndoe Brothers, of Boston, Mass., there was something interesting in the shape of a cylinder job-press. The inventors and manufacturers having had a practical experience of a quarter of a century in the printing business, devoted to the finest quality of work, saw the necessity of a better and more powerful job-press for producing fine work, combined with high speed, if necessary, for the ordinary grades; in fact a press capable of turning out all classes of woodcut or commercial printing, at any range of speed, according to the ability of the operator. The result of their undertaking in this direction is the McIndoe press, a new machine for fine printing with a speed of 2,500 per hour, and a weight of 4,000 lb. Perfection is claimed for it in the three important features of speed, solidity of impression, and distribution of ink. The frame is made of one solid piece of iron, no bolts or screws being used, and contains all the mechanism of the machine. The great advantage of this form of construction is that every part of its mechanism will be in line even if the machine should be placed out of level. The press has a swinging tooth attached to the rack, the pitch of which is raised above that of the driving rack, and within that of the cylinder gear. At the beginning of the stroke it swings up and engages with the roll, to which it is as firmly held as if it were cast in position. The forward movement of the bed brings the tooth of the cylinder gear and rack into mesh. As soon as the first tooth of the cylinder gear engages with the rack the swinging tooth drops down level with the surface of the rack, where it remains until it is returned to the first position, when the operation is repeated. The running gears are made after the pattern of the stop-cylinder form of construction, which is claimed to be the best for the finest quality of work. The rolling gear is placed above the centre line of the large driving gear, to ensure as perfect and even motion to the bed as is possible with a direct rotary connection. The bed, which is extra thick and heavily ribbed, passes over four wide rolls at the contact of impression. The connecting-rod, which transmits the motion from the driving gear to the bed, takes the strain by compression during the moment of impression, instead of a tensile strain, so common in other machines of a similar movement, thereby making it as rigid as possible. The cylinder is very heavy, and is shrunk on the solid steel shaft before the printing surface is turned, while the ink-plate is a simple yet valuable device for distributing ink without the aid of angle rollers, and the feeding device is no less clever.

The Campbell Printing Press and Manufacturing Company made a display of four presses, introducing the "Economic," the "New Movement," and other specialties. The "Economic" is an improved two-revolution press, in which the bed-driving mechanism is direct, with no multiplying gears to develop lost motion and consequent loss of register. The most defective feature of the two-revolution press has always been its liability to loss of register, but this difficulty, it is claimed, has been entirely overcome in the "Economic" by the continuous register rack, which gears bed and cylinder together throughout the whole printing stroke. The press is fitted with quadruple air springs, non-breakable gripper motion, and all the modern improvements. The "New Movement" is a pony press with a record for colour work and accurate register. It delivers without tapes, clean side to the fly, and will fly a sheet with as small a margin as one-sixteenth of an inch. It has both table and screw distribution, and its bed and cylinder are especially accessible. The Campbell hand cylinder country press, designed especially for use in country offices, is also to be seen here.

An interesting feature of the Campbell Company's exhibit was a relic a century and a half ago—the first printing press in New Hampshire. This antiquated object, which is about as destitute of machinery as a clothes-horse, is of the most primitive pattern, having been built by Thomas Draper, Boston, Mass., in 1742, and purchased by Daniel

Daniel Fowle on Oct. 7, 1756. It was afterwards owned by John Melcher, the first state printer of New Hampshire; later by Frank W. Miller, of Portsmouth, N.H., and now by the Campbell concern. The old-fashioned ink-balls and all the old type that was used with the press in its early days have been preserved, and during the progress of the Exposition they have been used in printing slips on the old press for distribution to visitors. Over 230,000 of these slips had been given away up to Sept. 15. They contain the following:—

“Printed on a press 151 years old by Campbell Printing Press and Manufacturing Company. World’s Fair, Chicago, September 15, 1893.

Once I was young and spry as any of my name;

Now I am old and slow, but I get there just the same.”

A press manufactured to meet a special demand was the Cox Duplex, exhibited by the Duplex Printing Press Company, of Battle Creek, Mich. It has a flat-bed, type-perfecting machine, built for daily newspapers of 2,000 to 10,000 circulation, and for weeklies and monthlies of large circulation, the design being a saving of expenses, time, and trouble. It had an easy running speed of 4,000 to 5,000 complete papers per hour of any size from four to eight pages, and the expense and annoyance of stereotyping are obviated. In this respect it accomplishes what has long been desired. The secret of speed in the Duplex is not in rapid running of the machine, but in the fact that two impressions on the opposite sides of the sheet are simultaneously printed on two beds, and that the impressions are taken with both the forward and backward movement of the cylinders, which have a travel of only thirty-six inches in the largest-sized presses.

Nine specimens of the improved “Universal” printing presses, invented and manufactured by M. Gally, of New York, constituted the next exhibit. These were job presses of more than usual weight, strength, and durability, fitted with improved distribution, improved bridge blocks, improved changers, and the least possible liability to breakage in all parts. They are adapted to all kinds of work, from the lightest card work to the heaviest embossing and wood printing. One of the styles (No. 3) is especially intended for printing on any thickness of board, inlaying book-covers, hot or cold stamping or embossing, and the finest and heaviest classes of cut and solid tint printing, including half-tone engravings. Style No. 4 is built only for very heavy embossing and book-cover stamping, and has no inking apparatus whatever.

The “Optimus” and other presses manufactured by the Babcock Printing Press Manufacturing Company attracted considerable attention. The “Optimus” is a two-revolution typographic machine, which delivers printed side up without touching the printed surface. Its patented improvements are a safety gripper mechanism which registers accurately, an air valve for removing the spring when desired, adjustable piston head, roller or journal bearings, reversing mechanism, positive spiral slider mechanism, front delivery, impression trip, cylinder-lifting mechanism and knuckle joint. It is claimed for it that it does excellent cut and colour work, delivers heavy cuts without smut or off-set, wears well at high speed, and has an admirable delivery.

C. B. Cottrell and Sons made a display of six machines, including the most recent and important improvements in the printing press design, and marking clearly the progress of all styles of impression printing. Presses Nos. 1, 2, and 3 are different types of the two-revolution press, combining strength, durability, simplicity, speed, and convenience of handling. They are extensively used for printing books, magazines, newspapers, and illustrated catalogues, and are especially adapted to the printing of half-tone engravings. Among the patented improvements peculiar to these presses may be mentioned air-springs, with patent piston and vacuum valve; patent governor attachment for putting on and throwing off the spring, controlling it automatically; patent attachment for controlling the momentum of the cylinder, insuring perfect register and speed; patent trip-at-will for throwing off the impression if a sheet is missed or not properly fed; patent hinge roller frame by which the form rollers can be instantly uncovered for removal without unscrewing the sockets; patent sheet delivery, with adjustable skeleton delivery cylinder, the wheels of which are set into the margins to prevent smutting; patent power backing-up motion, by which the feeder can back up his press for the grippers to take a sheet without leaving the platform; patent geared sliders, by which unity of movement is secured between the bed and sliders protecting the rollers from undue wear. Press No. 4 is a flat-bed perfecting press, which prints on both sides of the sheet while going through the machine once. It is built on the two-revolution principle, having two cylinders and two beds, and embodies all the improvements of the two-revolution press, besides many others. One of these is a patent automatically shifting tympan, which supplies the second impression cylinder with an entirely new and clean tympan at regular intervals while the press is running at full speed. This effectually prevents offset, and enables the press to print cut work on supersized and calendered paper. Press No. 5 is a stop-cylinder printing press, in which the bed is driven by a crank motion, and the cylinder derives its motion by being geared directly to the bed while printing. It is supplied with six 3½-inch rollers, which cover a full form, and is equipped with the various patent devices described above. It is very strong and simple, and is capable of working the very heaviest forms of the finest illustrated work. Then there is a machine called the country press, designed to supply the needs of country printing offices. Its strength and rigidity, together with the air springs, permit of high speed, and the appliances for the convenient handling of the press, together with its extreme simplicity, are especially adapted to offices where skilled labour is not always obtainable.

When

When you reach the exhibit of the Miehle Printing Press and Manufacturing Company you find an improved two-revolution machine that is described by its exhibitors as possessing a perfect, swift, noiseless, and everlasting bed motion. Seven or eight years ago its inventor, Robert Miehle, was a pressman in the employ of Poole Brothers, railway printers, of this city. He began experimenting to satisfy himself as to the causes which produced the intermittent movement of the bed in the Napier press he was at work on, and while doing this conceived the idea which, completed, has made him famous. Strange as it may seem, it devolved on a practical pressman to teach printers and mechanics how a type bed should run in unison with a moving cylindrical surface. Miehle accomplished this by using a large, straight, actuated gear wheel and double rack fixed to the bed, one line of the teeth being above, the other below. The gear wheel moves from the line above to the line below, alternately driving the bed forward and backward. On the gear wheel is a large roller which, after each stroke is completed, falls behind a straight cam, or slide, the toothed wheel rolls off the rack, and the type bed is then actuated by a veritable crank motion, which graduates its speed, carries it over its centre, accelerates it again and drops it into mesh with the lower rack to give the bed its next movement. This most ingenious device places Mr. Miehle, a young Chicago pressman, among the distinguished inventors as the creator of a new mechanical movement. But aside from the bed movement Mr. Miehle has carried his practical knowledge as a pressman into every detail of the machine. Thus the manipulator of the press will find himself getting at his form rollers without soiling his hands or seeking the aid of his feed boy; he will find his angle rollers distributing his ink as evenly and as cleanly as the form rollers; and he will find the feed guides, sheet delivery, everything, in fact, arranged with the view of aiding the pressman in the rapid production of work. There are twenty of these presses in operation in Chicago offices alone.

One of the exhibits that seemed to have an attraction for printers was that of Golding & Co., of Boston. It consisted of five Golding jobbers, three pearl presses, and a heavy embossing machine. The Golding jobber is constructed on a plan that affords great strength and durability and ensures perfect alignment of parts. The impression shafts are of crucible steel, as are also the side-arms and pinions, while hardened steel studs are supplied on parts subject to the greatest wear. By a patented arrangement a continuous rotary movement without cams or slides is obtained, giving a period of rest for feeding, a dwell on the impression, and a quick return. The maximum speed of the eighth is 3,200 per hour; of the quarto, 2,500; of the half medium, 2,000; and of the half super-royal, 1,800. The ink is supplied by the automatic brayer fountain, the operation of which is simple and accurate, all classes of work coming within its range. The Pearl press is a well-built little machine, and seems to have become a favourite with printers of specialties like druggists' labels and envelopes, or any kind of work that calls for great speed. The larger sizes are capable of doing nearly all the work that could be put on a 10 by 15 inch quarto medium. By means of a duplex fountain and a reversible disk movement a perfectly even colour can be carried. Any speed is attainable within the ability of the feeder.

Colt's Armory Printing and Embossing Company, of Hartford, Conn., exhibited four jobbers and three embossing presses. These machines, it is claimed, combine all the best features of other presses of that kind, with many new devices owned exclusively by this company, insuring finer work than any of the older styles.

The North Press Company had on exhibition its eighth-medium web-feeding press, which prints from one to four colours at each impression, and will make 5,000 impressions per hour. The press will make, if desired, one, two, or three cuts to each impression without the removal or addition of a single part or appliance.

The Linotype, as one of the latest representations of the advances in type-composing machines, attracted considerable attention. By this machine it was stated that all previous records of rapid and perfect typesetting were eclipsed—one operator being able to set 400,000 ems in one week, or over 8,500 per hour. The Linotypes were produced instantly and ready for use on the press by fingering keys, very like those of an ordinary type-writer, the keys serving temporarily the purpose of collecting in line metal matrices bearing individual letters, against which the slugs or linotypes were cast in metal type. The machine produced finished printed matter of the highest quality, and permitted the face or style of type to be changed at pleasure. The operator could read and correct the matter as he proceeded, thus avoiding the usual errors in correcting. The art of working the machine could be acquired in a very short time.

The only printing press from Germany came from the largest manufactory in that country; it was the "Maschinenfabrik Augsburg," of Augsburg, Germany. It consisted of two presses, one being a large rotary for the printing of high-class illustrated work, capable of 12,000 impressions per hour. It will print sixteen pages at a time, folded or unfolded, and on both sides of the sheet. The arrangement for ink distribution

distribution is among the strong points of the machine, and the offset paper roll, for the protection of the printed sheet from smut, is a perfect guard, which does not need to be renewed oftener than twice a year. All parts of the press are easily accessible, and the specimens of fine illustrations turned out by it are veritable works of art. The other press is a flat bed, for printing in two colours, and this also turns out a class of work that shows the remarkable degree of perfection that has been reached by the Augsburg Company in the manufacture of printing machinery. The press is simple in its construction, and yet shows ingenuity of invention in the adjustment of its parts and the methods employed to produce the best results at the least expense and trouble. The manufacturers of these presses at Augsburg, Germany, employ 2,000 workmen, and have sold more than 4,000 of their machines.

Machine Shop.

In the model machine-shop, south of Machinery Hall, and forming a continuation of the boiler-house, were to be seen all the ordinary machine tools, such as would be found in a well equipped machine-shop of the present day performing the usual operations of such an establishment. It was most interesting to enter this building and see iron and steel, as well as soft metals, turned and planed like wood and cut and punched like so much paper. Of the American exhibitors, several of the leading firms showed excellent appliances. The Hillis & Jones Co., of Wilmington, had a fine display of boiler, locomotive, and bridge shop tools with punches and shears of good design. A plate-edged planing-machine, of recent type, for planing the edges of boiler, ship, and bridge plates, of massive design, and well adapted to boiler-shop work was a conspicuous exhibit. A punching and shearing machine for plate work was especially adapted for boiler-makers' and ship-builders' requirements. For flattening ship and bridge plates, with six rolls only instead of seven as in the ordinary type, the plate-straightening machine exhibited, as recently patented, appeared a most useful machine.

Painting Machines.

The requirements of the vast structures of the Exposition necessitated the invention of some contrivance by means of which the painting and calcosining of the walls might be performed efficaciously, cheaply, and rapidly. For this purpose a peculiar machine was employed, on the principle of the atomizer or spray. A large tank containing the liquid calcosine or paint had two lines of hose connected with it. A five-horse power electric or steam motor was made to pump in air until an internal pressure of 20 lb. or more to the square inch was indicated. Two workmen then took up the nozzles attached to the far ends of the hose and sprayed the colour on the wall or ceiling. Fourteen of these painting machines were employed in the great buildings, each of which required the services of three men, but painted as rapidly as twenty painters with hand brushes. A single machine, working eight hours, I was informed, painted as much as 30,000 square feet.

Milling Machinery.

At the north-west corner of Machinery Hall there was a collection of milling machinery which was characterized by two points. First, the collection of superior American machinery of this class, and next the conspicuous substitution effected in later years of roller mills for the burr mill-stones as well as the greater improvement in flour-dressing machinery. Rolls of noiseless roller mills, the workmanship of which was excellent, at once attracted attention, the castings were clean, the lines clear, the finish of the machine work was fine, and the polish of the chilled steel rollers was perfect. There was a splendid collection

collection of flour dressers with centrifugal reels, purifiers, and dust collectors, wheat steamer flour and bran packers, one of the latter of which could pack 100 lb. of bran into a space 44 in. by 40 in. in one minute. The centre of attraction, was, however, the plan-sifter, the latest invented bolting machine, having a gyrating motion, the smoothness of which was a wonder and a surprise to all interested in flour-dressing machinery. A noteworthy feature of the whole exhibit was the absence of noisy bevel gear and counter shafts, owing to the introduction of the link belt here and the endless leather belting. In the same group were a series of crushing, grinding, and attrition mills for pulverising the hardest of materials, of which the design and workmanship were good, and the proportions of the heavy mills appeared consistent with the work for which they were designed. An interesting exhibit also was an automatic grain weigher, with scales and elevator complete.

In the French section there was a complete exhibit of eight mills, with their accessories, practically illustrating Schweitzer's Rational System of flour mills. Although rather adapted to use in farming, it recommended itself to the miller by the results obtained, although the workmanship was scarcely first-class. The production of millstones is pre-eminently a French industry, and the Department of Seine et Marne exhibited a dozen millstones, not made as formerly, but of burrs extending from eye to skirt, and through the whole thickness of the stone, and hooped with four iron bands. The eye was of the usual diameter, 12 inches. The stones ranged from 54 inches to 18 inches in diameter, and from 48 inches downward. They were composed of one solid stone taken from the largest quarries in France, and the dressing is clean and good.

In the Machinery Hall there was a series of roller mills from Brunswick, Germany, plansifters and purifiers, which for design, workmanship, and finish were quite equal to the best American. Adjoining this was an exhibit from Dresden of a "Dustless Reformed Purifier," the name of which properly designated its purpose. It was a pretty little machine, well made, simple in its details, and up to the present time 1,100 of them have been sold in London alone. I was informed that the inventor proposes to have these machines manufactured in America, in order to avoid the exorbitant import duties now in force, which are quite prohibitive as far as the importation of these machines into the American market is concerned.

Spain had an exhibit of a machine for crushing and separating nuts, as well as mills and models for the production of pastes, vermicelli, chocolate, &c.

Amongst the exhibits of Switzerland silk bolting cloth—the one great factor in flour-dressing machinery—was exhibited.

Great Britain showed six millstones for rice grinding, quarried from Derbyshire Peak, nicely dressed by machinery, which were destined for the large rice mill at New Orleans, in Savannah.

There were three other cloth-cutting machines—the Weyburn, the Phillipsohn and Leschziner, and the Fenno. The two last-mentioned were of the same pattern and same method of working, and supplant hand labour in about the same proportion. The Weyburn has an arbor of piping overhead, is very much more clumsy and complicated than the Caldwell, though it runs by electricity; it also has a circular knife. The Fenno has a single bar over the table, a double arm. The operator moves the cutter within prescribed limits, and slides the cloth from time to time within those limits.

The German edition of the Fenno machine was of stouter build, had no bar over the table nor framework above it, but stood beside the table, the double arm being high enough to allow the operator to
pass

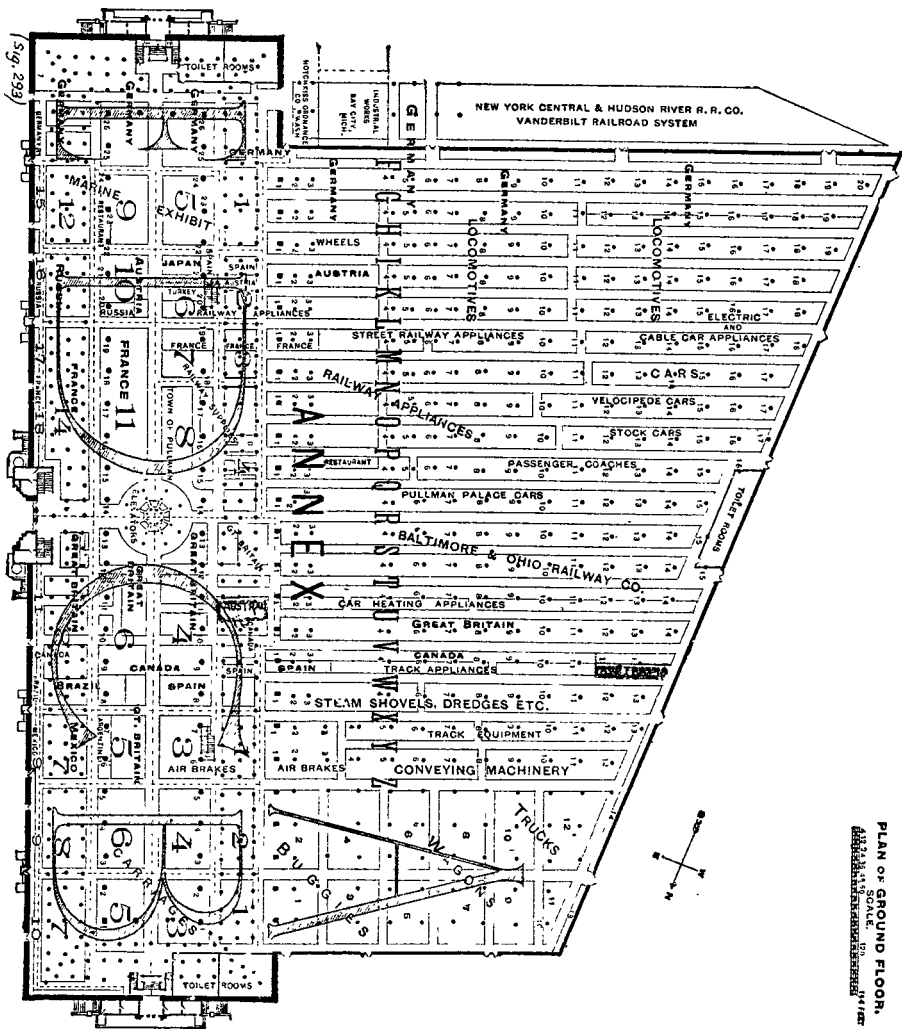

pass under and move freely, as with the Fenno; it was also a hand or power machine; it was of coarser build and not so finely finished, and did not sharpen itself while in action, as does the Fenno, which, in fact, is the only one of these machines that does. It would be impossible for the novice to decide as to the merits of either machine while seeing them work under the guidance of expert operators, so far as the execution goes; but certainly everyone would have an individual fancy or preference on account of other features mentioned. Machinery Hall was the home of machines of all imaginable forms and descriptions, and for all kinds of work, from the great Corliss engine down to a little kneading-machine. One would hardly find a machine in the whole collection that did not in some way replace hand labour directly or indirectly. As, for instance, in weaving with the hand-loom of centuries ago—slow, tedious, and tiresome—it took at least one operator to each machine. These are replaced by rapid-power looms of complicated construction to produce all kinds of fabrics from the heaviest woollen goods to finest silks and laces, and one operator can tend several looms, and one loom do the work of many old ones. Knitting-machines, as now used, have made it unprofitable to knit by hand, as well as undesirable, because of the great difference in the labour. There were sewing-machines for buttons on cloth, for button-holes, for any and all kinds of goods or garments or embroidery in any design, however intricate or difficult, or on fabrics of finest texture, in an incredibly short space of time, and better and more accurate than expert hand-work. It seems just as incongruous, however, to see men doing this kind of work as to see women working in a brickyard.

Moulds for Metal Castings.

A new system of making sand moulds for metal castings was exhibited by the Tabor Manufacturing Co., and a full description and drawings of these machines will be found in Appendix.

Saw-mills.

The saw-mills, situated out of doors, on the south side of Machinery Hall, were put in full operation every afternoon. The process exhibited was as follows:—A log, for example, from 18 to 20 feet long, and 24 inches in diameter, was taken by a link-belt chain off the ground up an incline to the mill-door, 20 feet above the ground, sawn into 1-inch boards, the boards edged and ended, the slabs cut into 4-foot lengths and laths, and the whole operation usually occupying 2 minutes. The band-saws, 12 inches wide, were splendid pieces of mechanism, and reflected great praise on their makers. The variable friction feed saw-mills was an excellent and a novel substitute for the belt feed.

Transportation Building and Annex and Exhibits.

For the first time in the history of Exhibitions a special building was provided for the reception of exhibits connected with transportation. In all former exhibitions the subject was treated as a sub-section of some other division, and the locomotive looked upon as a part of the machinery exhibit. The reason for this was not far to seek. In America long distance travelling by train is quite an ordinary matter, and, consequently, the United States has developed the service of travel by railway to a greater extent than any other country. Then, again, in America the railroad is the pioneer and makes the settlement, whilst in most countries the towns exist and demand the railroad.

Description of the Building.

The Transportation Building was unique in its architecture. Its gorgeous exterior decoration and its superb golden door identified it at once. Its situation on the western bank of the central lagoon, looking upon the Wooded Island, brought it directly in the highway of the greatest traffic. Its polychromatic front bore the names of illustrious railway and marine inventors, and sculptured groups idealising the different forms of transportation. The north and south entrances were also elaborate, and bore the individual statues of many of the famous men who had originated and developed the scientific treasures within the building. A peculiar feature of the vast annex was the fact that it was found necessary to carry the Intramural Electric Railway over its roof, and the elevated railway from the city also entered the grounds over it. The descent from these aerial stations was at the south-western corner of the main building.

The main building measured 960 feet in frontage by 250 feet in depth. From this extended westward to Stoney Island avenue an enormous annex, covering about 9 acres, which was only one storey in height, and in which were to be seen the more bulky exhibits. Along the central avenue or nave the visitor might see facing each other scores of locomotive engines, highly polished, and rendering the perspective effect of the nave both exceedingly striking and novel. Add to the effect of the exhibits the architectural impression given by a long vista of richly ornamented colonnades, and it may easily be imagined that the interior of the Transportation Building was one of the most impressive of the Exposition. The building was refined and simple in architectural treatment, although very elaborate and rich in detail. In style it savoured much of the Romanesque.

The main entrance consisted of an immense single arch, enriched to an extraordinary degree with carvings, bas-reliefs, and mural paintings, the entire feature forming a rich and beautiful, yet quiet, colour climax, for it was treated in leaf, and was called the golden door. The remainder of the architectural composition fell into a just relation of contrast with the highly wrought entrance, and was duly quiet and modest, though very broad in treatment. It consisted of a continuous arcade with subordinated colonnade and entablature. Numerous minor entrances were from time to time pierced in the walls, and with them were grouped terraces, seats, drinking fountains, and statues.

The

The interior of the building was treated much after the manner of a Roman basilica, with broad nave and aisles. The roof was therefore in three divisions. The middle one rose much higher than the others, and its walls were pierced to form a beautiful arcaded clerestory. The cupola, placed in the centre of the building and rising 125 feet above the ground, was reached by elevators. The total floor space was nearly 20 acres. A 75-foot transfer table traversed the annex along the western line of the main building. Railway tracks were laid in the annex at right angles to the transfer table. The heaviest locomotives and cars could be run direct from the installation track, which ran alongside the southern end of the building, upon the transfer table, which took them to their proper tracks inside the building. The length of these tracks was such that an entire train could be shown connected as when in actual use. The annex opened into the main building in such a manner as to afford long and striking vistas down the main avenues and aisles.

I have already referred to the polychromatic decoration of the building, and the architects in the first conception of their design of the building carefully prepared its features externally, with a view to the ultimate application of colour, and many large plain surfaces were left to receive the final polychrome treatment. The ornamental designs for this work in colour were so interwoven in pattern as to produce an effect similar to embroidery. The colours themselves comprised about thirty different shades, which, however, were so delicately and softly blended and so nicely balanced against each other that the effect was that of a single beautiful painting. The general scheme of colour treatment started with a delicate light red tone for its base, and this was kept entirely simple and free from ornament in order to serve as a basis for the more elaborate work above. The culmination of high colour effect was found in the spandrils, between the main arches, where there was produced a high pitch of intensity of colour, and reliance was placed on the main cornice of the building, which was very simply treated, to act as a balancing and quieting effect in the general composition. In the central spandrils a beautiful winged figure was placed, representing the idea of transportation. This figure was painted in light colours and had a background of gold leaf. The colour scheme, as a whole, culminated in the great golden doorway. This entire entrance, 100 feet wide and 70 feet high, incrustated over its entire surface with delicate designs in relief, was covered throughout its entire extent with gold, and colours in small quantities were worked in between the designs and reliefs so as to give the whole a wonderfully effective aspect.

Statuary.

At the entrance to the south door of the building stood, on the right, statues of Stephenson, Barrett, Scott, and a figure typical of water transportation; and on the left there were statues of Montgolfier, Vanderbilt, Watt, and a figure typical of land transportation.

Mr. Proctor's most important works were the equestrian statues decorating the landing in the lagoon opposite the front of Transportation Building. The cowboy, as shown, was not the idealised hero of Eastern State novels, but a true representative of the manly western ranger. The horse, a typical bucking broncho with vicious eyes and ready for a spring, was curbed in by the rider's muscular hand. One could feel the quivering of the rebellion shocking his blood and gleaming in his eyes. Grim-visaged and with tense listening expression in every muscle, the Indian gazed from under his shading hand out over the prairie. The sculptor of mountain lions had caught the live sinuosity of the red man as well and portrayed the subtle mental kinship between him and his horse. This statue also was in front of the Transportation Building.

New

NEW SOUTH WALES EXHIBITS IN TRANSPORTATION BUILDING.
MODEL OF LITHGOW VALLEY ZIG ZAG.

New South Wales Court.

Our main space in the Transportation Building, containing over 1,000 feet, bounded on the north by Canada, with an alley-way on each of the other sides, was altogether too limited for our exhibits, and I was compelled to place the yacht's gig of Fanner, of North Sydney, after having it at first located in this space, in a very elevated position in the Fisheries Building, where it was an object of great attraction; and the sleepers and rails, sent by the Railway Commissioners, in another part of the building allotted to those exhibits, and where space was specially provided by the kindness of Chief Willard Smith. The limited space of the court was still further encroached upon by an elevator which ran to the next floor of the building, and for which space had been granted prior, I believe, to our allotment. The court though small was very attractive and well arranged. The large model of the celebrated Zigzag railway in the Blue Mountains, one of the famous feats of modern engineering skill, was placed at the south-east corner of the court, while the very interesting model of the large dry dock at Cockatoo Island, said to be the second largest in the world, was placed at the west end, and both models received much critical inspection. The cabs sent by Glencross, with their ingenious sliding doors, and the saddle by McGrath, Wagga, as well as the whips sent by Hodgson Bros., of Goulburn, were placed in good positions. Goodwin's wool waggon, for which room could not be found in this court, was placed in Agriculture and loaded with wool as an exhibit. The model of the R.M.S. "Austral" in this court was one of its chief features and with the photographs of the "Ophir," sent by the Orient S. N. Co., was always surrounded with visitors, who compared this model with those of the various steamship companies of the world in the immediate neighbourhood. I think the large photographs of our bridges and rolling-stock and charts hung on the walls, both inside and outside of the court, were the exhibits most carefully examined, especially by railway authorities. On the whole, although small, this court contained very distinctive exhibits, and from its character being representative rather than practical, formed a striking contrast to the immense engines of the London and North Western line in its western side.

Locomotive and Rolling-stock Exhibits.

It would be impossible to enter into a detailed list, not to speak of a description of the locomotive and rolling-stock collected in the annex of this building, and forming an extension of it. Nearly every great American Company and firm were represented.

The groups included in this Department were:—

GROUP.

- 80.—Railways, railway plants and equipment.
- 81.—Street-car and other street-line systems.
- 82.—Miscellaneous and special railways.
- 83.—Vehicles and methods of transportation on common roads.
- 84.—Aerial, pneumatic, and other forms of transportation.
- 85.—Vessels, boats, marine, lake, and river transportation.
- 86.—Naval warfare and coast defence.

Various English firms were represented, as well as those of France and Germany. The Canadian Pacific showed a standard passenger train and locomotive. Refrigerator cars formed a very interesting part of the exhibits of the various Companies.

Outside the building, near the terminus of the Elevated Line, was the remarkable exhibit of the New York Central and Hudson River Railroad Company, part of which was contained in a building specially erected for the purpose of exhibiting chiefly the drawings and photos of railway work and of scenery, &c., and part consisting of a series

series of carriages and a locomotive. This locomotive deserves special mention as being the fastest locomotive in America, and as having at times done considerably over sixty miles per hour. This locomotive was named the Empire State Express (No. 999), and with its full train of assorted Wagner Vestibule Cars represented the highest point of excellence in the American department of railway rolling-stock construction. Beside this splendid exhibit of an entire train was shown the old original locomotive which was first used on this railway-line, together with its train of coaches; this old-fashioned train came to Chicago from Pennsylvania, and at times developed a speed of fifty miles per hour. This locomotive was named the De Witt Clinton, and with its train of coaches was the first railway-train run in the United States. Its first trip was made on the Inshawk and Hudson River Railroad, on August 9th, 1831, when it ran from Albany to Shenectady and back. The following details are of interest:—

Weight of the engine, 6 tons.
 Cylinders, $5\frac{1}{2}$ in. box \times 16 in. stroke.
 Driving-wheels, 4 ft. 6 in. diameter.
 Boiler, 30 in. diameter.
 Capacity of tender, 375 galls.
 Weight of train of three coaches, with seats on top, 5,000 lb.
 Length of coach, 7 ft. 4 in.
 Width of coach, 5 feet.
 Seating capacity, ten persons.

Firewood was carried in two barrels on the tender.

The Baldwin Locomotive Exhibit.

The display of the Baltimore and Ohio Railroad consisted of two principal parts: historical engines and models and drawings collected from all parts of the world, as well as a considerable collection of permanent-way material. The historical collection of the Baltimore and Ohio Railroad will be found described in Appendix N.

The Baldwin Company occupied the most important place as regards the number of engines shown, in the annex of the Transportation Building, there being no fewer than sixteen locomotives in this exhibit. Placed beside these engines were those of the Brooks Co., of Dunkirk, N.Y., to the number of nine. These two firms occupied the principal portion of the space provided for this class of exhibits. Nine of the sixteen Baldwin engines were compound, on the system introduced by the firm some years ago, which has been adopted on several hundred locomotives, so that it may be considered a standard type. This Company has supplied New South Wales and Queensland since 1877, and, as is well known, special attention was directed to the products of the Company some time ago by a Royal Commission. I had the opportunity of conversing with a proprietor of these works on this subject. The following figures from the authorised publication of the Company are representative of the most important facts connected with the works as at present organised:—

Number of men employed	5,100
Hours of labour per man per day ..	10
Hours of work per day in principal departments ...	24
Horse-power employed	5,000
Number of buildings in works	24
Acreage of works	16
Number of dynamos for furnishing power to drills, punching-machines, &c., and for lighting	26
Number of electric-lamps in service	3,000
Consumption of coal per week (tons)	1,000
" iron " " 	1,500
" other materials per day	40

The erecting-shop of the Baldwin Works is 397 feet long and 208 feet wide; it contains 19 tracks, each long enough for four locomotives. Two galleries run down the building for the accommodation of

of 100-ton electric cranes. The engines built vary from the small mining or plantation locomotives weighing 5,000lb. in working order to the heaviest type of nearly 100 tons. These latter were well represented in the Exhibition by a compound freight engine for the New York, Erie, and Western Railway Co., which weighed in running order 195,000lb. It has ten coupled wheels and a two-wheeled leading truck, the total wheel-base being 27 feet 3 inches; the high-pressure cylinders in this engine were 16 inches in diameter, and the low-pressure 27 inches, the length of stroke being 28 inches. The total length of engine and tender was 63 feet 8 inches, and the total wheel-base 53 feet $4\frac{1}{2}$ inches. Standing near this, the latest production of the Baldwin Works, was a full-sized model of the "Old Ironsides," built by Matthias Baldwin in 1832, and which weighed in running order less than 5 tons. It is difficult to suppose that if the Baldwin Works continue to flourish for another sixty years they will at the end of that time be able to show such a contrast with their present practice.

The Pullman Exhibit.

The Pullman exhibit was unique. The magnificent train of carriages, fitted up in an artistic and luxurious manner never before equalled, and the representation of the town of Pullman, in the vicinage of Chicago, carried a story which will well bear consideration. The whole exhibit represented the practical evolution of an idea originated by an American citizen, in a wholly new field of progress, in which there had not been even any tentative gropings in other countries, and worked out along lines of strong individual personality. Of the material benefit to humanity, in the form of great comfort in travelling long distances, both as regards rest and food, as well as the cultivation of artistic taste and refinement by the highest talent in the elaboration of the cars themselves, thus making the sleeping and dining car interiors object-lessons in decorative art, this beautiful train of Pullman cars was the expression. Still more effectual a representation of the principles by which the Pullman Company, with its capital of \$60,000,000 is actuated, was the town of Pullman, of which the model was there presented. From the time the "Pioneer," the first of Mr. Pullman's cars, was constructed, after a series of experiments during the years 1859-63 till the production of the present magnificent exhibit, there has been a steadily-increasing improvement in the character of these cars. The culmination was reached as shown in this exhibit in that exclusively Pullman device The Vestibule, which makes a solid yet perfectly sinuous train with practically complete immunity from danger to passengers in even the most violent collision, and with the striking result of an entire train under one roof, in which the traveller may pass from his dining-room to his sitting room or to his sleeping room, as in his own home. With the exception of the air-brake, which puts the control of the train so completely in the hands of the engineer, there has been no event of railway development so important in securing safety to the travelling public as the invention of the Pullman Vestibule. In its latest application, as illustrated by the World's Fair Train, the principle was extended to the locomotive tender itself, thus taking into its protecting arms not only the passengers but the employees in the baggage and mail cars as well; and this extension was so constructed as to act as a wind deflector, thus diminishing atmospheric resistance to the speed of the train. The vestibule feature was also enlarged in this exhibition train to the full width of the cars by extending the sides of the cars and enclosing the ends, together with an original and ingenious arrangement of vestibule entrance doors and trap doors on the steps. This eventually adds to the comfort of passengers by doing away with the wind pockets formed by the ordinary projecting hoods over open platforms; and as well provides a comfortable and protected place for brakemen or other train employees, whose duties may require them to ride occasionally upon platforms. But

But the making of the Pullman cars was only a preliminary step toward building up the Pullman Service, as it now exists in the United States. The traveller can now start from a city in the United States, Canada, or Mexico, and travel to all accessible points of the North American continent, and everywhere over hundreds of different railroads, managed by different companies, he will find the one harmonious, perfectly administered system of transportation. Whether the traveller goes on board a Pullman car in New York or Chicago, or the wilds of Arizona, he finds the same beautiful surroundings, the same cleanliness and order, the same comfort and attentive service.

The exhibit of the town of Pullman was very interesting in many ways. When the company found its workshops in St. Louis, Detroit, Elmira, and Wilmington were unable to keep pace with the evergrowing volume of demand for its productions, it selected Chicago, with its central position with reference to the railway system of the continent, as the natural site; but, in view of many weighty difficulties touching both finance and the labour question, a site near Lake Calumet, 14 miles away from the city was chosen, and 3,500 acres of land purchased for the purpose. This entire tract is now embraced within the boundary limits of the great city, and round the Pullman district as a centre there is a connected girdle of thickly populated communities. There can be no doubt that ere long the pretty town of Pullman, with its shaded avenues, its glimpses of bright water, its harmonious groupings of beautiful homes, and churches and public buildings, will be like a bright little island in the midst of the great tumultuous sea of Chicago's population. I must not forget to state that every house and flat, even the cheapest in rent, is equipped with the modern appliances of water, gas, and internal sanitation; that the sewage of the town is collected and pumped far away to the Pullman produce farm; that there are grounds for athletic sports; that all the merchandising of the town is concentrated under the glass roof of a beautiful arcade building; that there is a market house, the ornament of one of the handsomest squares of the town; that there are churches and a school-house where nearly 1,000 scholars attend; a library of over 8,000 volumes; a savings bank paying a liberal rate of interest, and conforming in its regulations to the greatest convenience of the wage-earners; and lastly, a theatre, that is quite an artistic gem. Such is the town of 12,000 inhabitants which the World's Fair model represented.

The social aspect of Pullman rests upon the fundamental fact that it is founded solely upon solid *quid pro quo* business principles. It does not concern itself with philanthropy. It is based on the business theory that the better the man the more valuable he is to himself, and just in that proportion he is better and more valuable to his employer. So far from starting with the theory that these working men are weaklings to whom things are to be given, and who are to be supported lest they fall, the starting point is exactly the opposite. The assumption is started with that the Pullman men are the best type of American workmen, who will work out valuable and well-rounded lives in proportion to their opportunities. By the investment of a large capital it is found possible not only to give them better conditions than they could get elsewhere but to give those conditions at prices wholly within their power to pay, and yet sufficient to return moderate interest on the investment, and thus to sustain and continue the work. This is the whole Pullman proposition in a nutshell. The philanthropy it affects is that which helps men to help themselves without undermining their self-respect or affecting their independence or personal liberty. During the eleven years the town has been in existence this principle has produced a set of workmen of the highest character, with \$600,000 in the savings bank, and with the bright border of homes which fringe the outer edge of the Pullman track, and which represent the invested savings

savings of nearly 1,000 workmen. This town illustrates, in a remarkable manner, the helpful combination of capital and labour, mental strife or stultification, upon lines of mutual recognition.

The following account of the annual meeting of the company, held on 20th October, 1893, will be found of interest:—

THE annual meeting of the stockholders of the Pullman Palace Car Company was held in the Pullman Building, about \$24,000,000 of capital stock being represented. All the directors whose term of office had expired were re-elected as follows:—George M. Pullman, Marshall Field, J. W. Doane, Norman Williams, and O. S. A. Sprague of Chicago, Henry C. Hulbert of New York, and Henry R. Reed of Boston.

The statement of earnings and expenses for the fiscal year, ending July 31, is as follows:—

REVENUE.							
Earnings of cars	\$9,200,685
Patents	30,021
Manufacturing, rentals, dividends, interest, &c.	2,159,189
Total	11,389,896
DISBURSEMENTS.							
Operating expenses, including maintenance of interior furnishings of cars, legal expenses, general taxes, and insurance	\$3,825,940
Proportion of net earnings paid other interests in sleeping-car associations controlled and operated by this company	1,037,507
Dividends on capital stock	2,520,000
Total	7,383,447
Surplus for the year, being excess of revenue over disbursements, carried to credit of income account	\$4,006,448

The usual quarterly dividend of \$2 a share for net earnings was declared.

President Pullman supplemented his annual report with the following general information:—

During the fiscal year a new contract has been made with the Boston and Maine Railroad Company for a period of twenty-five years. The contract with the Lehigh Valley Railroad Company, which expired June 10, 1889, has been renewed for a period of twenty-five years, expiring June 10, 1914. The contract with the Maine Central Railroad Company, expiring May 23, 1898, has been extended for a period of twenty-five years, expiring April 1, 1918. The contract with the Norfolk and Western Railroad Company, expiring November 13, 1899, has been extended for a period of twenty-five years, expiring August 1, 1917.

There have been built during the year 314 sleeping, parlour, dining, and special cars, and seven parlour cars have been purchased, the entire cost being \$4,782,123.27. The number of cars owned and controlled is 2,573, of which 2,320 are standard, and 253 tourist or second-class cars.

The number of passengers carried during the year was 5,673,129, and the number of miles run was 206,453,796. During the previous year the number of passengers carried was 5,279,020, and the number of miles run was 191,255,656.

There has been added during the fiscal year to the company's investments in shops and plant \$388,904. The value of the manufactured product of the car works of the company for the year was \$12,329,827, and of other industries, including rentals, \$1,084,881, making a total of \$13,414,708, against \$11,726,343 for the previous year.

Railroad Coaches and Cars—Improvements in Construction.

From a review of the various railway cars exhibited in the Transportation Building, written by an expert (C. C. Dick) for the *Chicago Herald*, the following particulars, which contain a number of details connected with construction, as viewed from the American standpoint will be found interesting:—

To show the advancement made in roadbeds and tracks the Geleise-Museum of Osnabruck, Germany, prepared a collection of sixty-eight exhibits, going by stages of development, from the most primitive style up to the present time. The wooden switch and frog shown, as used in mines even to-day in Hungary, for instance, is quite a curiosity. It is operated by throwing the inside rail the full width of the track. The first section of a track proper is of cast angle iron rails three feet in length, laid on stone sleepers and held together by a single iron nail through the joint. The first locomotive experiment

experiment was made on this style of road in South Wales, Great Britain, in 1804, and was unsuccessful. The next oddity is a section with a gauge of 7 feet, laid in 1850 by the Great Western Railroad, of England, on wooden stringers held together by crossties, and not abandoned until 1892. They also show the heaviest rail used, weighing 127 lb. to the yard. The halved and lapped joint in this rail might well be considered by American builders, as it insures a much safer, more solid, smoother, and noiseless joint than the one in present use. The compartment car of the German exhibit will attract the attention of some from the fact that it rides on three axles, one under each end and one under the middle. In rounding curves the end axles conform to the radius automatically and the middle one by lateral motion. The framework is of steel, has all openings on the side, Westinghouse air-brake, rain-water gutter, and is a fair representation of more than 50 per cent. of the cars in use in Germany. The present tendency there is for longer and heavier cars, a combination of the English and American styles, having end doors, with aisle along one side into which compartments open. The capacity of this car is five first-class and twenty-one second-class passengers, from which we would infer that the latter was the greater in demand, which we cannot wonder at, as the only difference is in the grade of upholstery. While not intended for a sleeper, by pulling out the seat cushion, raising the arm rest and giving the end arm rest a slanting position a very comfortable bed can be made. The car is devoid of mouldings, but neat and substantial, and the workmanship is good. They also show a special car, built more on the American plan, in which all the mouldings are of pressed steel; all trimmings and small side panels are of brass; the glass is heavy plate, set in brass frames, which lower into the body of the car.

At first glance the ordinary observer would decide that all foreign cars were much more solidly and stronger built than the American, from the fact that in the European built cars so much iron and steel is in plain view. Their method of construction is to make a bottom framework of iron with cross-braces, on which the wooden superstructure is placed, while the American plan is to build a wooden framework and strengthen it by plates of iron bolts and rods. As each is supposed to meet the requirements exacted of it very little is gained or lost by either method, but the American car makes a neater appearance by reason of the absence of so many bolt-heads, angles, and rods near the bottom of the car, which obstructs the view and is confusing to the eye. In the German and English cars, extending from below the windows to the bottom of the car and its entire length, is a plain panel unbroken by carvings or mouldings, on which the painter's skill can be shown, and when well-finished gives a mirror-like appearance and admits of a more pleasing degree of decoration. The English coach makes a beautiful showing by the lower third being painted in a rich carmine and the upper two-thirds a very delicate light blue, with gold-leaf trimmings. The inside finish is principally polished black walnut with panel of bird's-eye maple in lavatories, and satin-wood panels with English walnut centre in compartments. The ceiling is plain sycamore with walnut bands, and this together with some very good hand-carved capitals and architraves give the interior a very attractive appearance. Each sleeping compartment is fitted up with hooks, wallpocket, and a wardrobe. The upper bunk is rarely used except in cases of necessity. Near the middle of the car is a room closed by a door with inside lock. It contains four beds, and is designed for the convenience of ladies travelling alone. Lavatories with self-emptying washbowls of heavy silver-plate, which fold back flush with the wall when not in use, are connected with each compartment. The ceiling is made of lincrusta walton. The seats make a bed as in the German car. The rear end is fitted up as an observation car with a mounted map and views of scenery through which the car passes. This is one of five built and not especially designed for exhibition. The only exhibit shown by France is one second-class car, with seats on the top and designed for suburban traffic only.

The foreign coaches are shorter and lower than the American style, yet their carrying capacity is the same as ours if not more, all entrances being from the side of the car, thus gaining the space lost to American builders by the centre aisle. The object of the Canadian Pacific Company is to show a train as run in actual service over their lines, and the accommodation their patrons may expect while *en route*. Every part was constructed at the company's shops in Montreal, and is an extra strong and heavy train. Honduras mahogany is used for outside work, finished in the natural colour. Heat is furnished by steam from the locomotive, or in case it becomes disconnected, by hot-water heaters which are placed in each car. All wheels have wrought-iron centres, with cupped steel tyres. Second-class sleeper accommodations are far in advance of anything of the same kind used in the United States. The finish is plain, but the plan is the same as in the ordinary first-class sleeper. The interior finish of their sleepers is of the Spanish renaissance style, with woodwork in the body of the car of white mahogany or "prima-vera," imported from the western coast of Mexico. All passages are made of old oak. The bunks are constructed with 3-inch square panels and a 12-inch carved panel on each end. All of their doors, panels, and arches are very heavy, as not a particle of veneer enters into the construction of any part of their work. Their method of making a door is unique and in oak looks well. Over each table in the dining-car is a bronze alcove, with a miniature balcony underneath. Besides being a small sideboard for each table, it gives a very pleasing effect. The view of the inside of their first-class day coach is broken by arches resting on turned and carved columns, and makes a very beautiful car. A shelf for light baggage extends the full length of the car; all of the carving is done by hand, and some very good work is shown. Their chief aim is durability, which they combine with beauty and convenience; hence all their work is of high grade. In one car shown by the Pennsylvania Company, the windows

windows are fitted with a self-lifting device; by pulling on a small knob at each side of the window it is released, and rises by means of a counterbalance. By releasing the knobs it is fastened at any desired height and held securely.

This device makes a window more nearly wind and dust proof, and prevents rattling. Another invention in use on this car is a curtain fastener, allowing the curtain to be raised or lowered at will, and held at any point wished. The agent in charge of this exhibit pleaded ignorance as to the construction, and, in fact, to any information at all in regard to this attachment, but kindly referred me to the superintendent of their shops in Altoona. However, it is understood fifteen or twenty cars are fitted with this appliance, and it will become a standard fixture. In their office building they have an excellent exhibit of relics, models, and illustrations, showing from earliest modes of travel up to the present luxurious day coaches. To fully appreciate these advantages you have only to slip outside their building, where standing side by side is the first train run in the State of New York, and one of their present "overland flyers." By way of comparison it may be well to state a few dimensions: The first coaches were 7 ft. 4 in. long, while the present length is 80 feet; the former carried ten passenger, and the latter eighty-four. If a car could be constructed combining all the points of superiority we would have a perfect coach. While the Krable train will not compare with the other vestibule trains, it has several points worthy of investigation. The train on exhibition has been running for over a year, and has fully met the expectations of its inventor. The cars are very plainly finished in oak, but can be elaborated to any desired extent, and quite a number of improvements are contemplated in succeeding cars. By an arrangement of their chairs, which is peculiarly their own, they are able to convert a day coach into a first-class sleeper. By placing two chairs facing each other, elevating the backs, and placing a cushion on a framework between them, an upper bunk is formed, while the bottoms of the chairs make the lower berth. All linen, curtains, and frames are stowed away in the bottom of the chairs, which is fastened on a movable centre, enabling a person to ride at any angle desired. The end doors are double, giving twice the ordinary width, and in cases of crowds their passage is greatly facilitated. By placing the brake-staff near the end of the car and using a ratcheted handle, the handrail is superfluous. The two vestibules can be thrown together, and a very comfortable smoking or observation room made. The folding step when not in use forms a barricade across the passageway, preventing accidents from falling off or attempting to board the train while in motion. They claim their cars can be used in other trains, with or without vestibules, but some more convenient and safer way should be adopted than the one given in explanation.

One cannot fail to notice the lack of interest shown by the local roads towards the success of the fair. As they expect to derive a monetary benefit therefrom we should expect them to make an attempt at least at some sort of a display. Only one car is exhibited, and that is so far behind the times it is not worthy of mention. The displays of the Wagner Company and Pullman Palace Car Company are very like each other, and what is said of one will apply to the other to a certain extent. Both have a barber's shop, with bath attached, and tile floors in one end of the smoker. Day coach, sleeper, and dining car complete the train. The material is the best, the workmanship unexcelled, and the furnishings the richest and most luxurious that can be procured. The ceilings of the Wagner train are finished in stucco. The woodwork of the parlour car is of satin wood; that of the diner of Circassian walnut; and that of the sleeper of white mahogany. All trimmings are gold-plated. This company has no special improvements that they call attention to, while the Pullman Company has several, the most noticeable of which is their new standard vestibule, by which the whole platform is enclosed, affording greater protection to road men, as they do not go between the cars to make the connections. Persons going from one car to another cannot fall off, nor can anyone get on or off the train while in motion. This vestibule being built flush with the sides of the car no pocket is formed to catch the air, thereby reducing wind pressure, which is an important factor in making fast time. It has been placed on a number of cars, and has been adopted as their improved standard vestibule. Being full width, a greater resistance is offered, and the chances of telescoping greatly reduced. The greater part of the finish is of vermillion, a very hard and dense wood, from the penal colonies of India, and brought to Liverpool as ballast, where it is inspected by the company's inspector, and all that is fit for use is controlled by this company. It is a hard wood to work, and great care must be taken to prevent its splitting or breaking off in delicate work. It is well adapted to inside finish, as it takes a good polish, not easily marred, and will not shrink or warp to any extent. The colour is of a reddish cast, varying from a very light to almost black.

The different styles of deck windows and ceilings is another interesting feature. Their ten-compartment sleeper, each compartment finished in a different colour with upholstery to match, is very attractive. All trimmings are triple gold-plate, and the washstand tops are of Mexican onyx. At some time in the future it is intended to have this elegant train thoroughly written up, when all the important features and interior may be fully described. The exhibit of this company is the most complete on the grounds. The showing of their standard six-wheel trucks will give to many a chance to see the mechanism of this part of the car for the first time. The postal car constructed by this company is attracting very favourable attention by this class of employees. As the Government only pays for space in actual use by them it has been endeavoured to use every inch of space available. This is a sixty-foot car, and, by means of the new vestibule, the space on both platforms, which has heretofore been dead space, is now taken up by stove, toilet-room, and lockers, thus giving more space for Government use.

The

The top of the vestibule being connected with closed vestibule on locomotive, and braced by heavy iron bars from top of vestibule to bottom of forward end of tender equalizes top and bottom pressure, by which telescoping is rendered impossible in head-end collisions. Particular attention is paid towards lighting and ventilating by means of large double windows on side and an eighteen-light skylight over the letter case. The equipments are the latest designed Harrison bag-rack, an entirely new reversible letter case, improved paper boxes, which can be readily changed from double to single by pushing upper bottom back, where it folds out of the way. In the forward end of the car one section of letter case is hinged on the side, allowing it to be swung clear of the doorway, together with a drop-table, gives free access to end door. When the door is not in use an unbroken table and letter case extends across the end of car and partly down each side. Slip stanchions are placed among the racks to hold mail, which, when distributed, can be removed and entire car racked up. The finish is white and cherry, with trimmings of nickel and bronze, and is undoubtedly the most compact, convenient, and best arranged car ever equipped for the handling of mail.

Several seat and chair companies have made some very fine exhibits in all the latest designs. Two of these require especial mention. The Wakefield Rattan Company has a seat which is reversed by simply pushing on the back from rear to front. This makes the back the front, enabling both sides to be used, giving a greater amount of wear than in seats which revolve. It is made in single and double, finished in cane, leather, and plush. They also make a line of reed chairs for dining and buffet cars. The most comfortable seat shown is one made by the Scarritt Seat Company. The two main features are the slight elevation of the front of the seat, and the concave and convex back, which adapts itself to the contour of the person, and acts as a brace when in use. By a very simple and strong piece of mechanism the concavity and convexity is reversed, as the seat is changed from rear to front. The guides on front seat ends for back stays are a very good thing. Exhibits of car-heating apparatus, palace stock cars, refrigerators, steel, street, and electrical cars, and several novelties are shown, but space will not permit of a detailed description.

Marine Exhibits.

If a seaman visited the Fair with the idea of seeing what improvements the different nations had made in his particular industry, everywhere in the marine exhibit, wherever he turned he would find the improvement expressed in one word—steam. The marine exhibits at the Fair plainly demonstrated that the days of the sailing ship even as a freight carrier are rapidly drawing to a close. This was especially noticeable in the fact that for one model of the sailing-ship of to-day, fifty models of steamers were to be seen, and what paintings and models of sailing craft were shown in the galleries of the Transportation Building seemed to have been placed there as illustrations of the past.

So zealously did the officials of the Exposition work in the endeavour to gather a collection of models and paintings to illustrate the changes that have been made since 1492, that one could commence in one corner of the marine exhibit, in the east gallery of the Transportation Building, with a picture of the British ship, the "Sovereign of the Seas," built in 1637, showing all her heavy top-hamper, and follow the changes down by paintings and models of different vessels until he arrived at the steel-built East Indiaman with her telescope masts, which, without doubt, are perfection itself so far as it can be exemplified in a sailing vessel.

The first material change in shipbuilding, according to the paintings exhibited, was made about 1640, as seen in a ship called the "Royal Prince," built in that year, without the projecting stem or bow so common to all ships of that date. Side by side with the painting of this old ship were to be seen some fine models of the Baltimore clipper schooners. They seemed life-like; broad of beam above the water-line, but sharp in the bow, deep aft, long and low; they were the very picture of vessels built to carry canvas and hold their own close-hauled, without making much leeway. Some of the finest yachts have been built on the same principles as these schooners, and it was from models of these ships that the famous clipper ships sprang, by the adoption of the square rig for larger vessels. There was also a painting of the clipper ship "Great Republic," with four masts, her main-yard being 120 feet long, and her spread of sail consisting of 15,653 yards of canvas.

A collection of Chinese and Japanese models of sailing craft was shown in the east gallery, and they were very curious and interesting. The "Tek-pai," used on rivers and lakes, when loaded does not draw over 12 inches of water. The different parts of the vessel were tied together, and in case of her grounding, could be broken up and put together again in half a day. The seamen of this strange craft lived in a house, built of rushes, on her deck. The sampan, so familiar to Hongkong sailors, was also to be seen. It is the bumboat of China.

Germany made but a small marine exhibit, including three very fine models of iron ships, with masts on the telescope system.

No exhibit was made by any of the other nations in the line of sailing vessels, with the exception of Norway, which country showed some models of steel sailing vessels, which compared very favourably with those of the British build. Wire was used for rigging purposes in all the models on exhibition, taking the place of the hemp rope. Turn-buckles were used in place of the lanyard for standing riggings. Very little that was to be seen in blocks, lines, and anchors.

In this connection reference may be made to the great whale-back steamer "Christopher Columbus," which was regularly employed for transport purposes between the city and the Exhibition. As far as I am aware, this type of steamer is unknown in Australia.

The great whale-back steamer was built in the most remote shipyard of the United States, in the north-west corner of Lake Superior. According to *Engineering* :—

This new type of ship has been received with great favour on the American lakes, and the very extensive shipyard of the Whaleback Company, in or near the small Superior City, has more than it can do to fill orders. We remember seeing in 1890 the first of these craft at Buffalo, where a steamer and a barge attracted great curiosity as they lay in the harbour of that lake city. They attract no curiosity now, for they are rapidly being recognised as the cheapest and most convenient type of vessel for the bulk of the lake trade, and it is said that the tonnage carried by them is now almost as great as that conveyed by vessels of all other kinds upon the lakes. Be that as it may, the fleet of whale-backs is large, and is constantly increasing. But this new vessel, which is just now creating no little excitement in Chicago, is quite a new departure. So far as regards the hull and arrangement of engines, the standard system has been followed; on the structure, however, three decks have been built, giving a vast capacity for passengers; accommodation for over 4,000 was to be provided, but on a recent occasion, before the ship commenced her voyage to Chicago, she carried no less than 5,700 people, probably the greatest number ever afloat on a single vessel, unless we except the "Great Eastern," which, for anything we know, might have carried more. The ship is about 360 feet long and 42 feet beam; her engine power is between 2,000 and 3,000 horse-power, and her contract speed was to be eighteen miles an hour; this, however, has been exceeded, and she made twenty miles regularly on her station. A very remarkable feature about the "Christopher Columbus," as the new whale-back is called, is the short space of time in which she was built. All the iron used at the Whale-back Shipyard is manufactured at the ironworks belonging to the company, who possess extensive iron-mines in the vicinity. In this way the material employed in the "Christopher Columbus" was produced, and the ship was completed and launched eight months after the iron ore for her plates was delivered at the furnaces. This record adds a special interest to the vessel, and makes her an essentially American adjunct to the Exposition.

In this Building the great steamship companies of the world were very fully represented. The White Star Line had a special building erected near the "Puck" Building at the north-east end of the Horticultural Building—for official and representative purposes. In it were shown separate rooms, sections of the dining saloon, and other matters connected with their line. Other companies exhibited by means of dioramas, models, and other devices, varieties of life at sea. At one point in the building there was represented the side of a great Transatlantic Liner, or at least a section of it, 60 feet in length. Entering on the lower deck the visitor passed through the various rooms and ascended staircase after staircase for five stories, the rooms and their fittings and furnishings being identical with those of the real

real steamers. Of all these models that which attracted the greatest attention was the very large and beautiful half model of the ill-fated H.M.S. "Victoria," exhibited by Armstrong, Mitchell, & Co., of Newcastle-on-Tyne.

The French Transatlantic Company showed a number of well-executed dioramas portraying in a graphic manner the various incidents of sea travel. Every mode of transportation used in France from the earliest to the most recent date was represented, from the old sedan chair up to the latest pneumatic tire racing wheel. French civil engineering exhibits in the same building display a number of maps, plans and photographic views of many of their greatest works of skill. French seaports from Dunkerque to Bordeaux on the Atlantic and Marseilles on the Mediterranean show the resources they offer to trade and shipping.

The elevators in the building were themselves exhibits of vertical transportation; they were grouped in the centre of the building, eight in number, and led up to the dome of the building from which a beautiful prospect could be obtained, not only of the grounds but also of the working of the various railway and water systems within and without the grounds.

Of wheeled vehicles of every kind there was ample display on the main floor at the northern portion of the building. Some of these exhibits were an extraordinary contrast to each other; for example, a Lord Mayor's State Coach formed rather a startling contrast to a rude "carreta" made without metal by the untutored hands of Pueblo Indians. So, also, a gaudy outfit of a cart and harness from Palermo; land sledges from Funchal; a caleche from Quebec; a patent hansom from Sydney; and a Cuba volante appeared as remarkable examples of means of transportation employed in very different and widely separated countries. The bicycle exhibit displayed in the beautifully lighted and readily accessible gallery of the building was perhaps the largest and most varied ever collected together. Several nations contributed to this particular representation but the American makers both for the number and beauty of the displays were entitled to unstinted praise. This fact is not to be wondered at when it is understood that the use of the bicycle is almost universal throughout America, and not only do children of the tenderest years practise without the slightest fear on these vehicles, but it is quite a common circumstance to see happy couples, either singly or on the one bicycle, and not infrequently with an infant sitting in a kind of seat before them, speed gaily through the boulevards and avenues of the cities.

Our Sleepers and Rails.

The large western portion of the building, called the annex, to which I have already referred, contained over $2\frac{1}{2}$ miles of railway tracks. In this section were gathered the machinery and appliances used in constructing, maintaining, and operating all forms of railways. It was in this portion of the building that our sleepers and rails were laid, near the British section, and thus opportunity was afforded to place in contrast our durable hard-wood sleepers, or ties as they are called in America, with the wooden and iron sleepers of other systems.

The Krupp Exhibit.

The great exhibit of Krupp, of Essen, Germany, was placed in a building specially erected for it by the exhibitor on the lake shore north of the leather exhibit building, and south-east of the agricultural building. As I have stated elsewhere there were also exhibits by Krupp in Machinery Hall.

The

The pavilion consisted of a large iron hall 196 feet in length, 82 feet wide, and 42 feet high, and was constructed and erected by the Gutehoffnungshuette, of Oberhausen. The pavilion was provided with boiler-house, offices, &c. On the ends were two small towers, on the front extension two large vestibule entrances, and a high square tower in the centre; the panels on the front were decorated with coats of arms of Westphalia and Rhineland, and on the cornice were shields bearing the coats of arms of the various states in Germany.

This exhibit contained a large amount of railway material as well as a vast collection of naval and military ordnance. The largest gun in the world, 125 tons, was placed in this building, and was a great source of attraction; the successful transportation of this immense gun from Germany to Chicago created considerable interest, and the progress of the monster was daily recorded in the newspapers as one of the events of the time.

Herr Krupp expended \$1,500,000 in making his display.

The visitor entering the large hall from the north entrance found himself before a front of sixteen guns, from the middle of which the gigantic barrel of the Thunderer, 17 inches in diameter, was prominent. The barrel was a jacketed, built-up tube; it had Krupp's rounded wedge breech closure; its total length is 46 feet, and it had 120 grooves in rifling. The barrel, which had the immense weight of 121 tons, including the breech closure, was supported by a front pivot carriage with a weight of projectile of 2,205 pounds. With a charge of 903 pounds and an initial velocity of 1,981 feet a second and an energy of 60,002·8 foot-tons is developed, and the greatest range with elevation of $10\frac{1}{2}$ degrees is 968 yards.

This gun was made in 1886, and has since been fired with sixteen rounds with full-charge. A steel armour shell with the above-mentioned initial velocity can perforate, when striking at right angles, a wrought iron plate of $3\frac{1}{4}$ feet thickness at a range of two-thirds of a mile. Beneath this biggest of all existing guns was the counterpart, a petty bush gun, as it has been used in various expeditions in the interior of Africa. According to the purpose, the several parts of the gun have been dimensioned with regard to their weight, so as to allow of their being carried by men, if required, long distances. Between these limits there were a great number of guns of different calibres and purposes.

There were, moreover, five quick-firing guns, from 3 to 5-foot calibre, the barrels of 40 calibres of length, and in centre pivot ship carriage. Guns of this class constitute the main armament of cruiser corvettes and cruisers, and also form the intermediate calibres in the armament of armour-clads. All these guns are unexcelled in easy handling and great speed of firing. The 5-foot gun has a speed of over eight shots per minute, and has fired up till now 269 shots with full charges.

The 4-foot gun has a speed of firing of thirteen shots, aimed fire, per minute, and the 3-foot gun of over nineteen shots.

There were two small field guns. The first one, with a barrel of 680 lb. weight, is particularly suitable for use as the main armament of the field artillery, that is to say, as the heaviest field-gun in cases where the configuration of the roads and the grounds resemble those of the American States.

The next gun was a 3-foot mountain gun, with a wheel carriage. This gun must be carried on the backs of beasts of burden, and since the weight of the several parts must be suitable to this mode of transport its efficiency lies in comparatively narrow limits. Nevertheless the work of the gun is very good, and particularly its shrapnel fire gave very splendid results at Placilla, in Chili, during the last war.

The

The high perfection which the moulded steel castings have reached in the works at Essen is made evident by several important pieces. The excellent qualities of this material were shown in a unique way on three distorted spoke wheel centres which are bent in several ways. The spokes and the rim of the first one have been bent and twisted cold under the hydraulic press in order to show the tenacity of the material. Another has been entirely bent cold under the hydraulic press, and the spokes and the rim of the third one have been forged out while warm in order to show the forging property of the material.

The steel castings exhibited excelled by their very considerable softness and capability of elongation. They have an average of breaking load of 25 tons per square inch, and up to 34 per cent. elongation. The castings of great thickness are just as soft as in the small thicknesses. Herein lies the essential difference as compared with tempered steel. The cross sections are homogeneous and free from porous places. The castings are free from all strains; the material is not affected by rapid cooling of heated portions. After being at a red heat and put in water they can still be bent without breaking. Numerous test pieces taken from the exhibit showed the good properties of this material, which forms a complete substitute for forgings in many cases.

A boiler plate exhibited is the largest boiler plate yet made. Its length was 65 feet, its width 10 feet, and its thickness 1.26 feet, while the weight was 15.94 tons. The production of the plates of these dimensions allows of constructing boilers of the largest size from the fewest possible plates, with only one riveted joint in the circumference. Three pieces were exhibited as a test of the material:—A shallow dome-shaped piece produced by hammering while warm with wooden hammers from a plate of welding iron two-thirds of an inch thick; a distorted flue of a tenbrink boiler destroyed through want of water, constructed of Krupp's welding iron plate, and a distorted boiler end plate half an inch thick, boiler plate of homogeneous iron, distorted intentionally while cold under the steam hammer.

There was also a very large and complete collection of articles of steel, pressed and forged in dies, consisting of centrifugal vessels, protective caps for armoured towers and locomotive steam domes. All the different and various objects were exhibited in the pavilion in a very clever way, and from the wrought-iron balcony, which was designed by Halmhuber, of Dusseldorf, architect, and executed by Gebrüder Lipgens, of the same place, one has a general view of the whole display.

There were glacier fountains which were constructed by Dr. Raydt, of Hanover, and designed to cool the atmosphere of the pavilion in a novel and peculiar manner. The exhibits, together with the model of the ancestral home of the Krupp family, the model of the monument erected in honor of the deceased Alfred Krupp by voluntary contributions of the officials and workmen of the firm of Friedrich Krupp, the numerous water-colours and panel pictures, the photographs, &c., made an overwhelming impression upon the scientist and the layman.

Ordnance Exhibits.

In the Transportation Building and in the United States Government Building, was a very large, interesting, and varied collection of specimens of ordnance of various kinds, which attracted great attention. The very latest inventions in the way of ordnance, heavy and light, of all kinds were exhibited, and what made the display more interesting was that each new invention or improvement was accompanied by its ante-type of ancient time. For instance, in the British display, contiguous to some old smooth bores of the days of King George (guns taken from Nelson's flag-ship Victory) appeared the first attempt in rifled artillery. The Whitworth breech-loading
rifle

rifle was a creation of the Crimean war. It was effective while it lasted, and for some uses was a valuable accession to field and naval ordnance. But with the advent of steel armour plates and the introduction of heavier and more powerful ordnance the old Whitworth rifle ceased to be manufactured in England. Near this obsolete specimen were several of the Armstrong steel high-power guns of to-day. The English Government has ceased to manufacture any larger gun than that which is known as the 65-ton Armstrong, but no gun as large as that was on exhibition. The largest shown was a 30-ton gun which corresponded in type with the American 8-inch rifle. These Armstrong guns in their various sizes and weights form the heavy batteries of England's new battle-ships.

The German exhibit of heavy ordnance was chiefly confined to the Krupp Pavilion, already described.

Of the curious old Mexican field pieces captured in the Mexican war there was an unusual display. Some of these were very interesting, because of their antiquity. Many of the old brass pieces bore the date of the seventeenth century, and were unmistakably mounted in Mexico at the time of the Spanish conquest. The most curious of all this ancient display was what is believed to be the oldest breech-loading gun ever constructed since the invention of gunpowder. It came from China, and for many years had been in the naval museum at the Washington navy yard. The breech-loading attachment consisted chiefly of cutting out a section of the powder chamber, inserting a charge of powder, stuffing in a plug and firing it off. It was a curious contrivance, and showed that the principle of breech-loading guns was among the earliest ideas of civilised man. The gun was reported to be ever so many centuries old. Contrasting this little piece with the rapid-fire ordnance of to-day displayed at Jackson Park by every nation was well calculated to impress the human mind.

In the artillery display of every country there was something marvellous and novel, as is well-known modern rapid-fire ordnance has attained its highest state of development within the last ten years. The proved inventions in this line of artillery were so numerous that they became almost wearisome. The Americans had four types of equal value. These were the Hotchkiss, the Briggs-Schroeder, another type invented by Ensign Dashiell, of the navy, and yet another whose name I cannot now recall to memory. England exhibited the Armstrong rapid-fire gun, the chief feature of which is its calibre, its lightness, and the rapidity with which it can be handled. It has a 6-in. bore, weighs $6\frac{1}{2}$ tons, throws 100-lb. projectile with 17 lb. of smokeless powder, and is fired by electricity. The best trials of this gun showed a speed of five aimed shots in fifty-five seconds, four of them striking the target at a range of 900 yards. The powder used with this gun is known as cordite, a high-power explosive. This gun, therefore, may be regarded as the very highest type of modern rapid-firing ordnance. The Americans are improving the Hotchkiss so that it may be brought up to the British standard.

Captain H. A. Russell, of the ordnance department of the United States, exhibited a gun at the Government Building, showing the mechanism of the United States magazine rifle, model of 1893.

Krag-Jorgensen pattern.—This differs from the United States model only in being adapted to the Norwegian cartridge, which is of calibre .256 instead of .30, and which has shells with cannellured heads instead of flanged heads. The new loading clip, intended for the Norwegian service, is shown with the gun. The bayonets and sights differ from the United States model, also the gun-sling attachments, which are of novel form. Bayonets and sights for the United States rifle will soon be received, and the United States rifle itself, manufactured at Springfield, Mass., is expected about October 1.

In

In the French exhibit was shown the Canet rapid-fire gun, the largest gun of which type is $5\frac{1}{2}$ in. in calibre, and 11,000 lb. weight. It uses 24 lb. of smokeless powder and throws a 70-lb. shell. In rapidity of fire the French are ahead of both British and Americans, for at a trial of these guns at exhibition two years ago seven unaimed shots were fired in fifty-four seconds, and at another trial of another one which was smaller and of the same type, five unaimed shots were fired in twenty-four seconds. The Russian naval authorities have adopted the Canet type of rapid-fire gun for their service.

There were other types of ordnance displayed in their several departments by the different nationalities. There was a Danish gun known as the "Finspong," and a Dutch gun known as the "Gericke," the invention of Captain Gericke, of the Dutch navy. Then there was the "Gruson," which is the invention of a Prussian officer. This gun is lighter than either the British or American type, but it fires an average of thirteen shots in thirty seconds. Then there was the Krupp rapid-fire gun, which was on exhibition in the Krupp pavilion. This is a heavier gun than any except the Armstrong, but it is not so rapid. The largest type carries 17 lb. of powder and a 76-lb. shell, but its highest speed is seven aimed shots a minute.

In the Transportation Building were several rapid-fire guns manufactured by private English firms. The best of these is known as the Maxim-Nordenfeldt. This gun is $4\frac{3}{4}$ in. calibre, weighs $2\frac{1}{2}$ tons, and throws a 45-lb. projectile. Trials made in England with this gun proved that at a range of 100 yards 4-in. steel plates were pierced with ease. The chief beauty of these small pieces, however, is the speed with which they can be fired. The gun of this make, with 3-inch calibre, or what is known as a 40-pounder, can be fired thirty-five times a minute. The 2-inch gun, or 3-pounder, has attained a speed of sixty shots per minute, or one every second. In fact, at one trial this gun fired sixty shots in fifty-nine seconds. In this same exhibit was perhaps to be found the most effective machine gun of any of the smaller calibres. It is known as the Maxim automatic gun, of which there were two on exhibition. One of them, which weighed only 50 lb., attained a rate of 600 shots a minute. The other was a larger piece, weighed 364 lb., had a powder charge of 3 oz., and threw a little baby shell weighing 1 lb., but it threw it at the rate of 250 a minute. Then there was a gun called the Skoda rapid-fire gun, which was to be seen in the Austrian exhibit.

Display of Projectiles.

The projectiles ranged in size from 1 lb. to 1,800 lb. The latter was the projectile for the big Krupp gun. It was as large as a barrel and as tall as the average man. The average service projectile, however, weighed from 100 to 250 lb. The biggest American shell on show weighed 1,100 lb., and was for the great 12-inch gun on exhibit in the War Department. The ancient and obsolete projectiles were also displayed in great numbers. They included everything, from what is known as the old "bar shot" and "chain shot" down to the ingenious explosive projectiles invented during the civil war by the Confederates, some of which were very novel. The "bar shot" was made by splitting a cannon ball in two and connecting the two halves by means of an iron bar; their purpose was to cut rigging and ship spars. The "chain shot" was on a similar principle, except that two cannon balls were connected by a long heavy chain. This was employed for the same purpose as the bar shot.

Another curious exhibit was an old-fashioned furnace for heating shots to fire at ships. Probably the last time a red-hot shot was ever fired was at the battle of New Orleans. Here I may relate a funny story about a Confederate officer who had charge of a red-hot shot battery at Fort Jackson. The science of war was new to the
Confederates

Confederates of those days, as well as to the Federals, and the officer could not be expected to know much about firing red-hot shot. His battery consisted of two guns. For two hours he blazed away at the passing fleet, and after the affair was over every shot that had been put into his guns was found in the ditch below the muzzles of the guns. The secret was that the men, in their supreme haste to get rid of the red-hot shot after it had entered the gun, ran the gun out so quickly and with such force that before the captain of the gun could reach the lanyard to fire, the hot shot would roll out at the muzzle, and the result was that nearly every shot he fired was only a blank cartridge.

The Bethlehem Iron Company's exhibit, adjoining that of Japan, was one which deserves particular mention, on account of the striking show from their famous gun and armour works in the Lehigh Valley. Here there was an exact reproduction of this company's 125-ton steam hammer, said to be the largest in the world. The exhibit itself is divided into three sections. Passing to the left, through one of the great legs of the hammer, the first section was entered, and here were two immense steel forgings, the barrel and jacket of a navy 13-inch cannon, which were splendid examples of the hollow forgings Bethlehem turns out from its famous hydraulic presses. In the course was a smooth forged trunnion hoop for securing a 12-inch 50-ton army gun to its carriage. At the front of this section was a navy 12-inch breech-loading rifle, fabricated at the Washington Gun Factory of Bethlehem, fluid pressed, hydraulic forged steel. It weighed 45.2 tons, was 37 feet long, had a muzzle velocity of 2,000 feet a second, and fired an 850-lb. projectile with 425 lb. of powder, with an energy sufficient to perforate $22\frac{1}{2}$ inches of iron. In the second section was a model of a 113-ton ingot of steel for which the armour plates are forged. Directly opposite was a pile of forged steel hoops and three splendid examples of steel armour and a nickel-steel ventilator for the monitor "Puritan" 7 feet in diameter, forged in one piece without welds. The largest was a curved nickel-steel plate, 17 inches thick, one of thirteen required to form the barbette of the battle-ship "Indiana." While its shape displayed the power of the huge bending presses of this company, its exquisite finish showed the marvellous machine facilities possessed. The next was a case-hardened nickel-steel plate, $10\frac{1}{2}$ inches thick, which had been subjected to an attack of the enormous energy of 25,040 foot tons, during which the five 8-inch 250 lb. Holtza armour-piercing shells were completely pulverised, without seriously injuring the plate. The third plate was the first heavy steel plate made in the United States, and was $11\frac{1}{2}$ inches thick. Near this was one of the most remarkable articles of the exhibit—a fluid compressed steel ingot, 15 feet long, 54 inches in diameter, weighing 48.3 tons. From a similar ingot, weighing 65 tons, the shaft of the Ferris wheel in the Midway Plaisance was made. In the third section was a hollow hydraulic forged shaft, 67 feet long, and 20 inches in diameter, forged in one piece. There was also an exquisitely finished shaft, 40 feet long, 27 inches in diameter, weighing 30 tons, which was made for the Old Colony Steamboat Company's "Puritan," and near this was a fine example of a built-up crank for the Pacific Mail Steamship Company.

Intramural Railway.

In the "White City of Great Distances" an indispensable provision was that of transportation from one portion of the grounds to another. Looking at the map of Jackson Park, and noting the distances of some of the main buildings from one another, the question must naturally have arisen as to how the visitor could get about the immense spaces with expedition and convenience. There were no fewer than six methods of transportation in the grounds, three by water and three by land. The gondola is too well known to require further

further reference. The electric launch was one of the features of the water exhibits and was a very graceful and speedy method of conveyance from one building to another. Steam launches carried visitors from the North to the South Lagoon and *vice versa, via* the Lake. Transportation could be effected either by the wheeled chair or by the Sedan chair on *terra firma*; but the last and best mode of conveyance was by the intramural railway, a round trip on which gave an excellent idea of the various buildings and the neighbouring sights in a most comfortable and rapid transit. As an experiment in the realm of electric engineering this interesting mode of transportation deserves a somewhat comprehensive description.

The northern extremity of the line, which made an almost complete circuit of the grounds, only that portion facing the lake being excluded from its detour, was situated at the east end of the Fisheries Building; at this end was located the north loop over that portion of the lagoon. This loop was an excellent device to avoid the trouble and inconvenience of switching, as one train could follow another round the loop and thus take up its position in readiness for the next trip. I may remark here that a similar device was provided at the other end of the line at the south loop, situated to the south-east of the Agricultural Building.

Starting from the north loop the line passed the Fisheries Building and extended to the extreme northern end of the Park, passing through that portion of the grounds where the various State buildings were situated; the line then followed the western boundary of the Park, there being stations in close proximity to the Women's Building, Midway Plaisance, the Grand Court of Honour, and the Horticultural Building. The line crossed the annex of the Transportation Building and the Main Terminal Station of the Exposition, and after passing the west end of Machinery Hall Annex reached the southern loop, west of the Krupp Building. After leaving the northern loop the line served the State Buildings, the Women's Building, Midway Plaisance, the Horticultural Building, Administration Building, Machinery Hall, the Agricultural Building, the "L" Line Terminus, the Ethnological Building, Forestry, the Leather Building, and the Dairy Building, besides several important isolated exhibits. It will thus be seen that the intramural was a very great convenience to those having business or pleasure which called for their presence at points in the grounds which were a considerable distance apart.

The power-house, where were situated the engines and dynamos for generating the current necessary to work the line, was situated at the south-eastern part of the grounds, behind the Forestry Building. The total power produced was about 5,000-horse power, steam being obtained from five double Babcock and Wilcox boilers, thus making ten in all; and five engines performed the duty of driving the dynamos. Oil was used as the fuel. The power plant consisted of five engines and five generators of various sizes and types, ranging from 268 to 2,000-horse power. The smallest generator was of the direct driven type, which was connected with a McIntosh and Seymour engine of the high-speed tandem compound horizontal type, running at 150 revolutions per minute, connected with a Dean condenser. This engine and generator were capable of operating twenty ordinary street cars and yet occupied a total floor space of only 10 x 20 feet. The General Electric Co. were stated to be building six of the large generators for the Brooklyn (N. Y.) City Railway Company.

The switchboard was made of enamelled slate and was a striking feature of the installation. The board was composed of five panels, one for each machine, each panel containing all the instruments necessary for the control of the machine to which it belonged, including triple

triple pole switches, shunt rheostats, ammeters, automatic circuit breakers, lightning arresters, lightning switches, &c. The generators were adjusted to run in perfect harmony so as to divide the load exactly in proportion to their relative capacities—a nice problem, with generators of such varied sizes and types.

The line was raised on wooden trestles to a general height of 25 feet from the ground, and was carried on these by means of light iron girder work. The motors on the leading car were supplied with current by means of an iron block or shoe sliding on a steel rail placed outside the track, which acted as a conductor, the current being returned by the other rails to the wires below. The joints of this conductor were made with an ordinary fish-plate on one side and on the other with a strip of copper.

The curves on the line were rather sharp, those forming the northern and southern loops being 100 feet radius. On either side of the rails were bolted balks of timber, similar to those in use on the elevated lines in New York and Chicago, the object of this arrangement being to prevent the cars from being precipitated to the ground if the wheels were to leave the track. The track was double, and the total length when considered as single track was $6\frac{1}{4}$ miles.

A uniform fare of 10 cents was charged, which seemed rather high to those accustomed to the 5-cent fare general on all the city street railways, but this charge appeared reasonable when the outlay of capital was taken into consideration, as well as the somewhat exorbitant tax levied by the Exposition authorities. Tickets were bought and fares collected in the same way as that in vogue on the above-mentioned lines.

The trains consisted of a motor car and three trailers, the former equipped with four 50-horse power motors. An air-brake system was in use, which was worked by a small motor on the leading car, driving an oscillating cylinder pump. The signal whistles also were worked by the compressed air which operated the brakes.

Fifteen trains of four open carriages, seating 100 passengers to each car, and occupied three-quarters of an hour in the round trip. The first car of each train was provided with four motors, developing 133-horse power each, at 25 miles an hour. The power plant had a capacity of 3,700 kilo-watts. Six thousand passengers could be carried each hour. A part of the mechanism was of especial interest. The track was equipped with a block signal system, and electricity was employed to release the block, setting the signals of safety, and there was a device which threw off the current and set the brakes on the train in case the motor-man ran past a danger signal, and it was stated that a signal out of order acted in the same manner, and so notified the motor-man.

It will not be out of place to mention here that similar automatic block signal systems are in use on the main railway lines of the United States, and are worked either by electric or pneumatic power, the only difference being that the red discs are used to warn the trains of danger in place of the semaphores used in this instance. Of course on steam roads the current does not automatically stop the train as it did in this instance.

The current was carried from the power-station to the trains through a conductor consisting of a T rail, supported on insulating blocks, just outside of the track. Four sliding shoes, two on each side of the car, make the connection with the conductor, the current returning through the wheels to the rail, and thence through the steel girders of the superstructure to the power-station. To make the necessary connections between girders large plates of copper have been riveted to the steel with copper rivets.

The

The intramural railway and its power-house formed a portion of the exhibit of the General Electric Company.

There could be no doubt as to the satisfactory nature of this experiment. As regards safety, no accident has occurred in connection with its employment, although vast numbers of passengers have travelled on it, and, as I have said, the curves at the loops on the line were very severe. All the inconveniences and discomforts of steam carriage were avoided. It has been asserted that as a result of this, and similar experiments, that the electric motor will soon supersede the steam locomotive as regards heavy and rapid transit. On this subject an able article from the *Philadelphia Ledger* contains some useful information:—

Edison's first conception of an electric motor for cars was of a locomotive proper, powerful enough to take the place of the engines on a steam road in the hauling of heavy freight or fast passenger trains. As far back as 1879 he had a motor running up and down hill at Menlo Park on a rudely constructed railroad. But the first commercial application of electric motors to the moving of cars took place on street railways, and on the trolley lines the power required is so small that it is applied directly to the wheels of the cars, no locomotive being used. Recently, however, the General Electric Company has constructed a real electric locomotive, now on exhibition at the World's Fair in Chicago. It is a double-ender, a specially constructed machine of a type that may soon take the place of steam locomotives on some of our larger railways for special service. The Baltimore and Ohio Railroad, a pioneer in the construction of steam locomotives, is also to be the pioneer in the use of electric locomotives. That company has built a costly tunnel under the City of Baltimore for its through trains, and immense electric locomotives built for it by the General Electric Company will be used to haul both passenger and freight trains through the tunnel. This will do away with the nuisances arising from coal smoke, dust, and cinders, and the tunnel itself will be made as light as day by 4,000 incandescent lamps, fed from the same central station that supplies power to the locomotive. The latter will be 1,200 horse-power and will consist of three separate trucks coupled together to form one motor. There will be twelve drivers to each locomotive and the weight of them will be from 90 to 100 tons. The power-station now in course of construction is to contain five generators, with a capacity of 700-horse power each at 600 volts—which is little more than the pressure used on the ordinary trolley-line.

There is not much that is experimental about this proposed use of powerful electric locomotives except the question as to the cost of operating, and that is a minor question in the limited use to be made of the motors by the Baltimore and Ohio Railroad. Even though electric power should be more costly than steam power, the advantages to be gained will offset the increased cost. But it is confidently believed that electric locomotives can be operated as cheaply as by steam locomotives. The latter are less efficient than compound stationary engines in a centralized plant, and the economies in the generation of power are expected to offset the losses resulting from double conversion from mechanical to electrical energy, and then from electrical to mechanical energy. These losses are considerable, but have been greatly reduced since Edison made his early experiments by the invention of improved methods of constructing dynamos and motors.

The experiment at Baltimore is being made on such a large scale, and with such liberal expenditure of money in providing the best available plant, that it may be expected to give an almost conclusive answer to the question whether electric locomotives can be economically used on the elevated and suburban railroads now operated by steam locomotives.

President Uhlman, of the Union Elevated Railroad, Brooklyn, is represented to have said that electricity was not practical as a substitute for steam, and that it would cost \$100,000 to make a test of it, but, as a matter of fact, electricity is now successfully used in the intramural (elevated) railroad at the World's Fair in Chicago, and the success of the surface trolley-lines proves conclusively that the system could be used on elevated structures. It cannot make any difference whether the road-bed is on the surface of the street or is on an elevated structure, except that a trolley-line can be more cheaply applied to an elevated structure than to a surface road. The question of operating cost remains. The trolley is the cheapest means of propelling cars of roads that cannot use steam; it remains to be seen whether it is cheaper than steam, or as cheap, and the experiment of the Baltimore and Ohio railroad will help to answer that question.

Under any circumstances, however, the introduction of electric in place of steam locomotives must proceed slowly. Existing roads cannot afford to throw away their motive power to substitute another unless it promises to pay for the sacrifice. An exception may be made in the case of a big corporation having short suburban branch lines. These might be equipped with electric locomotives, and the steam locomotives now in use be transferred to the main line, so that there would be no loss account through the sacrifice of existing motive power. But the elevated railroads of New York could make no use of discarded steam locomotives, and could scarcely sell them. It is not to be expected, therefore, that electric locomotives will rapidly take the place of steam locomotives. At best they will be slowly introduced, and at first for some special service, such as that of moving trains through the long tunnel under the city of Baltimore.

Ferris

THE FERRIS WHEEL—WORLD'S COLUMBIAN EXPOSITION.

Ferris Wheel and Ice Railway.

Whilst on this topic it may be as well to refer to some other pieces of engineering work of interest in connection with the Exposition. I mean the Ferris Wheel and the Ice Railway, both of which were located in the Midway Plaisance, and to the movable sidewalk on the pier at the south-east end of the Fair grounds.

As a mechanical triumph the Ferris Tension Wheel stood out boldly as one of the wonders of the age, and the creation of the brain of Mr. G. W. G. Ferris, of Pittsburg, Pennsylvania. Alone, and for a time unaided by capital, scoffed at by cynics and obstructionists who pronounced the invention a monstrosity at best, which would never turn, Mr. Ferris persevered until he realised the height of his ambition, and astonished all the skilled engineers of the world.

That the Ferris Wheel surpassed the Eiffel Tower of the Paris Exhibition there is no doubt, and it was a more wonderful achievement because it was a venture on unknown grounds, while the Eiffel Tower was constructed on well-known scientific principles. Twenty-five thousand dollars were expended in hard work and calculations in laying the plans of this remarkable invention before a dollar had been put into construction, and the accuracy of the figuring was shown by the perfect safety and success of its operation. The immense structure, consuming in its various parts over 4,000 tons of iron, 2,600 tons of this being in motion, under control of two immense engines, rose above Midway Plaisance 264 feet. The thirty-six coaches were models of comfort, and were daily filled with passengers, who enjoyed the magnificent scenery and the cool exhilarating amusement. These coaches held sixty persons comfortably, giving a combined carrying capacity of 2,160 passengers. The work of erecting such a prodigious piece of machinery as the Ferris Wheel is regarded on all hands as one of the most important feats of engineering ever done in the United States, and one, therefore, that called for unusual skill. It was entrusted to the F. J. M'Cain Company, of Chicago, a firm which has successfully carried through some of the most difficult undertakings in the way of engineering that has ever been achieved in recent years. There was required to put up the wheel about 540,000 feet of timber. The staging was put up 230 feet on each side, and in erecting this towers 90 feet high were put together, lying on the ground and then up-ended, when a derrick was set on top, by means of which the balance of the staging on either side of the wheel was erected. At first the staging was put up 140 feet high, or about the altitude of the axle, when the first half of the wheel was put in place. The balance of the staging was then put up as it became necessary to use it. The iron was raised with four derricks, having 56-foot booms, one on each corner of the staging. After the raising of the towers two small derricks, one on each side of the wheel, were brought into use to raise the staging. Four hoisting-engines were used in the erection of the wheel, and it required twenty 1,000-foot coils of rope on account of the great height to which the enormous mass had to be lifted. The raising of the shaft formed the most difficult part of the operation, as has already been noticed, owing to its enormous weight and the height to which it had to be raised.

While the erection of the Ferris Wheel is certainly a feather in their cap, and an achievement on which they may justly be congratulated, it is but one of many notable feats of engineering which the F. J. M'Cain Company have accomplished both in Chicago as well as in other parts of the country. F. J. M'Cain, the President of the Company, has erected some of the most difficult works of this class yet done on the American continent. He put up all the ironwork for Machinery Hall, a work of immense magnitude and taxing his utmost skill, and he did a similar work for the Spectatorium, where 50-ton loads

loads had to be raised to a height of 135 feet. The immense plates, channels, and angles, which formed the structural work on the wheel, consuming over 1,800 tons, were largely rolled by the American Iron and Steel Works at Pittsburg, Pa, operated by Jones and Laughlins (Limited). Much of the success of this remarkable triumph of mechanical skill was due to the perfection of the steelwork furnished by this firm to the Detroit Bridge Works, where it was carefully prepared for the various parts of the great structure. Mr. Ferris virtually depended on the superiority of the material rolled at these works for the strength and successful operation of his invention.

In conceiving the Ferris Wheel the inventor evidently had in mind the great strength and durability attained in the construction of large bicycle-wheels, and this principle has been carried out on a gigantic scale. These rods held the entire weight of the wheel, and were 85 feet in length by $2\frac{9}{16}$ in diameter, reaching from crown to axle, and were made by the Carbon Steel Company of Pittsburg, Pa. This firm also furnished the lower and upper pins and other parts which contributed to the wheel proper. Cynical doubters said that these rods would vibrate, and could not be made strong enough to suspend and revolve such ponderous weight; but Mr. Ferris had every confidence in the ability of the Carbon Steel Company to furnish the graceful spokes of his wheel, and to their workmanship and skill is due that ease of motion noticed while riding around the wheel. When the inventor consulted skilled engineers and told them that he proposed to hold hundreds of tons weight in the air with rods only $2\frac{9}{16}$ inches diameter they said no firm in the country could make them strong enough for the purpose of keeping the wheel rigid and round. They asserted that it was a question if a hanging wheel consisting of 1,700 tons of steel could be constructed to revolve, and that it was impossible to put such a mass in motion. Mr. Ferris consulted the Carbon Steel Company relative to the spokes capable of suspending this ponderous mass of metal, and they said it could be done—and how well it was done was attested by the daily revolutions in the Midway.

The most interesting feature of the construction was the raising of the main axle on which the wheel revolved. It was, moreover, the most difficult part of the erection, considering the enormous weight of the shaft and the distance it had to be carried from the ground to the top of the towers. Including the hubs, the shaft or axle weighed 70 tons, and the height was 137 feet. It was raised by eight 24-inch blocks, using a 2-inch rope. This was probably the heaviest weight ever raised to such an altitude, and it redounds to the credit of the F. J. M'Cain Co., to which firm this part of the undertaking was entrusted, that the great axle was so successfully placed in position. This remarkable piece of steel was a masterpiece of mechanical skill and art, being the largest piece of steel ever forged. It was turned out by the Bethlehem Iron Company, of South Bethlehem, Pa., and was 33 inches in diameter, 45 feet long, and weighed 56 tons, supported on two towers 137 feet high. Once in position this great axle revolved with ease. Then came the work of hanging the wheel upon it. Beginning at the bottom the heavy castings which formed the outer crown or periphery of the wheel were hung one by one to the rods which carried the weight of the wheel. Slowly the circle was completed, and the last of the sections, each of which weighed 5 tons, was raised to the height of 270 feet to drop into its place. As the last bolt was fastened the critical period in the construction of the wheel as well as the enormous axle was reached. Would it turn, or would the great weight cause a friction impossible to overcome? The powerful engines were started and the gigantic iron monster gracefully moved around this triumph of mechanical skill, not only to the satisfaction of the inventor and the world, but to the Bethlehem Iron Company, who may be justly proud in what may be termed the key to the
the

the whole invention. This company, like many other immense iron manufacturers in Pennsylvania, control many specialities, and are among the leading iron manufacturers in the world.

It will be interesting to know where the great outer rim, over 800 feet in length, was made, with its remarkable gear teeth that connected perfectly with the chain running over the sprocket wheels. These two important details, which gave life and motion to the immense wheel, were the work of the Griffin Car Wheel Company, of Detroit, Michigan. Although the castings furnished by this firm formed only a small amount of the vast amount of iron consumed in the construction of the wheel; they were the real factors to the perfection of its mechanism.

The glory of the wheel was added to by electric illumination. The wheel was wired for a total of 2,000 sixteen candle-power incandescent lamps, supplied with a current obtained from two large 400 ampere dynamos furnished by the Western Electric Company. A row of lights was placed around the outer edge of the wheel, and a second row half-way between the outer edge and the axle, the current being taken from the triangular standards by means of large collector rings 5 feet in diameter. The lights were made to project so that when viewed from the midway the appearance was that of vertical bands of light 250 feet in height. The fixtures for carrying the lamps, the means of conveying the current to the moving wheel, and, in short, all the numerous details, were designed and worked out by the Western Electric Company.

Among those who had more or less to do with the construction of the Ferris Wheel, a conspicuous place may be allotted to the Walker Manufacturing Company, of Cleveland, Ohio, whose immense works are on the south-west shore of Lake Erie. Their specialities have hitherto been machine model gears and cable railway machinery, the company having built over twenty complete cable railroad plants. Their share in the construction of the Great Ferris Wheel was the making of the gearing and sprocket wheels, some details of which will be of interest. The first set of drivers had a 14-inch face, and 6-inch pitch keyed to a 16-inch shafting. The second motion, a 6-inch pitch and 27½-inch face, the largest gear in that set being 22½ tons, keyed to an 18-inch shaft. Its pinion or mate weighed 9 tons, and was keyed to a 16-inch shaft. The sprocket wheels were about 11 feet in diameter, with seven teeth or sprockets. The finished width of the sprocket wheel was 7 inches, and was keyed to an 18-inch shaft. The teeth of the sprocket wheels were accurately machined, so as to have a correct pitch measurement to agree with the links that engaged with the rim of the wheel proper.

There were two complete sets of this machine, one on each side of the pair of engines. This double set of gearing insured the propulsion of the wheel without twisting.

The thirty-six cars used to convey passengers around the wheel were perfect in construction and admirably adapted to their peculiar use. They were made by Thomas Clark and Sons, general contractors, 175 and 177, Aberdeen-street, Chicago, who have splendid facilities for all kinds of technical work of this description. These cars were 13 feet in width and 26 feet long, containing forty chairs for passengers, although the carrying capacity for each car was sixty people. They were built of yellow pine, with corrugated iron roof, and in all details of construction were strong and durable. The windows were of ⅜-in. French plate-glass, calculated to resist the strongest wind. There was no great motion in the cars as the wheel revolved, owing to the manner of their suspension on 6½-inch steel trunnion pins which passed through the outer cord.

Barre

Barre Sliding Railway.

On the extreme southern edge of the Midway Pleasaunce ran what was known as the Barre Sliding Railway. It was a French invention, and was first given a practical demonstration before the public in the Paris Exposition of 1889. This would form an elevated road, the cars having no wheels. The rail was 8 inches wide, the substitute for the wheel being a shoe, which set over the side of the rail, and was practically watertight. Immediately behind each shoe was a pipe connection, in which was water under a pressure of about 150 lb. This water was forced under the shoe, and produced a film which raised the entire train about one-sixteenth of an inch from the rail. Connected with every second car was a turbine motor, which got its water-power from the same source as did the pipe connecting with the shoe. The power was delivered from a main pipe extending the extreme length of the road, and lying under the track in sections of 50 feet; that is, the application power was changed at every interval of that distance. The speed claimed by the inventors was 120 to 160 miles per hour. A speed of about 100 miles an hour has been demonstrated on a track less than one-third of a mile long.

Movable Side-walk.

The Movable Side-walk was a novel and interesting method of transportation, in operation on the pier at the south-east end of the Exposition Grounds. It was 4,300 feet in length, and had some remarkably sharp curvatures. The side-walk moved continuously in one direction, and was divided into two longitudinal sections; one moving at a speed of 2 miles, and the other, on which the seats were placed, at the rate of 4 miles per hour, so that a passenger could step from the stationary platform to the slowly moving one, and then to the faster one, where he seated himself, and was carried as long as he wished to ride. He then stepped off in the same manner, without shock, as the relative motions of the sections were so slightly different that the most timid person had no difficulty in stepping from one platform to another while the motion was taking place. As a protection against accidents, an automatic mechanical device was placed on the main circuit, and at intervals of 30 feet throughout the entire length of sidewalk there were bell circuits and push buttons, by which the entire tram could be almost instantly stopped, the platforms and continuous rails taking the place of a brake, the instant the power was shut off. A novel feature of this side-walk was that it would not require the services of a motor-man or operator. Its seating capacity was 6,000 passengers at one time, at a speed of 6 miles an hour; thus, 36,000 passengers could be carried past a given point in one hour. Its trucks each weighed almost 1,500 lb., and the platforms 1,200 lb. each. There were 340 of these platforms and trucks, making a total weight of 918,000 lb. The motor trucks, of which there were 10, weighed 12,000 lb. each, the total weight being about 519 tons. The General Electric Co. furnished the electrical equipment and had charge of the installation. The electrical equipment consisted of 24 fifteen horse-power railing motors, two of which were placed on each of 12 motor cars. The conducting wire was supported between the lower platforms on the stationary timbers by means of special wire insulators. The collecting device was supported from the underneath side of the overhanging of the slow platform, keeping the entire distribution circuit concealed. The rails were not braided together, as is usually the case with electric roads, and the continuous flexible rail which passed over the top of the wheels of the trucks made a continuous return circuit, the return lines being simply attached to the rails at one point.

Exhibits

NAPHTHA LAUNCH ON LAKE MICHIGAN.

Exhibits of small Steam Launches, Naphtha Launches and Gas Launches.

As is well known, the continent of North America possesses the largest system of inland lakes in the world, together with some of the finest and largest rivers, of which the Mississippi, the "Father of Waters," is the longest and widest river in the world. As a consequence of this there is a constant and ever-increasing demand for small vessels capable of navigating these large rivers and their tributary streams, and of being handled by private parties for their own amusement and recreation. The result of this demand has been that several firms have been formed for the purpose of supplying the demand, which produce annually thousands of these small pleasure-craft, and these launches may be seen daily during the summer months on the harbours of New York in the east and of San Francisco on the west, and cruising about the great system of inland lakes in the north, and on the rivers of the south. Notwithstanding this, it was a surprise to me to see so few exhibits of this class of boats in the Transportation Building of the World's Fair, there being only one exhibit of naphtha launches, one exhibit of steam-launches, one exhibit of oil-vapour launches, and one exhibit of electric launches.

Naphtha Launches.

Although this form of self-propelling boat has been on the market of America for some years, I think that it is comparatively unknown in Australia, and therefore a short description of it will not be out of place in this Report. When these launches were first introduced on the waters of the continent of North America there was an impression that they were mere toys, and would soon be ousted from the field by the older and longer-established steam-launch. This erroneous impression was probably created by the small size of the motor employed to propel them, as compared with the steam-engine and boiler used in steam-launches. Time, however, has shown that for small craft the naphtha motor is more suitable in every way both for pleasure and business launches, as it is entirely automatic, is situated in the stern of the boat, and thus allows far more room for passengers, and produces no smell or smoke.

The only Naphtha Launch exhibited was built by the Gas Engine and Power Co., of New York, who build launches from the 16-foot 1 horse-power boat up to the 40-foot 10 horse-power cruising launch, fitted with all the conveniences and luxuries which can be put in the small space at command. This cabin cruising launch had a length of 40 ft.; beam, 8 ft.; forward deck, 8 ft.; pilot-house, 6 feet 9 inches; saloon, 7 ft.; closets, 1 ft.; toilet-room and galley, 4 feet 9 inches; engineers' space, 1 foot 10 inches; engine compartment, 5 ft.; after-deck, 4 feet 10 inches. The hull was cedar-planked, excepting the garboard strakes, which were of oak; steam-bent oak frame; upper strake and planksheer of oak; white pine decks, which were calked; hull painted white; copper fastenings throughout; extra shoe on keel; brass rudder and skag; and name each side of bow in brass letters. The forward compartment was finished in mahogany, and raised 8 inches above main roof. It was fitted with plate-glass windows to slide down, and had hatches in roof on each side for entrance. There was a brass steering-wheel, and chain gear and bells for signalling engineer. There were damask curtains to the windows; hair-filled, leather-covered cushions; and linoleum or carpet for floor. The saloon was finished in mahogany, and had sliding plate-glass windows on each side. The seats had extension lids to form bunks, and lockers underneath. There were hair-filled, plush-covered cushions made in sections, to be used for seats or bunks, and two plush-covered pillows filled with feathers. In addition, there were damask curtains to the windows, a Wilton carpet, two cabin-lamps with

with shades, bevelled edge, full-length mirror in door between saloon and galley, and two closets in the after end of saloon, fitted with bevel-glass swinging-doors, one with hooks for clothes and the other with shelves, and one folding mahogany table.

As regards the source of power in these launches : Naphtha is vaporised in a copper boiler, or "retort," and is then used expansively in an engine somewhat similar to a steam-engine. Part of the vapour is used in a ring burner to heat the coil. After the vapour is used it is condensed in a copper keel condenser and used over again.

The exhibit made by this Company was a very comprehensive one, and showed specimens of all their launches, in which the finish was admirable and the hulls were solidly constructed.

The prices of these launches were as follows :—

16 feet	1-horse power	\$764
18 "			2 "			857
21 "			2 "			1,013
25 "			4 "			1,162
30 "			6 "			1,813
40 "			10 "			5,250

Steam-launches.

A fine exhibit of small steam-launches was made by Thos. Kane & Co., of Chicago. The launches exhibited were fitted with patent oil-burning boilers and engines, and showed very careful and well-finished workmanship. The "Racine" boiler used in these boats is a sectional boiler of the porcupine type, and combines lightness, quick steam-making power, freedom from priming, and absolute safety. It consists of a main central upright column, with welded ends, the upper part of which acts as a dry steam-dome, while at the lower part arms with smaller wrought-iron pipe, welded at the end, are threaded into and radiate from it. These tubes are filled with water, thus preventing them from burning out. It will be seen that there are no riveted seams to cause leakage, and that it is practically impossible to explode it. The utmost carelessness could accomplish would be to open a tube, causing steam to escape as from a safety-valve. An exhaust steam-heater heats the feed-water to nearly boiling-point, thus making a great saving of fuel and deadening the noise of the exhaust.

On the outside of the boiler is a neat jacket of Russia iron. Between the outside and inside jacket is a layer of asbestos, to prevent the radiation of heat. Every boiler is furnished with steam-gauge, water-gauge, hand-pump, safety-valve, heater, automatic water-regulator, atomizer, and trap. Marine boilers are supplied with whistle, three gauge-cocks, fusible plug, and everything necessary to pass Government inspection. These boilers are made of the best quality of charcoal, lap-welded wrought-iron pipe, tested to a hydraulic pressure of 300 lb. to the square inch. It will thus readily be seen what an effective heating surface is obtained, and also the advantages in weight, safety, economy, &c., over the usual tubulous boiler.

There are two different styles of engines used in these launches ; for the smaller sizes, from one to four horse power, a Pierce double pitman engine is made use of. The novelty of this invention consists in the piston-rod being made of much greater length than usual, and instead of being guided by the customary crosshead, is extended downward to a tubular guiding-sleeve, seated in a horizontal crossbar which is cast solid with the frame or trunk of the engine. Motion is communicated from the piston-rod to the crank by the pitman. By means of these forked pitmans strains are avoided by transmitting power from both sides of the pitman rod to the crank, and it is impossible for an inexperienced operator to get the engine out of line when

when taking up wear. For the larger-sized engines the Racine automatic is used, which is a double-crank vertical engine. There are two bearings for the crank-shaft, which are cast solid with the frame and are long and large in diameter. The crosshead slides are also cast solid with the frame. The crank is of steel, and is balanced against one half of connecting rod. The connection rod has brass boxes. The piston is hollow and has snap packing rings, which are turned larger than the diameter of the cylinder, then split and sprung together and turned the same diameter as the cylinder, making a perfect fit at once. They are self-adjusting, tight, yet free in their action. The piston rod and crosshead pin are steel. All working parts are made adjustable to wear.

Up to and including five-horse-power engine and boilers are on one base, above this size on separate bases. Engine and boiler complete include sight-feed lubricator, necessary oil-cups, shaft coupling, brass plunger pump, hand pump (for producing the necessary air pressure when the boiler is cold), exhaust heater, automatic water regulator, steam-gauge, water-gauge, safety-valve, smokestack, oil-burner, and oil-trap.

These boilers may be made into coal or wood burning boilers by removing the cast-iron deflecting plates in the fire-box.

Sizes and draught, &c., of these launches are as follows :—

Length, 19 feet;	draught, 16 inches;	one-horse-power
" 22 "	" 18 "	two "
" 22 "	" 20 "	three "
" 25 "	" 20 "	three "
" 30 "	" 26 "	six "
" 33 "	" 28 "	six "
" 40 "	twelve "
" 50 "	fifteen "

There was in the Transportation Building only one exhibit of launches, propelled by means of gas or the vapour of petroleum; a boat of this class was on exhibition in the water of the north inlet, and prospective purchasers were welcome to take a trial trip in it out into the lake. The engine was similar to a gas-engine, and used the vapour of petroleum or mineral oil, which was carried in a tank in the bow of the boat, and which was exploded above the piston by means of an electric spark from a small battery.

An exhibit was made by a German firm of motors propelled also by means of oil. In the Transportation Building were shown motors or locomotives, and one was shown in actual operation on the tracks near the terminal station.

A launch which was of the same system of propulsion was also exhibited in the lagoon south of the Agricultural Building, where also the naphtha launches were shown in actual operation. This was the Daihmler system, and seemed to be very satisfactory.

Link-Belt Exhibit.

An interesting and novel exhibit was made by the Link-Belt Machinery Company of Chicago in the Transportation Building. The name of the company suggests the business which they do in the use of a detachable chain-belt for the transmission of power, but this primary use of chain belting, extensive as it is, is of minor importance compared with the use of these link-belts as the basis of elevators and conveyors for the saving of time and labour. These carriers, designed for that particular object, after the experience of many years, are used with economy in almost, if not every industry, in handling from floor to floor and point to point any material in bulk, barrels, bales, bundles, or bags. The business is a singular one, and the company almost the only concern in the world successfully engaged in it.

The

The exhibit showed six machines all in operation. The number of these, as well as the height of the four elevators and the length of the two conveyors, was necessarily limited by the space available, but the principle was illustrated, and the different adaptations of the devices to meet varying conditions were readily suggested. The first exhibit was a package and miscellaneous freight carrier, which was practically a travelling platform on an endless chain designed for the purpose. It is used in railroad, steamboat, and private warehouses, breweries, packing and canning warehouses, starch, soap factories, &c. At the rear of the exhibit was a conveyor made of peculiarly curved steel scrapers, attached to chain and running in a steel trough. This conveyor was so arranged as to show its application to locomotive coaling stations, but the type is used for handling coal under all conditions, ashes, earth, grain, stone, or and in fact every loose material. For raising these materials to any height, a continuous bucket elevator was exhibited with a very cleverly designed boot, in which choking is impossible. The buckets were of steel, and overlap, giving clean discharge at head, and plenty of time to fill at foot at slow speed.

The other elevators shown were a package elevator, made of trays freely suspended between two chains, and used in dry goods houses, candy factories, book-binderies, printing establishments, bakeries, starch works, &c., to handle their products from floor to floor. A freight elevator, similar in design, with swinging trays, but with the latter intermeshing with fingers or skids on the floors, so that the elevator will pick up or deliver its load automatically at any floor where the skids are set for the purpose. These elevators are used in warehouses, for heavy freight, cotton bales, and barrels in sugar and oil refineries, &c., and have recently been very successfully applied as a permanent fixture in the hold of steamers for the rapid handling in and out of the cargo. Another elevator was shown for flour and sugar barrels and sacks, with carrying arms, that, when tripped automatically, deliver their load at any desired floor. The capacity of each elevator of the above type is from 600 to 1,200 barrels per hour. All of these machines were driven from a central motor with Manilla rope transmission and automatic tension carriage, a form of drive now being extensively adopted in the United States, and of which the Link-Belt Machinery Company were the pioneers.

The exhibit also included quite a number of component parts and short sections of many elevators and conveyors, as well as a large collection of various styles and sizes of chain. The boxes in which much of the shafting runs are bushed with fibre-graphite, and are never oiled. The company uses this material extensively, and with most excellent results. The whole exhibit was surrounded by a very unique and attractive railing, on which are displayed several hundred views framed in link-beltting of the various elevators and conveyors built by this company in operation.

MANUFACTURES AND LIBERAL ARTS BUILDING FROM SOUTH-WEST.

Manufactures Building and Exhibits.

Description of the Building.

THIS building was constructed for a twofold purpose. In it the exhibits representing not only the manufactures, but also a portion of the liberal arts of the world were accommodated. Notwithstanding its immense size, for it was the largest and most important structure in the Exposition—indeed the largest covered area in the world,—it was most symmetrical in its proportions. Despite the fact of its large extent every foot of available space was taken, and it was even asserted by conservative judges that more than double the space could have been assigned to most worthy exhibits, and even then the clamor for more room would not have been wholly satisfied. The immensity of this building alone was intensely wonderful in its grandeur. It was three times larger than the Cathedral of St. Peter's in Rome, and four times larger than the old Roman Coliseum, which seated 80,000 persons. The central hall, which was a single room without a supporting pillar under its roof, had in its floor a fraction less than 11 acres, and the entire building could comfortably seat 300,000 people. There were 7,000,000 feet of lumber in the floor, and it required five car-loads of nails to fasten the 215 car-loads of flooring to the joists. The exterior outline covered an area of nearly 32 acres, and, including the galleries which encircled the interior, afforded in the aggregate 44 acres of exhibiting space. This large structure was covered with an arched roof of steel and glass, affording ample light and ventilation. It measured 1,687 feet x 787 feet; the height of the walls was 66 feet; the height of the four centre pavilions, 122 feet; the height of the four corner pavilions, 97 feet; the height of the roof over the central hall, 237.6 feet; the height of the roof truss, over the central hall, 212.9 feet; the height clear from the floor, 202.9 feet. The span of the truss was 382 feet; the span in the clear was 354 feet. The width of truss at base, 14 feet; at the hip, 32 feet; at the apex, 10 feet. The weight of the truss was 300,000 lb., and with the purlins 400,000 lb. The cost of the building was \$1,700,000. The materials consisted of 17,000,000 feet of lumber; 12,000,000 lb. steel in the trusses of the central hall; 2,000,000 lb. iron in the roof of the nave. There were 11 acres of skylights and forty car-loads of glass in the roof. Within the building a gallery 50 feet wide extended around on all the four sides, and projecting from this were eighty-six smaller galleries, 12 feet wide, from which the visitors could survey the vast array of exhibits and the busy scene below. The galleries were approached on the main floor by thirty great staircases, the flights of which were each 12 feet wide.

“Columbia Avenue” 50 feet wide, extended through the mammoth building longitudinally, and an avenue of like width crossed it at right-angles at the centre. The building was rectangular in form, and the interior was divided into a great central hall, 380 ft. x 1,280 ft., which was surrounded by a nave 107 feet wide. It was in the Corinthian style of architecture, and in point of being severely classic excelled nearly all the other buildings. The long array of columns
and

and arches, which its façades presented, was relieved from monotony by very elaborate ornamentation. In this ornamentation female figures, symbolic of the various arts and sciences, played a conspicuous and very attractive part. The exterior of the building was covered with staff, which was treated to represent marble. There were four great entrances, one in the centre of each façade, which were designed in the manner of triumphal arches, the central archway of each being 40 feet wide and 80 feet high. Surmounting these portals was the great attic-storey, ornamented with sculptured eagles 18 feet high, and on each side above these side arches were great panels with inscriptions, and the spandrels were filled with sculptured figures in bas-relief. At each corner of the main building were pavilions forming arched entrances, which were designed in harmony with the great portals. The building occupied a most conspicuous position on the grounds. It faced the Lake, with only lawns and promenades between. North of it was the United States Government Building, and south the harbour and the injutting lagoons; west of it was the Electrical Building and the lagoon separating it from the Wooded Island. The building was provided with 10,000 electric lights, and the aisles were lighted with ornamental lamp-posts bearing shielded arc lights.

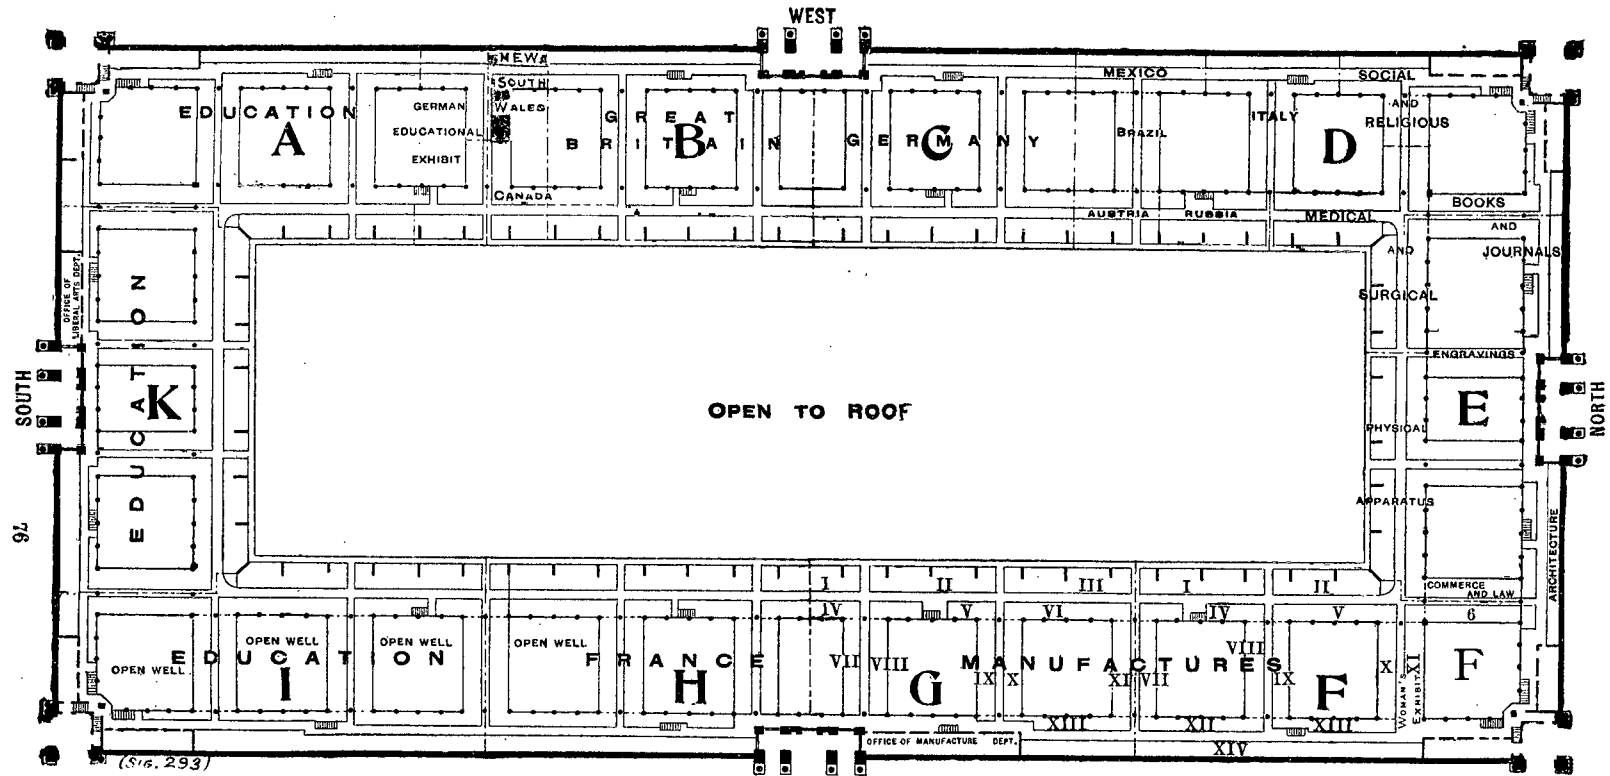

The Roof.

The great roof of this building was erected with a rapidity that is without a parallel for a work of similar importance. The weight of iron was 6,000 tons, and the contracts for the manufacture and erection was signed by the Edgemoor Bridge Works, Wilmington, Delaware, on December 24th, 1891. The term of the contract provided that the roof was to be delivered complete by the 15th August, 1892; so that the contractors had to manufacture the material, to carry it nearly 1,000 miles, and to erect it within a period of less than eight months. On May 24th, 1892, a large amount of the ironwork was on the ground, and by that date the first complete bay of two great ribs, with the complicated longitudinal girders and bracing, were in place. The time of the erection of the first bay was fourteen days, and the rapidity of the work well illustrated how completely elaborate were the plans of the engineers entrusted with the carrying out of the details of the erection. At a later stage, with further experience on the part of the workmen, the time for the erection of a bay was reduced to ten days.

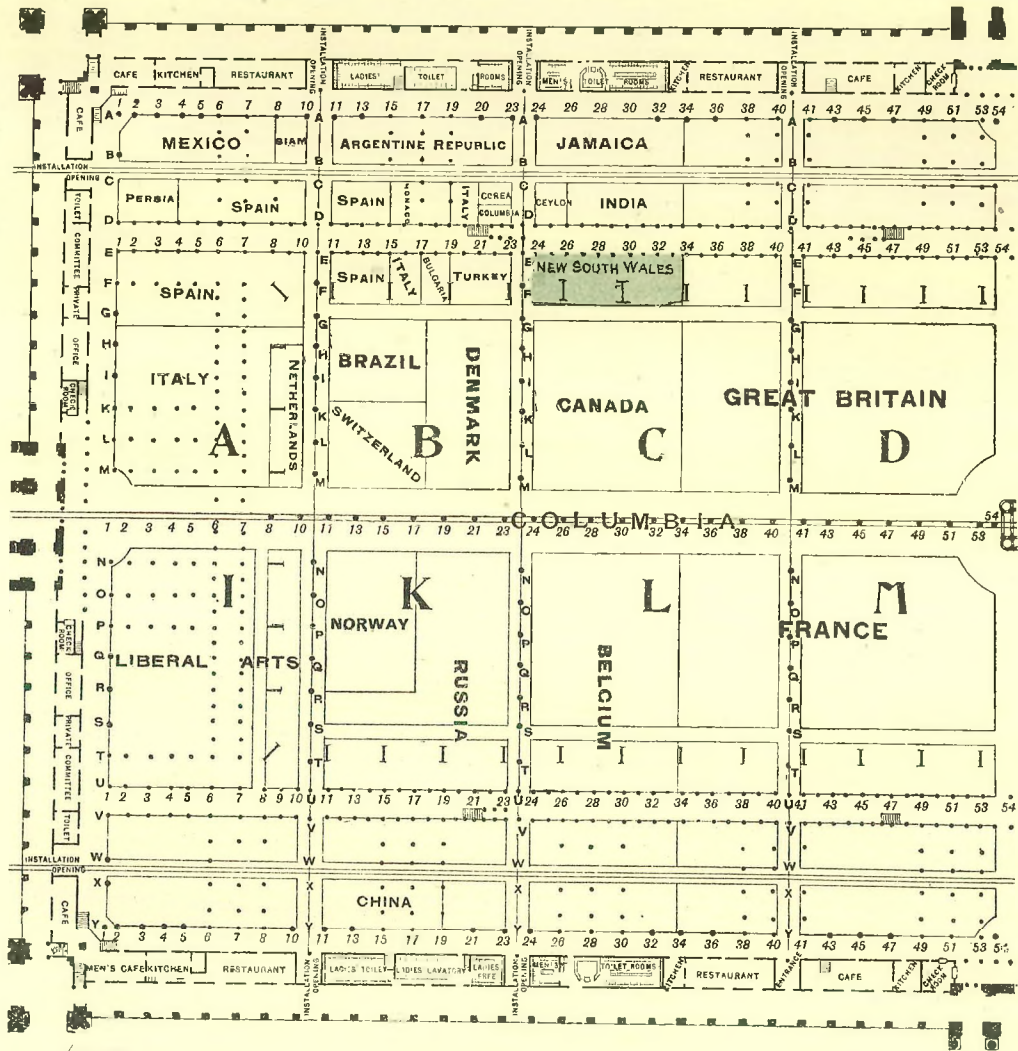

A somewhat unusual procedure was had recourse to in the building of this as well as of the other great structures in Jackson Park; in order to facilitate the progress of the work the whole floor of the building was laid complete beforehand. A firm and level platform was thus obtained to work upon—an advantage that will be appreciated by those who have ever been responsible for the erection of large roofs, especially when founded upon marshy ground. The Columbia Avenue, already referred to, was a remarkable highway, and contained a number of striking features, to some of which, such as the Yerkes Telescope and the elevators which carried visitors to the roof, I shall again return. The front of the Japanese space was built in pure Japanese architectural design with grotesque but elaborate decoration, coats of arms, and figures of animals. The Austrian and the German spaces were fronted by most magnificent displays of art and architecture. The French space had caryatides leaning against each other and supporting the arches overhead and constituting eleven bays, enclosing the whole section. The main door was semi-circular in shape, and the tympanum beautified by ornamental pictures and sustained by Corinthian columns. This door led into the first hall, and from it one could pass into all the various halls and courts, in each of which was a separate characteristic display. Other countries had more or less elaborate frontages, but all represented some characteristic

MANUFACTURES SPACE — NEW SOUTH WALES
GROUND PLAN

W Fitzwilliam Terry,
Superintendent,
June 1893.

SECTION NEW SOUTH WALES COURTS, MANUFACTURES BUILDING,
SHOWING FURNITURE EXHIBITS.

NEW SOUTH WALES COURT, MANUFACTURES BUILDING.

characteristic national architectural feature. The great width of the avenue, the immense height and expanse of the roof overhead, and the moving throngs of visitors, made the avenue one of the first sights of the Exposition.

New South Wales Court.

When in September, 1892, I arrived in Chicago for the purpose of arranging for space for our exhibits in the various buildings, I found that I had come too late to obtain a place in the Columbia Avenue, the main avenue of the building, all the space in this locality having already been definitely and officially granted to various other countries. I then selected a very excellent position, in the next main avenue, having Canada to the east, Great Britain to the north, Persia to the south, and India, Jamaica, and Ceylon to the west. The space was beneath one of the great galleries of the building, and in it were some of the immense steel trusses of the building. The plan that I adopted for the general outline of the court was at once effective and economical. I divided the front into three great arches, thus severing the space apparently into three courts. Over the centre arch was placed the coat of arms of our country sent from Sydney, appropriately coloured, and on each side over the other arches I placed the great photographs of Sydney looking from the east and from the west respectively. The central front was made to advance a few feet from the wings and handsome balustrades adorned each of the spaces at the foot of the arched openings of these wings, while festoons of indigenous and characteristic flowers were painted down the walls. The whole floor space was 5,090 feet, and the wall space about 10,000 feet. Round the internal walls and on the back wall of the avenue at the rear of our space were placed the large photographs of all the New South Wales business houses, mercantile establishments, banks, insurance offices, and several of our streets. In the south space were placed the eucalyptus, and leather exhibits, blacking, soap, boots and shoes, asphalt tiles and similar articles. In the centre court the handsome furniture suites made of colonial timbers sent by the Commission were placed, and in the north space the Government Printer's bookbinding display. The beautiful billiard-table of Australian woods, by Heiron and Smith (so unlike the American billiard-tables), and the fur exhibits were placed in the front of the North Court, while in the back portion of the court were the exhibits of miscellaneous clothing, waterproof manufacture, and the horse-shoe exhibits. The various plumbing and sanitary exhibits were well placed and the hospital beds for which room could not be found in the Women's Building were located here, where they were examined by many interested persons. The watch exhibit of Mr. Benjamin was also kept in this corner for fear of accident, as also were the coins sent by Mr. Hyman. Here also were the exhibits of Mrs. Hetherington Carruthers, also excluded, for want of space, from the Women's Building, and various other exhibits. This court was well decorated, and with its blue walls, its numerous large photographs, and its excellent exhibition, was visited by many persons; in fact it was a thoroughfare between the courts in front and those in the rear.

It would be impossible to give even an outline description of the immense number of exhibits of all kinds from all parts of the world representative of the progress in Manufactures and Liberal Arts collected in this great building, and, consequently, the remarks I shall make in connection with them must be regarded merely as an outline of the chief matters which attracted my attention in the various courts. No mere catalogue would suffice to describe the encyclopedic nature of the exhibits from nearly every country under the sun, and to render anything like an adequate description of some of the exhibits would demand the highest talent of the ablest expert in the several departments.

PORCELAIN

PORCELAIN AND ART.

One of the most thoroughly artistic and beautiful collections of porcelain at the World's Fair was that shown in the British Section. It was composed chiefly of porcelain from the factories of Wedgwood, Copeland, and Minton. As is well known, the English manufacturers now possess the art of reproducing the most lovely of porcelains, Sèvres. As a matter of fact, the "Bleu Turquoise" and the "Rose Dubarry" reproductions are considered by many experts to be more exquisite in their note of colour than the modern specimens coming directly from the Sevres factory. The exhibit showed a splendid massing of fine, useful, and decorative china and was very impressive, inasmuch as it did not comprise the opaque, pie-crust compositions now so much in vogue. The luminous porcelains were almost entirely used as a body embellishment, and all the decorations were by hand, and not printed. A case filled with the celebrated English porcelain Pâte-sur-Pâte made a pretty picture, and it is questionable if ceramic manufactures have ever attained a higher artistic point than in the making of this class of porcelain. The process is of Chinese origin, consisting of the application to the surface of the vase of thin layers of liquid white china clay, in which the subject or picture is drawn or executed. The work on the vase is completed when in an unfinished, or, rather, unfired, state, and, as the liquid white clay is absolutely opaque until it has been vitrified by the fire, it requires great experience to foresee the effect which the vitrefaction will have on the different thicknesses of clay. The result is very like cameo work, but the process infinitely more difficult. The cameo artist sees at once the effect he wishes to obtain, while in the Pâte-sur-Pâte it is impossible to determine the result until after the firing. The artist of this lovely porcelain was by Solon, of London. In tone the vases were powder blue, metallic green, black, and dark brown, which acted as a satisfactory body-colour for the white embellishments. In form the vases were cylindrical, flat, and in the shape known as Pilgrim. The most beautiful in the collection was one of pure Grecian shape, illustrating "The landing of Cupid's crew." There were also plaques in the same ware which were highly decorative. The scheme of designs for the modern sculptured or cameo glass were those representing female figures in various attitudes, nymphs flying from Cupid's darts, and vanishing apparitions floating heavenward. The reliefs were mostly accentuated. Jardinières, both large and small, were distributed about the entrance to the booth, and they were also placed on stately pedestals within, this felicitous arrangement of faience producing the effect of a well-equipped room. There were dainty tables, which held their fragile burdens of tea-sets of milky-white porcelain, embellished with festoons of the poetical laurel, the natural tonality of the leaf being followed. There was a spring-time freshness suggested by this green and white decoration which was refreshing to a degree. Her Royal Highness the Countess of Airlie had allowed a reproduction to be made of a dinner service that has for many years been used in her family. It was a brilliantly coloured transcription which brought memories of flowers found in kitchen gardens, made slightly grotesque by being conventionalised. A cabinet of dark wood contained many objects of clever workmanship. In it were four examples of Henri Deux ware, which is, perhaps, better known as Faïence D'Orin; also, umbrella-handles painted with moss-rose buds, urn-shaped turquoise, blue vases exquisitely decorated by well-known artists who have become famous for their painting on porcelain. In the year 1815 Swansea porcelain was highly valued, but it is now almost impossible, except among the old collections of china, to find an old bit of it. None but an expert connoisseur could, however, tell the old from the modern, so accurate were their productions.

The

The Victoria Ware is very popular in England, and the shapes found in this exhibit were very graceful, but the colour was opaquely treated and the gold decorations seemed excessive. Copies of the Sèvres plates used by the Royal Family of England were interesting from the association and as examples of unrivalled skilful workmanship. They were placed in plaque position. The dessert plates used by Her Majesty the Queen at Windsor Castle had a clear white surface to which was added a border of blue embellished with thistles and gold. Balmoral Castle is supplied with the dessert service of thistle decoration, and one on which is a bunch of pink heather tied with blue ribbon. A lovely plate of the Rose Dubarry colour, on which were tied garlands of roses and forget-me-nots, was a reproduction of one used in the Queen's household. It would be difficult to find a colour more pure than the green used in the service of the Prince of Wales' yacht. Over the surface of the green were studded points of gold which intensified its luminousness. The most beautiful of all these royal porcelains was the dessert plate used by the Prince of Wales at Sandringham. It was in tonality white and turquoise blue with the jewelled motive of decoration. The jonquille, powder blue, and Bleu-de-Roi colours manufactured by Messrs. Minton were lovely creations. So many years they worked diligently to obtain paste and colours equal to those of the Sèvres factory, and their industrious efforts have now been crowned with success. Copies of vases after the Sèvres artizans as on their shelves of glass in cabinets were quite as fine and valuable as any specimens of porcelain could be. The pierced bottle-shaped examples in blue and soft cream were exquisite.

The collection of Royal Worcester displayed in the British section was a comprehensive summary. For many years Worcester porcelains, whether soft or hard, have not only been counted amongst the most beautiful of ceramic manufactures, but, in a mercantile sense, the most important of all the English porcelain factories. Each year the blue and white, an imitation of the waukin, is seen less and less frequently, a matter to be regretted, as it was undoubtedly one of the most artistic productions of the Worcester manufactory. Without doubt the most beautiful examples of Worcester were the pierced or lace-work bowls and vases. They were endless in form and colour embellishments, and have been deservedly popular. As is well known, no fine collection of fine bric-a-brac is complete without one. The porcelain is enduring; it never loses its brilliancy of colour, and the glaze remains always uncracked. One of its most charming decorations is the passion-flower on an ivory white ground. The thin or egg-shell china was unsurpassed, both in shape and texture, and the golden-jewelled work made by this factory was equal to any manufactured by the Viennese. They were the first to introduce the ivory-finished porcelain; but their trend was to overdo its circulation, thus making the repetition tiresome, and the desire for the coloured pieces which are luminous, inevitable. The sculptural examples in the collection were excellent, the modelling was good, and the subjects interesting. Among these was a reproduction of the jubilee bust of Her Majesty, with sculptured trophies, emblematic of the Navy, India, the Colonies, and Art and Science. A soft metallic green and old rose pink was a new colour in the motive of decoration. Table china was exquisite in tonality, embellishment, and grace of outline.

There was a moderately large collection of Staffordshire ware. In it were many distinctly pretty specimens, especially examples of the gold and green bronze, combined with the milky-white china.

The Cauldon china, although a thoroughly English production, was exhibited by a Chicago firm. There was much that was novel in the showing, and the exquisite floral designs on its highly-glazed surface looked very like a veritable nosegay. The dessert and entrée plates,

plates, teacups and saucers in the most dainty design, all bearing the new Cauldon mark (the old mark not being used now any longer), were works of art. The body of the plates was white, with slightly scalloped edges and a gilt finish, a wreath of purple pansies on a ground of what is called guinea-hen dot. The cups and saucers had carnations, sweet-peas, and asters apparently thrown over their surface; and this careless and unstudied effect was charming. It was difficult for a number of years to obtain good specimens of Cauldon, but many of these new specimens were unique, and the opaque examples were quite equal to those made by the Royal Worcester factory.

Coalport, a porcelain that has become in the last few years very much in demand in America, is deserving of its popularity. The gold and jewelled work on this porcelain was very superior, and the massing of fine and decorative china was charming. The beauty of the green as well as the soft yellow could not be surpassed. The pink or Rose Dubarry did not appear equal to that produced by other English porcelain artizans. The specimens of plates with pierced borders and hand-painted centres were very lovely. The jewelled bon-bon boxes, table-bells, ink-stands, sedan chair, tea-caddies, wine-jugs, and small vases were exquisitely beautiful. A noticeably attractive vase had, as a main colour, rich dark green. On one side was a portrait medallion of Tennyson; on the other side an ideal portrait of Elaine. The quality of the paste used by the Coalport manufacturers is of the best.

The exhibits from Burslem, of Doulton ware, was contained in one of the few booths in the British section worthy of the Columbia Avenue and the Exposition. The size, the beauty, and the variety of the specimens shown were worthy of this world-famed establishment. The Columbus Vase, 6 feet high, of symbolical design, having two fine pictures painted by M. Labarre, representing on one side Cupids Asleep, and on the other Cupids full of Joy, Gladness, and Inspiration was a fine piece of work. The Diana Vase, 5 feet high, was a triumph of the potter's art, made of the finest china body, the contraction of which from the clay state to the first burning was not less than one-fifth of the total height. In this show there were also the Dante Vase, the Chicago Vase, and the Love Vase, exquisite works of art, with paintings and designs of the highest order by world-famed artists. Portrait plaques and articles of utility of various kinds in this ware, and stamped with the Burslem trade mark, were shown.

The splendid piece of work, the Shakespeare Centre-piece, made of porcelain, 50 inches high, and richly decorated in warm, high-colouring, deserves special mention. Four figures of Schonk, representing History, Poetry, Tragedy, and Comedy, ornamented the corners and supported a vase with eight panels, whereon were painted by Bouillemier Shakespeare's heroines—Juliet, Lady Macbeth, Cleopatra, Desdemona, Portia, Sweet Anne Page, Beatrice, and Cordelia.

French Exhibits.

The French exhibits of ceramics, &c., were shown in the second court of their space in the Manufactures Building, and the best of these was unquestionably that of the Government Sèvres exhibit. Here were shown about 200 large china pieces with reproductions of works by Chapu, Injalbert, and Aube. There were also some low reliefs in glass paste, together with some splendidly fired pieces. The walls of the Government Room, which contained these exhibits, was hung with a plain tapestry warp, with the characteristic "R.F." stamped upon its surface in darker note than that used as the body colour. The showing of Sèvres was interesting, and many examples exhibited the exquisitely delicate workmanship that has been the envy of all producers of fine porcelain throughout the world. The
modern

modern specimens of Rose Dubarry were, however, somewhat disappointing. They were wanting in brilliancy of glaze and colour and did not, in any particular, equal the reproductions of the old Sèvres pieces which, as I have already said, are now so skilfully manufactured by English ceramic artizans. The large vases of Bleu Turquoise and Le Bleu de Sèvres were thoroughly artistic in shape and colour. The massing of the vases in the different cabinets was very effective. The shapes were endless and the different colours, placed as they were against a background of soft red, composed a harmonious ensemble. The tall, slender necked vases in tea-leaf colour and jonquille were very lovely. Luminous globe-shaped vases of Mazarin or Marie Louise were mounted about this stately room on pedestals. The colour effect was felicitous, and the examples so arranged could not fail to delight connoisseurs of porcelains. The flammé, lavender, pearl, apple-green, pistache, and the white specimens possessed all the creamy and pearly softness and depth of glaze qualities which were always imitated in great perfection in the *pâte tendre* of the early period.

The largest display of porcelains in the French exhibit was that of soft paste or underglaze. The luminous porcelains were entirely used as a body for embellishments, such surfaces being almost exclusively used by the French for decorative and useful china. The scheme of decoration was bunches and garlands of roses, cupids and butterflies disappearing into fleecy clouds. Many examples were beautifully painted, and were really works of art in respect of this character. Many tall lamps and vases had on their milky white surface portraits of Madame de Pompadour, who was for many years the strenuous patroness of all the plastic arts when they were in their infancy in France. Some of the specimen reproductions, though not valuable in character, were fine, and illustrated the different periods and qualities of the soft paste. French handicraftsmen are especially successful in the production of porcelain bronze and Limoges enamels. The enamelling is worked on copper, and follows very closely the early Byzantine examples. Since the introduction of the higher classes of the faïence and porcelains the Limoges enamels have not been so popular as articles of decoration, but they are often beautifully worked and classic in their proportions.

The exhibit of Delft art ware was attractive. In outline many of the pieces were quite as artistic as anything from the Netherlands. The variety was greater, but the glaze was not as brilliant nor as fine in texture as that of Holland. There were in the collection many lovely examples in blue and white; but the Rouen, which consists of several colours, was decidedly more satisfactory. There were also novelties in Geolithe ware and architectural enamelled terra-cotta. The use of terra-cotta and the artistic modelling of the available plastic material were not, of course, new, but the combining of exquisite colours harmoniously in one model was new, and the result was most pleasing. Examples of Geolithe ware represented piquant French women in costumes decidedly French, and they were the works of the sculptors Decame and Saurageone. Terra-cotta architectural enamels were more classical, and followed friezes by Lucca Della Robbia, and figures by Michael Angelo and Mercié.

German Porcelain.

The ornate gate which forms the entrance way to the booths of Germany constituted an imposing architectural feature. The pagoda-shaped tower in the central portion of the section afforded pedestal-like support for the striking green copper statue of Germania, which is eventually to be placed on the top of the new House of Parliament, in course of erection in Berlin. The central section of the main room is occupied by the Royal porcelains of Berlin. This
factory

factory was, in its infancy, the pet mercantile industry of Frederick the Great; in fact so alive was he to its becoming a staple article of commerce that for many years he did great damage to the parent porcelain establishment (Meissen, near Dresden) of his monarchy. The paste of which it is made is second only to that of Dresden. The blue and white pieces of Berlin were exquisite both in design and shape, the most beautiful example being a plaque 3 feet in diameter. The floral designs on its highly-glazed surface suggested tangled gardens; in many dinner services the nosegays seemed to have been carelessly thrown over the surfaces of the plates, and the unstudied effect was beautiful. The factory moulds in a unit the largest pieces of porcelain ever successfully fired, and models from one mass of clay the vase, and in relief, as a decoration, bunches of intricately wrought flowers. Usually such additions are made by welding. A novelty in Berlin porcelain was a polychromatic enamel in form and colour decidedly oriental. Some examples were encased in a network of fine gilt and silver. The porcelain tiles of Berlin are perhaps as fine as any made by any factory. The great difficulty met with in the enamelling and vitrifying of porcelain tiles is the almost impossibility of preventing crazing. The beautiful tile-painting of the Emperor William the Third, which formed a panel of the side wall of the Royal room, was pronounced by connoisseurs of porcelain to be the finest work of its kind ever accomplished. On the slab, which was a large one, the decoration was effected in shades of soft leaf green. A medallion, illuminated in gold, formed a background for the portrait of the Emperor, which was painted in profile.

The first European manufactory of true porcelains was at Meissen, fifteen miles from Dresden, in the beginning of the fifteenth century; and it is generally acknowledged that the fineness of its quality has never been surpassed. The examples from the Royal Saxon factory of Dresden china in the German section were varied and beautiful. The candelabra and chandeliers were particularly lovely. A superb table of milky white porcelain, with a border of dull pink in a cameo motive, was most unusual. Fixtures arranged for electric lights were moulded into flowers, which were highly coloured. The large vases of bleu-de-roi and jasper, as the main note of colour, with historical and ideal paintings as a decoration, were harmoniously effective. There were also a number of fine reproductions of the original Royal Pinakothek in the museum at Munich. The German green glass was much admired, and there were a number of very attractive specimens shown.

Italy's Ceramics.

Italy's show was chiefly remarkable from an artistic standpoint for the beauty of its Capo-di-monti, Italian faïence, and Venetian glass. There was, however, only a meagre representation of Capo-di-monti, undoubtedly the most beautiful of Italian porcelains. The specimens shown were moulded in high relief and richly coloured.

The parent factory of fine enamelled and decorative crockery is supposed to have been in Italy. The designs as compared with the faïence of France, Belgium, and the Netherlands were not so varied, and there was little disposition shown to bring out new shapes and schemes of decoration. The glaze was less luminous, and the outlining of the subjects less sharp. Faïence, however, from the sunny country of the Mediterranean, has about it a decided charm. It is daintily coloured, and even the heavier wares have a filmy, lacy appearance which is fascinating. There were many specimens of Sicilian blue and a few good pieces of blue and white in the Florentine massing. The inventive ingenuity of the Venetian artisans of the Salviati and Murand factories was exhibited in a wonderful variety of glass productions. These factories use all known transparent colours, and
opaque

opaque single and mixed colours. The surpassing thinness of Venetian glass enables the clever designers and handicraftsmen to make it into extravagant, and sometimes grotesque shapes—at least, frequently they are too grotesque for table uses. The soft and unusual blending of its colour tones was among its chief charms. A glass mosaic picture of Othello formed a section of the side wall in the Salviati booth.

Spain's Section.

The section of Spain in Manufactures Building was contiguous to that of Italy. But its exhibits in ceramics were poor. The few large specimens of earthenware of good glaze, but wanting in precision of outline, were Spain's only ceramics. There were a few examples of Millefiori glass, and a number of pretty specimens of other glass work, but on the whole the exhibits from old Castille were disappointing.

Belgium's Exhibit.

Perhaps the most artistically attractive exhibit of what is known as art earthenware was in the Belgian section. It comprised imitations of Delft, Rouen, St. Armand, Rhodian, Gris, Majolica, Barbotin, and tiles. The Belgian artists and manufacturers have imbibed the progressive brilliancy of the French; the nucleus of their art is French. The architectural pieces and decorative panels shown by the manufactory of Keranies and the arrangement of the booth in which they were shown were very excellent. The room was well equipped; a high mantel of carved oak occupied the central portion of the booth; the fireplace was set in green and yellow majolica tiles. On each side of the mantel was placed a tile wainscoting, which in tonality and finish had all the appearance of a piece of Persian tessellated mosaic. On the wall plaques of rare glaze and design were hung. One followed the Chinese decoration, another the Rouen or many-coloured delft. The blue and white delft has a softer note of colour than the original ware from the Netherlands, and it is less luminous. Some Rhodian ware, which is the copy of the Persian pottery, was excellent, both in colour and glaze. Every piece was fired successfully and every tone and design had a sharpness which was unusual in many-coloured clay compositions. The large bottle-shaped examples of Rhodian were very beautiful. The luminous surface of the Barbaton was excellent. The St. Armand exhibits followed the delft in motive; the white was not so creamy, and raised on its surface was a dainty primrose-shaped flower. In this collection were several lovely examples of Nevers ware, not of the faience order, which in the sixteenth century was usual, but vases and plates in shape and colour of a much higher order than was then manufactured. A film-like tracing of lacework was applied in thin, liquid, white china clay on a surface of dark blue. The opaqueness of the clay made the vitrification in manufacture very difficult, but the work was not unlike cameo. Black delft has never attained great popularity, and outside of its purity of glaze has little to recommend it for decorative purposes. The Gris composition, which had a faint suggestion of Nancy ware, was attractive, especially the examples of animals. The central feature of this harmonious booth was a faience vase of large dimensions, which proved conclusively the skill of the Belgian ceramic artisan.

Russia.

The superb Russian exhibit of the Imperial lapidary works at St. Petersburg, Ekaterinburg, and Barnauhl, consisted of two very remarkable pieces of a rich green jade, one in the form of a Roman vase about 13 inches in diameter and 10 inches high; the other an oblong vessel 15 inches by 8 inches, scroll-like in form, in the style of Louis Quinze. Both dishes were of such thinness and translucency that their colour seemed to be continually changing. They were accompanied by a very striking cup of rhodonite, a cup of milky quartz with transparent

transparent spots, and a small bowl with movable handles, made out of one piece of milky quartz. The central feature of the exhibit consisted of three magnificent cabinets of a hard stone mosaic, which, with the dishes grouped round them, formed a most remarkable representation. The central cabinet and the one to the right showed on their panels richly-coloured tropical scenes. The one had a blue frond of lapis-lezuli, the leaves being of green kalkanski jasper, and the plumage of the tropical birds being formed of various colours of amethyst, lapis-lezuli, and other gems. The other was remarkable in having a white frond and showed a pelican with a fish in its beak, set in a rich bit of forest scenery.

Danish Porcelain.

The exhibit from the Royal Porcelain Manufactory of Copenhagen occupied the centre of the Danish division. This factory, which has existed for 114 years, is famous for its productions of valuable ceramics. The hard paste of which this porcelain is made is of spotless white glaze. The decorations are applied partly under and partly over the glaze, and in either case the independent embellishment showed careful study. The under glaze furnished decidedly the finest specimens. The designs followed the objects of air and water, animals and flora. Among the most beautiful examples were the pieces of rococo style in blue and white, which were luminously beautiful. The simplicity of these porcelains was one of their chief attractions, and the decorations were always complete and executed with skilful understanding. There were various pieces of useful china in the exhibit, the most beautiful being the old blue fluted, with lace borders. A dinner service that was especially lovely had as its decoration bunches of purple and white violets; another which evoked universal admiration in its embellishment was very like Royal Berlin, but in its outlines showed better composition. A noticeable feature of this section was a tile picture, of which the subject was that of "The Daughters of Argir" drinking to their father. The Danes are successful in their manufacture of terra-cotta, and follow in this plastic the sculpture of their own country. "A Captive Mother," by Stephen Sinding, which was exhibited in the Fine Arts Building, had been copied with good effect in this medium. Black terra-cotta is much used by them with pleasing results.

Japanese Ceramics.

Japan exhibited an immense quantity of enamels of all grades, many of a merely commercial standard and others debased by misdirected subservience to French art. The Namihawa vases were notably fine, showing on a delicately coloured field *fleurs-de-lys*, winged dragons, a phoenix, and other decorations. The 8 feet high cloisonné chrysanthemum vases, at the south entrance to the Japanese Court, were among the largest pieces of enamel work ever produced.

Austrian Glass and Ceramics.

Austria exhibited a lavish display of glass artistically treated. Lobmeyer, of Vienna, showed some remarkable examples of intaglio engraved glass, as well as of glass decorated with gold, applied in the high relief in Louis Quinze, rococo, and other forms. The entire Austrian section showed the influence of an exceptionally advanced system of industrial education, under which well equipped art schools are maintained in towns of only 10,000 inhabitants.

American Ceramic Art.

The highest ceramic art in America is found in the Rookwood Pottery. The impulse which inspired its establishment originated from the Japanese display of porcelains at the Centennial Exhibition of 1876.

1876. It is a faience made of the clays found in the Ohio Valley. The embellishments are entirely under-glaze and original in design; the colour grounds are beautiful, especially in the darker notes, and the depth of the lustre is very beautiful and in some respects quite equal to the porcelains of China and Japan. There was little novelty in the shapes, but they were for the most part well-balanced compositions. A most unfortunate feature of this exhibit was the fact that Rockwood Pottery never appears to advantage when massed. There was too great a sameness of colour, and the effect of a number of pieces was dull in the extreme. I was informed that this factory employs one Japanese artist who produces very beautiful work. One of his vases in a brilliant transparent red, with a design of stalks worked in the same shading, was very noticeable. The dragon and birds designed by this Oriental artist were wonderfully attractive; and the "tiger-eye," which is considered the acme of ceramic art, has been successfully made by him in his factory.

TEXTILE INDUSTRIES.

The art of clothing is unquestionably one of the most useful to mankind in the whole domain of useful art. The exhibits of this class were large and important, nearly every country represented having some display more or less characteristic.

The progress of the art of weaving since the advent of the Jacquard machine has been wonderful. The advance from the old hand loom, which was exhibited in operation in the Louisiana State Building, to the lovely fabric woven in Manufactures Building by American and imported looms, was self-evident.

On entering the Austrian section the attention of the visitor was at once arrested by the picture of the Emperor of Austria, a faithful likeness, woven in the factory of Julius Leon, of Vienna. The work of producing the picture occupied nine months, and the number of cards used in the design was 19,984. Three months were required for punching the millions of holes. For this production the maker received, as he well deserved, the expression of the Emperor's entire satisfaction with his work. No artist's pencil could have made more delicate lines and shadings; the loom and the weaver performed the duty well and artistically.

Saxony, in the German section, had a complete exhibit, showing the results of experienced skill and practice. The production of her laces, embroideries, trimmings, and buttons are valued at a large sum annually; and the fine arrangements of the beautiful brocaded silks, velvets, ribbons, pictures (woven), labels, and dress goods of the Cresfeld manufacturers were greatly admired. Great Britain had many excellent exhibits, but Coventry, Nottingham, Manchester, and other great cities were but feebly represented, no doubt on account of the provisions of the M'Kinley Act. Neilson, Shaw, and M'Gregor, of Glasgow, exhibited over 140 different highland clan, and family tartans. Some fine damasks, linens, lawns, sheetings, and woollen goods from Ireland were shown. The Ottoman and Persian Empires and India sent hand-woven rugs and carpets, many of them exquisite in design. The command in the Koran prohibiting its followers from reproducing the images of living things has not been without its advantage; it has served to develop, as was shown in these exhibits, the wonderful beauty of the geometrical designs.

Spain was well represented; rugs, carpets, tapestry, blankets, of bright hues and designs, from Barcelona, were shown, whilst the Institute Industrial de Tarrasa sent articles of fine clothing. It produces yearly 6,500,000 lb. of woollen goods. The Fabrica de San Pedro

Pedro in Mexico exhibited shawls, blankets, and spreads of fine texture. There was a fine assortment of embroidery, damasks, and brocades, the designs of which were superb.

Brazil produces its own cotton, and manufactures cloth enough out of it to supply the entire Republic. The quality of these goods was excellent, and the colouring so rich, not gaudy, that they resembled cloths.

Verviers and Ghent, in Belgium, as is well known, are the chief seats of woollen goods of excellent quality, and both towns had splendid exhibits. Sail cloths and bagging, produced by their manufacturers, were also shown.

In the French courts were some of the most tasteful, and at the same time the most expensive, exhibits of this class.

In the exhibit of tapestries France stood foremost. Her world-renowned gobelins and beauvais tapestries rival in richness of colouring, beauty of execution, and artistic skill and naturalness the finest efforts of ancient or modern painters. These Gobelin and Beauvais tapestries are sometimes called government or national tapestries, on account of the manufactories where they are made being endowed and controlled by the French Government. Besides these national tapestries there were others exhibited by private firms, known as the Aubusson tapestries, thus called after the town where they are manufactured. The artistic genius of France, combined with centuries of patient study, research, industry, and practice, has made French tapestries the wonder, not only of this age but of the past three centuries.

Of the different pieces of gobelin tapestry on exhibition at the World's fair, the most striking were "The God-child of the Fairies," designed by Mayerolle, and "Arts, Science, and Letters in Antiquity," designed by Ehrman. These tapestries were valued at \$100,000 each, and for artistic design, wealth, and beauty of colouring and regularity of finish were the equals, if not the superiors, of any tapestries, ancient or modern. Each of these tapestries took over eight years to complete. Some idea of the patience and skill required may be formed from the fact that it takes a skilled artisan a whole day to do 1 square inch of this tapestry, and the slightest mistake in the colour of the threads or their proper adjustment will destroy months of valuable labour.

The most striking of the Beauvais tapestries were two panels of birds, by Gaudefroy, and two sets of furniture in silk tapestry, designed by Chabal, and consisting of garlands of flowers, one a pink silk ground and the other a moss green. These sets, it was said, were worth their weight in gold.

Nothing but merino wool is ever used in gobelin tapestries, while in the Beauvais they use wool and silk. The managers of the gobelin tapestries consider that the use of wool alone gives a softness of texture which cannot be obtained with silk and wool mixed.

The merino wool used by them is manufactured in France of the finest quality, and is dyed by their own chemists. The discovery of coal tar, or aniline dyes, has enabled them to give 14,000 different tints to the wool, but of these only 600 are actually used, for the reason that many of the 14,000 colours, if used, might change with age, and thereby mar the harmony of colouring so necessary to the artistic beauty of the tapestries. Amidst the Aubusson tapestries, exhibited by ten private French firms, there were many pieces which almost rival the Gobelin and Beauvais tapestries. One of the most attractive of these pieces represent a game of "Blind Man's Buff." It was a garden scene with a happy mixture of children and adults, full of life, light, and merriment. But even this was thrown in the shade by a piece of tapestry representing "Cupid." It was supremely beautiful, and the
flesh

flesh tints of Cupid almost rivalled in softness and delicacy of colouring the natural "satiny" skin of a living infant. This piece of tapestry was valued by Thamot at \$1,000. There were also two sets of furniture exhibited by the same firm upholstered in tapestry, one which tells the story of Don Quixote, and was valued at \$6,000; the other was in the renaissance style, and was sold to Mrs. Baumgarten, of New York, for \$5,000.

Braquenie & Co., of Paris, had on exhibition many beautiful specimens of Aubusson tapestry, amongst others a grand piece representing the "Stairway of the opera-house in Paris," all aglow with light, life, and brilliant lights and moving forms. An interesting item in connection with this piece was that the figures in the tapestry were fac-similes of the firm's own family. This piece was valued at \$7,500. "Spring" and "Autumn," by the same firm, was also worthy of notice. They were valued at \$2,700 each. A remarkable piece of ancient tapestry was exhibited by Croc Père et Fils. It was $3\frac{1}{2}$ yards wide and 2 yards high; it was a mythological subject, very old, and of Brussels manufacture, as was shown by the mark "B V B," this double B V B, with a shield between, being the mark placed on tapestry manufactured in Brussels in the fifteenth century. It was a remarkable piece of work, and the colours in it are apparently as fresh to-day as they were 400 years ago. This firm had also on exhibition two panels of Aubusson tapestry, one representing a "Blonde," the other a "Brunette"; they were charming in design and execution.

There were also many pieces of woven work from the Jacquard looms which rivalled hand-made tapestries in beauty and richness.

There were admirable reproductions of old tapestries, but the most striking piece exhibited by them was a large and beautiful panel, made especially for the World's Columbian Exposition. It represented the discovery of the new world and the union of France and the United States in the cause of liberty. Two female figures—one a white woman draped in the folds of the American flag, the other an Indian maiden—occupied the centre of the panel and represent the past and present of America. To the left of these figures was a tableau representing the "Landing of Columbus," while on the right Lafayette and Washington stood with hands clasped, pledging each other and those around them to the cause of liberty. This tapestry was 15 feet wide and 12 feet high, and took over one year to make. It was a beautiful artistic work, and was valued at \$1,000.

French embroideries, like French tapestries, are the perfection of art in needlework. This was evident from the multitude of rich and rare embroideries scattered with prodigal profusion throughout the French section. I simply mention a few of the most striking of these embroideries. Madame Leroudier, of Lyons, whose reputation for artistic embroidery is known throughout Europe, and who has gained repeated honors at different expositions of decorative art, had twelve panels on exhibition at the fair, valued at \$33,000, which were the reproduction in needlework on coarse silk, three metres high, of twelve compositions from the pencil of Claude Audran, called the "Grotesque Months." Each of the twelve panels had a divinity of Olympus, in all six gods and six goddesses, each in the centre of a temple, pavilion, or tent, and each panel was decorated at the top and bottom with attributes, ornaments, lakes, and flowers suitable to the month and god or goddess represented. This unrivalled work was accomplished by means of the "passe" stitch, and cost the artist eight years of labour.

Turning from these panels one was struck by a magnificent piece of bullion work, "A Trophy of the Renaissance," consisting of a coat of arms intertwined with laurels and resting on a massive shield of

of crimson velvet. In this work there had been twenty-five different stitches used, among others the long, satin, shell, couchin, chain, and outline stitch, French knot velvet. There were several different kinds of bullion introduced into the work, and they were arranged with such artistic skill as to prevent any monotony of colour and give the necessary shading, while cardboard was used underneath the bullion to give the requisite shape to the armour. This shield was made by the working women of the firm of Van Grois and Biriote, of Paris, and took three years to execute.

Another piece worthy of notice was a garland of flowers, done in rococo embroidery—formerly renowned as ribbon work—one of the oldest forms of raised embroidery, and only indulged in by the wealthy, on account of the cost of the material used.

Terra-cotta Manufactures.

The employment of terra cotta is more common and better known than that of any other material used for constructive or decorative purposes. Its use dates from the earliest periods of history; in fact brick was the building and decorative material of antediluvian days. Comparatively speaking, in Australia, we have not attained any great degree of excellence in this manufacture, although we have clays well adapted for the purpose.

The word terra cotta, a name in itself Italian, signifying baked clay, was first applied by Italians more to the purposes of ornamentation than of construction; the base of this material has always, however, been the same. Many lovely examples of antique Egyptian and Roman terra cotta statues, bas-reliefs, metopes and friezes still exist; and the exquisite bas-reliefs of Luca Della Robbia are known to all lovers of the beautiful. A feature of Roman ceramic art, as shown by many exhumed specimens, was its historical friezes. The oldest examples of American baked clay have been found among the relics of the ancient cliff-dwellers of the Pueblos. Many of the vases and jugs possess grace of outline and judgment in the use of colours. Terra cotta has great lasting qualities when made of the proper mixtures of clays and when well fired. It will not vegetate as stone will, often causing decay. It is a porous material, and even when water freezes in its pores, the strength of the composition is so great that it will withstand the natural expansion without injury. In beauty of colour it has a great advantage for decorative uses; almost any colour can be produced by the correct use of chemicals, and they are found to be less apt to change under atmospheric influences. The beauty of all things decorative should grow, and as terra cotta is comparatively cheap it has become an important factor for ornamental uses and the modelling of statues. In terra cotta can be found a scope for freedom with a capability of supplying the demand for decoration in durable material. Aside from the use of terra cotta for the modelling of statues, it forms an essential feature in the construction of buildings. It forms the facings of walls in interiors; it paves floors. Bas-reliefs, capitals, piers, arches, shafts, corbels, chancels, and arcades are comprised of it, and this amenable plastic is found to be more imperishable than granite.

In reviewing the exhibits of terra cotta at the Exposition an American expert states as follows:—

The artisans of France, conspicuous always for their artistic ability and finish of style, sent to the Exposition a number of charming examples in terra cotta or Geolithe ware. The use of this available plastic composition for the modelling of figures, combining in the figures several exquisite colours, harmoniously, was quite a new feature, and the result was most pleasing. French women, in costumes and bonnets decidedly Parisienne, formed an important part of this display of terra cotta in the French section. They were the works of Sculptors Sarrageone and Decame. These statuettes were fascinating, capricious, and daring. The architectural enamelled terra cotta

cotta shown in the same division was more classical in its selection of subjects. It followed friezes by Luca Della Robbia and figures by Michael Angelo and Mercie. Its colours were strong and its surface luminous; many pieces bore a strong resemblance to the old Roman and Greek specimens of terra cotta. The setting of the booth containing the architectural enamels of France was most pleasing. Columns of malachite-green terra cotta, in grotesque designs, acted as supports for a canopy top which formed an appropriate ceiling to the booth.

The purity and robustness which characterises the work of the Danes was not found wanting in their modelling in terra cotta. Black terra cotta is much used by the Danes, and there was an interesting and comprehensive showing of it in the division allotted to Denmark. One bust was of Dante, an excellent example of the possibilities of this artistic material. "Terpischore," "Young Augustus," "Cupid," and "Psyche," and many other figures by such sculptors as Thorwaldsen, Kroyer, and Bissen have been followed. There was simplicity, grace, and suppleness in all that these artisans of the North undertook. Their work was strong, well executed, and never sensational.

Italy's collection of terra cotta was disappointing. It was natural to look to the Italians for the best work in this medium. There were several very large figures to be seen in this section. One or two grotesque pieces were admirable, but for the most part the figures lacked classical feeling, and there was a striving to follow the French, but the spirit of the figures was lost in the excess of detail.

England's terra cotta at the Fair was excellent, the most noteworthy examples being the works of George Tinworth; his historical and allegorical bas-reliefs, both in the Fine Arts and Liberal Arts Buildings, were exquisite pieces of work. There was also a terra cotta fountain modelled by Mr. Tinworth called "Cheerfulness," but it was hardly equal to his bas-reliefs. The replica of the group "America," by John Bell, which was presented to Chicago, was a skilful example of England's work in terra cotta.

The collections of terra cotta exposed in the German section of the Liberal Arts Building presented few new thoughts. There were, however, a few good pieces of bas-relief work, in colour and effect very like the old examples of Wedgwood china, and these were attractive.

Some of the finest specimens of architectural terra cotta exposed in the Fair were of American manufacture. The fine art terra cotta shown by the artisans of the United States was not equal to that shown by some other countries.

The wonderful perfection and surpassing beauty of tiles, and their limitless appreciation in the embellishment of houses, has become one of the essential liberal arts. American tiles have during the last ten years attained great excellence. Up to that period Americans were apt to turn to those of foreign manufacture for artistic designs and durability. The American tiles are possessed of permanent sheen, and, owing to the thickness of the enamel, they attain unusual brilliancy. The English tile is undoubtedly more durable. It is less in danger of crazing. The enamelling on the English tile is very thin. Consequently, when the tile proper contracts, the enamelling is less in danger of crackling.

The collections of American tiles at the World's Columbian Exposition were not at all what they should be. The most comprehensive showing of them was arranged in a soda-water fountain, thus playing a double part of advertising. The fountain was composed of three appropriate symbolical tile pictures in relief. The motive of the central and largest panel was "Thirst." A street fountain was playing streams of water or soda, high into space; a crowd of eager citizens and their families were represented as hurrying to moisten their parched throats. To the left was a relief representing "Air." Flying apparitions symbolize the sentiment of the picture. The third subject was "Water." The most effective tiles shown in the United States section were those in one tone, which may be found in every possible colour and shade of colour. There was a meagre showing of "terra vitra," which is neither a plain enamel nor "faience." It is a combination of materials producing the impression of age with decided truthfulness.

An interesting display was made in the English tiles. They were arabesque in their general conception. The designs were not original, but there was dignity of thought in the arrangement and setting of the screens that was wholesome and satisfactory.

The most artistic and beautiful collection of tiles at the World's Fair were those exposed by the artisans from the Netherlands. Hung on the wall of their section and resting on easels were examples of tile pictures, beautiful in their enamelling and colour. The joining of the Dutch tiles as they are arranged to simulate a picture was excellently done. In a reproduction of Rembrandt's famous canvas, "The Burgomasters," which was comprised of seventy distinct tiles, could be seen the accuracy of their workmanship. Most of the Holland tiles are in milky white, with designs in cobalt blue, but one or two examples were in soft sepia tones, which transcriptions were after Anton Mauve's sheep pictures. The dull brown so prevalent in this noteworthy artist's colouring makes the use of sepia especially appropriate.

The Belgian artists and manufacturers have imbibed brilliancy and progression from their association with the French, and they have never surpassed the French in any artistic undertaking, except in the making of earthenwares and tiles. The showing of tiles, especially those in yellow and green majolica in the Belgian division, were worthy of sincere praise. The blue and white tiles did not equal the work of the ceramic artisans of Holland; they were less sharp in colour.

The

The beautiful and luminous tile painting of Emperor William II, which formed a panel of the side wall of the royal room, in the section occupied by Germany, was pronounced by connoisseurs of porcelain to be the finest work of its kind ever accomplished. The slab was a large one. The decoration was made in shades of leaf-green. The portrait of the emperor was set on a medallion illuminated in gold. The portrait was in profile. These porcelain tiles, which are made in the royal factories in Berlin, surpass in beauty any others in the world.

Cloak-making Industry.

The most important exhibits in this class, as might naturally be expected, were shown by American exhibitors. There was one striking peculiarity which characterised every display of cloak and winter clothing throughout the whole of the building; cloaks and garments fitted for the purposes of the wealthy were exhibited everywhere, but garments of the ordinary kind, adapted to the purposes of the humble or for useful ordinary wear, were conspicuously absent. A very excellent display was made by a New York firm, whose exhibit was one of the finest to be seen. I was informed that an estimate of the value of the stock shown by this firm placed it at about \$250,000 and it was stated that it cost about \$30,000 to exhibit it. The booth had four entrances and each entrance was guarded with rare specimens of the fur-bearing animal world. Within were white bears, grizzlies, cinnamon and black bears; red, white, blue, and grey foxes; lions, tigers, panthers, buffaloes, elk, deer, wolves, leopards, antelopes, Rocky Mountain sheep and goats, prairie dogs, wild cats, &c., and the whole of these representations were overlooked by a splendid specimen of a black bear standing upon a globe and holding a torch after the style of the Liberty Statue on Bedloe's Island. The 20-foot pillar upon which this exhibit rested was wrapped in layers of red, white, and blue fox skins. This firm exhibited, among other garments, the following: a mantle and muff of imperial crown sable tails, which required nearly two thousand animals for its construction and was valued at \$18,000. Near it was a sable skin mantle marked at a value of \$13,500. Cases of wraps, capes, and jackets were placed around the sides of the booth made of skins of nearly every fur-bearing animal and the marked prices ranged from \$65 upwards. In the display of a Cincinnati firm there was a remarkable garment, the price of which was marked at \$2,000. It was a handsome 56-inch mantle of Halifax mink, with sable-tail trimmings. It was stated by the representative of this firm that mink would be the future fashionable fur, and it was probable that capes and mantles would be worn in preference to jackets on account of the sleeves now worn on dresses in America. Speaking of the price of seal furs it was explained that, on account of the scarcity of seals, the prices had advanced about 250 per cent. during the past three years. A beautiful mantle, lined with ermine, the outside being of cream cloth embroidered in handiwork of silk and gold floss, was marked at \$1,500.

A firm of St. Petersburg exhibited the most costly furs and garments of every description, together with seal-skins, boots, shoes, and slippers. Skins of nearly every Russian animal made into garments were arranged in somewhat cramped space, and the total value of the exhibit was placed at the enormous figure of \$300,000.

The most costly garment that was shown here was a circular of Alaska seal, lined all through with sable, attached to which was a Kamschatka 12-inch collar, marked at \$3,500. A lined circular of sable legs, with 15-inch sable collar, was marked at \$1,100. At the time when these were manufactured the workmen and women received wages ranging from \$30 a month upward, according to the statement of a representative of this firm.

The United States Government gave the contract for obtaining seals from Alaska for twenty years to the firm of Liebes & Co. This firm forwards all the sealskins to London, from whence they are exported

exported to America and all over the world. The reason sealskins are sent to London is that the London dye is better and darker than that of any other country.

The most interesting and educational feature of the seal industry was shown in the booth of Treadwell & Co., a firm which not only manufactures cloaks, capes, and wraps of all descriptions but actually cures, dresses, and prepares the skin in a very excellent manner. I found, however, this firm is also compelled to go to London to purchase the skins of animals killed in America. They buy them in what is called salt pickle. The entire process could be seen in operation at their booth. Their factory is at Albany, N.Y., and they are the only firm in America who use their own dye and guarantee that it will not fade or crack for twenty years. This firm has dressed sealskins for sixty-one years and their dye is said to be so perfect that after ten or twelve years' wear they can match any part of a garment without detection.

French Silks.

The French exhibit showed the excellency of their silks to perfection. The designs were as elegant as they were rich and their colouring was excellent. The "Sun on the Ocean," woven by Bardon and Ritton, of Lyons, was a work of art in delicacy and in colouring, and rivalled painted marine pictures. The "Falls of Niagara," woven by J. Bachelard, Lyons, was another masterpiece, and the prayer-book, woven by Henry, of the same city, equalled the work of the best printing press.

In the Committee-room of the Women's Building the most celebrated tapestry of Bayeux was represented by a life-size photograph sent by the city of Bayeux, and a large number of specimens of its special work. In the gallery above the French space in the Manufactures Building was the silk exhibit from Lyons. Here were beautiful velvet portières specially made for the Columbian Exposition, which bore the arms of France and the United States, the cost of each being upwards of \$1,000.

American Textile Industry.

The textile industry has made wonderful progress in America during the past few years. The silks of Paterson, N.J., are said to rival those of Lyons, and a woven landscape of the Columbian World's Fair, with the American eagle, by Johnson, Cowdin, & Co., of Paterson, was a true work of art. Twenty thousand cards were required to produce this banneret, and the artist, aided by an assistant, worked six months at the design. Much credit is due to the Crompton, the Knowles, the Shaum and Ulinger looms for the progress made in textile fabrics. They have cheapened and at the same time have increased the production. The improvements in spinning, knitting, and other machines have so reduced the cost of fabrics that the price of the richest and best are gradually being brought within the purchasing power of the masses of America.

Exhibits of Lace.

Lace was shown in all its loveliness in the courts of various countries, but perhaps those of Belgium were the most elaborate. They consisted of Mecklin, round point, Venetian, guipure, duchesse, point appliqué, point de Bruges, Valenciennes, Venetian point, and the beautiful lace called dentelles Louis Quinze. Italy not only had a large exhibit of lace but also had a comprehensive exhibit of ancient embroideries, while Spain furnished only a moderate quantity of its beautiful work in laces. In the French court there was a lace cradle valued at over \$30,000, and the laces were real works of art made entirely by woman's deft fingers.

Screens

Screens for Home Decoration.

The most thoroughly beautiful and artistic modern screen at the Exposition was shown in the French section. It had five leaves, each leaf representing one of the five senses. Its frame was inflorescent in design, and carved out of wood. Each panel was in itself a lovely picture, executed by the hand of a skilled artist named Rochegrosse.

In the same section were several unusually handsome screens set with Beavais tapestries. Each one had a different motive of embellishment. The subjects were interesting, and the extreme nicety with which this tapestry was made, and the multiplicity of the shading and colours employed in its weaving combined to make a pretty picture. Screens following the Louis XIV, Louis XV, and Louis XVI periods, made by the French, either covered with rich brocaded stuffs or made of satinwood, hand-painted, were excellent examples of clever and artistic workmanship.

The most comprehensive and largest collection of screens at the Fair was sent from Japan. The most brilliant sample shown by these people from the extreme east was of large dimensions; its embellishment was applied in gold thread to satin of the same tonality. At the base was a rippling stream, above was a bamboo fence, the bamboo, a favourite device of the Japanese, which is typical of the mildness and gentleness of nature. Above the fence were masses of the royal flower, the chrysanthemum; also the blossoms of the peony tree. Another lovely example displayed demoniac figures in russet browns embroidered in old gold satin. Japanese lacquering has never been surpassed, and a most beautiful specimen of it was found in an oblong-square screen. Its body colour was of lustrous black; on it was a tracery of flowers in metallic green. It was bordered by a relief design in a Grecian motive, set in a frame of rich dark bronze. The simple and delicate leaves of the maple tree, turned red by the early frosts of autumn, is always laden with poetry and imagination for the Japanese, and it is one of their most exquisite and artistic designs. So much does this simple emblem convey to them that they work and paint it as if inspired to do so. A more lovely screen it would be difficult to find, than one illuminated by branches of maple leaves on dull brown satin, which was shown by these artisans in the Liberal Arts Building. The bronze screens encased in frames of pierced wood were massively effective. They are cast in one solid piece, and are intended to be used as permanent fixtures in halls and dining-rooms. Another screen of soft grey was ornamented with graceful sprays of white wisteria and thistles. A flight of sparrows formed its frieze decoration. The feathering of the birds and the down of the thistles, in this composition, stood out with marvellous truthfulness. [The dragon to the Japanese is significant of wisdom, and it is always depicted with five claws. This device was embroidered on soft pink satin which formed the leaves of a screen. A border of incut velvet outlined the satin and acted as a mat for the laquer frame, which was its outlining.

FURNITURE.

In suites of furniture and completely furnished apartments containing selected furniture and various objects of adornment, Germany, undoubtedly, took the lead. Some of the furnished rooms in the space of this country were magnificent to an extreme degree. Several of the royal rooms shown having exquisite fittings and furniture. There was a sixteenth century that was very interesting. The walls were hung with rich red damask, the wood used was oak handsomely carved and inlaid. The ceiling was a framework of gold in which were set paintings in oil. Adjoining this historically decorated room were the sitting-room and dining-room of King Ludwig. The
sitting-

sitting-room was in bleu-de-roi. Velvet massively embroidered with gold bullion lined the apartment; the furniture was covered with velours and embossed satin; candle fixtures, inflorescent in design, formed a conspicuous feature. The entire furnishing of this royal room were the original ones used by King Ludwig. The dining-room was faced with a dull brown textile, and the furniture was illuminated carved leather. I may here state that the examples of hand-cut leather in furniture in many exhibits were remarkably fine. In the Italian section there was a reproduction of a bedroom occupied by the present Queen of Italy, lined with soft leaf-green leather, giving an excellent idea of the finish and clever embossing of the Italian manufacturers. Aside from this exhibit and that of carved furniture of pine, rose, and walnut woods, there was but little decorative furniture in this Court.

French.

One of the sections of the French space was called Furniture-Hall, and was designed and decorated by Hermany. It contained some of the most expensive articles of furniture shown, one cabinet, for example, being valued at \$5,000, and lots of small pieces of furniture in tapestry, mahogany, or bronze, ranging in price from \$1,000 to \$5,000. Two cabinet antiques were the gifts of Napoleon I to the King of Naples. One was of rich dark mahogany, richly decorated by raised designs of fire gilt. The top of this piece of furniture was finished by a clock of intricate composition. The other old piece was also in mahogany. The door of this cabinet was composed of rare Sèvres plaques of the imperial era. Its table shelf was supported by porcelain columns of bleu-de-roi. The modern pieces were excellent, both in their concrete lines and their style of decoration. One of unusual attractions had the organic lines of a sedan chair. It was made of satinwood painted by hand in gold. On the gold background three pictures had been painted. One presents a piquantly-attractive woman seated on a garden bench, gowned in a costume essentially French. She is listening intently to music from a violoncello, the performer being a gaily-dressed cavalier. The green and bronze gilt cabinets in "Vernis Martin," a style of decoration named after a famous carriage-painter and inventor of colourless varnish, were unquestionably beautiful pieces of furniture, and one additional evidence that all that is French in household furniture never fails to fascinate Americans.

British.

In the British section two or three very excellent billiard-tables were shown. The most striking feature in the British section was the reproduction of Hampton and Sons (the great English manufacturers) of the historic banqueting-hall of Hatfield House, the seat of the Cecil family, and the house of the Marquis of Salisbury.

German Carved Ivory Work.

Near the silver work in the German Court was a large and most beautiful collection of carved ivory work, in which the very minutest pieces were executed with extraordinary skill, each example or detail being worked out in the most perfect manner. Beautiful miniatures painted on ivory were also an important artistic feature of this part of Germany's exhibit. In this court were also placed the trophies won by German Emperors and Generals and other distinguished men. There was in the collection of gifts those made to Kaiser Frederic, Kaiser William, Von Moltke, William I, William II, and Bismarck; letter portfolios in carved leather, embellished with the crown and seal of Germany in jewels and enamels, choice specimens of the goldsmith's art; elaborate loving-cups, and scenes of warfare worked art in relief on silver tankards; sceptres inlaid with valuable stones, books with covers of gold, and other articles.

articles. Another interesting historical souvenir was an inkstand in fire-gilt which was ordered by Ludwig at a cost of \$5,000. There were also several exquisite specimens of lapis-lazuli.

Wood-carving.

In wood-carving there were many beautiful representations, both in the manufactures and in the liberal arts sections.

The display of Italy was rich in design and splendid in execution. Figures grotesque and figures natural, figures large and small, mantel-pieces and mirror frames, cabinets and decorative panels, chairs and writing-desks were exhibited in profusion. Italian renaissance is the ideal style of the decorator and carver, taking as it does the most common of every day articles and clothing them with a new beauty and richness found in no other style. Birds, flowers, fruit, figures, cut with a degree of freedom and perfection found nowhere else, were exhibited. A renaissance panel exhibited by Antonio Zenetti was worthy of close study. Having about 6 in. relief, the whole panel had that grace and finish, those flowing lines and that softness of cut, peculiar to Italian renaissance. There were a large number of other works of art of equal if not superior workmanship by the same artist. Another artist displayed a double figure, Margaret and Mephistopheles, cut from one block of wood, which displayed considerable originality. One little figure for an electric light holder was wonderfully light and airy. A carved frame of laurel leaves, by Vincenzo Cadorin, with flowers, drapery, and figures, well balanced, was very graceful. The woods mostly used were rose, pine, and walnut.

The land of the poetical edelweiss (Switzerland) exhibited a great profusion of small carved wooden objects. The carving of the Swiss is wanting in impressionism and follows nature too closely as a general rule. There were, however, in the examples of carving found in this section many examples exhibiting boldness and relief and delicacy of touch. Many of the large articles shown seemed to suggest the idea that under all their apparent ornateness they somewhere or other concealed within the ambush of their embellishments a possible cuckoo clock which might at any moment send forth some unnatural sound.

The glass mosaics exhibited by Russia were of surpassing beauty, and in view of the fact that this industry has only attained excellence within Russia within the last twenty years the beauty of the exhibits both in material and design were surprising. A magnificent mosaic picture of Christ occupied a prominent position in this section, and it would be difficult to find a finer example of tessellation. The mosaic enamels and enamelling on silver was very lovely. In this court malachite and lapis-lazuli, converted into tables, mantels, vases, and jewellery, were well worthy of examination, and made a notable feature.

In the German exhibit the renaissance style of carving was heavier and not so soft in outline as the Italian, though suitable to the furniture it embellished. There was plenty of evidence, however, of the excellence of German carving. The statuettes by Fischer, of Munich, were very good. In the Baden section of the German exhibit some clean-cut coloured wood panels were shown which were sharply cut though of low relief. It is in the rococo style, however, that the Germans seem to excel. The examples shown were excellent in design and good in workmanship. Though called by some artists and architects a bastard style, the rococo is to the carver a style full of possibilities—deep cutting, free lines, and rich effect. In ecclesiastical carving there were some excellent exhibits.

France exhibited little carving apart from her exhibits of furniture. The most noteworthy exhibit was a Louis XIV, in walnut, by Forest of Paris. It was of good workmanship, the panel in the centre
of

of the mantelpiece representing peace. The lions, ridden by children, were followed by a maiden bearing fruits of peace in the shape of products of the field.

The carving in the British exhibit was massive and heavy, lacking the softness of the Italian in their renaissance; but, as an exception, the Gothic, as displayed in the choir front exhibited by Hems of Exeter, was very good, being soft and effective, without any superfluity of detail.

Austria had one example worth mentioning. In the salon of the Princess of Metternich there was a beautiful example of a room fitted up in the style of Louis XV, some of the furniture, however, being in the Empire style. It was rich in carving, the screen, mantel, overmantel, and piano being well executed.

Belgium had one good exhibit, showing the figure of a woman cowering before the storm, in which the pose was graceful and the drapery flowing.

Russia showed a large wall cabinet in walnut, equal, in finish of work, to that of any other country. The centre panel and the figures on the pilasters were worthy of close study. It was in low relief, soft and effective.

Entering the Danish section from the central aisle of the building there was a copy of the statue of Hans Christian Andersen, modelled by the greatest of Danish sculptors, Thorwaldsen. At the rear of this lovely example of plastic art was a room, or rather a section of one, containing the furniture that had been used by the great story-teller. The decorations were simple and the furniture quaintly attractive; every article in it was rich in interest. Nationality played small part when looking in this room, for Hans Andersen appeals directly to the hearts of the people of the universe; all nations love him. He has kept the spirits of his readers young, for he takes them often to that indescribably fairy land which was his chief abiding place. On a writing-desk lay his tall broad-brimmed hat. His works were placed in a bookcase, which occupied the corner of the room. A screen stood near it which could not fail to interest any child. It was composed of heads and figures cut from newspapers or periodicals. These were pasted on the frame of the screen, and many of the groups represented interesting historical stories.

CHEMICAL AND PHARMACEUTICAL PRODUCTS.

These were largely exhibited, chiefly by American and German houses. In consequence of the want of space on the ground-floor of Manufactures Building these exhibits were shown in the southern portion of the western gallery. The drugs and other pharmaceutical preparations were beautifully got up in the various booths, reminding one rather of confectioners' establishments than of the old-fashioned chemists' shops. Both the homeopathic and the allopathic sides of medicinal remedies were exhibited, and, as far as appearance went, it would be difficult to say which was the more tempting in its nicely-arranged and pretty remedies for "all the ills to which flesh is heir." They were rivalled by the extensive array of attractive exhibits of flavouring extracts, essences, and the like, chiefly shown by American exhibitors. Of course these preparations are quite a contrast to those in vogue some years ago as far as get up and the facility of administration are concerned; but the faculty in Australia is perfectly familiar with these innovations, both as presented by the British and American pharmaceutical firms. The Mercy Exhibit was contained in a separate building, erected for the purpose of exhibiting the innumerable forms of chemical and pharmaceutical products made by this firm.

BOOKBINDING,

BOOKBINDING.

This class of exhibit, as might easily be imagined, was scattered over the whole of the great building, each country preferring to keep its exhibit in the place in its own court considered best for its display.

The machinery employed in the manufacture of blank books and edition binding was somewhat incomplete, and contained very few of the newer inventions in this industry, although many of the old-fashioned machines had numerous small improvements and new details. Two paper-ruling machines, one an American invention and the other an American product, were worthy of remark. Both these paper-ruling machines referred to discard the old-fashioned brass pen, and used instead a brass disc. These discs were of various thickness of line, and the ordinary double and treble lines were cast in one piece. Each disc had a round hole in the centre into which was fitted a metal rod, and the discs were separated or spaced by other and smaller discs of zinc, these latter having, of course, a hole in the centre corresponding to the brass discs and fitting the same metal rod. The lines could be spaced any distance from the thirtieth part of an inch to the whole length of the rod. The ink was fed to the discs by means of a rubber roller which contained its supply from a piece of flannel which was laid loosely on one of its ends and fed with a brush in the old-fashioned way, the other end of the flannel conducting the superfluous ink into a metal trough. Over feeding was thus rendered difficult. The same principle, so far as brass discs are concerned, was adopted by both the American and German machines. Here, however, the likeness ceased, the departure being largely in favour of the German invention. They were both self-feeders, the German attachment being a marvel of neatness and simplicity. They both ruled two sides of the paper in one operation, and it was stated that the German machine could turn out 4,000 sheets of paper ruled on both sides in one hour with the attendance of only one person. There were no statements as to the amount per hour turned out by the American machine. Placed side by side, and the merits and demerits of each machine closely compared, the German machine undoubtedly appeared the better one. It took less than half the floor space of its rival, was stronger, neater, and better made, and many of the more important operations were performed more quickly and more accurately.

Of bookbinding itself the principal exhibits shown came from France, America, New South Wales, and Canada. Undoubtedly the French exhibits were produced in the best style, and that of New South Wales was next to that of France in good taste and excellence of work, while the American and Canadian showing was poor.

Printed books were very extensively shown. Germany, England, France, America, Bohemia, Italy, New South Wales, Denmark, Norway, and Sweden all contributed plenteously, and thus a good opportunity for comparison of the different national styles and skill was provided. Of edition work, Germany had a large exhibit, America was next in size, and France next, the other countries having but a small show. The workmanship of each nation in edition work seemed to be very much on a par. Germany had some fine samples of multi-coloured printing on cloth, a form not shown by any other country; in fact this is quite a recent invention, and appears not as yet to have come into use elsewhere.

Of fine hand-tooled leather binding there was a splendid exhibit, especially from Germany, which had a large and masterly show of all kinds. There was a superb case of these exhibits from London, which worthily represented the very best English binding. New York also had some splendid examples. There was a grand collection from Paris, whilst other countries sent specimens of skilled work of very
 excellent

excellent character. The whole collection was so rich and varied that it is somewhat difficult to make a selection of the best specimens. Among the books sent by the German Government bindery was one in white vellum, illuminated in the Grolier style, which was simply magnificent; another in brown morocco, in Harlein style, bound for and belonging to the late Emperor William, was conspicuous by its beauty, and had the initials of the Emperor and the crown of gold on the side. There was also a jewel-casket covered with white morocco, finely finished and illuminated by Herm, Graf, and Son, of Altenburg, and the price of this beautiful specimen of the bookbinder's art was \$750. Two books from the case of C. F. Bonaventure, of New York, deserved especial notice. One was a book in brown crushed levant, finished in the French style, with an inside double and dentelle border; the other was a red morocco book of Florentine style, illuminated green, and the inside doublet of blue morocco.

England's only exhibit of art binding was from the hands of the world-renowned Zachnsdorf, of London. Among other works the case contained a "Tennyson," in blue morocco, choicely finished in Derome style. There was also a beautiful specimen of renaissance work in dark green crushed levant. The *piece de resistance* in the English case was Zachnsdorf's "Art of Bookbinding," in crushed brown levant, illuminated in olive green; with bold and graceful floral design in gold, and panelled on the back was choice foliage.

France was represented by Leon Gruel, of Paris. Among the specimens I may mention a quarto in brown morocco, in Maioli style, a beautiful piece of work. There was also a book in Grolier style in brown morocco. This example of choice binding cost for a reproduction of this kind about 5,500 francs. A quarto in red morocco, style of Louis XIV, was also a gem. The standard Scandinavian countries had a remarkable exhibit of inlaid calf work, wholly of Gothic designs, a style of book decoration which appears to be quite fashionable in those countries. In this kind of finishing the design is cut out of the original calf binding and a piece of calf of the same shape but different colour is inserted in its place. So finely was this work done that no gold or other lines were needed to hide the junction of the differently coloured leathers.

SILVER-WORK AND JEWELLERY.

The most striking exhibit in the American section was the pavilion of Tiffany, the jeweller, and Gorham, the silversmith, both of New York. It occupied a corner at the central portion of the Columbia Avenue, while France, Germany, and Great Britain occupied the other three corners. From the central front of the pavilion a tall fluted shaft sprung up, with a plain but noble base and a grand Doric capitol, surmounted by a globe, upon which was poised, at an elevation of a hundred feet, a golden eagle, America's symbolical bird. On the front of the base was the simple inscription: "Exhibit of the United States of America." At either side of the main entrance, in the corner, were groups of columns, bearing aloft single tall shafts, terminating in globes. Arches, surmounted with carved and sculptured pediments, and a roof with low, flattened domes, made up the rest of this palatial edifice, which cost \$100,000 for its construction. The display in the pavilion represented a value of \$2,000,000, and was truly regal, comprising gold and silver wares, precious stones, rings, bracelets, chains, watches, clocks of elaborate character, and, in short, everything rare and valuable in the jewellers' and silversmiths' lines. There was also an extremely valuable and lovely collection of American pearls.

A unique example of American work was an incense-burner representing a rattlesnake strangling a duck. The scales of the snake were made from opal matrix; the rattles and head were set with
American

American pearls; the eyes were of luminous emeralds. The feathering of the duck was represented in coloured enamels. The incense escaped from the mouth of the duck. The magnolia vase, made by an American manufacturer, will always be remembered as a gorgeous piece of work shown at the World's Fair. It had little real decorative beauty. The form of this vase was suggested by a piece of pottery found among the relics of the ancient cliff-dwellers of the Pueblos. The eight handles around the neck were ornamented with Toltec symbols. The decorations were composed of American flora. Opal matrices formed the base of the vase. From the base sprung a lattice-work of cactus-leaves in high relief. About the cactus-leaves was a frieze of magnolias enamelled in natural size and colours of this chaste blossom of the mid-south. The magnolia vase was a doubly interesting production; it represented the American workmanship of to-day, and was a sequel of the earliest-known American pottery.

An erroneous idea has fixed itself in the minds of foreigners, and even of the American people, that silverware of the United States is machine-work. It is true that the smaller table articles are made from dies, but the larger pieces are entirely made by hand. The design is worked in from the back, and finished from the front.

England, the home of silverware, exhibited only a few small cases of antique design, which were reinforced by a combined exhibit of the Manufacturing Goldsmiths and Silversmiths Company, containing among other things a Columbian shield, on which were represented various scenes illustrative of the discovery of America, a piece of work more painstaking than artistic.

The silverware shown in the German division interested a vast number of visitors. This display of silver was deserving of all homage paid it, for it was a lovely collection. It was, with few exceptions, modern, made in Germany, and the exhibiting firm had its principal warehouse in Paris. In weight these compositions in silver were much lighter than the articles made in other countries, and hence they were less in price. The work was entirely that of the hand, even in the smaller table-furnishings. In design the modelling was Rococo and Empire. No new or original motives were followed. A strangely-fashioned wine-cooler was shown. It represented a ship of State in the Sixteenth Century. Parts of the rigging had been washed with gold, producing a charmingly realistic effect. Quaint betrothal-cups were a most artistic feature of this booth. A large plaque of oxidized silver occupied a prominent position; it was a copy in silver of a picture in the Louvre. The subject was the meeting of Louis XIV and Marie Thèrèse. It was indeed difficult to say enough in commendation of the German silverware, both useful and decorative. The display was very large, and the toy-pieces, such as bonbon-boxes, coaches, musical instruments, and tables were exquisite. The minute examples of work in gold were executed with rare skill, each object or detail of it reaching great perfection.

The artisans of France, conspicuous always for their creativeness and brilliancy, sent to the World's Fair many beautiful examples of silverware. The compositions were all modern, and many of them were essentially French. A coffee-service, in Louis XVI designs, was modelled by the French artist, Cheret; another showed a frieze composed of children. The modelling of the figures was exquisite, and was the work of the factories of Carrier-Belleuse. An unusually attractive tea-service had for its decoration chrysanthemums applied in relief on a hammered surface. Renaissance and arabesque designs have been wrought with great skill by these silversmiths. An entirely new coffee-service was in the form of a gourd, an extremely pretty design.

The virility of the Russian was observed in much of their silver, especially in the modelling of small silver figures, which, like their

their bronzes, were individually characteristic of the country. Every detail of these figures was worked out with technical understanding. The models of men were teeming with life. The Russian section contains only small articles of silverware, but the variety was endless in shape and design. The enamelling in colours equalled, if it did not surpass, any shown at the Fair. Red and blue enamels applied to the larger pieces were remarkable illustrations of the goldsmith's art. The transparent enamels were also very lovely.

Norway's contributions in silver were very like those of Russia. Their transparent enamels on silver were charming, and in many respects equal to the incrustations accomplished by the artisans of the land of the Czar. The display of old cups, tankards, head and dress ornaments in old silver from the Scandinavian country was comprehensive.

There is about the work of the Danes a purity and robustness that is refreshing. They are satisfied to tell the legends of their own country. Interwoven in their work, in silver, is found a motive that is distinctly northern. The National Museum at Copenhagen contains many valuable specimens of gold and silver, and the modern artisans copy the antique in every instance. The most noticeable example of work shown in the Danish section is a silver shield with scenes in the life of King Valdemar, the conqueror. The centre is descriptive of the great battle of Ehlsland (called volmer colours). According to the legend the colours fell down from heaven, bringing victory to the Danes. The top medallion discloses Queen Dagmar disembarking at Ribe and being received by the king and his attendants. One side shows the queen on her deathbed; the other side pictures King Valdemar and his son imprisoned. The remaining medallion represents the Justice Court of Jutland. Surrounding the centre picture are allegorical figures. There is also a large assortment of table services shown in the renaissance designs.

The most thoroughly artistic and dainty collection of silverware exposed in Jackson Park was the work of the Japanese. For so many years the people of the Orient have kept all the valuable pieces of silver and "shippo" ware made by them in their own country. The process of making this silver "shippo" is most interesting. The metal is smelted to the degree of malleability, then hammered into the shape. After being shaped the surface is smoothly polished with grindstones, removing all irregularities. The shaping and polishing are done by hand, then rubbed with a stone-cleaning powder, and finally washed in pure water. The sketches for the designs are made directly on the surface in a black Japanese ink. After the design is sketched, gold or silver wire is pasted to the sketch, each line being outlined. Two kinds of wire are used, flat and square. The paste hardens in the firing. The enamel is then applied between the spaces formed by the wire. The first transparent application of the enamel acts as a body colour. The colouring is most difficult, and requires great patience. There are about 350 shades of pigments used in the making of "shippo" ware. The enamel has to be applied to the depth of meeting. The wire and each application requires a separate firing. The third firing is always necessary in the finer examples. After the firing the article is polished with various grindstones, then with red oxide, and afterwards with soft wood. The brilliancy of the surface never changes under climatic influences. A most curious specimen of silver "shippo" was shown, of which the subject was a life-sized duck, the feathering of which was excellent. The Japanese are also very successful in inlaid work. A beautiful bit of silver had a frieze decoration of flowers, which were constructed by the inlaying of coloured metals. A regal piece of silver was a ship. The prow of the boat was fashioned like an eagle, symbolical of strength.

East

East India's showing of silver was most interesting. There were several different patterns. They were all crude, but extremely pretty. The Cutch work was usually a design of birds flying in grasses. The patterns were hammered in from the back, and finished from the front by the use of chisel-like instruments. The Lucknow patterns disclose jungles; the Madras, elephants; the Cashmere, the lotus leaf and flower. The larger silver bowls were especially decorative.

MANUFACTURE OF PAPER FROM WOOD-PULP.

In the German Official Building, elsewhere described, was a large exhibit illustrative of the chemical mode of preparing wood-pulp for the manufacture of paper, and in the Forestry Building several specimens of the pulp were shown. The illustrations of this modern mode of manufacturing paper were, however, a disappointment, and it was with difficulty that I was able to collect satisfactory information on the subject. For the following particulars I am indebted to the labours of Mr. Terry, Superintendent of the Liberal Arts Court, who obtained the information from reliable sources:—

Two distinct kinds of wood-pulp are used in the manufacture of paper—(1) mechanical wood-pulp, (2) chemical wood-pulp. The former is pulp produced from the log by mechanical means entirely. In the case of the latter the wood is cut into suitable sizes and treated with chemicals which dissolve the gums and resins, leaving a nearly pure cellulose.

The chemical pulps are further divided into varieties named after the solvent used. The two principal of these are called "sulphite" and "soda" pulps or fibres, each filling a separate place in the manufacture of paper.

For the manufacture of mechanical pulp or ground wood-pulp, or simply wood-pulp as it is usually called (the chemical pulps are generally called fibres), the principal woods used in the United States are spruce (*Pinus sylvestris*) and poplar; other woods used are basswood, balsam, horse-chestnut, and birch.

Three distinct operations are recognised:—

- 1st. Preparation of wood.
- 2nd. Grinding.
- 3rd. Screening and bundling.

Preparation of Wood.—The logs, averaging 6 feet in diameter, are usually conveyed to the upper storey of the mill; there sawn into sticks about 15 inches long. The bark is removed on a machine called a "barker." The sticks are then split into halves or quarters. The dark streaks and big knots, if any, are removed by a man with a hatchet, after which the sticks descend by gravity to the grinding-room.

Grinding.—The grinders consist of a grindstone resting in a complicated frame and rotating on a horizontal axis. Against the periphery of the stone the sticks are forced by hydraulic pressure, and are held in positions parallel to the axis of the stone. This latter is about 15 in. across the face and 36 in. in diameter. Streams of water are kept constantly playing on the stone, keeping it cool, and washing away the pulp. In this manner the pulp is made, being simply a product of the action of the revolving stone against the wood.

Screening and Bundling.—The pulp is then pumped into the machine-room, where it is screened, all the good pulp and water passing through slots cut in brass plates; the slots are usually about $\frac{1}{16}$ to $\frac{1}{8}$ inches wide. After this the pulp is run over a wet machine—a machine similar to a cylinder paper machine, but having no dryers. The pulp now contains about 33 per cent. of water, and is folded into bundles and tied into packages of 100 lb. each. The time occupied from the logs going into the mill to the pulp being tied up in bundles is not many minutes.

The mills in the United States are run night and day for the sake of economy, and from inquiries I made on the subject I doubt if a mill could be made to pay working in the day-time only.

Spruce-pulp brings about \$20 (about £4 3s.) per ton of 1800 lb. pulp and 200 lb. water at the mill. The price in December last was much higher than that owing to scarcity of water in the mill districts. Spruce costs from \$5.50 to \$8 per cord, according to locality. Poplar is cheaper, ranging from \$2.50 to \$5, but does not give so much pulp per cord as spruce.

The different processes used for making *Sulphite and Soda Fibres* have such essential differences that a statement of the processes and machinery would fill a large volume. There appears to be little doubt that the process which would be the best to adopt for the first attempt at making *Chemical Fibre* in New South Wales would be that of a quick-cooking sulphite plant, turning out about 4 tons daily. This could be erected in the States for \$50,000. Such a plant would not return profit in itself in America, but might be run to profit in connection with a paper-mill. One sulphite mill in the States cost over \$500,000, and turns out 35 tons at what would be a good profit if the market there were a little larger. The

The raw materials for the production of 1 ton of sulphite would be about as follows:—

2 cords (256 cubic feet) spruce wood.
300 lb. second quality sulphur.
100 lb. limestone (containing at least 90% sodium or magnesium).
1,000 lb. coal.

The mill to which reference has been made employs about 120 hands and runs night and day. A 4-ton mill would employ at least twenty men. The cost of labour per ton in a well appointed mill is from \$9 to \$12.

Sulphide unbleached brings about \$58.00 per ton at the mill for first quality. Its largest fields are in the manufacture of newspaper and wrapping paper, and it is quite rapidly driving out the use of jute fibre for wrapping paper.

Appended is an estimate of the cost of a 20-ton mechanical wood-pulp mill.

ESTIMATE OF COST OF MACHINERY FOR 20-TON MECHANICAL WOOD-PULP MILL.

8 grinders	\$8,000.00
1 steam feed cut-off saw	700.00
1 log-jack and table	700.00
4 barkers	800.00
1 splitter	200.00
4 wet machines	3,000.00
4 screens	2,500.00
2 water pumps	}	500.00
2 stock "									
Piping	1,000.00
1 blower	250.00
Shafting, pulleys, &c., say	3,500.00
8 turbines, gearing and harness for say 10 ft. head	16,000.00
1 boiler and heater	1,500.00
									\$38,650.00

The turbines should furnish 200 h.-p. to do the above work.

The above mill would furnish employment to thirty to forty men. Cost of labour per ton \$3.60. A strong 2-storey wooden building 100 x 50 ft., would furnish plenty of room for operating.

As I have stated, the German exhibits of wood pulp and the processes employed, as shown in the German Official Building, were, perhaps, the most important at the Exposition. In Germany the manufacture of paper pulp, or as it is distinctively called wood cellulose, has assumed great importance during the last decade. The Mitocherlich system is a simple one, consisting in the action of an aqueous solution of bisulphites upon suitable kinds of wood at comparatively low temperatures. These bisulphites possess the power of chemically combining with the incrusting materials, which surround and bind together the individual fibres of the wood, forming soluble compounds, which are readily separated from the cellulose by washing with water. The particular solvent used in this process is bisulphite of lime. It is maintained by the manufacturer working this system that the pulp produced by it is stronger than that resulting from other methods. The species of wood employed almost universally for the production of cellulose—as the pulp is distinctively called in Germany, belong to the Coniferæ (*Pinus abies*, *Pinus sylvestris*, and *Pinus picea*), and the supply of them from Northern Europe and America is almost unlimited. The cellulose which each of these kinds of the Coniferæ yield is much alike in character, and the fibres are distinguished by comparatively great length and strength. The wood cut into logs with the bark removed and knots bored out is sawn into short lengths, and afterwards sliced across the grain of the wood. The boiling process is then carried on with regulated temperature, and afterwards the work is carried on in the digester, peculiar to this process. The steaming of the wood occupies about twenty hours as a general rule, and whilst the period of preliminary heating is about ten hours that of the actual boiling is forty hours. As a matter of fact the various secondary processes, such as filling, emptying, examining the interior of the digester occupy a considerable period, and the whole process of digesting takes up a period of about 100 hours. This is a long time, but as a set-off it is said that the excellence of the product is beyond question. As soon as the liquor is run off from the digester the cellulose is washed out with water into large tanks, placed immediately

immediately beneath the digester, when it is further washed till free from waste lye. It is then conveyed to a machine, by the aid of which it is smashed up and purified, and finally is made into thick sheets, dried and perforated (to meet the requirements of most custom authorities) on a paper machine, so as to be ready for export.

As a matter of comparison with the above figures, the following information, furnished by Mr. James Beveridge, analytical and technical chemist of Gravesend, at present in charge of a pulp-mill in Sweden, will be found of practical value.

Cost of manufacturing 1 ton of White Paper on Thames. Average of 6 months' work, 1891.

	Quantities of Raw Materials per ton paper.	Cost of 1 ton of Paper.			Remarks.
		£	s.	d.	
Pine wood	3,257 loads.	4	4	4	Pine (white) logs, imported from Sweden.
Sulphate and soda wood pulp.	t. c. qr. lb. 0 0 0 22½	0	2	2½	Chemical wood pulp by soda process.
Mechanical wood pulp ...	0 0 3 4½	0	4	2½	Simply ground wood.
Sulphite wood pulp ...	0 1 0 16½	0	13	0	Chemical sulphite process pulp (wood).
Loadings	0 1 1 19½	0	4	9	China clays.
Wrappers	0 0 2 19¾	0	7	0½	Brown paper.
Cord	0 0 0 6	0	1	6½	
Brimstone	0 3 0 5¾	0	14	10	Sicilian best thirds, brimstone.
Magnesite	0 4 2 12¾	0	8	1¾	Magnesia stone (carbonate) from Greece.

		£	19	13 11¼	
Less wrappers made	0	4	10½	
		£	19	9 1	

The net cost of making a ton of paper during previous half-year, £18 15s. 0½d.

NOTES.—A load of pinewood logs is 50 cubic feet solid measurement.

A standard is 216 cubic feet of piled logs, and contains 162 cubic feet solid measure, or 3·24 loads.

Sulphate, soda and sulphite wood pulp is chemically prepared fibre. Prices of these *c.i.f.*, Thames, ranges from £9 to £11 10s. (14/2/92).

The coals used per ton paper is high. This is owing to the fact that our two main engines (700 i.h.p.) are not compound type, and consume 3½ lb. coal per i.h.-power per hour. If an engine of compound type was used, 2½ lb. of coal would only be consumed per i.h.-power, which would mean a saving of from 15 to 20 cwt. of coal per ton finished paper. Other paper-mills consume 3 to 3¼ tons coal per ton paper.

Wall-

Wall-papers.

In wall-papers the United States exhibit were undoubtedly the best. The pavilion of the National Wall-paper Company contained a collective exhibit of the principal productions of five of the prominent manufacturers of the National Association, the general idea being to illustrate, in a condensed form, the various grades of the highest class of productions in every branch of this important art. The pavilion itself, a very beautiful structure of the renaissance order, designed especially by Paul Groeber, of New York, attracted the attention of the visitor by the simple grace of its lines and the charming distribution of its enrichments in "Lincrusta Walton," the whole being finished in ivory and gold. There was a series of rooms opening from a central apartment which was two stories high with a sloping riste to the ceiling proper. The first storey contained samples of H. Bartholomae and Company's machine and hand-made papers, a new departure being marked in the fact that in both grades silk hangings to match either class of manufacture were also exhibited. They had also a new process of surface relief, which gave a very refined effect owing to the extreme delicacy with which the outlines, gilded outlines, were treated. The scheme of this room, both in detail of treatment and the pressed paper panels above cabinets, was strictly of the empire order. The side walls of the second storey proper were treated with an empire wall-paper decoration embracing pilaster and capitals, frieze, top and bottom borders, and panel hangings with centre medallion, admitting of extension or contraction as the prospective wall surface of any apartment might require. The decorations of the sloping wall pediments above were carried out with panel mouldings, medallions, &c., and the flat of the ceiling completed with a diapered pattern framed in with a rich laurel ornament. The colour throughout the lower part of the wall was in soft tones of old rose, leading up to a warm cream as the background of the ceiling, with cameo effects of old rose, presenting the most complete and artistic wall decoration. F. Beck and Company, of New York, were represented in the north-east apartment. This room was replete with every character of high-class wall decorative hangings. One case contained a choice selection of satin-surface pressed papers, embracing examples of the Italian and French schools of design, while the excellent manner in which these goods were displayed, together with the artistic grouping of the colours, lent further value to a most interesting exhibition feature of their productions. Directly facing was a very clever collection of their leather wall-papers, embracing lacquered metal, ivory and canvas faced metalised finished hangings. The remaining case contained examples of hand-printed chints, damask and tapestry papers, supplemented by a decided novelty in their printed burlap and jaan jean damasks. The balance of their noteworthy exhibit was composed of a choice collection of "Lincrusta Walton," which is solely manufactured by this firm. This selection completely illustrated the uses this valuable substance can be applied to, and this was further enhanced by the admirable manner in which each example was finished, showing effects in leather, repousse metal, faience glazes, and representations of carved wood; the ceiling of this room was divided into panels with ivory beams, the intermediate space being hung with "Lincrusta Walton," laid in with gold leaf and lacquered with azure, the high lights being wiped off. The walls were also hung in the same material, simply treated in flat colour of a soft salmon tone; the relief detail in the empire style applied to the woodwork was also of lincrusta, the same being finished in ivory. The wide frieze display of Robert Graves and Company, of New York, was very handsome. Notable among them was an exquisite naturalesque rendering of the wisteria vine, also of the lilac, together with a very pretty festoon of wild roses with cupids, additional grace being lent to this composition by the scattered blossoms thrown here and there. They also showed a choice selection of pressed papers for parlour decoration, while

all

all were marked by great refinement of colour. The cameo effects were remarkably beautiful. Another case exemplified this firm's achievements in raised flock painting, a process hitherto almost entirely monopolised by English manufacturers. The sharpness of the detail in each of the examples, and the extremely characteristic drawing of the lion and the crown, and of the familiar old thistle of Scotland, were especially to be commended. The ceiling of this room was hung with one of their pressed papers, the woodwork finished in ivory and gold, the general effect being highly assisted by hand-painted draperies, the subject being the wisteria vine. The north apartment contained the exhibit of Warren, Fuller, & Co., of New York, the successful competitors at the Paris Exposition of 1889, where they earned the distinction of the silver medal. This very interesting exhibit contained examples of this firm's most noted productions, several being covered by letters patent; among the most noteworthy was a Columbian design by G. de Louvres. The collection embraced flock, pressed and leather papers. Messrs. Nevins and Haviland, of New York, occupied the remaining south end of the pavilion; their principal exhibit was a very forcible illustration of the immense improvements made in machine-printing in the two large cases, the majority of the patterns being of that grade. Nothing more chaste or more beautiful could be found than their representation of satin damask, both design and colour left nothing to be desired. Their hand prints were also of equal moment, the blended tapestry hanging above the cases being particularly fine. The exhibit also contained a very excellent specimen of coloured "flock upon flock," and the first striking off of their allegorical wall decoration, especially designed for this occasion by Walter Crane, the printing of which was an achievement of which the wall-paper industry might be proud. The skill in patching up some forty-eight colours with only half that number of blocks and producing such a finely balanced effect was worthy of the highest praise.

Next to this exhibit England displayed the finest collection of wall-papers shown, and decorations shown were represented by four different firms, all having a very creditable display, the most noteworthy being that of Jeffry & Co., of London. They availed themselves of the space allotted to them by the erection of four sides of a room, with chimney breasts, overhanging coves, doors, and ceilings. Both interior and exterior were decorated, each space being separately treated and complete in itself, thus enabling them to show quite a variety of very handsome designs and colourings. On each side of one of the entrances to the enclosed room space was the trio decoration designed by Walter Crane in which he made use of the ever pleasing pilasters. It was a composition of three panels, inclosing child figures representing the arts—music, painting, and poetry. The treatment of the pilaster itself was pleasing in colour, while the field was treated in subdued tones of yellow flock, enriched with gilding. The frieze of singing birds perched upon the frame of a half-suggested lyre acted as a chorus to the figures and formed a variation in a lighter scheme of the main lines of the paper. They also showed some very fine examples of antique leathers, flocks, hand-prints, varnished and oil finished papers, together with samples of papers used in Victoria House, which was handsomely decorated with antique leather papers, of splendid design and rich colouring.

Strange to say, although France manufactures some very fine papers and decorations, she was unrepresented by any firm making a display of these goods. Germany had a very fine exhibit. Austria was represented by one firm, which showed an example of a new leather imitation wall hanging or tapestry, and christened it "Skytogen," which had the appearance of real leather, the surface coating being of leather pulp, made as a very durable and waterproof wall covering. The exhibit of Japan contained a number of fine examples of leather wall-paper, in the manufacture of which they excel.

TILES

TILES AND TILE-MAKING.

The art of tile-making was lost for upwards of 2,000 years, but was rediscovered some 300 years ago; and to judge from the specimens, ancient and modern, exhibited at the Fair, the more recent productions are far in advance of the ancient. Examples of tiles taken from the Pompeian ruins showed irregularity of size, colour, and hardness, difficulties which apparently they were unable to overcome. The art of to-day has improved to such an extent that innumerable change of colour, as well as varying sizes to blend and fit perfectly, are produced by all the best makers. The exhibits themselves were not so numerous as might have been anticipated, but what was wanting in quantity was more than made up in quality. The show of Great Britain was small. The exhibit of A. Hereford was very good; in fact the tile mantel exhibited by him was a splendid specimen of the art. A Jackfield firm showed in their space a structure of faience, which formed a receptacle for fine exhibits. The height of the structure was about 20 feet. It was in the form of a colonnade supporting an entablature in a style which was classical, and leaned somewhat to the renaissance. Each of the shafts of the column contained one painted and three modelled panels; the lunettes and spandrels were hand-painted in an underglaze. Within the floor space there was a division made by central screens and side wings, which allowed sufficient floor to be seen to indicate the pavement of the different sections. One part represented the chancel of a church, the other showed the lining of a palatial bath-room, and in the other compartment was exhibited matters of public and domestic architecture. In the ecclesiastical department the principal object of interest was an altar piece—"Our Lord in Glory;"—in it very fine mosaic was introduced, and symbolical representations in variously coloured and beautifully figured tiles formed the panels. Below the pictorial part of the reredos was a dado 3 feet high in under-glaze painting in green and brown, having above and below a border of gold; the whole work was a most interesting representation of artistic work.

In the German exhibit the display of encaustic, mosaic, and ceramics exceed that of all other countries, both in quantity and quality. The German vitreous inlaid tile is undoubtedly the best description of this tile made.

The French exhibits included some splendid mosaic tile-work busts. A statue of Cleopatra, made expressly for the Exposition, illustrated what can be done in mosaic colour-shading; the rich robes and surroundings gave a first-class opportunity for colour effects. Two other busts, made for the Madeleine Church in Paris, were very good specimens of the art, as were also two copies from the Louvres, representing Le Poussin and Rubens.

Amongst American representations there was a magnificent representation shown in the north-west corner of Manufactures Building, which was stated to be the finest sample of tile ever shown in America. It was employed in the construction of a soda-water fountain of very large size.

LEATHER EXHIBIT.

Among the very interesting exhibits at the World's Fair, as might naturally be expected, leather held a very prominent place. A separate building was erected for the special exhibit of this article and its applications just north of the Forestry Building. But many countries preferred to show their exhibits of leather work in their special sections in Manufactures Building. There was not much waxed leather to be seen at the Fair, although it is believed by many leather manufacturers and carriers that no leather equals waxed for durability

durability and serviceable wear. The exhibits of waxed leather from the Western States of America were very excellent. The most recent methods of making leather were exhibited. And all the various processes done by machinery, such as whitening, graining, blacking, and pasting, all of which processes except whitening can be done by machinery better than by the old way. The only countries exhibiting belting were the United States, Austria, and Japan, and New South Wales, but the American belting was unquestionably the best. It consisted of examples of single, double, and three ply and was all oak-tanned. In Machinery Hall the largest belt in the world was shown. It was 203 ft. long, 8 ft. 6 in. wide, and weighed 5,176 lb.; 569 hides were used in its construction, and it was three ply and waterproof. The next largest belt was shown in the Leather and Shoe Trades Building. It was 144 inches wide and 200 feet long. The sole leather of Pennsylvania, California, and Ohio was very good. That of France, Germany, and Japan was less firm and solid than the American. Patent and enamel leather as used for fancy shoes, saddles, harness, and military belts was shown by various countries. This leather is manufactured from tanned calf-skin, ox and horse hide. One American firm had a very fine display of enamel and shoe leather in imitation of oak and other woods, in the shape of a splendid pavilion made of leather, 50 feet long and 20 feet wide. The roof was supported by eighteen square pillars which were completely covered with enamelled leather, and the work was so finely done that at first glance the visitor imagined that it was wood and not a leather covering. In morocco and dongolo leathers, and small grains—kid and fancy goods—France and Germany had splendid displays. The exhibit of harness leather was very fine, and consisted of a very excellent show from America, France, Germany, Russia, Austria, and Japan. Like belting, harness leather is made from clear selected hides of uniform substance. Labour-saving machinery recently invented saves much heavy work, especially in the scouring and setting out. Amongst the leather exhibits there was one great curiosity. It was the hide of an elephant, which weighed when green 800 lb. and when tanned 500 lb. It was 20 ft. long, 16 ft. wide, 3 in. thick, and required two years for tanning. In the same exhibit were several walrus hides. This kind of leather is used for polishing purposes.

Among machines used for currying, the American Union Splitting Machine took a foremost place. It has a fixed knife, and is the oldest machine known. A later and more perfect machine is the Belt or Band Knife Splitting Machine, the knife of which is an endless band of steel, which revolves with the edge of the knife close to the side of the rollers through which the leather passes. The lower roller is made of rings, each ring capable of springing so as to allow the unequal parts of the hide to pass through.

In the gallery of the Leather Building there was a boot and shoe factory at work showing all the various machines employed in the trade. No machine has yet been invented for cutting all the different parts of a shoe, the difficulty consisting chiefly in providing for the adaptation of the quantity and quality of the leather to its appropriate place. This work is done by hand, except in the case of the cutting of the soles, which can be done in the rough by a machine designed for the purpose. In this factory, in actual operation for the inspection and edification of the visitor, were sewing-machines for joining the various parts of the shoe—machines for making complete button-holes; others for sewing on buttons, lasters, rough rounding and channeling—that is, for cutting a furrow in the bottom of the sole to lay the thread in; sewing the sole to the upper; leather splitting machines for both upper and sole leather; levellers, edgers, scarfing, burnishers, treeing machines, and others. All these machines have, to a great extent or less degree, supplanted hand labour.

The

The Stanley Manufacturing Company exhibited an improved M'Kay sewing machine which could turn out, with the aid of skilled labour, from 600 to 1,000 shoes per day of ten hours, doing the work of from twenty to thirty men sewing by hand. The style of stitching done by this machine was not at all similar to hand-work, being a wide departure from the usual forms of hand-work and other forms of stitching, and establishing an altogether new principle called the chain stitch. This machine had all the latest improved appliances, and stood in remarkable contrast to the original machine in use in 1864.

The Goodyear Company exhibited among other machines one for sewing the welt to the insole, the process being known as the inseam. After this the outsole is put on and stitched through both welt and insole, practically as done by hand but supplanting hand labour in the ratio of about one to thirty in favour of the machine. This machine showed wonderful ingenuity on the part of the inventor, inasmuch as the work performed was almost an exact reproduction of hand-work. In Section A there was a consolidated hand-method lasting machine. The operator dropped the last into the upper placed in the machine. By applying his knee to a lever the machine was put in operation, then a steel arm and hand with a quick motion grasped the upper leather and drew it to the right or left or straight out as the operator willed, and drove the tacks at the same time. While watching this machine work the visitor was forcibly reminded of the flexions of the human hand and arm. The relative value of this machine as against hand-work was as forty to one hundred in favour of the machine.

In strong contrast to the last-mentioned machine was the Copeland Laster, of entirely different design, construction, and method of working. The operator placed the shoe in the machine and by moving the lever drew a pair of straps around the shoe; this held part of the upper in proper place on the last; then, by bringing another lever into play, other straps were drawn against the shoe; then by pulling on a lever at the right and one at the left the upper was gathered at the heel and toe. Now taking a machine tack-driver, that had been filled automatically while he was working, the operator rapidly drove in the few tacks necessary; and the lasting was done in much less time than the process can be recorded. While all classes of work can be done by this machine it is said to be specially adapted to the finer kinds.

The Globe Buffer Company exhibited the Globe button-hole machine. This was an extremely interesting machine, which cut the hole in its proper place and sewed and barred it at the square end of the hole; that is, it put an extra stitch across the outer end of the hole. This is the only button-hole machine which does this, the others requiring what is known as the boring machine to perform this particular operation. An expert by hand will button-hole from one to one and a half cases, of from sixty to seventy-two pairs in a case, per day of ten hours, while this machine will button-hole thirty or more cases in the same time, and do it a great deal better. The Morley-Bennet Sewing-machine Company exhibited a machine for sewing on buttons. The little machine had a hopper at top, into which the buttons were put. It fed itself, did its own spacing for the buttons, sewed them on at the rate of 225 per minute, the operator only being required to hold the shoes and to take them away, the machine doing the rest. As compared with hand labour the ratio is fifty to one in favour of the machine. The "sewing" or leather splitting machines, of which there were many, could not be said to supplant hand labour, as it would be impossible to do this work by hand. The same is true as to the "lap-scarfing" machine. The work of these machines is to taper leather at the edge so that it may be folded over without being thicker at the edge than at other parts. A shoe in process

process of making, from the hide to packing in the case, passes through about sixty working men's and women's hands, and those sixty, with the help of machinery, do the work of about 800 men and women working by hand alone.

Exhibits of Safes.

In no other country in the world are burglars so skilful at their trade, or so bold in carrying out their plans to a successful conclusion. In America burglars have been known on several occasions to drag a man from his bed, and hustle him, perhaps for a distance of a mile or more, along the streets of a city to a bank, and there to have forced him at the muzzle of a revolver to open the safe and to hand over the cash to the marauders. No safe can be called actually and really fire and burglar proof which has any opening through the solid front door, Whether the opening referred to be for the dial plate or for the handle which shoots the bolts, it is still the weak point in the safe as has been seen many times, for by means of this opening, no matter how small or how closed up it may be, it is there just the same, and is the point on which the skilled workman brings his powers to bear.

The latest invention in the way of burglar-proof safes contains within the door, which has a plate-glass front on the interior, a time-lock which is so set as to open twelve hours after the safe has been closed. The door has no opening on the outside. The bolts close with a snap, and it is impossible to open the door till twelve hours have elapsed. Within the outer door there is another operated with an ordinary dial combination and handle within the outer door. Thus it will be seen that a fire-proof is not necessarily burglar-proof, nor is a burglar-proof safe necessarily fire-proof.

Musical Instruments.

Musical instruments, as might be expected, were largely represented. Not to speak of the immense variety of pianos, organs, and other instruments exhibited by the leading German and American makers, who undoubtedly took the lead in this department, there were in several of the official and State buildings some magnificent instruments showing the latest improvements. The large organ in Festival Hall was an instrument of great sweetness and power. In many of the courts, especially of foreign countries, the national musical instruments were shown, and formed a very interesting display.

Horology.

The leading American manufactures of watches, clocks, and other instruments for measuring time were well represented, and in their booths, which were very handsome structures, the various processes of the business were all shown in actual work. The Waltham Watch Company had a large number of artisans daily employed in their court, and crowds of people continually surrounded the glass walls watching the procedure. Independently of the numerous representations of horology exhibited by the leading foreign and American makers, the great clock in the centre of the building deserved special mention. The clock tower was 120 feet high, which stood on a base 40 feet high. Fronting each of the four grand avenues were four portals 16 feet wide and 28 feet in height, and on each side of these were panels with inscriptions relating the story of Columbus. On the frieze at the top of the first story were shown the shields and escutcheons of each of the forty-four States of the Union. The second storey, which contained spacious reception-rooms, was 12 feet high, and extending around it was a balcony 10 feet wide. The mechanism was placed above this, occupying a room 20 feet square. The clock itself had a face 7 feet in diameter,

diameter, and on it was shown the hours, minutes, seconds, and the day of the month. Above the chamber containing the mechanism was a chime of nine bells. The dome was surmounted at a height of 120 feet by a globe 16 feet in diameter.

Gates at front of German Section.

The trio of hand-forged gates forming almost the entire front of the German section were a prominent feature in the Manufactures Building, and attracted the attention of every one who passed along the great Columbia Avenue on account of their originality, their massiveness, and their beauty. One hundred and fifty men worked for six months with hammer and chisel, all other tools and instruments being excluded, to complete this splendid monument of German workmanship. The central gate, the largest of the three, was 40 feet high and 21 feet wide; the two smaller gates were each 30 feet high and 15 feet wide, while the three combined measured, together with the connecting gratings, 150 feet in length. The total weight of this masterpiece of smithing was 33 tons. Although the big gate alone weighed 15 tons, its portals could easily be moved, so neatly adjusted was the work, and so finely hung was it in its steel bearings. The cost of this work of art, for such it was, was stated to be \$50,000. The design was in the rococo style, chaste and beautiful. This style appears to be best suited for this style of work, and in the present instance it gave the whole a semblance of lightness, airiness, and boldness which was truly artistic and beautiful. The garlands and festoons, slender vines with flowers and leaves, tiny shoots and spendrils, sprouting out boldly on top, appeared so light and so full of life that it was difficult to believe that they had been shaped with hammers and chisels in toilsome work. The designs for these gates were different from each other. Every flower, every leaf, every twig of the ornamentation, except a little black paint to prevent the rusting, appeared as hammer and chisel left it on the anvil or in the vise. A close inspection of the bunches of grapes gracefully hanging on the vines, and of the roses and daisies here and there strewn in, revealed the mark of the hammer and chisel. Not a file touched the work, and this was what gave it its natural and unaffected look, while at the same time it attested its genuineness as a pure piece of hand forging. This artistic smithing, illustrated by these big gates, is a resurrection of the chaste and very artistic style of this class of work as it was many centuries ago, fostered and nursed by the art-loving Catholic priests and monks of Southern Germany and the Tyrol, then German, and for which the Germans of the Middle Ages were then famous. The Thirty years war, 250 years ago, which transformed Germany, during its long duration, from one of the most prosperous to one of the most poverty-stricken countries in Europe, buried this particular branch of artizanship, and it has only recently—since the Franco-German war—again revived.

Whilst on this subject I may refer to that prominent work in hand-hammered copper, Professor Begas' Germania group, which towered high above the German section in the Manufactures Building. It was the work of the famous coppersmith Heinrich Seitz, of Munich, a member of a family which has existed for generations. This was a beautiful piece of work intended, as soon as the Exhibition was over, for erection upon the new building for the German Reichstag, now nearing completion in Berlin.

Yerkes' Telescope.

At the north end of the great Columbian Avenue was the 40-inch Yerkes' Telescope, made by Warner and Swasey, of Cleveland, Ohio, a firm which also had a large collection of telescopes for colleges and private observatories exhibited in the north gallery of the building.

The

The Yerkes' Telescope is the largest refracting telescope in the world, and was the gift of Mr. Charles T. Yerkes to the University of Chicago. Through the kindness of Mr. Yerkes I have been provided with the following particulars in regard to this interesting astronomical instrument:—The column and head were of cast-iron, and rose to a height of 43 feet, and weighed 50 tons; the polar axis was of steel, was 15 inches in diameter, $13\frac{1}{2}$ feet long, and weighed $3\frac{1}{2}$ tons. The declination axis, also of steel, was 12 inches in diameter, $11\frac{1}{2}$ feet long, and weighed $1\frac{1}{2}$ tons. The tube was of steel, 64 feet long, and 52 inches in diameter at the centre, tapering towards the end, and weighed 6 tons; the driving clock weighed $1\frac{1}{2}$ tons, and was located in the upper section of the column. It was wound automatically by an electric motor, and was controlled by a double conical pendulum. It was geared to the main driving-wheel, 8 feet in diameter, which, when clamped to the polar axis, revolved it, together with the tube and all its accessories, weighing in all 20 tons, in exact sidereal time. All quick motions, slow motions, and clamps, both in declination and right ascension, were operated by hand, and also by electric motors controlled by a switch-board placed within easy reach of the astronomer. The assistant astronomer likewise has full control of all motions from the balcony which surrounds the head, and which, together with clock, is reached by the spiral staircase. The total weight of the telescope is 75 tons.

This great telescope was incomplete as it stood in the building. It lacked the lenses, which were in course of manufacture by Alvin Clark and Sons, of Boston, when the 40-inch lens, the greatest ever made, is perfected, which will occupy several months. The telescope will finally be placed on an observatory at Lake Geneva, Illinois, and then the University of Chicago will possess a greater instrument than the Ross or the Lick Telescope.

The cost of this gift of Mr. Yerkes was about \$60,000. An observatory is being constructed for it at Geneva Lake, and a special feature of this building will be a movable circular floor, 80 to 90 feet in diameter, which can be raised or lowered by the operator of the telescope by the pressure of an electric button. This will do away with cumbersome galleries and stairs, and will be one of the most novel features in the equipment of the telescope.

ELECTRICITY BUILDING.

Electricity Building and Exhibits.

IN the building devoted to electricity and its applications New South Wales was allotted a space of 1,000 square feet in the gallery. I made application for this space on the occasion of my first visit to Chicago, because when I left Sydney in June, 1892, it was clearly understood that certain exhibits belonging to this department would be forwarded. When I found ten months later that no exhibits in this class had been provided I resigned the space. On the whole I was not displeased at this result, inasmuch as I am sure under any circumstances we could have provided no exhibits in any way comparable with the magnificent displays of other countries, more especially of America, where electricity is yoked to the uses of man in a thousand forms. Although New South Wales had no exhibit in the Electricity Building I consider it desirable to make some reference to the most remarkably complete representation of electric science and its practical applications that, up to this time, the world has ever seen.

It has been rightfully said that never in the world's history has there been such a display of the comparatively new force of electricity as was shown at Jackson Park. The only previous Exposition at which electrical force was realised to any extent was in Paris in 1889. There it occupied a comparatively small space in a building devoted to other purposes. The improvements, the development, and the new uses to which the science has adapted itself have so expanded that one of the most important buildings at the World's Fair was given over entirely to an exhibition of electrical science and its myriad forms of application. It was not at all surprising that this grand building should have been erected for the exhibition of the powers and the results of the working of this "mysterious and subtle form of energy" in the United States of America; for in every town, whether old or recent, in the east as well as in the far west, the electric light from arc and incandescent lamp is everywhere seen; electric power transmitted from the nearest waterfall drives the mills set up to saw the wood and dress the stone for the buildings of the future and as yet undeveloped city; and in the older towns, in the private residence as well as in the public street and park, in the factory and warehouse, the electric light is everywhere employed.

The wonderful strides made in the field of electrical appliances during the past few years were represented in miniature in the display made at the Exposition. The commercial and economic applications of electricity and exhaustive tests of the efficiency of the same in comparison with other and older methods of accomplishment. In addition to these practical features, object lessons of interest and instruction, showing the development of the science from its formative or initiatory stage to the present time, were presented. The accomplishment of this object took the form of an historical exhibit, embodying models, drawings, and crude machinery made and used by the pioneers of the science.

The Building.

The Electrical Building was 345 feet wide and 700 feet long, the major axis running north and south. The south front was on the great quadrangle, or court of honour; the north front faced the lagoon; the east front was opposite the Manufactures Building; and the west faced the Mines Building. The general scheme of the plan was based
on

on a longitudinal nave 115 feet wide and 114 feet high, crossed in the middle by a transept of the same width and height. The nave and transept had a pitched roof, with a range of skylights at the bottom of the pier and clerestory windows. The rest of the building was covered with a flat roof, averaging 62 feet in height and provided with skylights. The second story was composed of a series of galleries, connected across the nave by two bridges, with access by four grand staircases. The area of the galleries in the second story was 118,546 square feet, or 2.7 acres. The exterior walls of this building were composed of a continuous Corinthian order of pilasters, 3 feet 6 inches wide and 42 feet high, supporting a full entablature, and resting upon a stylobate 8 feet 6 inches. The total height of the walls from the grade outside was 68 feet 6 inches. At each of the four corners of the building there was a pavilion, above which rose a light open spire or tower 169 feet high. Intermediated between these corner pavilions and the central pavilions, on the east and west sides, there was a subordinate pavilion bearing a low square dome upon an open lantern. The building had an open portico extending along the whole length of the south facade, the lower or Ionic order forming an open screen in front of it. The various subordinate pavilions were treated with windows and balconies. The details of the exterior orders were richly decorated, and the pediment, freizes, panels, and spandrils, had received a decoration of figures in relief with architectural motifs, the general tendency of which was to illustrate the purposes of the building. The appearance of the exterior was that of marble, but the walls of the hemi-cycle and of the various porticos and loggia were highly enriched with colour, the pilasters in these places being decorated with scagliola, and the capitals with metallic effects in bronze.

The electric exhibits in the building of greatest interest were those of America, Great Britain, Germany, and France.

The Department of Electricity differed in one supreme particular from every other department of the World's Fair. The rapidity of electrical development finds no parallel in any other range of discovery. To the electrician ten years is a century, and even in one year all his pet theories may vanish under the light of some new discovery. Further the science of electrical development has advanced just far enough to teach electricians that they are merely on the threshold of unbounded worlds of knowledge. The World's Fair Department of Electricity, marvellous as it was when compared with the electrical knowledge of ten or twelve years ago, may prove to be crude and insignificant before the close of the present century.

Dr. Elisha Gray, Chairman of the Electrical Congress, in his eloquent opening speech at the Electrical Congress, referring to this subject, said:—

The rapid strides that have been made in electrical science and electrical invention in the last twenty-five years have marked a new era in our civilisation, and this age may well be denominated the electrical age. Who knows what the next quarter of a century will bring to us through the medium of electricity? To some people it seems as if the limit were nearly reached, but who knows? The grand results that have thus far been attained were not accomplished by any one nation or individual. We as Americans are proud of our native land—the land of Franklin, Morse, and Henry—but we are also proud of our fatherland, and we believe that the fatherland is just a little proud of us, although we neither of us say this too often or too loud. The fatherland of America is all the civilised world outside of its own borders.

And the venerable Baron Helmholtz, still more lucidly, perhaps, expressed in one of his addresses the remarkable contrast between electrical knowledge of some years ago and the present time, when he said:—

I have been occupied by electricity, that is true, and perhaps age has this privilege, that it is honoured more than youth even if the merits should be doubtful. Now I think at present I am the most aged man of the present electricians.

The beginning of my career was when the phenomena of electricity were most delicate experiments which were performed by some physicists in their laboratory. We
can

can move at present great machines of the greatest power, and at the time when I began to study electricity we could not move a little magnetic needle suspended on a silken thread, the finest which we could find. We balanced two such needles with opposite poles to get any token of an electric current. The most delicate token or index of the electric current was the galvanised frog. He could do nothing more than make an oscillation, a contraction. We could not move the slightest apparatus, but we showed that there were feeble currents, and we had no constant electro-motive force. We were obliged to work with the simple elements of copper and zinc, without sulphate of copper, elements which altered every moment, which had in the first instance a great electro-motive force, then went down and down and down so that after some instances there was nearly no force at all, only traces of the former force.

Now all this is altered. In the beginning of my career, when we did not know anything of the great discoveries of Faraday, of the use of currents which have developed into currents which can drive the mightiest engines. I may say that the present generation, if I include myself in the present generation (laughter); has seen a greater development of science than any generation before us. The history of the world and the history of science has grown rapidly during our lifetime, and it is a great pleasure for us old men to see now what electricity has reached in its new stages, and to admire the newest developments which are collected on this festival occasion here in your great Exhibition. I thank you. (Applause.)

The scope of the electrical department was, broadly speaking, twofold in character. One great division of the department was an illustration of the commercial and economical uses of electricity. In this division were embraced all the machinery and devices which enter into the practical application of electricity in every-day use. It exhibited the latest inventions for creating the three great economic commodities—light, heat, and power. The exhibitors in this division were all corporations or firms, and many of them vigorous rivals.

The second division of the electrical exhibit related to the development of electrical science. It embraced its progress from the earlier and crude inventions to the latest marvels. The historical feature was illustrated by priceless relics of the early inventors, models, drawings, and maps, and every other connecting link between past and present development. The scientist was able to make critical analysis of the claims of inventors by actual experiments. Within the walls of the Electricity Building the greatest electricians of the world gathered for mutual enlightenment and counsel. Special demonstrations and experiments, which only the initiated understood, were made for the benefit of the learned few. The practical exhibit claimed the crowds, and as many of the spectacular electrical features were presented out of doors this department was doubtless the more popular.

From the nature of the electrical exhibit it was found dispersed in all parts of the grounds. The Electricity Building itself held only a fraction of the real exhibit. The machinery and devices for electric lighting and the motive power in all parts of the grounds were also competitive exhibits.

Classification of Exhibits.

The classification of the exhibits was comprehensive, embracing apparatus illustrating the laws; the myriad phenomena of electricity and magnetism; electric telegraph signals and cables; dynamical electricity, batteries, machines for the generation of electricity; appliances for the measurement of the force; for the transmission and storage; motors; telephones, phonographs, telautographs, kinetographs; plants for furnishing heat, power, and light; appliances for use in surgical and dental work, and in therapeutics; appliances to relieve pain, and others which destroy life; appliances for use in chemistry, metallurgy, and kindred sciences.

Electric Lighting of the Buildings.

The electric lighting of the buildings and grounds was a demonstration both of power and beauty in arc and incandescent features. About 8,000 arc lamps of 2,000-candle power, and about
130,000

130,000 incandescent lamps of 16-candle power, offered in themselves an object lesson in latter day lighting methods. But these were merely multiples of the ordinary standard powers. Greater extremes were shown, from the powerful arc light of 8,000-candle power to the delicate incandescent lamp of $\frac{1}{16}$ -candle power, which gleams like a tiny fire-fly.

Official returns gave the following statement of the number of arc lights employed for the illumination of the grounds and buildings:—Arc lamps in Manufactures Building, 1,200; in Agricultural Building and annex, 500; in Transportation Building proper, 350; in Horticultural Building, 250; in Mines and Mining Building, 200; in Machinery Hall, 250; in Fisheries, 50; in Illinois State Building, 77; total arc lights in main buildings, 2,877.

This estimate does not take into consideration any lights on the grounds, or any of the lights used by individual exhibitors, nor does it include any of the incandescent illumination. The chief electrical engineer, who has furnished important information on this subject, stated that the contract with the Westinghouse Electric and Manufacturing Company for incandescent lighting called for the furnishing of dynamos, feeder, and convertor capacity for 83,410 lamps of 16-candle power, and 6,212 lamps of 19-candle power, or a total of 89,622 lamps; and inside wiring, or wiring to lamps, for 50,410 lamps of 16-candle power, and 6,212 lamps of 10-candle power, or a total of 55,622 lamps.

It was stated that the estimated distribution of this lighting, as furnished by the same authority, was as follows:—

Fine Arts Building and annexes	16,242
Woman's Building	3,000
Administration Building	5,000
Music Hall, Peristyle, and Casino	4,368
Total in buildings to be lighted wholly with incandescent light						28,610
						28,610
Horticultural...	800
Transportation	2,500
Mines and Mining	3,000
Machinery and annex	1,000
Agriculture	4,000
Manufactures	10,000
Fisheries	500
Total for use in main exhibit buildings						21,800
						21,800
Decorative lights in flower-beds and about grand basin...	6,212
Total lights to be wired						56,622

Additional capacity of dynamos, primaries, and converters for—

Service Building	Lights. 1,500
United States Government Building	5,000
Buildings of States and Foreign Governments, and buildings on Midway Plaisance	26,500
Total						33,000

The distribution of these incandescent lights according to their application is as follows:—

(1) For use inside buildings lighted wholly with incandescent light...	Lights. 25,918
(2) Decorative lights on exterior of buildings	5,442
(3) Decorative lights on ground	6,212
(4) Lights in main Exposition buildings for offices, &c., and for use of concessionaires and exhibitors	19,050
Total						56,622

To supply these there was a subway system or main trunk line in the grounds of 76,000 feet of duct, and in the whole duct system there were over 225,000 feet of duct. The main subway contained about

about 25 miles of feeders, and the ducts carried over 40 miles of duplex cable. Departing from these details for a moment it may be stated that it was found necessary to adopt such a system as this for the accommodation, health, and comfort of an estimated number of 750,000 visitors, and 100,000 exhibitors and their employees. The piping necessary for this purpose, and so employed, would maintain the sanitary condition of a city of half a million inhabitants.

It was no wonder that the fire authorities and the insurance companies stood aghast when this stupendous and highly dangerous enemy to their interest was being placed in position. That there have been so few accidents from the application of this dangerous force proves fully that the scientific minds who have mastered it in all its details thoroughly understood their business. The electric plant at the World's Fair might be divided into three sections, controlled by three different companies. One company had the illumination of the grounds and buildings; another company supplied light for the Electricity Building, and also the power for the electric launches; and the third company illuminated the Great Terminal Railroad Station.

In the Palace of Mechanic Arts, as we have said elsewhere, was found the principal source of the supply of the electric light. In this building the visitor could enter into a subway or tunnel and walk upright in a lighted passage which was nearly square and not arched. This subway was brilliantly lighted by electricity; he could walk through it to the Electricity Building or to the Mines and Mining Building; if he should pass under the bridge west of the Manufactures Building he could see how the wires were fastened under it, and following the labyrinth he would again descend into the earth on the other side and enter another subway like the one he had left. This second subway ran along the entire west line of the Manufactures Building 1,700 feet, and the distance from the bridge to the west line was 300 feet. The subway continued under the north portico of the Manufactures Building, then crossed the bridge to the north in the same manner as it crossed the former bridge, then passed again underground and ran over to Fisheries and Government Buildings where it stopped. The entire way was lighted with sixteen-candle power 100-volt incandescent lamps, placed in series across a section of the 500-volt power circuit wires that were attached by glass insulators to the ceiling. The subway was double, and each section were similar in size and appearance, being 6 ft. 6 in. square, built of 2-inch tarred planking spiked to 3 x 8 inch timbers set 12 inches apart, and made fire-proof by a 1-inch coating of cement held in position by expanded metal laths. The capacity was far in excess, the visitor was told, of any possible demand, and 240 large wires were supported on glass insulators in both main sections. While provision was made for supporting, in addition, telephone and fire-alarm (service) cables containing innumerable cables. Connections with this subway and its branches were made with the main buildings through trap-doors, and along the line by 1,500 man-holes. In addition connecting with it directly and indirectly were nearly 93 miles of 6-inch "pump-logs" placed in trenches. These accommodated telephone and telegraph lines for fire-alarm purposes.

For the electric power circuits in this subway, conductors with a capacity of 200,000 feet of wire, were laid. For fire-alarm and police signal service 350,000; for the telephone circuits, cables for main distributors, the equivalent of 750,000 feet of metallic circuit was furnished; for branch conductors 100,000 feet of wire and insulation, each wire being separately braided and the two twisted together; for the arc-light circuits 264 miles of copper conductor, and for the incandescent circuit several hundred miles of Grimshaw wires; and of smaller Grimshaw wires several million feet were used in the buildings, while half a million feet of larger size were used for main feeder.

Coming

Coming now to the solar centre of the Fair the origin of all the lights along the roadways on the Wooded Island, and on the domes and pinnacles and walls of the principal buildings it will be found that 7 acres out of the total of the 26 acres of floor-space on the floor of the palace of Mechanic Arts were devoted to the great power plant, the source of all the light and illumination we have referred to. It was an immense engine belted to two equally immense dynamos driving direct two 10,000-light Westinghouse alternators from one main 30-foot driving pulley. The plant consisted of two 72-inch belts, one over the other, which transmitted the power to the 9-foot pulleys of the dynamos. Although this engine was not so conspicuous as to dwarf the surrounding machines, it was in reality capable of developing 2,500 horse-power, while, as is well known, the great engine at the Philadelphia Centennial, which I have seen in use at the workshops of the Pullman Palace Car Company at Pullman, was rated at only 15,000-horse-power. In adjoining sections of the building were ten 10,000-light alternating machines driven by ten 1,000-horse-power engines, while two 4,000-light alternators and the necessary exciters were driven by engines of less capacity. The twelve 10,000-light machines were all of the same pattern and furnished a current of 2,000 volts potential. The total capacity of these fourteen Westinghouse machines aggregated 158,000 sixteen-candle power lamps, the equivalent of 25,000 horse-power in steam was generated in the boiler plant which adjoined the power-plant building.

Arc Lights.

The arc lights, which were 1,550 in number and placed 65 to 75 feet apart in the central portions of the grounds. The entrances to the Art Gallery were lighted by these arc lights. The dome of the Administration Building was lighted by the incandescent system. All the lights everywhere in the grounds were so arranged as to enrich the points of beauty and provide as far as possible symmetrical decoration. Around the main entrances of the principal buildings, and in the grounds on ornamental posts, were placed one, two, and three arc lamps as well as clusters of lights, and in some cases there were brackets supporting incandescent lamps of high candle power in coloured-glass lanterns. Each of the posts referred to abutted on a man-hole, from which the leading wires passed up through a curved, vitrified pipe into the mast and thence to the lamp connections, each alternate lamp being on the same circuit. Over 10 per cent. of these lamps were on the patrol circuit, which was lighted from the setting to the rising of the sun. In the vicinity of the main buildings the lights were placed at an equal distance therefrom of 40 feet uniformly spaced on one side of the pathway. Single lamps lighted all bridge approaches, and a 3-light cluster was placed in the centre of each. In the above enumeration it must be clearly understood that the lighting of exhibits is not taken into consideration, nor those lights required in the operation of Machinery Hall in so far as power-plant was concerned. In other words it does not take into consideration the lights provided for by special contract; not those in the annex of the Transportation Building, Forestry Building, or in the pumping-plant in Festival Hall. These latter were furnished by private firms with dynamos specially installed for the purpose. In the glass dome of Horticultural Building a special lighting effect was secured by the suspension from the trusses of fifty arc lamps in circular rows, having ten in the upper row and twenty in the lower two rows.

Decorative Lighting.

The decorative lighting was limited to the outlining of the main lines about the Grand Basin. In the first place the shoreline of the basin was outlined by a row of lights; then the border of the flower-beds

beds was outlined in light; then the main cornice line of the buildings, extending completely around the Grand Basin at a uniform height of 60 feet, was marled by a row of lights; and, lastly, the Administration Building was outlined with lights, each horizontal line of the architecture, the ribs of the great dome, and above all the corona was shown in dotted lines of light. The glorious spectacle presented by this wonderful series of lights on every evening during the currency of the Exposition was magnificent in the extreme. The effects of light on the water and on the buildings, which appeared like great white marble palaces, was of an indescribably beautiful character. Besides the decorative lighting just described, the use of incandescent light on exteriors was mainly confined to the lighting of the Wooded Island and the use of lights here and there to produce a soft glow in colonnades and loggias. In carrying out the system of lighting, the two most difficult problems had reference to the lighting of the Art Galleries with their 2 miles of reflecting screens, and the lighting of the dome of the Administration Building. The lighting of the dome of the Administration Building in particular was very unique and effective. On the floor of the dome, which was octagonal in shape, there stood in the eight angles eight great spreading candelabra of special and beautiful design, each bearing fifty 16-candle power lamps. High up, at the spring of the interior dome, was a gallery running clear round the entire dome as has been described elsewhere. This gallery had a metal railing upon which stood fifty-six 7-light standards, forming a grand corona of light 120 feet in diameter. Far up, above and through the opening in the false dome, were seen the beautiful painting upon the ceiling of the outer dome, as it was illuminated by a circle of arc lights which were themselves hidden from view between the two domes. I may instance another effective piece of lighting in the Fisheries Building. The large circular pavilion on the east side, as I have stated elsewhere, was used as an aquarium. Around it were arranged continuous concentric rows of great tanks. The sides of these tanks were of clear glass and were continued to the ceiling by stained glass screens, so that the observer walked in a covered corridor whose sides were of glass and through which could be seen the representatives of the finny tribes disporting themselves in their native element. At night no lights were visible, but the tanks were lighted by hundreds of incandescent lamps placed under screens above the tanks, so that the light did not strike the eye, but was diffused throughout the water, lighting it up as effectively as in the daylight.

The Terminal Station, Festive Hall, and Wooded Island were lighted by a separate machine, located in the German exhibit space in Machinery Hall.

In lighting the interior of the mammoth Manufactures Building the plan adopted was to provide five circular electroliers or coronas, four of which were 60 feet in diameter, and the centre one 75 feet, built of angle iron and suspended from the arches. The lamps were about 140 feet above the floor, and from 40 to 70 feet below the roof. These electroliers were suspended by means of a steel shaft securely bolted to a bridge passing across the centre of the circle, bridge and circle having a footpath nearly 3 feet in width, guarded by a suitable railing, along which the lamp trimmer travelled when carboning the lamps, the trimmer ascending one of the big arches to the supporting shaft and then descending by means of a ladder attached to the latter. To the four smaller electroliers 75 arc lamps each were suspended, and to the large centre piece 110 arc lamps, the lamps being hung in pairs and sustained by cords passing over insulated pulleys, each lamp balancing the weight of its mate. The large electrolier in the middle of the hall was suspended directly above the clock tower. It was 12 tons in weight.

Flash-

Flash-lights.

Next to the display of fireworks on the night of the Fourth of July, the vast multitude present within the Exposition Grounds viewed with greatest interest the working of the search-lights on the battleship "Illinois" and on the roof of the Manufactures Building, where four of these lights were placed at each corner of the roof. Notably was this the case when the balloon went up. It was perfectly invisible until the search-lights caught it in the heavens and held it in their glare. At one time there were three search-lights aimed at the balloon, and they held it in the clouds like a ball of fire. One search-light was from the battleship, one from the Manufactures Building, and a third from the whaleback steamer on Lake Michigan. The effect of these streams of light aiming at a focal point and concentrating their glare on a small and definite object was very pretty and aroused much enthusiasm.

Other Electric Light Exhibits.

As a brilliant example of the purely ornamental application of electricity I might refer to the great electric fountains in the Court of Honor, on each side of the MacMonnie Fountain, as described elsewhere.

Perhaps one of the most incongruous uses of the electric light was to be observed in the Midway Plaisance. It was one of the oddest things in the world to go into the Dahomey village for example and see over the door of each little bark hut an electric lamp. In like manner the Samoan and Javanese thatched huts, lighted with electricity, were as great an antithesis of barbarism and civilisation as could be observed anywhere.

In the disposition of space in the Electricity Building the main floor was devoted to the heavier exhibits, such as commercial apparatus for furnishing light, heat, or power. The galleries contained the ladder or wire exhibits and all the lighter scientific apparatus, and this latter portion was a centre of historical interest, containing as it did a large number of models of all kinds and other precious relics.

In this exhibit were many interesting things, and among them were shown models representing the exact sizes of copper conductors necessary to light up 8,640 sixteen-candle power incandescent lamps by the tree system of distribution, and also by Edison's celebrated feeder system. The comparison was largely in favour of the latter.

The General Electric Company of London and Manchester made a very nice display of electrical apparatus and supplies.

The British Government Postal Telegraph Department made a very complete historical exhibit of old and new telegraph instruments. Here was also shown a sample of a telegraph post pierced by the woodpecker, which, as is well known, mistakes the humming of the wind through the wires for the noise caused by the insects which are its favourite food.

On entering the building the first important exhibit was that of the Bell Telephone Company, in which was a complete central station. Models of the telephone from its inception to its present condition were exhibited. In this section there was also a modern theatorium in which visitors were enabled to hear orchestras performing in New York or Boston.

At the entrance to the south door of the building was a colossal statue of Benjamin Franklin in his well-known attitude of drawing lightning from the clouds, and on the wall, over the arched entrance, was the inscription—"QUI FULMEN CÆLIS ERIPUIT ATQUE SCEPTUM TYRANNIS."

General

General Electric Company's Exhibits.

In the large and magnificent exhibit of the General Electric Company was shown a case containing specimens of the various vegetable fibrous growths experimented upon by Mr. Edison in his search for the substance best calculated for an incandescent lamp filament. This search involved trips to all parts of the world, cost the investigator \$200,000, and resulted in the selection of a Japanese bamboo, which is now cultivated on special plantations.

In the centre of this very large exhibit was a direct connected engine and dynamo and was the only one left of six similar generators originally constructed for the Old Pearl-street Station of the Edison Electric Light Company of New York. It was erected in 1882 and has been in service ever since. There are now only six other generators like this one in existence, which are in operation at the Edison Station, Milan, Italy.

A generator similar to this one was exhibited at the Paris Electrical Exposition in 1881, where it excited the astonishment of the savants on account of its size, novelty, and boldness of design.

Although in the light of recent development this machine may be considered of small capacity, still it was several years before direct connected generators were reintroduced.

This machine averaged a service of five hours per day for over ten years, was in excellent working condition when dismantled to be exhibited. It was estimated that this machine must have made nearly 300,000,000 revolutions, which would have rolled the armature eighteen times around the world.

There was a machine exhibited similar in size and detail of construction to those installed for the lighting of our Houses of Parliament some time since. This old machine was the first Edison dynamo built, being one of the fifteen which were used at Menlo Park for the first exhibition in public of electric incandescent lighting ever made. It was built early in 1880, and has been run constantly ever since for ten years at Menlo Park, and afterwards at the Edison Lamp Works, Harrison, New Jersey. It was taken from its duty in the Pump Room to be sent to the World's Fair. While on exhibition it was run as a motor.

The General Electric Company had a large display of all the specialties of the science. There was a room specially provided in this place with lighting arrangements of a decorative kind, arranged so as to change the amount of light carried by the various meters, the object being not only to show but also to test their accuracy. Professor Thomson, the electrician of the company, showed specimens of all the specialties of alternating supplies and devices.

By far the largest and most striking exhibit in the building was that made by the General Electric Company in its space in the centre of the main floor. The central piece of this display, and the one which perhaps attracted the most attention from the layman, was the great Edison tower of light, a tall shaft extending almost to the roof, with a colonnade about its base, the whole studded with miniature incandescent lamps arranged in geometrical figures, and in red, orange, and purple colours. These were wired on various circuits, each connected with a separate key on a keyboard, so that a variety of combinations both of shapes and of colours were thrown into action by the simple pressure of the proper keys. This tower was illuminated every evening in the week, and Tuesdays, Thursdays, and Saturdays, between 1 and 8 p.m. The changes were rung to the tune of waltz music, which added to the charm of the display.

The

The tower was surmounted by a huge model of the Edison lamp. This was made of small prisms of glass, 40,000 in number, carefully wired to an iron framework within. This bulb was 10 feet high, and it required the services of eight men for five weeks to wire the prisms together. The total number of lamps on the Edison tower approached 5,000, and the aggregate candle-power was equivalent to that emitted by 20,000 sperm candles. From a scientific point of view the tower had no interest whatever, nor was it artistic or original in design, but as a spectacular achievement it was an undoubted success, if judged by the throngs that viewed it.

Few are aware of the extent to which the incandescent light has come into use. Only by a knowledge of the variety of shapes and sizes in which it is made can a comprehension of the variety of its uses be attained. Just north of the tower of light the General Electric Company made an exhibit of all the different sizes, shapes, styles, and types of lamps made. In this 2,500 commercial lamps were shown, no two of which were alike. In addition to the completed ones, lamps in all stages of manufacture were shown, thus constituting this display an educational one of a very high order. It was the most complete exhibit of incandescent lamps the world has ever seen.

To the west of the tower-light was what was termed the power transmission and mining exhibit of the company. While this will prove less interesting to the average visitor than many other displays, to the student and electrician it was one of the most attractive, for here was shown some of the transformations of energy which have rendered the applicability of the electric current, so far as is known, almost universal.

To follow these transformations one must go first to Machinery Hall, as I have already stated. There the combustion of the oil under the boilers chemical energy converted the water into steam. This in the steam-engine was converted into mechanical energy, which as such drives the great dynamo electric machines by which it is converted into electrical energy, and thence transmitted by wire to the Electricity Building for use in all of the numerous ways in which energy is utilised for man's comfort. Follow a single one of these circuits, and see what it does. In the centre of this space stood a large mine pump capable of raising 500 gallons per minute to a height of 650 feet. This was connected by gears to an electric motor, to which the wires followed lead. The electrical energy in the wires was transformed into mechanical energy in the motor, and that through the agency of the pump was changed into water-power. The pump delivered water under 650 feet pressure to a Pelton water-wheel, which brought it back to the mechanical form, and through its shaft drove the armature of another electric generator of peculiar construction. The current generated by this machine was not of uniform direction, as was that which was transmitted from Machinery Hall, but it changed its direction between thirty and forty times a second.

This was what is termed an alternating current, and was introduced at this stage to show still other methods of transformation not possible with currents of continuous flow. In this particular machine there was generated not only one of these alternating currents but three, whose impulses did not coincide, but succeeded each other at regular intervals, so that after the third current had given its maximum impulse in a given direction it was followed at the proper interval by a maximum impulse in the first circuit, and so on.

This was called a three-phase generator, and from it extend three circuits—one for each of the separate currents—these three circuits being accommodated by three wires. The three-phased alternating currents next went to what are termed step-up transformers, by which the nature of the current was changed. By this means

means the current corresponding to a large stream of water falling through a small distance was changed to one corresponding to a small stream of water falling through a great height. This change of character is desirable where energy is to be transmitted great distances, for thereby the cost of transmission is enormously decreased.

But these "high-tension" currents, as they are called, which are best suited to economical transmission, are not so well suited for utilisation, so they must be transformed down again for use to their original character, resembling the larger stream of water flowing more slowly or through a lesser height. This was done by a "step-down" transformer, which is the reverse in principle and construction to the "step-up" transformer before referred to. The "step-down" transformers were placed in the space devoted to the mining machinery, and the current issuing from them was used to illuminate incandescent lamps, arc lamps, and what are termed three-phase motors.

The latter were employed, some of them to operate mining machinery, and others to run direct current generators, thus returning after many transformations to the form of current by which the energy was originally transmitted from Machinery Hall to Electricity Building.

This object lesson of the conservation of energy and its transformation is one of the most interesting in the whole domain of physical science, and, while for many years it has been known to be theoretically possible, has only within a comparatively few years been practically attainable. It may be said to be the crowning triumph of electricity, for it is through the development of electricity alone that the completion of the great cycle has been rendered possible, and we have been able to verify in practice what even as a theory was astounding.

Westinghouse Electric Company.

Second only to the General Electric Company's exhibit in point of extent, but not inferior to it in either popular or scientific interest, was that of the Westinghouse Manufacturing and Electric Company, whose space was scattered somewhat over smaller areas. This company also showed the principle of the transformation of energy through all of its commercial and possible forms, and displayed on a considerably larger scale how the current from a single alternating circuit may be utilised for all things for which power is now employed. The system adopted was that of Tesla, whose wonderful discoveries in other directions in the electrical field have startled the world.

As a spectacular display of the popular kind this company had constructed a great sign on the south wall of the building in which a bust of Columbus, the name of the company, and the dates 1492 and 1892 are outlined in incandescent lamps in red, white, and blue. There were in this sign 2,085 lamps in all, each of a nominal sixteen-candle power, making an aggregate illumination equivalent to 33,360 sperm candles.

Under the south-east gallery this company made two displays, which, when in operation, always attracted crowds. Few of those who witnessed these performances understood their portent, however, but though of extreme scientific interest they appeal also to the untutored eye. These were the Tesla experiments with high potentials and the experiments or demonstrations with what is known as the Tesla ring. The latter consists of a large ring, about 3 feet in diameter, made of a coil of soft iron wire. Upon this again are wound four coils of insulated copper wire arranged in pairs, each pair being connected with a separate electrical circuit carrying currents alternating in direction, the impulses or changes of direction of the two currents alternating with each other in point of time. The action of these two currents upon the ring itself and the space surrounding it is such as

to

to produce what electricians term a rotary magnetic field, which is somewhat similar in its effects upon magnetic bodies to what would be produced by the poles of a huge permanent magnet if the latter were very rapidly revolved around its axis. The effect is more striking, however, from the fact that the apparatus itself is quite stationary. Whatever it is that is moving is invisible, but that something is in motion is rendered evident by the movement of metallic objects brought within the influence of the ring. A copper egg, the size of an ostrich egg, was immediately set spinning on its end if placed in the centre of the ring. This has been denominated Columbus' egg, probably because it stands on end. A bunch of keys was at once given life, and took up a slowly rotary motion under the same conditions, and metal discs were revolved on their axis when brought in proximity to the coils.

This property of such a ring to cause metallic objects, especially of iron, to take up a rotary motion was the joint discovery of Nikola Tesla, in the United States, and of Prof. Ferrari, of Italy, and forms a most prominent mile-stone in the development of electrical application to the arts. Here it was displayed as a simple toy, but it is the basis of one of the most important inventions in electricity, that is, the polyphase electric motor, which is now assuming commercial importance.

The high potential experiments referred to were conducted in a pavilion erected for the purpose, which was darkened by closing the doors to render the effects more brilliant. In these a current somewhat akin to lightning was caused to jump and spread out around the edges of large plates of glass interposed in their direct path, and their appearance is both vicious and startling. The force of these discharges was many times greater than is sufficient to instantly kill a man, and in fact is so great that if a hundred men in line, each clasping his neighbour by the hand, were to receive one of these shocks they would all be as effectually and instantaneously killed as if struck by one of Jove's thunderbolts. Other experiments of more technical interest were also performed.

The Telephone Pavilion at the south end of the building was one of the most absorbing from an educational standpoint. The telephone itself is probably the most remarkable of the world's inventions, but familiarity with it has caused the public to cease to wonder at its performance. There are comparatively few people, however, who know how the telephone service of large cities is accomplished. Here was displayed in full view a complete central exchange, with the movements explained by the attendants who were there for the purpose.

Within the temple, suspended from the ceiling, was a telephone receiver fitted with intensifying cones connected by wires with Chicago. At the other end on special occasions concerts were given whose notes might be distinctly heard by all those assembled in the building at the Fair. Upon either side of the main hall-way of the temple, suspended from hooks on the wall, were a number of small telephones connected with transmitters in the German Village in the Midway Plaisance, and through these in the afternoons and evenings one could hear the music of the bands stationed at the distant point.

The long-distance telephone was also shown in operation and the public were invited to test its capabilities by speaking and listening over a line connecting Chicago and New York. No charge was made for this service and the experiment was enjoyed by thousands every afternoon.

If one was historically inclined he would be greatly interested in the historical collection of telephone transmitters and receivers which was also shown in this building. Here were to be found all that

that remains of Bell's telephone of 1875, the first electric telephone that ever transmitted speech, and models of each successive improvement from that date to this.

Last but not least was Prof. Bell's radiophone, by which one was enabled to speak and hear over a ray of light. The receiver of this instrument was at the north front of the pavilion, and consisted of a parabolic reflector into the focus of which was inserted the bulbed end of a short piece of glass tubing, while to the other was attached an ordinary hearing tube, such as is used on phonographs. In the bulbed end of this glass tube, which was placed in the exact focus of the mirror, was placed a little burnt cork, and this was all that was required, except sensitive ears, to interpret the message borne on the light ray. The transmitting instrument was in the gallery, 90 feet away, and was equally simple, consisting of an arc lamp as a source of light and a lens to direct its rays in parallel lines upon a small glass mirror, which reflects them down to the receiving parabolic mirror just described. The reflecting mirror was exceedingly thin and acted as a diaphragm against the back of which the words were spoken. The vibration of this mirror varied the intensity of the reflected rays received by the cork, and the varying energy thus received was converted by the cork into sound waves, which were conveyed to the ear by the hearing tubes. This experiment was not adapted to promiscuous presentation, but was shown to the favoured few whose credentials showed that they would appreciate it.

Western Electric Company's Exhibit.

Closely allied to the Telephone Company is the Western Electric Company, the authorised manufacturer of all the telephones in this country. A part of its display also ably supplemented that of the Bell Company, as its telephone apparatus, including switchboards, was the most complete ever got together. Every piece of apparatus was shown, both complete and in its various parts, and these different types were arranged in chronological order. As an educational exhibit this part of the display was superb. The popular taste was also catered to, by the beautiful scenic theatre which this company fitted up. Nor will any one forget, who has visited the Electricity Building, the great lightning tower in the centre of the company's display, with its zones of light chasing each other from the floor to the ceiling and then spreading out in four directions in mimic lightning flashes, only to disappear in the revolving globes and pendants at the ends. This unique display was composed of 2,632 incandescent lamps of sixteen candles each, or 42,112 candles in all. The Egyptian Temple, with its classic figures of the inhabitants of Cheops engaged in electrical vocations, and its illumination by concealed lamps, was the most beautiful thing, from an artistic standpoint, in Electricity Building, and reflected the greatest credit upon Messrs. Patterson and Tucker, of the Western Electric Company, who were responsible for its design and construction.

Arrangement of Exhibits.

In the building, as far as possible, specialities were grouped; all the wire exhibitors were placed together, the carbon manufacturers were in one place, testing instruments were in another, and so on.

Mammoth generators, such as are constantly used in street railway service, were numerous. Three of the largest were of 450-horse-power, 300-horse-power, and 150-horse-power respectively.

Another display of considerable proportions was that of insulated lighted lighting systems for hotels and large business houses. The most modern type of direct connected compound engines and dynamos were shown.

Foreign

Foreign Countries.

Amongst these Germany, France, England, and Russia had the best exhibits although other countries were also represented.

France occupied two blocks of the building in the centre and one in the west and another in the north-west portion of the building, besides displays in the north-west bay. In the exhibit of this country there was a most conspicuous display of the latest forms of arc-lights as used in light-house service, one of them being of 200,000-candle power.

Germany had a very large display. In her space were shown three of the most perfect search-lights ever made. One of them, the largest ever constructed, with a 7-ft. 6-in. projector. This light, placed at a sufficient altitude, it was stated, would furnish ample illumination for a lawn-party or ball, 70 miles distant. As a matter of fact, a smaller light, by the same makers, exhibited at the Frankfort Exhibition, performed this identical feat for a German nobleman, at a distance of 45 miles. The firm of Siemens and Halske, of Berlin, exhibited a dynamo of 1,000-horse-power, one of the largest ever constructed, and with it furnished lighting and motive power for the German portions of the Exposition. Altogether this part of the German exhibit was represented by thirty firms in the electro-technical field and forty-three in mechanics, optics, &c., and Berlin, Nuremberg, Cologne, Frankfort, and Hamburg were the cities most strongly represented.

German Post-office Exhibit.

Germany had a complete post-office exhibit, containing a history of the service and exhibiting the application of the telegraph and telephone to the scheme.

In the gallery of the Electricity Building this exhibit illustrated fully by means of models and apparatus the mail and telegraph system. It was in charge of the Secretary of the Director-General of the branch of the German Government Service. The graphic descriptions provided explained all the arrangements for the conveyance of letters, &c., by messengers who were the forerunners of the organised public post. In addition there was an interesting collection of models of post-offices, postal-cars, distributing waggons, and three splendid specimens of German letter-boxes, as well as a number of other particulars connected with the postal system. The pneumatic tube system, first introduced by Dr. Von Stephan, Postmaster-General of the German Empire, was illustrated in a practical manner by means of a miniature plant. The pumps for compressed air were worked by hand power. In this section of the museum were also to be seen a collection of German postage stamps, dating from 1867 to 1892, such as would make the heart of any stamp collector leap for joy. Postal and railroad maps of the German Empire gave the following statistics in regard to the number of post-offices in that country and the increase, namely:—

In 1872 there were	7,334 offices.
In 1892 there were	27,864 offices.
Increase	20,530 or 279 %

The same map showed that Germany had one post-office to every 1,774 inhabitants. The telegraph system as part of the postal service was also demonstrated in a striking manner by numerous telegraph apparatus, from the old-fashioned "Step-by-Step" system with receiver also by apparatus with continuous current, and those which have to be charged. Then the Morse system was shown with improvements, two circuits demonstrating the present system. This section also included the Gans-Weber apparatus, originally introduced at the laboratory

laboratory at Gottingen, also Steinheil apparatus. While the standard Morse machine is in use in Germany the Sounder is spreading intelligence through America. Telegraphy was first introduced into Germany in 1846.

An extensive and thorough display was that of the telephone system of the postal service. Duplex switchboards, with keys for 6,000 subscribers, and the manipulation in connection therewith, was demonstrated by the officials of the court. The first telephones introduced into Germany in 1881 were shown, and, as a contrast; those in use at the present time. In 1883 Germany had 5,510 telephones, and in 1892, 79,908. The long-distance telephone extends to about 500 miles, from Berlin to Königsberg, and also from Breslau to Hamburg. The price for a three minutes conversation on this route is one mark, or 25 cents, or 1s. The switchboards contain sand dials of three minutes run, by means of which the operators regulate the length and price of conversation. Altogether the postal museum was instructive, and arranged in a manner characteristic of German thoroughness; and it was a very interesting object lesson on this subject to compare this exhibit with that of a similar character in the United States Government Building.

Comparison of the Exhibits.

In the opinion of Chief Barrett, the exhibits in the Electricity Building proved that America, which, as might be expected, had the largest exhibit, took the lead in the general application of electricity; that foreign countries excelled in workmanship; that the artists from Germany and France showed exquisite workmanship—what they do by hand the Americans do by machinery, and of course the work is inferior. America led in the extent of the exhibit, Germany came second, France third, and England last of the countries making a large exhibit.

The Telautograph.

In the west gallery the Gray National Telautograph Company made an exhibit of the latest, and one might almost say greatest, electrical marvel. Professor Elisha Gray has been known to the world for many years for his improvements in telegraphy, but his latest invention, the Telautograph, or long-distance writing-machine, quite eclipsed his previous efforts. More or less has been heard of this device for the last few years, but it has only recently been perfected for commercial uses. It consisted of two instruments, a transmitter and receiver, each provided with a roll of paper of convenient size for writing. Both instruments together were about half the size of an ordinary typewriter. In writing at the transmitter an ordinary pencil was used, near the point of which two small cords were fastened at right angles to each other. These connected with the instrument, and, following the movements of the pencil, regulated the current impulses, which then guided the receiving pen at the distant station. The paper was shifted forward by a little lever, giving an electric impulse, which moved in like manner the paper in the receiver at the other end of the line. The receiving pen was a capillary gas-tube, supplied with ink and placed at the junction of two aluminium arms. The electrical impulses conducted over the wires moved the pen of the receiver simultaneously and in the same direction as the pencil of the sender, and an ink tracing was left which was an exact reproduction in every dot and flourish of the original writing or drawing. The exhibit was arranged like a central station, and any two subscribers could be placed in communication through it in the same way as they now are through the telephone. One wrote what he wished and kept or destroyed what he had written, the other received and retained this communication in the handwriting of the sender,

sender, and that was the complete yet sole record of the transaction. Accuracy and secrecy were secured, the wires could not be tapped or the message overheard; no operator was necessary, and any kind of figures, from shorthand to Chinese characters, might be sent with equal ease. As one sat writing at one table it seemed almost uncanny to observe at an adjacent table a pen with no guiding hand producing at the same instant his own familiar writing. This invention is in many points much superior to either the telephone or the telegraph, and it is quite sure to encroach considerably on their domain, as one advantage of its invention negotiations might be conducted between parties in widely separated places, and contracts signed and exchanged without their coming together, or minute instructions be given to bankers or brokers without any room for misunderstanding or dispute.

Cooking by Electricity.

In the north gallery another recent and clever application of electricity was shown in regard to its use in cooking. Electrical ovens, models of convenience and neatness, were exhibited. They were made of wood, lined with asbestos to prevent the radiation of heat, and were lighted inside by an incandescent lamp. The temperature of the oven was indicated by a thermometer, and a large mica-lighted door showed the progress of the cooking within. Wires offering resistance to the passage of the electric current, and thus producing the heat, were arranged in the oven, and switches placed at different points allowed the application of the heat wherever desired. If a turkey was roasting more rapidly on one side than on the other, instead of taking it out and turning it about, a second switch was closed and the temperature was raised as required. All sorts of utensils were provided with attachments through which a current could be passed; coffee was boiled and steaks were grilled by electricity; there were flat-irons having small silk-covered copper wires fastened at the back, so that a high and equable temperature could be maintained at the bottom, while the top, made of a non-heat-conducting substance, remained quite cool. In fact this apparatus seemed so to alter ordinary and well-known conditions that the kitchen became almost a parlour and cooking was converted into a pastime. In this display there were also register stoves by means of which rooms could be electrically heated.

Other Exhibits.

In the south gallery there were exhibits showing the mode of hatching chickens in electrical incubators, and it was stated that the records of other processes or even that of the maternal hen were completely broken by this plan. Wires were led through compartments, where by means of switches and thermostats an absolutely uniform temperature was maintained throughout the period of incubation. I was informed that the time was lowered from twenty-one to nineteen days, and that almost every egg produced a lusty chick.

Another contrivance was an electric cloth-cutting machine which was intended for use in large clothing manufacturers' shops and was reported to save one-half of the labour while giving better results than those obtained by any other method. It performed its work with the greatest ease and precision, and the cost for motive power was said to be less than \$5 per month. Another novelty was an electric boot-black; one sat in a comfortable chair and put a nickel in the slot when immediately one brush cleaned the boots and the other gave them a radiant polish.

In one of the cases the advance of telegraphy was shown by contrasting a Morse receiver of 1893 with the original Morse of 1837. Near this exhibit was an interesting testimony to Cyrus Field's labours; it was the grapnel with which the broken cable of 1865 was successfully recovered.

By

By another electrical machine the speed and course of a ship were indicated. This instrument was connected with the compass as not to interfere with its movements, and at the same time to show a continuous chart for each fifteen minutes of the distance traversed and any variation that might have taken place in its course.

Submarine Telegraphy.

In submarine telegraphy the Commercial Cable Company made a very instructive and interesting display. After the several failures of 1857, 1858, and 1865 of the attempt to connect Europe and America by cable, success was achieved in 1866. Since that year electrical communication has remained unbroken between the eastern and western hemispheres, and submarine telegraphs have multiplied, until now the different lines of the globe have an aggregate length of 139,600 miles. The Atlantic Ocean alone is at present spanned by ten cables in more or less continuous use. The Commercial Company's system is composed of two main cables from Cape Canso in North-eastern Nova Scotia to Waterville on the south-west coast of Ireland. From the latter port the cable is laid to Bristol with aerial land-lines to the chief cities of England, Wales, and Scotland, and another to Havre, with an underground line to Paris. At the American end a double cove cable runs from Cape Canso to Rockport, Mass., with aerial lines to Boston and New York, and a second cable running direct from Cape Canso to New York. The efficacy of this last line was well demonstrated during the blizzard of 1888, when it was the only one open from New York to the outer world, and messages to Boston and other places were transmitted by way of London. The total number of cables operated by this company is 6,935 nautical miles. In the exhibit here the whole process of transmitting messages between Europe and America was shown. An artificial cable, with all the properties of the real Atlantic cable, was employed. Signals were sent through it and received by recording instruments of the same shape, and the same time was occupied in sending from the one side of the pavilion to the other, as from one side to the other of the Atlantic.

Boilers used for the production of Power.

The advancement in electrical engineering in America, as shown by the exhibits at the Fair, has been very great within the last few years. In the matter of the production of power for electric lighting, Americans are using almost exclusively high pressure water-tube sectional boilers; a large number of these boilers were on exhibition at the Fair, the companies represented being the Heinie, Babcock and Wilcox, Sterling Boiler Co., Root Boiler Co., and others of like character. The feature of these particular boilers was the fact that instead of using the large diameter or shell the boiler was made up of a number of pipes put together in sections, these smaller diameters or pipes being capable of carrying a higher pressure, and owing to the fact that in bursting only one tube at a time would be destroyed, the damage would not be very great—hence the name, Sectional Water-tube Boilers. Where large steam plants were in operation, instead of using the old-fashioned chimney to provide sufficient draught, Americans used what are called "Economisers," which consist of a series of tubes, placed in what would ordinarily be called the smoke flue, and passing through these tubes to the boilers, the feed-water; this process heats the feed-water to a degree representing approximately 10 lb. of steam; the draught was produced by mechanical means, a large exhaustor and engine being employed, whereby the draught could be increased or diminished so as to accommodate itself to the varieties of coal and conditions of service. Feed-water heaters were also employed with beneficial results. The more economical stations carry a boiler-pressure of 125 lb. of steam per square inch, that is at least in compound-condensing and triple-expansion

expansion engines of various types, some of the more prominent being the upright engine, connected direct to a dynamo. The principal feature of these engines consisted in the fact that the steam was handled by a single valve, admitting to the high and low pressure cylinders an equal volume of steam under all conditions of load, which is a decided advantage, and the only practical means of applying compound engines to electric light service, as the variation of load in stations increases and diminishes according to the number of lights used by the customers. The Westinghouse Current Company had an exhibition of six 1,000-horse-power engines and a number of smaller ones upon this principle, the total capacity of which was 7,800-horse-power. The dynamos principally used for central station lighting were made on the alternating principle; this principle admits of carrying a higher voltage, thereby reducing the diameters of the wires necessary to carry a given current, as compared with the old direct current system. The losses in transmission are decidedly less. The average voltage carried for medium sized cities is 1,000; this voltage is reduced at the consumer's residence or place of business by means of a transformer to a current of 50 or 100 volts, suitable for ordinary lamp service.

Long Distance Transmission.

An interesting exhibit at the Fair was an illustration of how electric current can be transmitted over long distances for lighting or power. The Westinghouse Electric and Manufacturing Company have a dynamo supposed to derive its power from a water-wheel situated in the mountain country, and generating a current of 2,000 volts. This wire is supposed to be 28 miles in length. Where a current is transformed through a suitable dynamo or transformer to a current of such voltage as to be commercially practical, this apparatus probably solves one of the necessities of the times, and it points to the time when the immense power of Niagara Falls will probably be used for commercial services within a radius of 500 miles from Buffalo. Power electric light, both arc and incandescent, is derived from this machinery; the arc lights in use have a wide flat carbon, and will burn for one week without renewal. The incandescent lights used on this system (which is the same as that which lights the Exposition grounds and buildings) are what is known as the new Westinghouse stopper lamp, which consists of the ordinary globe, into which is a common stopper, such as would be seen in a druggist's bottle, and through it passes two small iron wires; to the ends of these wires is attached the films, and instead of the vacuum in use in the old style lamps being employed, a gas is employed, which adds to the life of the lamp. The price of this new style of lamp has been reduced to $17\frac{1}{2}$ cents, as compared with 50 cents for the old style apparatus. The armature of the dynamo is sectional in form—that is, instead of being wound in two or three coils, there are a number of coils wedged into its outer diameter by means of a wooden wedge; the object of this is, in case the dynamo should burn out only one section would be injured; the operator in charge would only have to drive the wedge out, and replace the coil with another.

Nikola Tesla's Experiments.

About a year ago, in order to demonstrate the harmless character of the electric fluid when properly regulated, Nikola Tesla deliberately put himself in contact with a current having a strength of 250,000 volts. Since that time this remarkable performance has been repeated several times with satisfactory results. This gentleman worked for some considerable time with Edison and afterwards with the Westinghouse Company, a company that still uses his inventions and machines. He invented the rotatory magnet for transmitting electric power to great distances. The principle of the rotatory magnet, of which he is the discoverer, is to be employed in the electric plant now being established

established at Niagara Falls, and which is expected will be sufficient to transmit electric power to factories and other establishments as far distant from the source of supply as Chicago and other cities. I was informed that he is now working with a machine by which he expects to revolutionise the present methods of producing the electric light, and which, if successful, will produce a better light at a cost greatly less than that at present paid. One of his presentations at the Electricity Building exhibited his progress with the new apparatus. In a dark room, with an apparatus supplying alternating electric currents of 800,000 voltage, he produced atmospheric vibrations showing a light equal to mid dawn. Explaining this demonstration, Mr. Tesla said:—

With these alternating currents of 800,000 voltage I cause the air particles to vibrate 400,000 times a second. Now, if I can increase the atmospheric vibrations, say 1,000,000 or 10,000,000,000 times, I can produce sunlight in this room. Of course I can increase the vibrations by increasing the voltage, and there is no trouble about increasing the voltage. I can make the voltage 8,000,000 as easily as 800,000. But I am not yet ready to handle 8,000,000 volts of electricity. Currents of such strength would kill everybody in the room. I expect, however, to learn how to control a larger voltage. When I have increased the atmospheric vibrations, perhaps a thousand times, the phenomenon will no longer be electricity. It will be light. I regard the words light, heat, and electricity as being interchangeable terms. Sunlight is a more remarkable phenomenon than electricity. Sunlight does not harm anyone, unless he is exposed for a long time to a fierce glare. A man can stand for a brief interval without harm near a red-hot stove. I am satisfied that sunlight can be made from electricity without doing harm to anybody, and I expect to discover how it is done.

He further said:—

We are going to use electricity for almost everything. We are going to know all about it, and, above all, we are going to know how to control it. Even now it is the safest motive power we employ. If the steam-boiler in a large factory bursts it is likely to kill a score—perhaps a hundred people. A horse running away with a carriage full of people may kill all of them. Electricity rarely kills more than one man at a time. A live wire in this room might kill one man, but hardly two men. Electricity is like a rattlesnake. It strikes its victims one at a time. But it will not long be possible for it to kill anybody. We are going to harness it and make it absolutely safe. As a motive power it will be safer than engines or horses, because it will never get out of harness. Just as soon as we learn how to harness it so as to secure perfect safety—and I think that time is not far distant—electricity will take the place of fire and steam, and will be the only agent employed to light and heat and move the entire world.

When I stand before an audience and receive into my body a charge of electricity of 250,000 voltage power I do it to show how harmless this agent can be made with proper handling. I am enabled to accomplish this feat by the use of alternating currents, and any able-bodied man, not unusually sensitive to electric force, can perform the same feat, if he will use the same machine that I do. I have simply learned how to put the harness on that amount of electricity. But 2,000 volts from any other machine would kill me as quickly as it killed Kemmler at Sing Sing. I have devoted my life to electrical research, and my only ambition is to discover how this wonderful power may be harnessed and made to do the work of man safely and satisfactorily.

Electricity as applied to Mining.

In the Mining and Electrical Buildings some novel and interesting displays are made of the late devices and equipments for the mining and hauling of coal and ore. Some of the largest mines in the United States are now entirely handled and manipulated by electrical inventions in the hands of comparatively few employees. A visit to these two buildings left no question on the doubter's mind. Here was displayed every conceivable device that is of utility in mining. Electricity lighted the shafts, drove the drillings, worked the pumps, did the hoisting, drew the loads, and furnished the supply of fresh air. Every wheel that turned did so as a result of the application of the electric current. In these two buildings were seen all these instruments. In the Mining Building many of them may be seen in operation.

From an able article on this subject I extract the following instructive remarks:—

The adaptability of electric power for various purposes in connection with mining operations is now a well accepted fact, and although its application for such purposes is already extensive it is probably only the beginning of a much greater use. It is roughly estimated that over 300 companies in the United States engaged in mining now employ
electricity

electricity in their operations. In underground workings the chance of accident resulting from loss of life and destruction of property is at the best great. Humanity and economy both demand that any means that will secure greater safety should be eagerly grasped. Electricity tried under the arduous mining service has been shown to be perfectly efficient, safe, and reliable. With electricity there is neither friction, heat, nor condensation. There is no leakage nor loss of power when not in use. It is not affected by heat or cold, and does not vitiate the air, as is the case with steam or compressed air. The rapid decomposition of timbering, a source of great expense in all mines, due to bad air and heat, is to a great extent obviated. Many will naturally suppose that electricity will increase the risk of fire. As a matter of fact it greatly decreases it, as is shown by the statistics and actual test displayed in the Mining Building. With proper safety devices it is practically impossible to start a fire from the current. To the engineer accustomed to speed indicators, pressure gauges, and indicator cards, electrical methods of measurement seem particularly simple. If necessary, motors can be controlled from a distance.

By conversion into electrical force, water-power, even at a considerable distance from the mine or mill, can be made valuable for all purposes, and steam-power can be so located as to secure fuel and water cheaply. The introduction of electricity has in this way made important reductions in the cost of power, and there are cases in which it would be impossible to run without its help. Several mines in Colorado are operated by electricity which could not be worked by steam on account of their situation on the face of precipitous cliffs, up which the transportation of water and fuel would be nearly if not absolutely impossible.

Generators can now be obtained of any size and design to run at any reasonable speed for belting or direct connection to engines or car wheels. The largest generator in the world ran during the currency of the Exhibition in the power-station of the intra-mural railway at the World's Fair. It was of 2,000-horse power and directly connected to a compound condensing engine running at seventy-five revolutions. The electric generator was substantially the same as the motor, and both could be relied upon to give an efficiency of from 90 to 95 per cent.

When the power is carried over long distances the cost of copper is the largest item of expense. The long-distance transmission of power was first brought prominently before the public by the experimental line constructed between Lauffen and Frankfort two years ago. The power of the Lauffen Falls was converted into electricity, transmitted 115 miles to the Exposition at Frankfort, and there operated a number of motors. The distance was beyond the limits of commercial success, but it demonstrated the possibility of the system. To-day, plants are in operation and transmitting current for power and light at Walla Walla, Hartford, Portland, Pomona, and Telluride, the distances varying from 4 to 13 miles.

In no application of electricity, except lighting, engineers say, has such success been obtained as in the operation of railways. Above ground it has already supplanted animal power in many cases. For underground haulage the ready control, compactness, and freedom from smoke render it still more desirable, and already electric locomotives are employed in some thirty mines. The electric locomotive is so designed as to occupy no more space than the car which it is to haul. With any other method of traction considerable more height and width would be necessary. In coal-mines in which there are narrow seams this is especially noticeable, as much rock has to be blasted away to admit of the passage of mules. By using electric locomotives the blowing down of the roof is entirely done away with. The increased speed also permits a larger tonnage to be taken from the same outlet, and with fewer turnouts, switches, and cars. Locomotives are now to be obtained of any size and to operate on any track gauge not less than 18 inches. At Rock Springs, Wyoming, there is in operation a locomotive of eighty horse-power. It is operated by a single motor geared to both axles, the connection to the axles, however, being made through a flexible coupling allowing the entire weight to be supported on springs. The larger sizes of locomotives are generally constructed with one motor, and the smaller with two. In all locomotives in use the speed under load varies from 6 to 12 miles an hour.

Electric hoists are largely in use and follow as nearly as possible the methods and constructions approved for steam hoists. The governing mechanism is similar, and the brakes and clutches are the same. The rotary motion of the motor avoids the use of connecting rods entirely. If it is desired to lower by power the current can be admitted to the reversed motor. For small hoists used in winze and timber construction work electricity is well adapted, the power connection being easily and quickly changed. The simplicity of the application of electricity and the consequent economy is well exemplified in the Brooklyn docks of the Wilson steamship line. Nine electric hoists have been in continuous operation there for two years. Special hoists for underground are equipped with ironclad motors so as to be thoroughly protected.

A number of large pumping plants are now in operation equipped with electric motors. It is necessary in order to turn the reciprocating motion of a plunger pump into rotary to equip it with crank shaft and connecting rods. This at the same time insures a steady flow of water. The general practice has been to stop and start in order to decrease the capacity. The machines may also be controlled by varying electro-motive force supplied them from the generators. In the Electricity Building was shown a Blake pump directly connected with a slow-speed multipolar motor of 100 horse-power requiring only one gear reduction. The capacity of the pump was 500 gallons at 500 feet head.

The

The statements made regarding hydraulic pumps apply equally well to air compressors, except that as air has not the inertia of water it can be automatically loaded and unloaded without throwing any strain upon the mechanism, the motor running constantly at a fixed speed. A decided saving of power can be effected by locating drill compressors near to the drills, thus avoiding losses by leakage and shrinkage in the pipes.

Although it has been a matter of great difficulty to make an electric percussion drill which would stand the continual abuse and hard usage to which air-drills are subjected, they are at present in constant and successful operation. The drill consists of an outer iron pipe casting, inside of and attached to which are two coils and the ratchet mechanism. The plunger, equipped with the ordinary chuck and rifle-nut, is in the centre of these coils. The coils are supplied with current alternately and draw the plunger up and down at a speed fixed by the generator which supplies the current. Electric diamond drills are in use for drilling solid holes and for removing cores for prospecting purposes. For prospecting both above and under ground the electric drill is particularly available, as it is extremely light and compact, and temporary wires can be run to places where it would be difficult to carry steam pipes or boilers.

Electric coal cutters are largely used in the bituminous mines. In the machine most employed the coal is undercut by means of bits set in a rotary bar on the end of a sliding frame which is fed into the face of the seam. Other cutters are constructed with a sprocket chain, to the links of which are affixed cutting tools. Machines of this kind can be fed either in or along the face of the coal for long wall or room working. In both of these the electric motor is built into and forms part of the frame, adding but little to its weight. In exceedingly hard or pyritaceous coals which cannot be cut with a continuously moving cutter an electric pick is advantageously used. Machines of this kind were exhibited at the World's Fair. The motor draws a projectile bank against a spring, and releasing it lets the pick fly back against the face of the coal at the rate of 150 blows a minute. Electric drills for putting in holes, for blowing down coal after it had been undercut, or from the solid, as is done in anthracite, are also used. A drill of this type of 100 lb. weight will easily drill a 1½-inch hole at the rate of 6 feet a minute in hard or soft coal.

It is often desirable, in order to obtain the best results from fans and blowers, to locate them at the most distant points from the surface. This is done more easily by electricity than by any other power, and the blowers can be readily advanced as the workings are pushed deeper. The electric motor is especially suitable for high-speed blowers, which are efficient and occupy but small space. Much saving in piping can also be effected by using higher velocities and forcing air out from the inside rather than sucking it from the surface.

It has been found that much more work can be gotten from men by giving them better illumination. By avoiding the use of oil lamps and candles, the air is left purer, and both time and power saved by doing work underground which would otherwise have to be done on the surface. Electric lighting also reduces the risk of accident by calling attention to conditions which would otherwise pass unnoticed. In gaseous mines, where many explosions have resulted from the reckless use of miners' lamps, electric lighting is invaluable.

The refining of black and blister copper has reached large proportions, fully one-third of the copper refined in this country being electrically treated, and considerable quantities being shipped abroad. By this process gold and silver are obtained from the matte the recovery of which would be impracticable by any other method. Gold, silver, and lead are also beginning to be refined electrolytically. Aluminium and silicon are obtained almost exclusively by electric smelting and reducing. Caustic soda, sodium, chloride of lime, and vermilion are commercially obtained by electrolysis.

Niagara Falls Cataract Construction Company.

At the Congress of Electricians, held in the Art Palace on the lake front, at the end of August, 1893, at which many of the most celebrated scientists of Europe and America, including Helmholtz, Edison, Elisha Gray, Silvanus P. Thompson, Professor Henry, Dr. Bell, Preece, Mascart, and a number of others were present, a number of most important questions connected with recent discoveries in electricity were discussed. Mr. George Forbes, F.R.S., Chief Electrical Engineer of the Cataract Construction Company at Niagara Falls, gave, for the first time, an account of the work being done in connection with this great enterprise. I may summarise the statements he made as follows:—The plant as it stands would furnish 50,000-horse power, which could easily be doubled at a minimum expense. The canal commenced 1 mile above the falls. From this main canal branches lead to factories and to the power house for electric distribution. The water falls through penstocks 140 feet deep, at the bottom of which are turbines with vertical shafts. All discharge water goes into a large tunnel

tunnel opening below the falls. The revolving field magnets of the dynamo are directly on the same vertical shafts. The armatures of the dynamos are stationary, and are wound so as to give directly a pressure of 20,000 volts, thus dispensing with transformers at the generating station. At the receiving stations the pressure will be lowered by transformers to a safe pressure to handle. The same pressure on the mains will be used for distribution to points near and at a distance in order to avoid complexity of wiring and to save copper. The wires will be carried partly on poles and partly in subways. Light and power were thus provided for the village of Niagara, and for the Pittsburg works near by. The aim was ultimately to supply power not only to factories in the vicinity of the falls but to Buffalo, Rochester, Utica, Syracuse, and Albany, and perhaps also to supply power to propel the boats on the Erie and other canals to New York State.

Professor Forbes thought the matter of towing by electricity on the Erie Canal would make transportation so cheap that it would revolutionise carrying business in New York State. The distance power to be transmitted would ultimately extend 350 miles. He had no doubt of the success of the attempt, for he had dealt with similar problems in India, and had been successful. Power was to be transmitted to Madras from mountains 350 miles distant at a cost that would make it the cheapest power in the world. The most serious problem was the method of transmission. The overhead system was open to the objection of interruption by sleet and lightning. The subway was almost certain to be carried on without interruption, so the electrical engineer was naturally led to favour the subway. Last Friday the first sod was turned on the subway that will transmit power for the Cataract Construction Company to the Pittsburg Reduction Company's works, $\frac{1}{2}$ mile distant. He thought a saving of \$3,000 each would be effected by building the dynamos without transformers.

In the discussion which followed in connection with this subject Professor Rowland, one of the foremost of American electricians, objected to Mr. Forbes' statements. He thought that instead of saving \$3,000 by dispensing with transformers it would be just the other way on account of frequent breakdowns due to the absence of the transformers.

Professor Jackson said we were all familiar with the transmission of power over short distances. Plants for transmitting power 10 to 20 miles had all been successful, but until the Niagara plant is in operation he feared we would simply theorise on long distance transmission, and not get down to practice. He hoped in two or three years we would know where we stood on long-distance transmission and distribution.

Dr. Bell had something to say on the subject of transformers and commutators. He thought the utilisation of electricity for towing on the Erie Canal was not so near as might be. The overhead line would be difficult to keep up, and the conduit was commercially impossible. We must employ overhead bare wires. No insulation that could be put on would stand high voltage. In theory the conduit was all right, but commercially its cost prohibited it. As regards the distance over which power could be transmitted he did not think any one would care to set the limit. A distance of 50 miles and under was enough to keep all busy for the next decade. If only coal was cheap enough power could be transmitted any distance. It was thus of more a commercial than an electrical problem.

Electrical Units of Measurement.

The report of the Chamber of Delegates at this Congress on legal units of measurement at this Congress was of great importance to the whole scientific world. It was unanimously adopted by the Congress,

Congress, representing, as it did, the most celebrated electricians of the old and new world. It was as follows:—

Resolved. That the several Governments represented by the delegates in this international congress of electricians be and they are hereby recommended to formally accept as legal units of electrical measure the following:

As the unit of resistance the international ohm, which is based upon the ohm equal to ten-ninths units of resistance of the initial C.G.S. system of electro-magnetic units and is represented by the resistance offered to an unvarying electric current of a column of mercury at the temperature of melting ice, 14.4521 grammes in mass, of a constant cross-sectional area and of a length of 106.3 centimetres.

As a unit of current the international ampère, which is one-tenth of the unit of a current of the C.G.S. system of electric magnetic units, and which is represented sufficiently well for practical use by the unvarying current which, when passed through a solution of nitrate of silver in water, in accordance with accompanying specifications, deposits silver at the rate of 0.001118 of a gramme per second.

As a unit of electro-motive force the international volt, which is the electro-motive force that is steadily applied to a conductor whose resistance is one international ohm, will produce a current of one international ampère and which is represented sufficiently well for practical use by 1,000-1,434 of the electro-motive force between the poles or electrodes of the voltaic cell, known as Clark's cell, at a temperature of 15 degrees C., and prepared in the manner described in accompanying specifications.

As the unit of quantity the international coulomb, which is the quantity of electricity transferred by a current of the international ampère in one second.

As a unit of capacity the international farad, which is the capacity of a conductor charged to a potential of one international volt by one international coulomb of electricity.

As a unit of work the joule, which is 10^{-7} units of work in the C.G.S. system and which is represented sufficiently well for practical use by the energy expended in one second by an international ampère in an international ohm.

As the unit of power the international watt, which is equal to 10^{-7} units of power in the C.G.S. system and which is represented sufficiently well for practical use by the work done at the rate of one joule per second.

As the unit of induction the henry, which is the induction in a circuit when the electro-motive force induced in this circuit is one international volt, while the inducing current varies at the rate of one ampère per second.

The recommendation of the henry as the unit of induction, when announced, was warmly applauded, especially by the American electricians, who delighted that the labours of one of their number should have been thus deservedly recognised.

Dr. Nichols presented a report of the committee appointed to consider the question of standards of light. The committee had much discussion upon the various forms suggested for standards and, in particular, upon the two special forms of lamp, known respectively as the amyloacetate lamp of Von Hefner Alteneck, and the pentane lamp of Vernon Harcourt. They were unable to arrive at a vote recommending either, however, and therefore recommended that all nations be invited to make researches in common on well defined practical standards and on the convenient realisation of the absolute unit.

Electric Launches.

The electric launches used at the Exhibition were an unqualified success and were the admiration of every visitor as they gracefully and noiselessly with great rapidity of motion and perfect safety cleaved the waters of the lagoon. They belonged to the Electric Launch and Navigation Company of New York, a firm specially organised for this purpose. The company received the contract for their supply on 27th August, 1892, and on 1st October they commenced to build the fleet of fifty-four electric launches, partly in Racine and Detroit, after designs made by a firm of naval architects in New York. On 1st May there was a sufficient number of them in place to satisfy all the requirements of the public, and during the currency of the Fair they were so popular as a means of transportation that the demand was greater than the supply. Two kinds of trips were provided by this fleet of boats, the round trip, distance about 4 miles, touching all the principal buildings of the Exposition (fee 50 cents), and the short trip (25 cents)

for

for passage between one terminal point and the other, or between intermediate points. Not a single accident of any importance has occurred in connection with these points nor any serious damage done to the boats themselves. This remarkable fact was due to two causes, namely, the weight of the boat (about 5,000 lb., of which about 3,000 was the weight of the battery and apparatus) is so placed as to render it very safe and solid in the water, and next the great ease with which the boat could be guided and manipulated.

The boats were 35 feet 10 inches over all in length, 31 feet 6 inches on the water-line, with a beam of 6 feet $2\frac{1}{2}$ inches and a draft of 28 inches, and each of them seated thirty persons. The hulls showed the finest possible lines, and were constructed of white cedar (natural finish) with the entire inner panelling and decks of mahogany (piano finish), thus presenting a very elegant appearance. The seats were leather cushions filled with hair, the steel stanchions were of ornamental shape and the awnings over the hull were brightly coloured. The operation of the boats was exceedingly simple; it was controlled by a small lever switch at the side of the wheel which was placed in the fore part of the launch. The lever allowed four degrees of speed and of two backward. The normal speed at which these boats ran was 6 to 7 miles per hour, but they had a reserve speed of from 8 to 10 miles per hour. At a normal rate of speed these launches have performed a service of from twelve to fourteen hours on a single charge, the cost of which has never exceeded 60 cents per boat per day. The battery placed in these boats and the propelling machinery were of very simple construction, no more complicated, in fact, than the apparatus which drives an electric fan, the propeller shaft was at the same time the motor shaft, thus doing away with all gearing. One of the remarkable things about these launches was the fact that they travelled through the water with such extraordinary ease and smoothness that they left absolutely no waves in their wake—a fact explained by their mode of construction. So long as the armature turned true there was no shaking and no vibration of the boat. One kind of motion only was imparted to it, and that a purely rotatory one. Another noteworthy feature about these launches was the great economy effected in operating them. They required no licensed engineer; any person of ordinary intelligence—any child, in fact—could operate and guide them, once the battery was charged; and this, of course, made a considerable difference in the wages to be paid. Then there was also the saving in other respects: no coal, no costly repairs, no extras of any kind were required.

The batteries were grouped in two or three divisions. In each launch there were seventy-eight cells. The charging station was situated to the east and south of the annex to the Agricultural Building, below the level of that structure, and consisted of a shed-like building, extending over the water of the south pond, and thus directly communicating with the water of the lake itself. There were twenty-five slips at this station, proving safe and commodious anchorage for fifty boats. The station was L shaped, the southern section forming the longer wing. In this place, between the hours of 11 p.m. and 7 a.m., all the launches underwent the process of being charged with new electric power in place of that exhausted the day before. When a launch returned to its dock at the charging station from its 40-mile run, the work of charging was begun, in less than one minute, by an independent switchboard connected with feeders from the large dynamos in Machinery Hall; but of course it might be conveyed similarly from any electric plant by a cable which on reaching the station was subdivided. The two wires were then directly affixed to each battery by means of plugs that fit into them, and, with the aid of an ampère meter, the degree of the power was regulated to the proper pitch. As much as from fifteen to twenty and
thirty

ELECTRIC LIGHTED BUOY FOR THE LAKE FRONT, CHICAGO.

thirty ampères may be used, but it was found more economical to use the lowest-named figure. In this way it took about six hours to charge each boat. The power absorbed averaged about 10 horsepower per boat, and as high as 2,000 ampères of current at eighty-five volts have been drawn in one night for fifty-two boats, but as a matter of fact there has never been any difficulty in the handling.

The first boat in regular service was sent out on April 13th of this year, and up to September it had run 2,000 miles; in fact the record of the launches as a whole was a most excellent one. Their chief points of excellence may be summed up as follows: beautiful outlines, perfect safety for the passengers, swiftness and pleasure in sailing in them, easy management, and large saving in their operating expenses. They promise almost as much for the navigation of rivers and the quiet waters of the sea, as the trolley for lines for the land, in proof of which I may add that a number of these launches have been purchased by a Venetian syndicate for use in the historic canals of Venice, where doubtless they will soon supersede the ancient, poetic, and historic gondola.

Electric Buoys on Lake Michigan.

A remarkable example of the adaptability to the service of man in a new territory of usefulness, was exemplified in the plan adopted for the lighting of the shore of Lake Michigan in the neighbourhood of Chicago. It was found necessary to place lighted buoys for 7 miles along the shores of Lake Michigan about a mile from the shore, from the mouth of the Chicago River to the Exposition grounds, to indicate the shoals. For this purpose there were erected thirteen spar-buoys. Each buoy, according to the *Western Electrician*, carried an incandescent lamp of 100-candle power, in a wrought-iron cage or lantern at the upper end of the spar, the lower end of which was fastened to a heavy cast-iron anchor. The current for each of these lamps was supplied from a small Westinghouse convertor of special design, placed on the upper end of the spar. These convertors were connected in series, the current for the entire series being obtained from a special Westinghouse convertor of 1,400 volts. This large convertor was placed at the outer end of the main pier at Jackson Park, where all necessary switches, &c., fuses, regulating devices, and Wurtz non-arcing metal lightning-arrestor were also placed. For this work a single-wire Bishop gutta-percha submarine cable was laid from the pier to the first buoy, then from this to the second and so on. From the last buoy at the city the cable returned by the most direct route to the pier at Jackson Park. It appears probable that this system of warning lights will, in the near future, be adopted for harbours on the sea-coast and for navigable rivers. The principle is clearly capable of great expansion and of application to a wider field.

The Palace of Fine Arts and its Exhibits.

OF all the buildings connected with the World's Columbian Exposition the Fine Art Palace was unquestionably the most perfect in every detail, and it would be difficult to refer to any other building elsewhere which surpassed it in beauty.

Description of the Building.

The building was in the Grecian Ionic style, and was a pure type of the most refined classic architecture, well befitting the exalted use to which it was applied. While the strikingly handsome and imposing exterior impressed every visitor, the effect was not in any way diminished by an examination of the interior of the building, and the whole work reflected the highest credit upon the architect, Mr. C. B. Attwood. The dimensions of the building were 500 feet by 320 feet, and the rectangle enclosed was divided into four large courts, separated by a central nave and transept. These were 100 feet in width and 70 feet in height, and at their intersection a dome was constructed about 60 feet in diameter. The building was 125 feet to the top of the dome, which was surmounted by a colossal statue of the type of the famous figures of the winged victory. The transept had a clear space through the centre of 60 feet, being lighted entirely from above, as I have explained elsewhere. On either side were galleries 20 feet wide and 24 feet above the floor. The collections of the sculpture were displayed on the main floor of the nave and transept; and on the walls, both of the ground floor and of the galleries, were ample areas for displaying the paintings and sculptured panels in relief. The corners made by the crossing of the nave and transept were filled with small picture galleries.

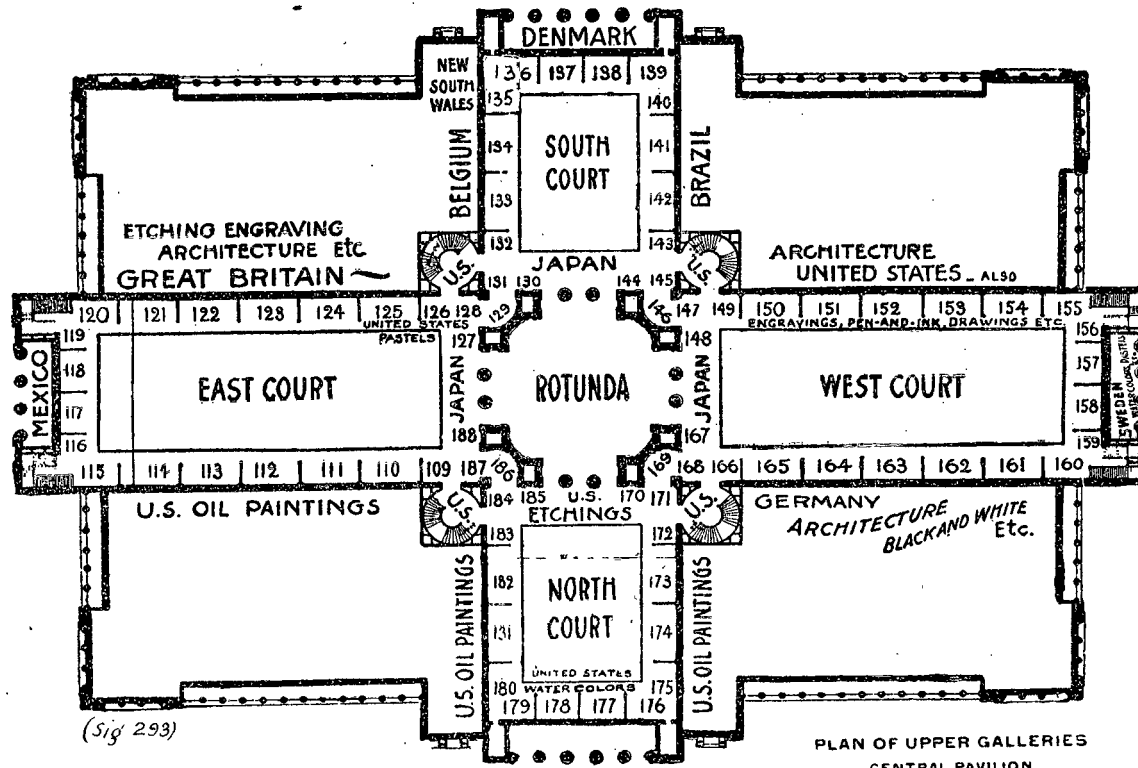

Around the entire building were galleries 40 feet wide, forming a continuous promenade around the structure. Between the promenade and the nave were the smaller rooms devoted to private collections of paintings, and the collection of the various art schools. On either side of the main building, and connected with it by handsome corridors, were very large annexes, which were all so utilised by various art exhibits.

The main building was entered by four main portals, richly ornamented with architectural sculpture, and approached by broad flights of steps. The walls of the loggia of the colonnades were highly decorated with mural paintings, illustrating the progress and the history of the Arts. The frieze of the exterior walls and the pediments of the principal entrances were ornamented with sculptures and portraits in bas-relief of the masters of ancient art. The general tone or colour of the walls was light grey stone. The construction was necessarily fire-proof. The main walls were of solid brick, covered with staff, architecturally ornamented, while the roof, floors, and galleries were lised. All light was supplied through glass sky-lights in iron frames.

The building was situated in the northern portion of the Park, with the south front facing the lagoon, from which it was separated by beautiful terraces, ornamented with balustrade, with an immense flight of steps leading down from the main portal to the lagoon, where there was a landing for boats. The north front faced the wide lawn and

ART BUILDING.

(Sig 293)

PLAN OF UPPER GALLERIES
CENTRAL PAVILION

and group of State Buildings. The immediate neighbourhood of the building was ornamented with groups of statues, replica ornaments of classic art, such as the Choragic Monument, the Cave of the Winds, and other beautiful examples of Grecian art. The ornamentation also included statues of heroic and life-size proportions. The annexes to which I have already referred on the eastern and western ends of the main building were each of the size of 120 feet by 200 feet.

In this building statuary was exhibited, as I have already said, in various parts of the ground floor of the building and elsewhere. In addition to Mattini's winged figure of "Fame," poised upon a globe over the dome of the building, this artist has placed several other works on the frieze; for example—"Architecture," a chaste figure, with a stern yet not unpleasing face, denoting intellectuality and study, the lines of her drapery being simple, and altogether different from the flowing robes of the voluptuous figure representing "Painting," every curve and line of whose face and figure spoke of gaiety and sensuousness. "Music" was represented by a pensive and poetic figure; while "Sculpture" was a more vigorous and robust figure than any of her sisters. On each side of these figures were two large-winged female figures holding garlands of flowers in their hands. There were two female figures on each side of the main entrances supporting the pediments to right and left of the doorway. These entrances were guarded by large lions, one on either side, designed by Theodore Baur and A. P. Proctor. The Royal Beast has been a favorite of architectural sculpture since the pomp and glory of the Persian Empire, and was employed to excellent advantage in the present case.

The east and west pavilions connected with the central pavilion by means of corridors were also used as galleries. The east pavilion contained the French Government exhibit, and also the French masterpieces belonging to American owners. The west pavilion contained the Italian exhibit and the exhibits of several other foreign countries whose space was limited. The central pavilion had two floors for the exhibit of paintings. The north-east section was given to the works of United States artists, and the south-east section to those of Great Britain. The south-west section contained the works of art sent by Holland, Spain, Russia, and Japan. The north-west section contained all the German paintings. In the galleries the water-colours were hung, as well as the overflow of oil-paintings. Between these four quadrangles were four courts and a central rotunda. The south and north courts contained the groupings of statuary, while the east and west courts contained the architectural exhibits. The central rotunda contained an heroic figure of Washington, by Thomas Ball, and on its sides were twelve spaces for figure-groupings furnished by different foreign countries.

There were also rotundas in each of the smaller pavilions, where statuary and architectural specimens were grouped. There were eighty galleries in all, including the east and west pavilions. These ranged from 30 feet square to 36 by 120 feet for the exhibition of paintings. There were also 108 alcoves, fronting on the court of the central pavilion, of which twenty-eight were on the first floor and eighty on the second floor, and much additional wall space was gained by their use. As regards the lighting arrangements of the building it may be stated that they were as faultless as could be devised. In all the pavilions, including rotundas, courts, and galleries, the modulation of natural light in the daytime was simple and effective. The system of artificial lighting at night was in itself a work of art, with its myriads of incandescent lamps shedding a mellow radiance over courts and galleries, and indeed the attractiveness of the art galleries at night was one of the features of the Exposition, but I have referred to this subject more particularly under the description of the lighting of the building in the account of the Electricity Building.

A remarkable charm to the effect of the edifice was produced by the water of the lagoon in front, which the architect had not been slow to make use of. The balustraded terrace of the broad flight of steps at the south front led down to the small lake in front, making a most imposing feature in the landscape, and it was one of the most creditable features of this Exhibition that the architects and those connected with the general designing and laying out of the grounds was the recognition of the important use of the landscape picture of which the ornamental waters of Jackson Park had been applied. As a matter of fact this was the first occasion on which it had been possible to make use of water on an extensive scale at an Exhibition; the natural conditions of the ground rendered it a necessity from the very first, and what might have proved a great drawback was utilised, not only for the purpose of landscape ornamentation but also as a provision for water-way communication from the artificial lagoons right out to lake Michigan.

A better representation from a greater number of different nations was seen in this building than had ever been brought together at any previous Exposition. The responses from various Governments and the enthusiasm of the artists everywhere provided a collection of the choicest productions of the World's great masters. Space was assigned to all the great countries in the World famed for the production of fine art productions. An idea of the scope of the fine arts exhibition may be gathered from the fact that it contained between 1,500 and 2,000 pieces in the American section alone.

In round figures France contributed 800 pieces, Germany 900, Dutch artists 300, England 600, Austria 300, Denmark 250, Sweden 200, Italy 600, Norway 180, and Belgium 400. There was also a loan collection of foreign masterpieces belonging to American owners, which were hung in three galleries at the west end of the east pavilion. They included all the illustrious names among artists, beginning with the dawn of this century and up to the present time—Millet, Rosa Bonheur, Carolus-Doran, John Constable, Millais, Meissonier, Alma Tadema, and a score of other famous names.

It was the aim of this department to exhibit a collection of the fine arts of the various nations so that each country might adequately represent its highest and most characteristic achievements in painting, sculpture, architecture, and decoration. In sculpture and architecture, figures and monumental decorations, bas-reliefs in marble or bronze, figures or groups in bronze, gems, cameos and intaglios were shown. Paintings in oil, paintings in water-colour, paintings on ivory, on enamel, on metal, on porcelain and other wares, and frescoe painting on walls were included within the grouping. And in addition there were engravings and etchings, prints, chalk, charcoal, pastel, and other drawings. All the works admitted to the department were first examined by juries duly constituted.

As I have already explained in a previous part of this report, I was unable to place all our exhibits in this department in the small allotment of space provided for New South Wales by the Exposition authorities; but in the space thus granted was placed the majority of the loan exhibits sent by the Trustees of the National Art Gallery. All our other exhibits were located in the hall and reception-room of Australia house. I have no doubt that they received much more careful examination there than if they had been placed in the art gallery, by the great numbers of people who thronged our building from day to day, and as the catalogues of these exhibits were one of the first that I received from Sydney the attention of critics was called to those pictures from the fact of their insertion in the official catalogue from the commencement of the Exhibition. It would be invidious for me to criticise these exhibits, but I may state that the popular attention

attention was greatly attracted to some of them, and many of the visitors expressed supreme surprise that anything so excellent could come from a country so young. In the visitors' books there were innumerable references to the pleasure and surprise of the various visitors, not only of America but also of other countries. Among the twenty-five sculptures selected by the artist correspondent of a leading American newspaper, the "Portrait bust of John Dillon, M.P." by Dr. McCarthy, placed in Australia house, was selected as a New South Wales representative of excellence," disclaiming any arbitrary standard, and calling special attention to these twenty-five, of which this representative was one for qualities inherent in each, but not as superior to all others in the plastic division of fine arts in Jackson Park." Especially did the beautiful water-colour representations of Australian flora attract attention from both the critic and the clown. I may here state that, in accordance with the provisions of the rules of the department, all the paintings and pictures, except those already so treated, were framed in gilt frames before being hung for inspection.

Entering the north court of the main building it was an easy matter to find the art exhibits of the different countries. Wide corridors or courts as they were called, as I have already explained, traversed the building from the four entrances, and converged at the rotunda beneath the great dome. At the right of the north court were the German galleries, occupying five rooms, numbered from thirty to thirty-five; the arms of Austria were above the door No. 36, and the exhibit, of that country, extended through the corridor leading into the west pavilion. Across the court, which ran through the palace from east to west, were the interesting exhibits of the Netherlands, of Japan, and of Spain, on the right hand occupying the entire south-west corner. Directly opposite was the fine art section, and, coming back across the east corridor was the representation of America, filling the rooms of the division and bordering the western wall of the east pavilion. The other sixteen rooms were the salon of France. The west pavilion was divided between the exhibits of Italy, Belgium, Norway, Denmark, Russia, and Poland, while Mexico and New South Wales were situated in the gallery.

The assignment of space was as follows:—

- United States—Galleries: 1, 2, 3, 4, 5, 6, 7, 8, 9, 37, 38, 39.
- United States—Foreign masterpieces from private collections: 40, 41, 42.
- France—43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58.
- Great Britain—12, 13, 14, 15, 16, 17, 18.
- Canada—10, 11.
- Russia—19, 20.
- Spain—21, 22, 23.
- Japan—24.
- Holland—25, 26, 27.
- Germany—28, 29, 30, 31, 32, 33, 34.
- Austria—35, 36, 59, 60, 61.
- Society of Polish Artists—62.
- Belgium—63, 64, 65, 66, 67.
- Sweden—68, 69, 70.
- Norway—71, 72.
- Denmark—73, 74, 75.
- Italy—76, 77, 78, 79, 80.
- New South Wales—
- Mexico—Space in gallery, south court: 134, 135, 136.

Architecture and sculpture shown in the rotunda, north, south, east, and west courts of the central pavilion, and in the rotundas of the east and west pavilions.

Water-colours, engravings, &c., shown mostly in the upper galleries of the central pavilion, 109 to 188.

The

The following was the classification :—

United States Section—Group No. 141, water-colours, 135 pieces; chalk and charcoal work, black and white, 517 pieces.

New South Wales Section—Group No. 139, sculpture, four pieces; oil paintings, 103 pictures. Group No. 141, paintings in water-colours, from Sydney, 119 pieces. Group No. 144, chalk, crayon, pastel, etc.

British Section Fine Arts—Group No. 139, sculptures, fifty-three pieces, containing the best specimens of Leighton, Woolner, Thornycroft, Swan, Rhodes, MacLean, Albert Bruce Joy, Goscombe W. John, Frampton, Fehr, Dressler, Allen, and Ford. Group No. 140, paintings in oil, 475 pictures, seven pictures by Sir John Millais. Group No. 141, water-colours, 205 pictures. Group No. 143, engravings, etchings, and prints (many artists' proofs), 193 pictures. Group No. 144, chalk, charcoal, pastel, and other drawings, seventy-four pieces. Architecture, 145 drawings.

Austrian Section of Fine Arts—Group No. 139, sculpture, nineteen pieces. Group No. 140, paintings in oil, 107 pieces. Group No. 141, water-colours, eighteen pieces. Group No. 142, paintings on ivory, enamel, metal, porcelain, and other ware; fresco paintings on walls, five specimens. Group No. 143, engravings, etchings, prints, seventeen examples. Group No. 144, chalk, charcoal, pastel, and other drawings, four pieces.

Brazil Section—Group No. 139, sculpture, six pieces. Group No. 140, paintings in oil, sixty-eight pieces. Group No. 145, antique and modern carvings, engravings in medallions or in gems, cameos, intaglios, seven pieces.

German Section—Group No. 139, sculpture, 120 pieces. Group No. 140, oil paintings, 421 pieces. Group No. 141, paintings in water-colours, eighty pieces. Group No. 143, engravings, etchings, and prints, fifty pieces.

Italian Section—Group No. 139, sculpture, eighty-nine pieces. Group No. 140, oil paintings, 202 pictures. Group No. 141, water-colours, forty-three pieces. Group No. 144, chalk, charcoal, pastel, and other drawings three pieces.

Danish Section—Group No. 139, sculpture, twenty pieces. Group No. 140, oil paintings, 159 pictures.

Russian Section—Group No. 139, sculpture, 139 pieces. Group No. 140, oil paintings, 111 pieces. Group No. 141, paintings in water-colours, three examples. Group No. 145, antique and modern carving.

Japanese Section—Group No. 139, sculpture, fifteen pieces on copper, bronze, marble, &c. Group No. 140, oil collection of 140 paintings. Group No. 141, water-colours, 156 paintings. Group No. 142, paintings on enamel, ivory, metal, porcelain, or other wares, and fresco paintings on walls, six examples. Group No. 144, etchings, engravings, and prints. Group No. 145, ancient and modern carvings on gems, &c.

Norway Section of Fine Arts—Group No. 139, sculpture, seven pieces. Group No. 149, paintings in oil, 117 pieces. Group No. 143, engraving and etchings. Group No. 144, drawings.

Belgian Section—Group No. 139, sculpture, forty-six pieces. Group No. 140, oil paintings, 214 pictures. Group No. 141, water-colours, seventeen pieces. Group Nos. 143 and 144, engravings and etchings, nineteen pieces.

Groups Nos. 143 and 144, engravings and etchings, nineteen pieces. Loan collection of foreign masterpieces in United States, 161 specimens. United States sculpture, 137 pieces. United States paintings, 800 pieces.

Holland Section—Group No. 140, paintings, water-colours, bronzes, &c.

Foreign artists had a powerful incentive to send their best work to America because that country had established a reputation as the best art market of the world. At no other time and at no other place had an artist received the stupendous price for a picture that an American millionaire has been willing to pay, but the climax was reached in this great exhibit.

The simple enumeration thus given will be sufficient to show the impossibility of portraying in the faintest manner any representation of this wonderful collection of the fine art exhibits of the leading countries of the world; and the information on the subject furnished in this report must be considered as only an indication of such main features as have occurred to me after careful personal examinations of the exhibits of the various courts.

General Remarks.

I have always been of opinion that there are at least two leading principles which ought to characterise or ought to be found in works of art; there should be the decided expression of national sentiment,

as

as a palpable influence affecting both the artist and his works; and there should be the expression of that which is beautiful to the eye, or the production of objects which are beautiful in form or colour. I am aware of the imperfection of this definition, and I am aware also that to a large extent it would exclude portraiture as it is generally practised. It is true that a portrait may be entitled to rank in the highest plane of pictorial work; a portrait by Rembrandt, if imbued with his splendour of colour and power of characterisation, must undoubtedly be classified with other examples of the highest craft of the painter. But when neither subject nor depicitor is above the commonplace, as was the case with hundreds of the portraits exhibited in the Art Palace, and is often seen elsewhere, I am not surprised to learn that juries have sometimes considered the wisdom of excluding portraiture altogether from exhibition, although obvious difficulties would attend such a course.

Referring now to the first element of excellence in fine art productions, it was a surprise to find the very marked absence of national sentiment from the very extensive collection of paintings in the American section. "Do your artists care nothing for your republic?" was the query a foreigner uttered after he had walked through the American galleries. "After I had seen the national exhibitions of all the foreign countries exhibiting with us, and had seen our own national exhibit, I felt like a man without a country," was the exasperated comment of an American who went to Jackson Park with high hopes of American art. In the British and other sections there could be no hesitation on this subject in regard to this point, and in some of the pictures the national pictorial art presented a close analogy to the literature of the country permeated with national qualities. Frank Dicksee, in his beautiful canvas "The Passing of Arthur," was English to the backbone. So were Hubert Herkomer in the "Last Muster," and Lady Butler in the "Roll Call." In both these pictures there were, it was said, portraits. That fact was less important than the truth of the general composition, the accuracy of its details, and the spirit with which such pictures revive the past glories or defeats of a nation. The "Taxidermist," by Sir Frederick Leighton, might or might not have contained portraits. The models who sat for its figures were English, the time, the interior, the accessories of the profession it illustrated were all English. Ford Madox Brown's "Romeo and Juliet" was national, although the subjects belonged to another age and another country; the creation of them in literature was the work of an Englishman. Frith's chromish series, the "Spider and the Flies," a leathery quaint, imitation of the Hogarthian principles of morals taught by frightful examples, was English because it told an English tale in English houses, in English costumes of a past period, and in cockney English of art.

Passing from Great Britain to Holland we find the national spirit glorious; and, truly, where the national spirit is glorious the art is spontaneous and superb. Among the 200 paintings in oil there were not a dozen that were not racy of the soil. In some respects the Dutch pictures, especially the marines, were as fine as any in the Fine Art Building. Peroff, in many respects the greatest of Russian painters, was gold-medalled in St. Petersburg, and received a travelling scholarship. He went to Paris, the Mecca as it is to-day of all students of art. After remaining there some time he wrote home that he could not complete a single picture because he failed to comprehend the life and character of the people. "It seems to be less useful," he wrote, "to devote a certain number of years to the study of a foreign country than to study and work out the immense wealth that is hoarded in the villages and cities of my own." Peroff returned to Russia to become the first, if he is not still the foremost, of the interpreters of Russian life in its sombre and profound truth.

In

In the Italian section were exhibited coloured colossal busts of their King, and a resplendent portrait of the reigning Pontiff—a beautiful work by Guardabassi. Their genre painters, as exhibited, gave Italian life from receptions in Doge's Palaces to the gaities of the village tarantella, and the wild grief of the peasant mother over the death of her babe. Corelli's "Ava Maria" was an epic handling of what Millet handled in a lyric manner, the "Angelus." In all qualities of fine descriptive painting the Italian work was very excellent. The "Venetian Sunset" of Ciardi was one of a beautiful group in which aliens who paint Venice were superbly rebuked for their extravagance of atmosphere.

Norway, Sweden, and Denmark were national in their pictures. The spirit of the North presided and the legends of the North pervaded the imagination and informed the taste in their paintings. The spirit was that of the ancient domain of the Scandinavian myth; of the schools that now bespeak the Scald and Saga, the Norseman, the Viking, the land of the Midnight Sun, the waters that sent down the first pirates and merchants of the midland seas and began the history of commerce by rage and pillage.

The German fine arts exhibit was a pæan to German glory. German mythology, German wars, German peace, German religions, German fables, German folk-lore, German music, German science, German drama, German literature, German sacrifices, German love, German retribution, German landscape, German rivers, German interiors, German romance, German heroes, German leaders—friends and foes alike; kaisers, chancellors, and pope; emperors, generals, poets, German festivals, German sorrows, German pleasantries—these filled the German section of Fine Arts. Meditating thereon, one can understand the irresistible strength of the passion for Fatherland that hesitates at no loss when national honour is at stake.

The magnificent collection of paintings in the French sections represented the characteristics and their national life and history as well became the country which undoubtedly at this time leads the world in this department. The works of the French masters were very cleverly disposed in splendid array, divided in three separate classes. On this occasion all the different schools appeared in the same hall, and Gérôme, Detaille, Maignan, Flameng, La Touche, Bonnat, together with a number of other well-known artists, exhibited pictures well worthy of their fame and talents. Amongst the loan collection of pictures was a painting of sheep by Rosa Bonheur, now a septuagenarian, living at Thomery, near the forest of Fontainebleau, where she has a stock pasture and a great studio. As is well known, she has long enjoyed the distinction of being the most powerful painter of animals. The stable in which her models rest is the ante-chamber of her studio and farm, and were protected from injury by order of the late Emperor Frederick during the Franco-Prussian war. It may be suggestive of the possibilities of women in art that of twenty-five works thus selected on broad principles the one depicting military life and that of the animated life of animals were both by women. I have no doubt that neither would have consented, if asked, to be put off in the women's collection. Very clearly neither of these ladies was a woman with a big W, but each was an artist with a big A.

Referring now to the second of the leading characteristics of Fine Arts—the introduction of the ideal in form and colour—it was noticeable in the modern exhibits of painting and sculpture that the interest in the beautiful was largely supplanted by a desire to express the truth. In the art exhibits of different nations at the World's Columbian Exposition (which may be considered as the latest movement in art) there was shown a predominance of the intellectual and scientific over the ideal and the sensual. The painters especially seemed
more

more desirous of recording facts than arousing emotions or arousing admiration. Sculpture, which must be produced by slower processes and of more enduring materials, had not been so readily influenced by the spirit of the times which had left its mark on the paintings. In the sculpture there were many works which showed that romanticism and classicism have still a strong hold on artists; and it was in the sculpture that a lover of the beautiful found most to satisfy him, in spite of the fact that colour appeals more strongly to the senses than form. The highest form of beauty is generally admitted to be the physical beauty of women, and when the term "a type of beauty" is used it invariably applies to a beautiful woman, or her likeness. Occasionally one met with a beautiful face or form among those portrayed in the work of the painter represented in the work at the Art Palace; but it often happened that the result was due as much to the natural beauty of the artist's model as to anything else—in other words, it was the result of selection rather than creation.

The type of beauty is often one of the characteristic signs by which the identity of an artist in his work can be recognised. The face of Saskia van Ulenburg, in a composition by Rembrandt, is often better evidence of its authenticity than a signature. Even in the faces which Leonardo da Vinci painted before he met her, there is a resemblance to the embodiment of his ideal of womanly beauty, which he afterwards found in Mona Lisa. Gainsborough's portraits seemed to bear a family resemblance to each other, and many other painters unconsciously or intentionally give to the faces or the figures of the women in their pictures something of their ideal.

In the British section the most striking examples of ideal beauty were shown in the classical compositions of Sir Frederick Leighton. It was in the willowy, somnolent figures of the Hesperides, clad in flowing drapery, the folds of which constituted a mark of identity in the work of this artist, that the type was most pronounced. The artist has represented

the gardens fair
Of Hesperus and his daughters three
That sing about the golden tree.

They were seated on the ground, with their pliant forms encircled with the coils of the dragon Landon, who assists them in guarding the golden apples which Hercules sent Atlas to seek while he performed Atlas's task of bearing up the heavens on his shoulders. In the pictures of Alma Tadema depicting scenes of antiquity there were some beautiful figures, but they were essentially English, just as the characters of Bulwer are English people in antique costumes and posed against a Pompeian background. Hans Makart has shown in the "Five Senses" the delight he took in the sensuous beauty of extravagant brilliancy of colour and voluptuous form. The figure personifying "Sight" looking into a mirror which she holds in her hand had perhaps more grace and finer proportions than the others. In his "Falcon Woman" there was a strange type of beauty: the face was fair, the features regular, and the pose pleasing, yet there was an indication of cruelty in the curve of her lips, and a baleful light shone in her large greenish eye. It seemed as if the artist had intended to express some of the characteristics of the hawk in the woman, and the title the "Falcon Woman" may have had a deeper significance than the fact that she carried a hawk on her arm. In Rudolph Bacher's picture "Ave Maria," in the same section, one found the earthly and ideal beauty contrasted in the faces of Mary and the Angel who comes to her bearing a lily. There was one picture in the German section which never failed to excite the admiration of women visitors. It was Paul Thumann's "Psyche," a pretty blonde figure, with gossamer wings, leaning over to look at herself in the water.

In

In Siemiradski's "Phryne," in the Russian exhibit, the artist gained his conception of a woman noted for her grace and beauty, who was chosen to personate the goddess of love and beauty at a feast given in her honour. The Polish artist Zmurko's cleverly-painted "Lady in Fur" was a beauty of the ingenuous type. Another Polish artist, Alchimowicz, exhibited "Milda, the Goddess of Love," of Lithuanian mythology. According to legend, she fell in love with a young fisherman, for which she was punished by the god Perkun (Thunder), who killed the fisherman and destroyed the amber palace in the depths of the Baltic Sea. Among the paintings by French artists there were not to be found so many examples of physical beauty as might have been expected in the exhibit of so great an art-loving people. With the exception of Bouguereau's immaculate virgins and cupids, most of the figures in the paintings of allegorical subjects, as Collins's "Youth" and "On the Sea-coast," L. Lamy's "Flowering Spring," Madeleine Lemaire's "Fairies' Car," and Dubufe's "La Fourmi," the beauty, when there is any at all, was altogether too Parisian to be considered as representing the French conception of ideal beauty. But in the French sculpture beautiful figures abounded. Chapu's "Jeanne d'Arc" had a face indicative of moral and spiritual as well as the beauty of outward form. Paul Dubois's figure of a young warrior, "Military Courage," was a fine type of manly beauty and strength, and his "Charity" was a fine example of the beauty of maternity. "La Cigale," by Marquestre, was a charming figure of a young girl, and there were many other examples illustrative of this point.

ADDITIONAL REMARKS ON FINE ARTS.

Fine Art of Russia.

Russian Art exhibited in almost every picture the depression and hopelessness of the people and the effects of political despotism. The problems that vex the philosophy and confound the fiction of Russia appeared to be the subjects of her pictorial art for the most part. In other national exhibits in the Fine Arts Building the brighter side of human life was found interspersed among illustrations of its dejections or its pathos; but in the Russian exhibit sorrow pervaded every canvas, either directly and avowedly or incidentally. In this respect the exhibit, though it was comparatively small, must be accepted as representative, because the Commission for Fine Arts had practically unlimited freedom to choose among the works belonging to the Emperor and to the National Academy at St. Petersburg. An analysis of the collection disclosed the generosity of the Czar who had sent over two of his most private possessions of the art of his own country and time, Repine's prodigious "Cossack's Reply" and Siemiradski's huge "Frina," which occupied the places of honour in the main gallery. No picture can enter the Academy at St. Petersburg as its property without the Emperor's approval, and none can be lent out of its precincts except by his consent. From the Academy, and therefore stamped with the seal of representative character, were a large number of paintings. These pictures therefore must be regarded as truly indicative of the character of Russian art. In all these pictures, as well as those of individual artists forwarded, exactly the same strains were wrought out in various forms. The "Celebration of the Sabbath," by Ashnazy, indicated by a prim and restrained woman, a Slav puritan, before lighted candles, self-suppression and anxiety depicted on a straight-laced face and imparted to a stiffened body. In another work by the same artist depression was illustrated in a totally different key. "A Talmudist Bridegroom" was on probation. The young man, dejected and reserved, was evidently paying a periodical visit to his expected father-in-law to report on his behaviour and to give proof of his worthiness of the bride. All the faces were unhappy and most of them peevish. In Herzke's "Jew from Kovna," a capital bit of portraiture, there was the misery of the race concentrated in a pair of eyes to which the artist had imparted cunning, grief, guile, and distress.

Spanish

Spanish Art.

The exhibit of paintings in the Spanish court was somewhat of a surprise and disappointment. An exhibit can scarcely be called national in which, representing this age in Spain, there was no example of the brush of Fortuny, none of the greater Madrazo and nothing of the greater Villegas. If the object of the collection had been to depict the lack of national character in painting in the line of true descent from its greatest masters, the 130 Spanish pictures might be relied on for that purpose. The impression the collection made was that the art of Spain, as illustrated at Jackson Park, was sterile on the ideal side; that it relied chiefly on literary interest for subject matter; and that its best technique was French. The voice was the voice of Spain, speaking from its romance and its history, but the hand was the hand of a salon.

From the Spanish capital five works were sent to Jackson Park, all from the National Museum of Painting and Sculpture. "Isabella, the Catholic, dictating her will" by Eduardo Rosales, was a pleasing example of historical genre which is too prevalent a choice with Spanish pictures of the present time. "The Lovers of Teruel" was a gruesome work, consisting chiefly in its dimensions and its painting of textures and bric-a-brac, by Don Antonio Munoz-Degrain. The third picture sent by the Spanish Government was "The Conversion of the Duke of Candia," by Jose Morino-Carbonero, who was also represented in another room by several interpretations of Spanish literature, all showing daintiness of feeling, pleasant humour and French tone.

The rest of the pictures were devoid of special characteristic significance.

Dutch Art.

While there existed a great contrast between the paintings of the modern Dutch artists exhibited at the World's Fair, and the works of the early Dutch painters, yet in a roundabout way the spirit of the old dutchmen, though changed and modified, can still be observed in the works of their descendants in art. The influence of the Frenchman of the Fontainebleau school, as far as the manner of painting is concerned, was observable; but throughout the whole of these paintings there was clearly indicated the desire to penetrate deeply into the secrets of nature, and to glorify the simple beauty and the sentiment the artists found in the landscape of their country, and the lives of its peasants and fishermen. In the work of Joseph Israels, who is generally looked upon as the leader of the modern Dutch school, Dutch peasant life was depicted with art and sentiment, just as in Millet's paintings one finds the story of peasant life in France. His "Alone in the World," was not only one of the most pathetic subjects in the Exhibition, but was fine in tone and altogether a distinguished piece of painting. It was a fine work, both in a literary and in a technical sense. When one looked at the figure of the old man worn with labour, seated by the bed-side of his dead wife, who had been his companion in a life of toil, the observer was impressed by the fact that the realisation had come upon the old man that he was truly alone, and that all that remained for him in the emptiness of the world were his memories. In the scenes of peasant life by Albert Neuhuys, the subjects were generally cheerful, and the colour richer than in Israel's works. His "Sober meal," showing a family of peasants at dinner, possessed that remarkable richness of colour and quality of painting which makes a picture intrinsically beautiful, and the subject was also well expressed and the figures admirably drawn; it certainly was one of the masterpieces of the collection. Besides these artists there were a number of paintings by Blommers, Offermans, landscapes by William Maris; architectural subjects by Klinkenburg; winter scenes were shown by Louis Apol and Bakhuyzen; while Poggenbeck

Poggenbeck and Mauve, as well as a number of other Dutch artists were fully represented. In fact the exhibit of Dutch art at the Columbian Exposition was of excellent character, as only artists of acknowledged merit and reputation were invited to participate, and a special effort had been made to secure the best examples of their work procurable.

The Loan Collection of Foreign Masterpieces.

While there were so many oil paintings in the Fine Art Palace, exhibiting examples of the work of the leading artists of the great art centres, and showing the tendencies of the different schools, the aims of individual artists and the probable value of the experiments in art which are now being made, the Loan Collection, containing the foreign masterpieces, the work of sixty-seven painters, living or dead, gave assurance that there are laws governing eternal beauty and that many painters have not sought in vain for them. Many of the artists were represented by several examples of their work. There were, for example, eight of Millet's pleasant pictures—the "Man with a Hoe," in all his deadly hopelessness; the "Shepherdess," the "Gleaners," the "Sheep Shearers," "Peasants Carrying a New-Born Calf," the "Haymaker," the "Pig Killers," and "After the Bath." After seeing these peasants, with their stolid faces and stupid movements, one feels how the sacred human soul can last through generations of toil and privation and realises what a painter Millet was.

There were also ten landscapes painted by Corot, in his own inimitable manner. It must be inimitable, for in spite of its great beauty no one of the younger artists is attempting it. They seem to realise that it was not any method or trick of the brush, but Corot's own nature which made his pictures what they are. The collection includes the great "Orpheus," the exquisite "Dance of the Nymphs," a bit of woodland with a white morning dawning over it, "The Path to the Village," with its blue sky, the big mysterious "Evening," from Jay Gould's collection, and another lovely little picture of the same subject, showing the black-green trees and the bowed peasant with the speck of red which forms his cap. The lonely "Shrimpfisher," the old-fashioned "Environs of Villa d'Auray," "The Inn," the little gem designated only as "Landscape," are all in the manner which is distinctively Corot's. The "Flight from Sodom" and the "Old Man Seated on Corot's Trunk" are somewhat different.

Seated on a bench in these rooms there was before one a group of little pictures by Delacroix, Corot, Rousseau, Millet, Daubigny, and Meissonier. Such an opportunity for comparison and distinctions was rare, and was also such a possibility of enjoyment. The Meissonier was a charming landscape in light bright greens, a "View Near Poissy." The only other Meissonier in the collection was the "Reconnaissance." The only Fortuny was the "Beach at Portici, Italy," a perfect blaze of light and life and colour, with a bright blue sky and great white flecks of clouds, making one feel that the vivid, passionate life of the Spanish land was present with Mariano Fortuny. Another picture of somewhat this tone was by Michetti of Naples. "Spring-time and Love" was its title, and it held a blue sky and a blue sea, with a grass-covered cliff and a slender tree with its long branches in rosy bloom, and the abandon of youthful figures joying in the sunshine.

For Gérôme there was "L'Emminence Grise" and "The Serpent Charmer," wonderful things. The powerful monk with his crafty, watchful vanity under the humility, has been shown in black and white reproductions with some little success; the "Serpent Charmer," with its blue background and some of the frescoing of the wall worn off, leaving bare brown spots, the row of the clear cut brown faces of the Sheik's party seated at the base of it, the inspired old heathen playing, and the tall slender boy holding up the snake in the background, was to be remembered long. In

In addition to these there were several paintings by Raffael, Carolus-Duran, Rosa Bonheur, L'Hermite, Monet Breton, Rousseau, Watts, Alma Tadema, Constable, Barrington, Morland, Israels, Knaus, and many other celebrated artists.

Water-colour Exhibit.

The water-colour exhibit taken as a whole was only moderately fine. It did not compare favourably with the exhibit in the stronger medium and was inferior in drawing and composition to the black and white, especially the etchings. The strongest effects in the lighter medium and in pastel were to be seen in the Italian section; the weakest in the British, but this latter section contained many admirable and beautiful aquarelles. It was to be regretted that Whistler was not among the aquarelle exhibitors. A little sheet of notepaper, with half a dozen brush touches by his hand, the very shorthand of pictorial effect, contains more idealism than a yard by water-colourists who might be named and who were to be seen on the walls at Jackson Park. Concentration is the very essence and the very soul of line, and since in the lighter medium line is the chief reliance of the artist, he who can crystallise most succinctly is the most valued. It is a paradox of water-colour work that the Italians alone carry it to its extremes. They use the medium lavishly. They are not afraid of elaboration, and they maintain a simplicity and strength—the masters that is to say—even in animals in which they are not approached by the Spanish or French who come next to them in this department. On the other hand the Italian bad water-colour is a worst possible deception. It is a waste of good paper under ineffectual colour and too often illiterate drawing. One of the queer vices of mediocre Italian water-colour is the inability of the draughtsman to put a correctly drawn head on duly proportioned shoulders. In many examples, the heads were nearly always too large even in fairly good work and seemed to be drawn by another hand than that which had produced the accessories or the draperies.

That alertness in draughtmanship which is involved in the basis of water-colouring is a natural trait of the French artist. The chic which most people eagerly demand in the tone of water-colour paintings is also pre-eminently French. The French water-colour school was not exhibited representatively at Jackson Park. Of the Society of French water-colourists who have their own special exhibits every year at Paris, which they call the Salon of French Aquarellists, considerably less than one half the membership was represented at the Columbian Exposition. At the Paris Exposition there were 114 artists in aquarelles, pastels, engravings, and medallions while at Jackson Park there were 550, but there were absent the works of a large number of the most famed representatives in this department. There were also water-colours by painters not identified with the French Society amongst which the Chef d'Œuvre of the French water-colour exhibit was the pastel entitled "L'Été" (Summer) by Mme. Marie Cazin.

The pastel is truly one of the most popular enemies of true art, and the safety of the pastellist, like the shelter of the water-colourist, is economy in dimensions. Mme. Marie Cazin, justly fearless in conscious power, has given her hand free scope in this charming composition as if she were handling clay or tubes. The scene was idyllic, the sea-shore, cool but not cold, a grey and lavender sky, accentuated with light indigo, rocks drawn with remarkable freedom, mothers and children, all blending in a summer scene of tranquillity, purity, and poetry. It possessed above all other qualities that of ideal beauty, that is to say, beauty of colour, beauty of line, beauty of physical elements, combined with the beauty of moral elements—the sweetness of motherhood, the innocence of childhood, the profound peace of nature, and the sublime custodianship of the sea which one feels

feels to be in the hands of God when infancy is left playing on its protecting sands. There were also some works very characteristic in tone by Boutet de Monvel and one water-colour by Edward Detaille, so well known by his depictions of military life. The decorative quality of water-colour painting was carried to a high degree by Madelaine Lemaire in two examples, "A Ball in 1830" and "A Farewell." While the first was necessarily little more than a fashion plate, it was painted with so much brilliancy as to command intense admiration, and it served also to show that after exactly sixty years women's costumes have got back to the fashions then in vogue. The second example was a sentimental subject, two men going away in a boat on a river and two young women bidding them adieu from the shore. There was a graceful blending of landscape with water, a happy general romanticism, marred a little by slightly defective drawing in one of the female figures. Madame Lemaire has been recognised for some years as the foremost of the women artists of France in water-colours and etching.

The Russian water-colour exhibit contained a large number of pictures, but, unhappily, they, like the oil paintings from that country, were characterised by the hopeless sense of sorrow which would appear to be a dominating characteristic of Russian art. The water-colours by Sokoloff were vigorous and well composed, the drawing was excellent, and a thoroughly artistic instinct was apparent in every touch; the subjects, however, showed clearly the unhappy strain to which I have just referred. There was the "Funeral of the Peasant," "A Country Inn," in which there was an indication of joviality, but it was brutal, and there was "A Private Supper," which was a coarse carousal. The "Charcoal Seller," a beautiful piece of colour, exquisitely harmonious, a lovely blending of sky and landscape, horse, a waggon, and drunken merchant was still another indication of what art finds most to express in Russian life—its hardship, its stupor, and its hopelessness.

Exhibits of Sculpture.

The collection of sculpture at Jackson Park was undoubtedly inferior to that of painting, and it was a common observation and a regret that many of the great modellers of the age were not represented. Neither Russia nor Italy exhibited sculptures such as might have been expected. Great Britain has never been so strong in sculpture as some of the Continental nations, but some of her best productions were shown at this Exhibition. The supremacy of Mr. Gladstone in the thought of his country was curiously disclosed in the British section. He was modelled by four of the most distinguished living British sculptors. A colossal figure of "The Grand Old Man" was shown in Donegal Castle, Midway Plaisance, by Bruce Joy, and this artist showed his impartiality by exhibiting the Marquis of Salisbury in the British sculpture section in the Fine Arts Building. Onslow Ford's Gladstone, a bust, was in the rotunda, as was Albert Toft's bust. The late Thomas Woolner made an excellent presentment of Gladstone, which was one of the group of works by him in the British exhibit. While all were good enough portraits, as portrait busts go, the face of the Joy colossus was exceptionally strong, "the fierce light that beats upon a throne" from the blazing old eyes being admirably caught in the treatment of the features. Hamo Thornycroft's "Mower" was perhaps the best figure in the entire British collection. It was free, supple, and alert, the type was muscular, but not heavy, and the action was spontaneous and direct. Sir Frederic Leighton indulges in sculpture as a luxury. He has modelled several notable groups, "An Athlete strangling a Python" being the best, while his "Sluggard" was modelled a dozen years ago, and is a fine study in anatomy.

The dramatic trend of French sculpture was redundantly demonstrated at Jackson Park. In many exhibits the action degenerated into

into violence or sank into maudlin struggle for theatrical effect, notwithstanding this defect and the other of neo-hellenism without Greek spirit, the French exhibit in plaster, marble, and cireperdue was strong, varied, and striking. The vigour of prevalent sculpture in France runs unfortunately to huge works, just as the painting for some time has consisted of canvasses too large in dimensions. Not the least valuable portion of the French sculpture exhibit consisted of the plaster cast of monumental architecture and ecclesiastical reconstructions which depicted the architecture of France from the eleventh to the nineteenth centuries, and were themselves a school of design. In this country's space were the "Age of Iron," by Alfred Lanson; "Quand même," by Antonin Mercié; and two examples of the work of Barrias, which were very excellent.

The exhibits of Germany contained many noble conceptions, for the most part well executed; "Saved" and "Eve," by Brütt; "The message from Marathon," by Max Kruse; and the "Von Moltke," by Bruno Kruse; were excellent productions of the sculptors' art. There were also a few good specimens of American sculpture.

In a room facing the central Corridor of Sculpture in this building there were some sculptures by Auguste Rodin, the celebrated French sculptor. The most remarkable were two illustrations of the Portal of the Museum of Decorative Arts, in Paris, a work which has aroused extraordinary fervour in artistic circles everywhere. This work was wonderfully beautiful and executed with the great delicacy peculiar to France's greatest sculptor. To appreciate their relation to the portal as a whole it is necessary to give a brief description of the entire work. The door is a series of dreams in bronze, not a mechanical or literal transcription of any portion of the Inferno, but a coherent and terrible presentation in appropriate symbols of the awful lessons it teaches of human sin and its consequences as seen by Dante. He calls it himself the "Door of Despair." It is an appalling summary of the universal tragedy of human existence. The lintel is surmounted by a group of nude, emaciated, and miserable figures, and below the cornice there is an image of man contemplating the terrible web of human destiny. The central panels contain clouds of figures whirled through space in irregular masses, with sudden flashes of light and depths of shadow, apparently incoherent, but actually having a subtle, philosophical, and artistic relation.

On the door-posts there are reliefs on a larger scale. One plane symbolises those who died without sin but are excluded from the light of heaven. Children, unconscious of disaster, caress their parents. Sinful death is illustrated in the groups of Paolo and Francesca, of which the two copies are in the Fine Arts Building. The first expresses illicit rupture of the lovers, the second their eternal torture and hopelessness. The story has been told by Boccaccio, Leigh Hunt, Sylvio Pellico, and others. Guido, Lord of Ravenna, gave his daughter, Francesca, in betrothal to the eldest son of Malatesta, Lord of Rimini, as a condition of peace. The bridegroom, being deformed, deceitfully sent his young brother, Paolo il Bello, as a proxy to be betrothed to Francesca and bring her to her future home. They fell in love and were put to death. Dante recalls this incident in the fifth canto of his "Hell." Francesca's reply to Dante's inquiry contains the original of Tennyson's "Sorrow's crown of sorrow is remembering happier things."

With these two groups is a third, "Andromeda." These marbles, seen detached from that of which they are a part, would naturally offend, and it was wise on the part of the authorities at Jackson Park to protect them from misjudgment as well as from injury by placing them in a private room away from the general exhibits.

Bronzes.

Bronzes.

In the bronze section of Fine Arts, Russia, France, Italy, Germany, Japan, and the United States were all well represented.

Amongst the Russian bronzes several were thoroughly characteristic of the country of their origin. There were exhibited a score or two of examples of the work of the late celebrated Eugene Lanceray, together with the latest achievements of Professor Bach, Ober, Gatscheff, and other academicians who are at the present time the exponents of the bronze art of Russia. A remarkable Russian conception of art in bronze was Ober's figure of the Cossack Dimitri Peschkoff, mounted on his horse "Gray," after he had done his memorable six months' ride of 5,488 miles through Siberia.

Two of the greatest bronze-founders in France were represented—Thibaut Frères and Le Blanc Barbedienne—with half a dozen smaller firms, who are rather intermediaries between the artists and the public than producers. An indication of how important an element bronzes are in the art and manufactures of France may be gathered from an inspection of the list of the principal works executed by Thibaut. These included about 250 public monuments erected in every continent in the world; of two dozen equestrian statues of equally wide distribution; thirteen great public fountains; thirty-eight animal groups, some life-size and some larger; 180 statues, chiefly ideal subjects of "natural size"; and subjects innumerable of smaller artistic and of purely commercial bronzes. The works produced by this firm bear the names of more than a hundred sculptors of established fame in this generation and the last, and their subjects illustrate very clearly the traditions and tendencies of French art in bronze. The Russian bronzes are the product of originals in wax models for the sole purpose of reproduction. The French bronzes have their beginning sometimes in a marble original, sometimes in a study in plaster. For example, that fine work of Barrias, "The First Funeral," was seen in a cast exhibited in the Art Gallery, and again in a reduced copy in bronze in the French Court in Manufactures Building. Both were executed under the eye of the artist, and the bronze was by no means the least faithful exponent of the beauty of form and depth of feeling of the original. Boucher's "A la terre," a wonderful study of the muscular action of the primeval toiler, was exhibited in plaster in the Art Galleries, and in bronze in the Barbedienne Pavilion. Auguste Caine exhibited three of his superb animal groups, one in bronze and two in plaster, side by side in the collection of sculpture. In France, in short, the medium is a secondary consideration; the art is strictly that of the sculptor.

Consequently the artistic bronzes of France deals mainly with the ideal, and in many cases the sculptor is so intent on preserving the artistic stamp on his work and preventing its duplication that he models it in wax and has the wax burned out of the mould before the metal is poured in. This, of course, is the well-known "Cire Perdue" or lost wax, process, a method of casting in metal as old as the Greeks, and of such curiously wide diffusion that the Cherokee Indians of the United States of Columbia are known to have used wax or resin in the models for their gold images. For the production of delicate details the process has some advantages, and is obviously well adapted to make a bronze unique by the destruction of its original. A bold and striking conception of "Mephisto," by the Russian Antocolsky, was exhibited in the Thibaut exhibit in the French Court of Manufactures as an example of this latter use of the lost wax process. One of the Barbedienne foundry exhibits deserves special mention. It was a large statue of Charles V. The armour of the Emperor could be taken off and a perfectly modelled body was revealed.

The

The Italian bronzes were divided between dignified and serious reproductions of statues and busts from the Vatican, and other collections and rather frivolous groups copied from modern pictures. The French keep the "Bronze de Fantaisie" in strict subordination; the Italian fairly run riot in it and detract still further from the essential dignity of bronze by the free use of silver and gilt on its surface. Among the innumerable small pieces in bronze of this country there were a number of decorative articles modelled on the work of Benvenuto Cellini and his school. But these, like many of the other Italian exhibits in the sphere of art, merely emphasised the fact that the craft and spirit of the renaissance is as dead in Italy to-day as are those of the classical antiquity from which they drew their inspiration.

The commercial bronzes of Germany exhibited bore but little of the stamp of art, while the artistic bronzes were such as would not commend themselves to commercial distribution. One might covet a reduced copy of Max Kruse's "Messenger from Marathon;" of Brütt's fisherman carrying in his arms the girl rescued from drowning; or of Herter's study of the other fisherman, who has caught "a fish rarely be met with"—a mermaid to wit—but the work of German sculptors, on the whole lend itself readily to the reduction, and therefore not to diffusion. It is more conspicuous for strength and delicacy, for originality of conception than for facility of treatment. As far as hammered metal work is like the great Armbruster wrought-iron gates at the entrance to the German Court, in the Manufactures Building, or Professor Begas' magnificent "Germania" group in hammer copper is concerned, Germany can challenge the competition of the world. But its art in bronze must be regarded as still in the formative stage of a vigorous and characteristically national growth.

Japan passed this stage long ago, and made a lavish display at this World's Fair of those elaborately pieced and chiselled productions in which the skill and patience of the artificer are easier to discern than the genius of the artist. There was a vivid imagination in the grotesqueness of the bronzes representing legendary heroes, demi-gods, and dragons, and a conscientious study of nature in the elaborately executed study of nature bird pieces which commanded admiration. There was about some of the most common-place pieces a richness of half lustrous colour that must be the despair of imitators. The Japanese treat bronze just as if it were a ductile metal, carve on it, ornament it with inlayism, and generally speaking, make the casting a basis of work for the tool. Where they have yielded to the influence of French art it has been to the detriment of the characteristic excellence of their work; where they maintain their antique traditions they occupy a place and an eminence all their own.

At the entrance of their court in Manufactures Building was a Japanese vase of exquisite beauty. It was made of bronze and inlaid with gold, silver, and copper, and was valued at \$1,800; its companion vase was purchased by the Mikado himself. Two vases, 400 years old, testify to the age of the art in Japan, and two candelabra, valued at \$1,000, were as elaborate products of the combined energies of the artist, the caster and the chiseler as could be found anywhere. A lot of vases of pear-coloured bronze, inlaid with black bronze, gold and silver, were very beautiful and characteristic of Japanese art. Such work can only be produced where manual labour is cheap, and where people have been trained through centuries for the purpose.

Liberal Arts Exhibits.

No separate building was provided for the Department of Liberal Arts, and so numerous were the different classes of exhibits relegated to this division, that it was found impossible to make provision for them in one building. The largest proportion of the exhibits were to be found in the great galleries of the Manufactures Building; two of its bureaus were located in the Anthropological Building. The Music Hall at the entrance to the great basin, and the Choral Hall, opposite the Wooded Island, were also included in this department.

As the central idea of the Exposition was to educate, by making all displays exponents of the World's advancement, no department afforded greater interest to the visitors than that of the Liberal Arts.

Each succeeding Exhibition, beginning with that held in London in 1851, has been the schoolmaster of the nations. No other single educational influence has been so instantly and so extensively active. This is because each national exhibit has been the exponent of that particular nation's advancement. The nation which has borne the palm of victory has been that whose progress in education, taken in its broadest and fullest sense, has been most pronounced. Recognising these truths, the promoters of the World's Columbian Exposition have given to education a position of high prominence in the centre of interest, and in the grandest of all the great structures the Manufactures Building. Here education was surrounded by her hand-maids—music, science, literature, charity, religion—and these, grouped together, as by their nature was most fitting, form the constellation of the liberal arts. These are the arts whose advancement has made the closing century glorious, and has made all mankind free in the light of truth and law and liberty. Very earnest expressions of demand for a separate building for liberal arts, or for education alone, were presented from all sections of the country before the opening of the Exposition, but a careful consideration of all the conditions led those directly connected with the department to the belief that the present solution of the question was satisfactory. The amount of space provided was fairly adequate, as compared with that given to other departments; its position was central, convenient, dignified, and worthy, and its location in one entire end of the great Manufactures Building was much to be preferred to any which would have placed the department away from immediate association with the remainder of the Exposition, a contingency that most likely would have arisen if a separate and distinct building had been provided. As a matter of fact this question was carefully considered by the Board of Control and an appropriation for an Educational Building was made in response to urgent requests from many educators throughout the land. An eligible site for such a building was carefully sought for but could not be found, and the purpose to erect a separate structure was abandoned, not from any lack of appreciation of the Department of the Liberal Arts, or from want of interest in its work, but wholly as a matter of expediency.

The department included twelve distinct and separate groups. The exhibits of the first group were divided between two bureaus, that of Hygiene and Sanitation and that of Charities and Correction, and were installed in the Anthropological Building, and will be referred to under that department elsewhere. The subjects under the control of the
Bureau

Bureau of Hygiene were the nursery and its accessories, athletic training and exercise, gymnasiums, food supply and its distributions, representations of dwellings and buildings characterised by the conditions best adapted to health and comfort; sanitary appliances and methods for dwelling-houses, buildings, and cities; hygiene of the workshop and factory, modified from that of the London Health Exhibition; sanitary supervision, including quarantine and the isolation of contagious diseases. The Bureau of Charities and Correction presented matters pertaining to the sick and the needy—asylums, homes, hospitals, dispensaries, appliances for the transportation and the relief of the sick and the wounded; prison management and discipline—models and specimens of police stations, houses of correction, reform schools, dress and equipment of prisoners, samples of convict workmanship, the Bertillon system of personal measurements, &c.

The second group included instruments and apparatus of medicine, surgery, and prosthesis, including drugs and medicines, dietetic preparations intended for the sick, instruments for physical diagnosis, surgical instruments, artificial limbs, and dental apparatus. This group was arranged in the north end of the gallery floor of the Manufactures Building. The exhibits from the Western States contained primary, secondary, and superior educational statistics, apparatus, and appliances were exhibited in a group, wherein were shown infant schools and kindergartens; text-books and diagrams, and specimens of work in elementary schools; specimens of domestic and industrial training for girls; handicraft teaching in schools for boys; specimens of school work in chemistry, physics, mechanics, &c.; art work, modelling, &c.; results of industrial work; exhibits of elementary instruction of Indians; schools for the deaf, blind, and feeble-minded; statistics, methods of instruction in public schools: descriptions and statistics of academies and high schools; buildings, libraries, museums, courses of study, &c., pertaining to colleges and universities; various branches of professional schools, such as law, theology, pharmacy, mining, military, commercial, &c. Distinct exhibits were presented by thirty states and territories; about forty colleges and universities, including six for women and seven distinctively for the coloured race, more than thirty normal schools, a series of training and manual schools and trade schools, sixteen art schools, collective exhibits from thirty business colleges, fifty schools for the deaf, schools for the blind, schools for those of feeble mind, &c. An extended exhibit showed the work of the schools conducted under the control of the Catholic Church. Educational exhibits were presented by the School Board of London; from New South Wales and Canada; from the Governments of France, Russia, Austria, Mexico, and Brazil; a very complete exhibit prepared under the orders of the Imperial Minister of Education of Germany. The exhibits from the United States occupied about 175,000 feet on the south end of the gallery floor; the foreign exhibits occupied nearly 50,000 more.

In the group of literature and books were exhibits of miscellaneous and educational publications; the great magazines, engraving, lithographing, maps and charts, &c. Then came instruments of precision, weights and measures, astronomical instruments, including the great refractor of 40 inches aperture; geodetic, hydrographic, meteorological, optical, acoustic and chronometric instruments, photographic apparatus and a gallery of photographs. Architectural drawings, specifications for foundations, walls, partitions, floors, roofs, and stairways; contrivances for safety, comfort, and convenience in the manipulation of elevators, doors, and windows; working plans for hoisting, handling, and delivering building materials, for paving and draining, &c. Statistics and publications of religious organizations and systems, showing the origin, nature, growth, and extent of various religious

religious systems and faiths; maps and reports of missionary societies, missions and missionary work; Bible societies, tract societies, and other publications. These were chiefly American exhibits.

In the group including music and the drama an interesting collection of instruments and literature pertaining to these arts was gathered in the galleries of the great building from all parts of the world. It included crude and curious instruments; music books and scores; drums, tambourines, cymbals, triangles, gongs, castanets, music-boxes, lutes, guitars, banjos and mandolines, harps and lyres, zithers, dulcimers, violins, the viol, viola, viola-da-gamba, viola-di-amore, the violincello, and the bass viol; the pianoforte, square, upright, and grand actions, and parts of a piano; the predecessors of the piano,—clavicytherium, clavicymbal, clavichord, manichord, virginal, spinet, harpsichord and hammer harpsichord; street pianos; the flute, flute-a-bec, syrinx, organ pipes, flageolet, clarinet, oboe and saxophone; the trumpet (simple) and the bugle (oliphant), alpenhorn, the trombone (with slide and with finger holes); the serpent, bassoon and bagpipe, key bugles, cornets, French horns, cornepeans, orphecleides, reed organs, melodeons and harmonicas, accordeons, concertinas and mouth organs, hand organs and organettes, automatic organs, orchestrions, strings, reeds and bridges, mechanical devices for the orchestra, &c. The grand pipe-organ in the Music Hall was part of this exhibit, as were also the chime of bells in the central tower, and the chime in one of the towers of Machinery Hall.

The Bureau of Music was a branch of the Department of Liberal Arts, and was under the charge of special officers.

New South Wales Liberal Arts Courts.

In the Liberal Arts Gallery New South Wales had a very excellent position, and, comparatively speaking, a fair share of space, but yet insufficient for our requirements. Our courts occupied 6,247 feet floor space and 10,000 feet wall space. Our space was bounded by Russia on the south, Canada on the east, and Great Britain on the north. In consequence of the shape of our allotment, and in order to make the best possible show of our numerous exhibits, I divided the space into a series of courts, and the plan of the court will exhibit at a glance the mode adopted. Over the main entrances, north and south, were the arms of New South Wales, and on each side of these a stuffed and mounted kangaroo and emu, with large trophies of our flags. Above the south entrance was the great panorama of Sydney, for the information of visitors, labelled as the largest photograph in the world, and on either side of this on the walls were the large photographs of Sydney in 1885 and 1892. An extensive wall space at the south avenue was devoted to the maps prepared by the Survey Department, and a similar space on the outer wall of the north end to topographical maps and charts. On the walls of the courts were displayed the numerous and beautiful photographic enlargements prepared by the Government Printer, with the exception of those representing streets, banks, &c., which were placed in the Manufactures Building. I may here remark that these photographs were one of the most popular, instructive, and attractive features of this and other courts, and as a collection were unrivalled. In the south court were placed the exhibits of the Technological Museum, in suitable glass-covered cases running the whole length of both sides of the space, as well as Mr. Maiden's herbarium and "century" of plants. Of the wool exhibits in this section I retained some characteristic series, but the principal portion I placed in the wool court in the Agricultural Building to complete the character of that very important section. A notice on the exhibits called attention to this arrangement, so that visitors so disposed might visit our wool court to see the exhibits. I constructed three large glass-walled cases for the numerous
birds

 CASE 908
 TABLE 291.

SECTION OF A NEW SOUTH WALES COURT IN THE LIBERAL ARTS BUILDING.

birds sent by the Sydney Museum, which were mounted and stuffed and placed in appropriate natural attitudes on branches of a tree with ground-work at the bottom of the case. In the fourth case were the animals sent, similarly prepared and mounted. Here a piece of rock scenery was made in the case, in which the animals were placed in such a way as to show as far as possible their peculiar habits under natural conditions.

In the courts east of the main avenue were placed in glass cases the various exhibits of the public schools of the country, arranged and classified; while on the walls were hung the photographs of the public schools buildings and of the University. In the northern of these courts were the exhibits of the Institutions for the Deaf, Dumb, and Blind in Sydney.

The most southern of the west courts (Newspaper Court) was the place provided for the consultation by visitors of the files of Sydney newspapers. Then came the *Sydney Morning Herald* court, and the *Daily Telegraph* and *Town and Country Journal* exhibits. The walls of these buildings and courts were covered with the pictorial representations belonging to the different newspapers and the *Pictu-resque Atlas Company*. In fine, there was in this part of the department a fair representation of the Press of Sydney. The next two westerly courts contained the exhibits of the Technical College, displayed on tables and in cases, and on the walls were the photographs of the "Wolverene" and Naval and Military Services. In this court also was the revolving-stand and exhibits of the Sydney General Post Office.

On the walls of the principal avenue, running between our east and west courts, were placed architectural drawings and photographs all along the length of the avenue in classified order. The north court contained on each side three bays, and the east side was devoted to the photographs of Messrs. Kitch and Co.; the Katoomba Council; Mr. Holden, of Kiama; Mr. Little, of Young; Mr. M'Fadyen, of Murrurundi; Marion & Co.; the Newcastle Council; Mr. Newman; the photographs of Orange and of the Sydney Municipal Council; while the west side contained Mr. Russell's beautiful astronomical photographs, as well as representations of most of the technical schools of New South Wales. In this court also were placed the exhibits from the Macleay Museum.

This is a mere running description of these courts and of some of the exhibits they contained, and represents but faintly the excellence of the arrangement. Much thought and trouble were expended on the installation of the numerous exhibits in this department and in the elaborate decoration, but the excellent effect and appearance of the whole rewarded all the efforts made for the display of the exhibits in this department.

Educational Exhibits.

As a number of valuable reports on the various Departments of Education by various writers have already been published in our country, it would be superfluous to discuss at any length the distinctive features of the systems of the various countries represented at this Exhibition. It will suffice to characterise succinctly the more representative exhibits, as well as the salient features of the advances made within the last few years.

Great Britain's Exhibit.

Although Great Britain occupied a large division of that section of the Liberal Arts Building devoted to educational exhibits its representation was not comprehensive in any particular. When the large amount of money appropriated by the English Government for the main-tenance

tenance of its Art Schools is considered, the meagre massing of work from the Art School of South Kensington was disappointing. There were, however, some fine examples from the Department of Science and Art of the Kensington Museum, in which the drawing was vigorous and the shading excellent. The drawing from cast, both of ornamental work and figures, was technically very satisfactory. There were a few examples of time sketches, nudes from life, and also hands from life, which evinced much cleverness. One picture from the Composition Class, an aquarelle, representing the interior of a working studio, was the only one of this class, and was not a very interesting production. The studies in historical style from casts in monotone were very good, as was also the pencil work in pen and ink for illustration purposes. The exhibit of the School Board of London, especially the work from the elementary schools, from children between the ages of eight and eighteen, was creditable. In the exhibits illustrative of Applied and Industrial Art the original designs for wall-papers were remarkably artistic. The examples which showed a sketch of a single flower taken as the motif for the composition and then conventionalised into rimlike or geometrical designs were characterised by undoubted skill. The plaster relief work, and one or two drawings from life, and one or two nudes were excellent, and illustrated the importance of the introduction of the industrial and applied arts into elementary schools.

French Educational Exhibit.

The French education exhibit at Jackson Park was an epitome of the education system of that country. It was compactly gathered together in the gallery, and constituted group 149 of the catalogue of the Liberal Arts Building. It was made up of complete sets of official publications containing the laws and rules of the school system, showing its anatomy and physiology, and illustrating by manual as well as literary means its operations and results. As an able American writer has said, central government in France, notwithstanding its Republican organisation, is dominant in the education system. In this respect it radically differs from that of the United States. In federating the States that constitute the American Republic it was not the design of the fathers, nor has it ever been the will of statesmen inheriting their convictions, to give to the Federal Government any control over education in the United States. That control was among the prerogatives reserved by the States to themselves individually.

There has been from time to time an effort to attribute to the education bureau of the Interior Department quasi-authority, or at least some show of a vital connection with American schooling. It has been unsuccessful. The bureau of education continues to be restricted to a fragmentary and more or less incoherent policy of publishing monographs on educational topics, and of classifying incomplete statistics for whose orderly and exhaustive gathering it has neither money, men, nor legal right. A bureau of statistics, scientifically managed, would confer upon students and leaders of education great service in the crystallisation of trustworthy facts exhibiting the status of schooling, general and special, in the United States from time to time. This function may yet be added to the work which the bureau of statistics in the Treasury Department now performs. It is not likely that public opinion would favour extending the jurisdiction of the education bureau even into the domain of statistics, and it certainly will never approve any interference by the Federal Government with the management of education in the States. That it was the will of the fathers to keep apart the Federal Government and the management of education was shown not only in the reserve by the States of educational jurisdiction in their own respective boundaries, but also by the more explicit evidence of allocation of public lands by Congress

Congress to the various States for school purposes, Federal authority being abrogated for ever concerning them in favour of inalienable State fee.

The French school system, unlike that of the United States, is as distinctly national as that of Prussia or England or New South Wales, and the Central Government has as exclusive a jurisdiction over its general direction throughout the Departments of France as a State Legislature exercises over the schools of a State.

The National Government of France takes cognizance of all kinds of instruction found useful to the people, and applies its own mould to the entire gradation of schools from Kindergarten to University, ramifying this control through every category of teaching. The national system has, indeed, more than one head. The Minister of Commerce, of Industry, and of the Colonies, maintains supervision over the national school of arts and trades, and in the exhibit at Jackson Park, made under the auspices of that department of the national Government, were evidences of the work of pupils in national schools of clockmaking in several cities. The same Minister exhibited the commercial instruction of France, with portfolios, photographs, &c., showing the work of commercial high schools at Bordeaux and Havre. The Minister of Public Instruction classified his exhibits under six heads—science and letters, institutes and learned societies, press and books, higher education—to which was attached the exhibit of the Pasteur Institute—classical education and elementary education—to which was attached the exhibit of the pedagogical museum. Grouped with these were the exhibits of the Polytechnic Association, for the promotion of public instruction, the exhibit of the National School of Arts and Trades at Aix, that at Angers and Chalons, special schools at Douai, the Central School of Arts and Manufactures at Paris, the Trade School of the East, the Franklin Society, whose business it is to propagate free public libraries, and several private schools of book-keeping and commerce.

State supervision of education in France covers its entire operation, and extends to every feature of it. The result is a diffusion of schooling unequalled in degree and precision. The public money, national, departmental, and communal, devoted to primary instruction in the country exceeds \$50,000,000 a year. In 1890 the total number of children of school age, that is between six and thirteen, was 4,729,511. Of this number, 4,579,461 are enrolled in primary schools—an extraordinary ratio to the credit of France. There is one elementary school for every 445 inhabitants, and the enrolment shows more than one in six of the population.

Nor is State supervision of schools in France abstract. It is actual; it is minute; it is incessant. To appreciate its minuteness and its directness it is necessary to understand the union that still exists between religion and government in France. All the religions are equal by law. Any sect which numbers 100,000 adherents is entitled to public money. Those now receiving appropriations from the State are Roman Catholics, Protestants, Jews, and Mussulmans in Algeria. Roman Catholic worship and places of worship cost the Government about \$8,000,000 a year; the Protestants, \$400,000 a year; the Jewish, \$40,000 a year; the Mussulmans a little more than the Jewish, and the administration of the religious appropriations cost the people about \$60,000 a year. All these are recognised in connection with instruction, which since 1881 has been obligatory, and since 1882 absolutely free. The highest schools or universities go by the name of Faculties of the State, and these include law, medicine, pharmacy, and fine arts. The Roman Catholic theological faculties were suppressed in 1885, but Roman Catholic universities continue to enjoy State aid. The council of Public Instruction consists of the minister, five members of the institute,

tute, elected at a general election, nine councillors, confirmed by the President of the Republic on nomination by the Minister of Public Instruction, and chosen from among directors and ex-directors of the Department of Public Instruction, inspectors-general and ex-inspectors, rectors, ex-inspectors of the academy, and professors engaged in public instruction. With these are associated two professors of the College of France, elected by their colleagues, a professor from the museum, a professor of the faculty of medicine, one from a high school of pharmacy, two from the superior normal school—one for letters, the other for sciences—one from a special normal school, one from the National School of Maps, one from the School of Living Oriental Languages, one from the Polytechnic School, one from the School of Fine Arts, one from the Conservatory of Arts and Trades, one from the Central School of Arts and Manufactures, one from the School of Agriculture, two from communal colleges, six representing primary instruction, and four from free schools under private conduct. All the members of this council hold office for four years each, and they are indefinitely re-eligible. Nine members, named by the president and six designated by the minister, constitute a standing committee whose business it is to study programmes and rules of education everywhere, and to give advice concerning lyceums, colleges, normal schools, text books, libraries, discipline, teachers, methods of teaching, examinations, gradation, and graduation.

Education in France begins with the Kindergarten, or as they term them, mother's schools (*écoles maternelles*). Instruction and play correspond substantially to those of like schools in other countries. There is more, however, of a combination of *crèche* with the Kindergarten in France. Women in France were engaged in industries before the Franco-Prussian war, but that event withdrawing the men from the country, had a corresponding effect to that of the civil war upon the employment of women in the United States—that is, it enlarged the number of occupations in which they are engaged. There is scarcely anything men do in France that women do not do. A man and wife, mother and daughter, concern themselves with money-making in France more than do the women of any other country. The schools are the natural resorts of mothers who desire to have their children pleasantly if not profitably occupied during the hours when they are themselves concerned with other than domestic cares. In the primary school instruction consists of moral and religious teaching wherever it is desired for any number of pupils, for each division of whom it is given by an authorised representative of one of the creeds mentioned. In addition to this, instruction includes reading, writing, the French language, simple mathematics, and the legal system of weights and measures. In the higher grades, arithmetic is carried into practical operation, and there are added the elements of history and geography, of the physical sciences, of natural history applicable to practical things, elementary instruction in agriculture and a number of industries, and hygiene. Surveying is taught to those who wish to study it, while drawing, modelling in various ways, singing, and gymnastics are obligatory upon all. There are also special schools for girls, or special classes in the regular schools, in which, in addition to these things, every kind of needlework is taught. There are also special schools for adults and for apprentices in various trades. The normal schools are kept up to a high degree of efficiency. These schools, like those of manual training and apprenticeship, are widely distributed throughout the departments, and receive appropriations from the Republic as well as from local revenues. Their course of study is under the general direction of the Council of Public Instruction.

It will be seen that the foundation of the school system of France is uniform and universal. The presumption is that every child of both sexes may be self-dependent, and the education scheme proceeds

proceeds directly toward equipping the child for a useful industry. In furtherance of this object the elementary instruction is strongest in those things that are indispensable for industrial production. All the teaching is practical. What they learn of physical science is aimed at industry; what they learn of natural science is designed to help them to become producers. Their study of drawing and modelling gives them that skill in early childhood when the hands are supple and the eye keen, which a little later will seek special development in some distinct path.

They seem to be untroubled in France with the idea that cultivation of the sense of form is going to make men and women "artists." They know, on the contrary, that it will make artisans and skilful judges of artisanship of the vast majority of the children. As for artists, they will be a small percentage out of the entire number, and their education begins much later in special schools, leading up to *Ecole des Beaux Arts*. The primary teaching in modelling and drawing has no specific relation to fine arts. It has a specific relation to complete mental development, and the result of it is that France controls the markets of the world in every higher form of skill.

The minute care which France exercises over her schools was shown by the exhibit of her Museum of Pedagogy. This consisted of 20,000 publications and stocks of all appliances, objects, and tools used in general and special instruction. Of course it was represented in a compact exhibit chiefly by catalogue. Many of the volumes, however, could be seen in the exhibit. One line attracted much attention. They were the classics of literature prepared for the schools of France under the direction of the Department of Public Instruction. The children learn to read the best literature as soon as they are able to understand language. Their time is not frittered away on silly fragmentary sentences that convey to them no meaning. It is assumed that the best reading is the best for the child, and the children of France learn to read masters of style in their infancy. Nor is the list restricted to the French language. Men of the highest ability are engaged to prepare books upon masters of all languages, and at its proper place in a progressive course of study the French child learns, for example, what Dante's "Divine Comedy" is, and becomes acquainted with Longfellow's "Hiawatha." Attached to each school, wherever funds permit, there is a good museum, consisting alike of books and materials, the use of which is free to the children and to the townspeople, under no restriction, except one of custodianship. In the Central Museum of Pedagogy there are gathered together publications relating to schools throughout France, and from almost every civilised country of the world. These publications cover not merely literature about schools, but school systems, courses of study, examination reports, and everything pertaining to the practical management of instruction.

A novel and unique feature of the French education exhibit was that relating to the commercial school organised by the Chamber of Commerce, Paris. It was founded in 1863 for the purpose of giving primary and secondary instruction in business, diplomacy, and trade. Students of both sexes are admitted on the same terms. There is a special course for women for the purpose of teaching them accounting and bookkeeping. After passing an examination a certificate is given to them, upon which they are able to secure higher employments in important business-houses. The certificate affirms that they are able to carry on commercial correspondence in French, and generally also in English; that they possess all the qualifications of expert accountants, and are trustworthy as well as competent. The young women having this certificate are eagerly sought by the heads of business concerns. The institution is modelled upon the
higher

higher commercial school of Paris created in 1820. Among those connected with its direction have been Adolphe Blanqui and Aimé Girard. The school has supplied to commerce and industry at the French capital, to the colonies, and throughout the provinces of France, a large contingent of their most valuable men and women of affairs. Its graduates become brokers, bankers, administrators, directors, and agents of all sorts of commercial and manufacturing concerns. In 1881 the commercial high school of Paris was equipped by the Chamber of Commerce for the additional purpose of giving complete special instruction to young people who had already graduated from the classical courses in other institutions and desired to devote themselves to commercial careers. The school teaches science, the historical development of manufacture, and all practical modes of general exchange. Its graduates study diplomacy if they so desire, and take a diploma which admits them to competition for appointment to diplomatic and consular posts. The Departments of Commerce and Industry of the Colonies and of the Customs service give precedence to students of this school.

With a generosity that characterises the attitude of France toward learning of all kinds, foreigners are admitted to the school on complying with the conditions of admission as freely as natives of France, and they are even permitted to follow special lines of study without undergoing a preliminary examination. The studies include, in addition to the French language, German, English, Spanish, and Italian; history and geography in their immediate relation to the commercial profession, arithmetic as applied to commerce and banking, commercial correspondence, bookkeeping, financing, geometry, design, commercial law, political economy, physical sciences, and stenography. Students must be in attendance from 7:45 in the morning until 4:45 in the afternoon. There are three hours of recitation in the morning and three in the afternoon. They take luncheon, if they choose, at the school, or are at liberty to go home, returning at 1:30. Luncheon at the school is served at 12 o'clock, and is followed by an hour and a half of recreation. There is a fine library for the use of pupils. There are special scholarships founded by various corporations and institutions, such as the Rothschilds, the Bank of France, Credit Foncier, the railroad companies, omnibus companies, gas companies, and members of the Board of Trade—in all nearly 200. The Government of France maintains twenty scholarships, disposed of at an annual competition. The whole number of pupils attending in 1893 exceeded 500 during day courses and 1,000 in the evening courses. Of this 1,000 one-fifth are women. The exhibit made by this school in the Liberal Arts Building consisted of class-books and albums showing the work of various grades and illustrations of work in design by the women. Many of the cleverest fashion-designers of the French capital are women who have studied in this school. It gives a combination of instruction peculiarly adapted to the industrial and artistic position of France in the world—the commercial with the ideal.

The entire series of text-books used in primary and secondary schools was shown. Copies of the course of study of each grade could be had on application in the exhibit. No teacher could fail to derive benefit from a study of the French educational exhibit. Its logic, its directness, its precision were equally apparent and were equally admirable. Of all the people in the world conducting free schools the French are the most frugal, the most sagacious in applying means to ends. That the work shown was the genuine work of pupils and not of teachers was evident from examiners' markings found throughout the portfolios. There was no slovenliness in the work, while there was a great deal of childishness. It was all neat, clean, orderly, and well arranged. As a national exhibit it surpassed all others in the Columbian Exposition.

I may remark that the anatomical drawings shown by the French in their educational section were very fine. These examples were mainly from the higher and normal schools and from the Association Polytechnique. There were but one or two specimens of drawing from life or cast, and only two strong reliefs in plaster; but their display of papier-mache bower models, used in schools for botanical instruction, although the collection was purely elementary, was very interesting. There were also shown in the same division the most perfect-coloured photographic negatives from Nature ever taken. These were the work of a Frenchman named Lippman. One negative showed a branch of a tree on which was perched a bird of brilliant plumage. The dense growth of the foliage was true to Nature in its colour notes, and the bird's feathers, which were red, green, and yellow, were exquisitely lovely. It is questionable whether the printing of photographs from coloured negatives has yet been successfully accomplished, although in a German exhibit I saw some in which this result was said to have been accomplished.

German Exhibits.

The School of Education for Artisans of Germany exhibited some excellent pieces of work, including some good drawings from life and casts. The illuminated designs for textiles and tapestry, done in water-colour, were very attractive. Pen-and-ink work of great fineness, for the embellishment of diplomas and programmes, is very cleverly done by German art students. Their plaster relief work and woodcarving were unusually attractive. Several busts were shown in both mediums which evinced considerable skill.

The first work of the Industrial Art Schools of St. Petersburg was shown in their architectural and ecclesiastical designs in water-colours. These were new examples from a composition class and a few from a life class. The institutions of the Empress Marie were well represented, not by drawings and paintings, but in embroideries and textiles. The weaving of rugs by children under twelve years of age, accomplished by the pupils of these schools, was surprisingly clever. The Kremlin at Moscow was chosen as the subject of a lovely needlework picture. The Demidoff School exhibited an exquisitely fine piece of embroidering on silk linen, intended as a present to Mrs. Cleveland, the wife of the President. It was all in white, and the subject was the steamship "Leo," the vessel which was sent from America to Russia during the famine of 1892 freighted with corn. Another charming bit of work from the same school was an intricately-wrought stripe for a fireplace, the copy of a scroka (head-cover), worn by the women of Vladimir in the 13th century.

German Bacteriological Exhibit.

One section of the German University Exhibit was under the care of Professor Dittmar Finkler, of Bonn University, and Dr. Lichtenfeldt, of Berlin. This was the department of bacteriology, which was fitted up most completely, and which showed all the peculiarities, the growth, the life, the harmful or harmless qualities of those infinitesimally small organisms which have been designated as Bacteria. This department formed an independent section in the exhibition the German Universities made in liberal arts. At none of the previous great Expositions has there been an exhibit in bacteriology. This is not to be wondered at, since the science itself is but a few years old. How this science, however, has grown within so short a space of time this particular exhibit showed. It was fitting that Germany, of all the countries, should make it, since Germany has been the principal factor in the creation of the science of Bacteriology.

German

German research in the field of bacteriology laid the foundation for its further development, because Dr. Robert Koch found a method by means of which it became possible to separate the different bacteria which formerly had always been encountered in a mixture. By this method the scientist was enabled to discern the real character of each organism, and by making use of Koch's culture system it became possible to raise the different kinds of bacteria and to study thoroughly their varying qualifications. This, from a scientific point of view, was the greatest merit of Koch. After having once originated his system of separating and growing bacteria it was no longer very difficult to discover new ones, and to learn the various facts concerning them. Correct ideas were thus formed as to the origin and nature of tuberculosis, cholera, diphtheria, typhus, and other infectious diseases.

It must not be forgotten that this whole science of bacteriology is, practically, but a few years old. It dates back barely forty years, when Professor Haenle, of Gottingen, discovered the presence of these minute living organisms, since christened bacteria, and of which science now knows that every cubic foot of air contains thousands, and every cubic foot of water millions upon millions. But the utilisation of this first discovery began but a few years ago.

In the bacterial exhibit of the German University exhibit there were comprised the natural history of bacteria, their chemical effects, and the etiology or genesis of the diseases they produce. Bacteria may be divided into pathogenic (disease-producing) and non-pathogenic ones. Of the latter there are now recognisable some three hundred kinds, and these have been made useful by German chemists in fermentation, dye-stuffs, &c. The disease-breeding bacteria, of which there are at present known some 500 kinds, are divided in groups (as in zoology), widely differing from each other in shape, characteristics, growth, and fertility.

Of these latter, the pathogenic class of bacteria, there was an excellent collection of photographs or views made from living specimens (magnified enormously of course) by Dr. Richard Pfeiffer, chief of the bacteriological section in Koch's institute in Berlin, under Dr. Koch's supervision. The vivid, lifelike pictures, included those of the bacteria producing diphtheria, typhoid, cholera (magnified a thousand-fold), tetanus, malleus, erysipelas, acute rheumatism, hog-cholera, pus (a whole group), &c., as well as the picture of the influenza bacillus, discovered by Pfeiffer himself.

There was on view a large number of microscopical preparations of living bacilli. These of course were only accessible to specialists visiting the exhibit, who wished to investigate for themselves. This collection was prepared by Dr. Robert Koch and three of his ablest disciples, Loeffler, Pfeiffer, and Fraenkel. A regular zoological museum of bacteria was also exhibited in the form of "cultures." Those made possible by adopting the method inaugurated by Koch on gelatine plates, and the further growth of each colony of bacteria arrested by some antiseptic fluid, showed the appearance of each army of bacteria at certain stages of development. There were in this collection some of the most virulent and deadly bacteria. To facilitate, however, the understanding of Koch's method of treating and raising bacteria, there was on view a whole worktable covered with all the apparatus needful, comprising appliances for sterilising and for the raising of culture-soil (Naehrboden) required for the growth of bacteria.

A peculiar and intensely interesting part of this exhibit was one prepared for the World's Fair by Professor Breiger. It was a collection of the swiftest and most powerful poisons on earth, all gained from the dead bodies of those that fell victims to various deadly bacteria. This class of poisons are termed taxines, toxalbumines, or cadaverines. They were

were exhibited in carefully-closed glass tubes, so that each kind could be closely inspected. Among them were such deadly poisons—all discovered in recent years—as neurine, betaine, gadinine, tetanotoxine, typhotaxine, toxalbumen of cholera, of typhus, cadaverine, obtained from a normal body, &c. There was also in this group two immunising fluids, *i.e.*, substances that will prevent diseases such as diphtheria and tetanus. But it must be added that the discoverer of the immunising fluids, Professor Breiger, has thus far tested their efficacy only on various animals, but not on human beings. So far as his experiments go, however, they have proved successful. These poisons, forming the extract of the poisonous substances excreted by various bacteria, are highly concentrated, and they are beyond doubt the most powerful life-destroyers yet devised.

Of interest, too, were the various appliances used by bacteriologists in their experiments and tests made on living animals, especially frogs, rats, mice, and guinea-pigs. There were tiny operating-tables made of steel or glass, and almost the exact duplicates in miniature of the operating-tables used by surgeons on human patients, to which these small victims of science were fastened with leather straps. This enables the scientist to make incisions or injections wherever needed for the purpose of demonstrating the correctness of some theory won by research. There was also a wealth of other curious instruments on view, including filters, suction pumps, and centrifugal machines.

To further enable visitors interested in bacteriology to derive all the practical good from it that was possible, an auditorium was fitted up in the southern corner of the gallery belonging to the German University exhibit. It was an exact copy of the auditorium used by the famous Professor Virchow for his lectures on pathology, fitted up with tables, where practical demonstrations were made.

During the currency of the Exposition Professor Dittmar Finkler lectured on Bacteriology to a select audience of specialists and scientists invited for the occasion, giving practical demonstrations. Professor Finkler is next to Koch, the greatest authority on bacteriology, and the author of a work in which are contained some of the most valuable results of his researches in this field. Professor Fraenkel, of Marburg, took part in these lectures later on, and both these gentlemen lectured in English.

American School Exhibits.

The educational exhibits of foreign countries as regards magnitude and variety were quite overshadowed by those of the United States of America. These exhibits occupied no less than 225,000 feet. In addition to the large and representative exhibits of public school-work from the various States, High and Technical schools were shown on a very extensive scale. A series of thirty-five screens in the west balcony illustrated the work of the Art schools, and there were ten or twelve exhibits of the manual training schools. One interesting exhibit represented all the work practically carried out from day to day by students of what was named a Business College; in which, in various rooms and at the desks usually provided in business offices, all the different stages of commercial transactions were performed by the student clerks. In the south portion of this department nearly all the forty-four States of the Union were fully represented, and, besides this, in the north-west portion as well, many of the leading religious, political, and social institutions in several of the States had their own separate and well-ordered collections. It was a characteristic of the American people that in some of these latter bays there was displayed the old, worm-eaten travelling pulpit in which Whitfield once preached, and in another, the equally ancient arm-chair of the "Dairyman's Daughter," both objects of great veneration, as well to the exhibitors as to the visitors.

American

American public schools were represented by specimen work from pupils, photographs, charts, and comprehensive statements with regard to the plan pursued in education. From the work for exhibition the committee selected fifty of the best manuscripts in each branch and forwarded these to the Public School Commission. Maps showing the situation of each school-house in each State; the cost of education in each county; the relative number of pupils in each county, town, and city; the schools for each of the past forty years. The relative number of pupils in primary, grammar, and high schools for the past forty years. Picture albums of schools, buildings, &c. History of the organization of the school system as shown by legislation; text-books arranged to show the old and the new systems.

American Schools of Art.

The educational section devoted to the exhibits of the work of the various American Schools of Art was very interesting and very extensive, nearly every Art school in the United States being represented. Although I both heard and read much of a laudatory character as regards these exhibits, after a very careful and prolonged examination I must confess I found a number of them crude, and none of them superior to the exhibits of South Kensington or our own Technical College. The water colours, the etchings, canvasses, casts, drawings from the round and the paintings from the various schools were, as might naturally be expected, of very various value. Many of the schools represented showed exhibits of very excellent character.

Catholic Exhibit.

The Catholic exhibit in the Liberal Arts was one of the largest shown. It contained exhibits of every kind from all the different classes of schools in the United States. A special effort was made by the Roman Catholic authorities of America to show that the schools under their charge were as well appointed, as well arranged, and obtained as good results as any schools elsewhere. Each important school had a separate court, and all the gradations of the school work were exhibited. The show was a very extensive one and was well arranged.

American Universities' Exhibits.

The great Universities of the United States had a remarkable series of exhibits. Harvard, Yale, and John Hopkins, and other of the highest institutions of learning in this great Republic, displayed many of their literary and scientific treasures, thus carefully completing the educational exhibit of the country.

Harvard's exhibit might be regarded as an historical review of the development of Universities in America. It included a complete series of University publications, photographs of the University grounds and buildings, the methods of work and study in each of the great departments—academic, scientific, medical, legal, &c.

It also contained an extensive series of photographs of stars, planets, and spectra taken at the Observatory, as well as interesting views of the various observing stations established by the University at Arequipa (Peru). There was also a large collection of minerals and a valuable number of classified meteorilites and numerous specimens in botany and comparative zoology examined by Harvard professors. Specimens of 262 papers published on chemical subjects, and about 100 out of 800 chemical compounds discovered in the laboratories of the University were also shown. I must not omit to mention also some of the results obtained in the physical laboratory. One of paramount interest was the
photographs

photographs showing the oscillation of an electric spark. Between two tin terminals the spark was made to pass, and the image formed on a rapidly revolving mirror was thrown on a sensitive plate. The spark appeared to the eye as one streak of light, but was drawn out by the rotating mirror into a comet-like tail. Then a bead-like appearance was noticeable in the photograph, due to the electric oscillation. The duration of an oscillation could be calculated by measuring the distance between the two beads and the known circumstances of the motion of the mirror. Professor Trowbridge gave this as $\frac{1}{150000}$ of a second. The photographs further showed that air does not conduct away the heat of the spark in less than three times the above function of a second, so that air is practically as inert as a plate of glass during the same period of time. Professor Trowbridge also exhibited cards showing ten lines of force due to an alternating magnetic field of frequency 1,000 per second. The lines were straight and radiated from the centre of the cylindrical core. These photographs served to establish the magnetic field is restricted to a shell $\frac{1}{4}$ in. thick in the case of a solid iron core $2\frac{3}{4}$ in. in diameter.

It would be difficult to find anything more exquisitely beautiful, and at the same time educational, than the Blaschka glass flower collection, which is the property of Harvard. The models of flowers and their parts were selected from the Ware memorial collection in the Botanical Museum. The collection now has 350 large and over 1,000 small models. When completed it will represent the principal types of flowering plants and cryptogams of America. The models of flowers, when made of the somewhat clumsy and exaggerated papier-mache manikins, made botanical analysis less difficult, but these dainty reproductions of flora were true to nature both in colour, outline, and size. The forefathers of these clever artificers were Venetians, but their studio is now at Hosterwitz, a few miles from Dresden. The firm consists of father and son. For many years they devoted themselves wholly to the construction of models of animals, chiefly marine invertebrata. In 1886, through the urgent request of Professor Gordale, director of the botanic gardens and author of "Wild Ferns of North America," these artisans consented to construct flower models. All of the flowers now manufactured by the Blaschkas go to America. When viewing the exquisite specimens in this collection it was difficult to believe that they could not exude a delicious perfume. There was in the showing a spray of rich purple clematis with leaves and clinging tendrils of tender green that was most lovely.

Besides these interesting exhibits this University showed a large number of the literary productions of her distinguished professors and graduates, amongst whom were the names of Longfellow, Professor of Belles Lettres; Oliver Wendell Holmes, Professor of Anatomy and Physics; James Rupert Lowell, Professor of French and Spanish Literature; John Lothrop Motley, Prescott, Bancroft, Asa Gray, and many others of her illustrious sons.

Considerable space was occupied by the exhibits of other Universities, and many interesting data were given in the various publications issued by their authority; but none of them appeared to me so large and so well displayed as those of Harvard.

Black and White Art.

Exhibits in Black and White were shown by nearly all the European countries and the United States in the Fine Arts Palace, in Women's Building, and in Liberal Arts. In the Liberal Arts Gallery, at its southern portion, were some excellent collections in the courts of the illustrated magazines, such as *Harper's*, *Scribner's*, and others. In the *Century* Company's exhibit there were also letters from Longfellow, Mary M. Dodge, Helen Hunt, Louise Alcott, Frank Stockton,

Stockton, William Cullen Bryant, and Alfred Tennyson. Interesting examples of work were exposed illustrative of photographing by direct process. The walls of the room were hung with original engravings and drawings from the hands of the many noteworthy artists whose clever work has been seen in the various monthlies of this company.

Work of the Deaf and Dumb and the Blind.

While the exhibits of New South Wales, Spain, and Japan were very interesting, those from the various States of America, from their magnitude and their full representation, call for special reference.

At the south end of the west side of the gallery in the Manufactures Building was a collective exhibit of an unusually interesting character. Very few persons examining the specimens to be seen there would believe that they were the work of the blind, the deaf, the dumb, and the feeble-minded, if it were not for the cards placed in the show-cases announcing such to be the case. As evidences of neatness in needlework, and of handiness in the mechanical industries, the specimens on exhibition compared favourably with those of pupils in various industrial institutions who possessed no physical imperfections.

A length of 300 feet at this end of the gallery was devoted to the exhibition of what can be accomplished by those who have not the full use of their faculties, under proper training. That the promoters of the exhibit succeeded in their aim was manifested by the general interest taken in it by the immense number of visitors who frequented that section of the Liberal Arts department.

On entering from the south end of the building the first booth contains a pictorial description of the National Deaf-Mute College at Kendall Green, Washington, D.C. Prominent in the centre of the display of pictures were the portraits of Dr. Thomas Gallaudet, LL.D., the founder of the college, and Edward M. Gallaudet, Ph.D., LL.D., its President and Professor of Moral and Political Science. There were several water-colour pictures of landscapes and flowers and a case containing photographic views of the college and grounds.

Close by was a book-case, the work of pupils of the Michigan School for the Deaf, at Flint, Mich. It was a handsome and solid piece of cabinet work, showing care and ability in the use of tools necessary for the cabinet-makers' art. The book-case was well stocked with books and literature of various kinds suitable for young people.

Next came the exhibit of the Indiana Institute for the Deaf and Blind. Among other things it contained a pleasing and well-executed assortment of tidies, afghans, capes and shawls in crochet, shoes and slippers, samples of carpet-weaving work, pieces of wood showing with what cleverness the pupils can use the turning-lathe, mats, inlaid work, brooms, and whisks, samples of chair-caning, machine-sewing, and bead work. There was also an assortment of skirts, capes, lace, and knit work.

St. Mary's Institute of Buffalo, N.Y., showed a group of views of the buildings, rooms, and grounds. The Maryland School for the Deaf at Frederick, Md., gave illustrations of the kind of work done there.

An object that attracted probably the greatest amount of interest in this quarter was a large oil painting of Her Majesty the Queen of England visiting a poor deaf and dumb woman in her little cottage, not far away from the Queen's summer palace at Osborne, Isle of Wight. The picture showed the Queen teaching the woman, whose name was Bectine Groves, some new pattern of crochet-work, and Bectine was depicted with an amount of interest in her features as she watched the royal fingers showing her the new pattern. Queen
Victoria

Victoria was seated on a plain chair, and Bectine stood before her. On the floor was a sturdy youngster, entirely oblivious to the fact that he stood, or rather sprawled, in the presence of royalty, as he reached out in different directions for a red wooden soldier and a white tin horse. There were no lackeys in the picture, and Her Majesty was shown as a good human soul trying to brighten up the life of an afflicted sister. The picture was historically truthful, and recently, when reminded of the visits, the Queen is said to have expressed regret that she was not so nimble with her fingers either in speaking the silent language or in crocheting as when she used to visit Bectine Groves.

The Clarke Institute for the Deaf, at Northampton, Mass., was the next exhibit that attracted attention by a series of views. Close beside it was an heroic-sized statue of Dr. Thomas Gallaudet, who was the first founder of the training for deaf mutes in America.

The exhibit of the Colorado School for Deaf Mutes showed flower-paintings, drawings, embroidery, and basket-work, inlaid work, clay-modelling, a wall map in relief, school-papers in point, sewing-cards, mat-weaving, knitting, and hammock and mattress making in miniature.

A varied and very beautiful selection of things spoke well for the training of St. Joseph's Institute of New York. It had three houses, one at Fordham, one at Westchester, and a third at Brooklyn, all three being close to New York City. There were specimens of embroidery wonderful in their beauty, tidies of intricate designs, sachets, dolls dressed in elaborate styles, shoes of strong and some of very fine grade, nearly everything that one could think of in crochet and knitting, and hundreds of things beautiful and useful.

Near the St. Joseph's Institute was a large bust of L'Abbe de l'Épée, which was presented to the deaf mutes of America by Felix Flessis, the French sculptor, on the occasion of the opening of the Congress of Deaf Mutes at Chicago, July 18, 1883. On the side of the bust was written a few lines to the effect that it was presented as a token of the friendship existing between the two republics, France and the United States.

A case of views giving pictures of the American Asylum for the deaf and dumb at Hartford, Conn., was the next object to be noticed. It showed the teachers and pupils actively engaged in their work. There were also views and specimens of work from the Pennsylvania Institute for the Deaf and Dumb at Mount Airy, Philadelphia.

In addition to these exhibits there were also booths containing exhibits of the American Institution for the Blind which had been gathered under the direction of a committee appointed by the American Association of Instructors of the Blind at their meeting at Brantford, Ont., on July 5, 6, and 7, 1892. Several institutions were represented. The American Printing House for the Blind at Louisville, Ky., had 103 bound volumes and fifty pamphlets in "New York Point;" 140 bound volumes and fifty pamphlets in "Boston Line;" a volume of the Gospel of St. Mark; a volume of "Arithmetique," Paris, 1786; a complete set of physical maps of the grand divisions of the globe carved in wood and mounted on stands; dissected maps of the United States and of Europe, also carved in wood and mounted on stands; flasks, plates, and matrices showing the method of making stereotypes, invented by the superintendent, B. B. Huntoon, for printing embossed characters.

The Society for providing Evangelical Religious Literature for the Blind, Philadelphia, Pa., H. L. Hall, Secretary, showed ten bound volumes in "New York Point," twelve volumes in "Boston Line," and

and twenty-four bound volumes of the *Sunday School Weekly* in "point" and "line." The Ohio Institution for the Education of the Blind, Columbus, presented for inspection framed photographs, groups, and plan drawing, relief map of Ohio in wood, a model of the leaning tower of Pisa, a model of piano action, organ-pipes, geometrical blocks, philosophical apparatus, plaster casts, specimens of "point" and pencil writing, books of mounted work in sewing, cutting, folding, and weaving, bead and clay work, brooms, chair-caning, and a large case filled with knitting, crocheting, and sewing, all forming a creditable exhibit for the institution which provided them.

The New York Institution for the Blind had a volume showing the various stages and kinds of chair-caning, books illustrating methods of sewing, knitting, &c., answer-papers in Regents' examinations, kindergarten album, clay and peas work, institution photographs, miniature samples of mattress-work, appliance for teaching staff notation, composing case for music, an original copy of the first embossed book printed by Hany in 1785, illustrations of the New York "point" system, examples of "point" in English, German, and Greek, and a pin-board apparatus for first lessons in point signs.

In the exhibit of the Ohio Home for Blind Men were framed photographs of the building and samples of large and small brooms. The Ontario School for the Blind, Brantford, Ont., showed willow and rattan chairs, clothes-baskets, and a variety of small baskets, with models for making them, as used by the pupils.

Rather more scientific was the exhibit of the Pennsylvania Institution for the Education of the Blind, Philadelphia, Pa. In it were outline maps of Pennsylvania and other States in wood and pasteboard, relief maps in clay, wood, plaster, and metal, cushions for wire and tablet work, pamphlets of school-work, volumes of essays printed by hand in "Braille" and "Taylor" systems, the first embossed book printed in America for the blind, card-sewing, mat-weaving, paper-cutting, pasting and folding, paper flowers, mattress and brooms, and an unusually large and attractive display of sewing, &c.

The Kentucky School for the Blind, at Louisville, Ky., sent a kindergarten department showing designs in cushions, stick-work, paper-folding, mat-weaving, card-sewing, clay-modelling, soap-carving, and building with blocks, together with some crochet-work in silk, wool, and cotton, hosiery, mittens, and lace tidies. The quality and quantity of the hand and machine sewing, as an exhibit, was such as would have done credit to any "seeing" school.

Caned seats and backs for chairs, mattresses, scrub-brushes, twelve varieties of brooms, hundreds of yards of rag-carpet, and framed photographs of the institution constituted the exhibit of the Pennsylvania Working Home for Blind Men at Philadelphia.

The most noticeable features of the Missouri School for the Blind, at St. Louis, were plates of iron, tin, copper, and brass for printing, made on the Hall-Braille stereotype-maker. Hammock-netting was also a specialty of the place.

Perkins's Institute and Massachusetts' School for the Blind at South Boston, Mass., showed dissected wall maps of the United States and Europe, maps made in cushions with pins, cases of sloyd work, and several boxes of botanical and zoological models in clay.

From the Illinois Institution for the Education of the Blind at Jacksonville came a large metal map of the United States made on the stereotype-maker, wood sloyd, horse-nets, hammocks, paper flowers, examples of paper-folding and pasting, mat-weaving, clay-modelling, together with school exercises and examination papers.

The

The exhibit of the Wisconsin School for the Blind at Janesville was rather domestic in character, consisting of bread, cake, cookies, Saratoga chips, canned fruits and vegetables, and pickles. Hammock and tennis netting, broom and brush making, carpet, rug, and curtain weaving were also shown.

American Printing.

The exhibit of the completed product of the press was shown in the north-west corner of the gallery, and chiefly by American firms. Of all these displays the finest piece of work was a copy of the Bible, executed by Barbee and Smith, of Nashville, Tenn., agents of the Methodist Episcopal Church South Publishing House. The size of the book was 17 x 28 inches closed. It contained 836 pages, and weighed 80 lb. It was made expressly for exhibition at the Fair, and was of very substantial character. Vellum was used for the leaves, and the printing was done with gold-leaf, \$210 of the article being used. Each page had a tinted border, twelve different colours being used, running in regular order throughout the book. Six impressions were required to print each page. The different figures were executed in coloured leathers, inlaid and figured with gold. But the inside of the front cover was even richer in finish than the outside, being embellished with the interior view of a temple executed in the same work. The book was said to have cost \$1,500, and required three months of constant labour to complete it. Had the printing been done in good black ink instead of with gold the effect would have been much better. Taken as a whole the collective exhibit of the printing industry shown by America was satisfactory. All the appliances of the trade in each of its branches, from the making of the type to its impression on the paper by the latest pattern of presses, were exhibited.

German Book-printing Trade.

The German collective exhibit was shown in the German Government Building, and was very extensive. As to productiveness and ability the German book-printing trade has no superior; and, in fact, the German book-printing offices do a great deal of work in scientific editions for foreign countries, especially France, England, Italy, Russia, and the Scandinavian countries. In printing Oriental and ancient languages Germany, without any doubt, occupies the highest rank. The principal publishers represented were—D. Bruehl, of Giessen; Waldow, of Leipsic; and Maeser, of Leipsic. There was also a large and rare collection of chromos by Schottlinder, of Breslau; Drugulin, of Leipsic; Foerster and Borries, of Zwickau; Grumbach, of Leipsic; and Sittenfeld, of Berlin, and others; and the productions exhibited were works so artistic in print, paper, and binding as to excite the admiration of the expert. Lithography and photo-printing were exhibited by Klinkhardt, Roeder, and others in a perfection of art. The German Government had no fewer than seven large tables covered with representations of the most splendid and complete specimens of the progress of printing in our times. Type-foundry work of every kind was also shown, and there was a choice collection of finished books of all kinds by all the leading German publishers.

As regards the material for printing, the exhibit of the Waldhof Zellstoff-Fabrik, of Waldoff, near Mannheim, Germany, must be mentioned; it was very elaborate, and was placed in three rooms of the German building. The chief feature of the first room was a collection of transparent photographs on glass which showed German pine forestry. This was done to emphasise the claim that the products of
Waldhof

Waldhof have a distinct advantage in forests of regularly-grown pines cultivated for several decades on scientific principles, while all other countries are dependent on uncultivated trees, the cellular structure of which varies to an extraordinary extent. In the next room was shown, among other things, cellulose bleached for coarse and fine writing-paper, cellulose bleached for copper-plate printing, and cellulose ready for nitration in wood form and paper form. Beneath the various jars were specimens of paper prepared from Waldhof's cellulose and other materials. The third room contained rolls of stock spread out, with the electric lights behind them, so that everyone was able to judge their purity. There was wood cellulose, bleached and unbleached, cardboard from pure pulp, printing and writing papers from pure pulp. In the middle division were papers made from Waldhof cellulose showing the different watermarks. There were also stands supporting rolls of writing and wrapping papers made from this cellulose, with weights attached to the papers. The writing-paper weighs 30 grammes per square metre, and supports a weight of 850 lb., while the wrapping-paper weighs 90 grammes, and supports 1,260 lb. The manufacture of wood pulp, or cellulose, will be found described elsewhere in this Report.

Exhibits of Musical Instruments.

At the south end of the gallery of the Liberal Arts Building was the space, 67,000 feet, devoted to the exhibits of Musical Instruments. There was to be found nearly every instrument producing musical sound, from small mouth harmonics to large pipe organs. Independently of this special exhibit there were collections of instruments peculiar to individual nations in their various courts.

The piano was very largely shown both by foreign and by American makers, but there could be no doubt that the American instruments, whether as regarded musical quality or ornamental finish, equalled, if they did not surpass, the best specimens shown by European makers. One of the greatest novelties shown in the piano exhibits was a tremolo attachment, the invention of V. J. Hlavac, of St. Petersburg. It was of simple construction, and not so liable to get out of order as attachments of this kind generally do, while by means of it a variety of pleasing effects were produced. It could be put into any grand without interfering with the ordinary use of the action. Although a number of the best known American manufacturers were unrepresented, yet the piano exhibit of the United States makers was a very creditable one. Its peculiarity consisted in the fact that very few square-built pianos were shown, the American piano being now almost exclusively built of the grand and upright variety. Amongst other improvements and novelties, the following were described by an expert:—In the A. B. Chase upright piano was an octave coupler, which couples the octaves above and below in the same manner as in the organ. A harmony attachment in the Malcolm Love upright was an arrangement by which one or more notes might be sustained independent of the loud pedal until the next chord was sounded. For a double-sounding board with open-air chambers between the two in the Hardman upright it was asserted that it prevented the "breaking" of the tone when forced. A pedal attachment for pipe-organ practice in the Henry F. Miller upright differed from others in that it could be folded up so as not to be in the way when not in use. The Automatic Piano Company, of New York, deserved special mention for an excellent attachment, which could be applied to any grand or upright. Its simple yet very ingenious mechanism was set in motion by a perforated paper roll in a similar manner to that used in the automatic organs, and was arranged to be run by electric or hand power. It performed any kind of music, from the simple Waldteufel waltz to the most difficult Liszt rhapsody.

The

The M. Steinert loan collection of ancient musical instruments was a very interesting exhibit. It contained a number of old spinets and harpsichords of various sizes and shapes, as they were used from 150 to 50 years ago, and most of them in remarkably good condition considering their age. Nothing so much exemplifies the marvellous advancement made in the art of piano-building during the last fifty years as an examination and comparison of these forefathers of the piano, and that instrument as it exists to-day.

The organ exhibit was an extensive one and the various instruments shown by American builders proved that great progress has been made of late years by American manufacturers. The large collections of various musical instruments in the German and American Courts were very interesting.

Stained Glass Exhibits.

In the German Court there were some beautiful exhibits of stained glass, and in the north-west gallery there were four or five booths containing the stained glass and other similar work by some Chicago firms, amongst which were some very excellent exhibits. The ecclesiastical painted glass window, marked as sold to a church in one of the South American Republics, was very beautiful, and several of the other specimens shown were admirable representations of colour and tracing in this class of work.

American stained glass owes its artistic development to John Lefarge, an artist, who is said to have improved the method of manufacture. This new American glass emits a soft opalescent light, with rich internal fire, the tints and colours of which can be varied from sombre opaque to the most dazzling brilliancy. The jewels used are obtained from Hungary, where the best qualities are produced.

Sewing Machines.

As might have been expected there were a large number of exhibits in the American portion of the north-west section of the gallery devoted to every variety of sewing-machine and similar articles for which the United States have become famous. Several of these machines professed to be improvements, and doubtless they were so, but as far as I could judge they were improvements only in detail. The exhibit of Singer & Co. and others were most interesting.

Anthropological Building and Exhibits.

As has already been stated under the description of the exhibits in Liberal Arts Building, the Department of Ethnology was one of miscellaneous character, and although generally known as ethnology it virtually included the several groups of ethnology, archæology, and anthropological laboratory, history, and natural history, the Latin American exhibit included the special exhibit of the relics of the time of Columbus arranged in the convent of La Rabida, the reproduction of the ancient ruins of Yucatan, on the grounds immediately north of the Anthropological Building; and the ethnographical exhibition of native people of America, who lived in their native habitations on the stretch of land along the eastern side of the south pond between the Anthropological Building and the Indian schoolhouse, the Midway Plaisance, and many other exhibits illustrative of the customs and habits of the various races of mankind.

The building itself was quite incomplete at the opening of the Exposition; it was originally intended that the exhibits belonging to this section should have been placed with the liberal arts exhibits in the gallery of the Manufactures Building, but the educational exhibits were so numerous, and required so much space, that it was ultimately decided to erect an additional Anthropological Building. Hence the arrangement and classification of the exhibits in this building were delayed, and, as I have stated, were not completed till after the opening of the Exposition.

The Building.

The building was 415 feet long and 255 feet wide, with a gallery 48 feet wide on all four sides. Thirty thousand square feet on the ground floor at the southern end were given up to the sections of hygiene and sanitation, and of charities and correction, belonging to the liberal arts. The remainder of the floor was occupied by the archæological and ethnological exhibits of foreign countries, States Boards and individuals, and the collections made by the assistants of the department who were sent to various parts of North, Central, and South America to make special explorations and researches under the direction of the chief of the department.

New South Wales Court.

New South Wales was well represented in this department, and the large and well located space it occupied, 4,666 feet, was a constant source of attraction in the midst of the numerous curious and interesting exhibits contained in this building. The space was divided into two large courts intersected by an important avenue. In consequence of the numerous large and important photographs provided for this department I found it necessary to erect wall screens 12 feet high round all our space, as well as to make bays in the courts. The north court contained the photographs and exhibits of Australian aboriginal life, while the south court was devoted to those pertaining to the South Seas. For the valuable exhibits of a small character glass-covered cases on tables were provided. The trophies of spears and war-like weapons attracted considerable attention from their conspicuous position and excellent arrangement. The pillars and walls were also decorated with exhibits. It was a universally expressed opinion that these courts, as an educational exhibit in their peculiar sphere, were most

KEY TO INSTALLATION.

The Department of Ethnology occupies all the space in the Anthropological Building except E and F in the southern end of the main floor. These are occupied by two divisions of the Liberal Arts Department—the Bureau of Sanitation and Hygiene and the Bureau of

(sig. 293)

FIRST FLOOR PLAN
ANTHROPOLOGICAL BUILDING,
WORLD'S COLUMBIAN EXPOSITION.

Charities and Corrections. The sections on the main floor are lettered from A to Y, and the columns on the main floor and in the gallery are lettered from A to Y, north to south, and numbered from 1 to 15, east to west. The letter and number following an exhibit in the catalogue marks the column nearest to the exhibit. The sign "Floor, J-6" indicates that the exhibit is on the main floor near the column J-6.

most instructive as regarded the habits and customs of the natives of Australia and of the islands of the South Pacific Ocean. The large photographs of native life especially attracted attention, and constant inquiries were made by visitors as to the purposes and history of the various implements and weapons, and especially as to the customs depicted; and the pamphlet circulated in this court, written by Mr. Frazer, was much sought after and highly appreciated. That portion of the cave scenery placed in this court was also the subject of much critical examination.

The collections in the Anthropological Building were of surpassing interest, and although it was remote from the centre of the park it was crowded from day to day by curious observers of the wonders it contained.

Village of Skidgate.

A most peculiar exhibit, occupying a very extensive space adjoining our own court, was the model of the village of Skidgate, Queen Charlotte Island, B.C., as it appeared in 1864, collected and arranged for the Department of Ethnology.

The most remarkable of all the Indians on the North American Continent, the Hydahs, of the Queen Charlotte Island, are haughty, dignified, proud, of fine physique and medium height, and superior morals. As a nation they are quite distinct from all the other Indians, and whatever their origin, whether Japanese, Egyptian, or Phœnician, it is quite clear that it has been quite distinct from that of the other Indians. Forming once a powerful and populous nation, they are now reduced to three villages, Massett, Skidgate, and Clew. They formerly numbered sixteen or seventeen large villages, now, with the exception named, all deserted and in ruin, marked by empty lodges and those remarkable totem poles for which the Hydahs have become famous. These totem poles are of all sizes, and are from a foot to 60 feet high, ornamented by carvings and painting, which are genealogical and symbolical, but in no sense of a religious character, and it is a common mistake to regard their carved figures as idols. These people are most skilful carvers in wood and stone and engravers in metals, which they work into various beautiful designs. There is a great deal of antiquarian, archæological, and historic interest connected with the Hydah Indians, which I cannot now dwell upon. Their traditions are especially interesting, and bear a strong resemblance to the cosmic theories of the South American Indians, and are not unlike in many respects to the sacred narrative itself; in fact many of them contain glimmerings at least of the Mosaic hypothesis.

The exhibit itself represented *Ilthcahgeetha*, the native name meaning Stony Beach. The people of the village were divided into three groups, living in separate parts of the village; first, the Western Group; second, the Large House people; and third, the Catherine's Point people. These people are divided into a number of clans, arranged in two groups or phratries, and are called from their principal crests the Eagle phratric and the Raven phratric. Custom requires that a man must not marry a woman of the same group. The members of the clans adorn their houses and their possessions with carvings of various birds, beasts, and fishes, representing their own crest or that of their wives. The houses are large square wooden structures, and with gable roof, and all placed facing the sea. The framework consists of four corner posts, which support the gables and outside posts of the roof; two pairs of inner beams are supported by posts in front and rear of the house. In the middle of the front of the house stands the carved posts representing the crests of the owner, sometimes also that of the wife, and the mythical traditions belonging to her family.

In

In the village of the Hydahs the houses of each phratry or clan stand grouped together. They consisted of the house of the Raven, the Moon house, the Owl house, and numbers of others with heraldic paintings, columns, &c. Some of these had totem poles, and all were decorated in characteristic animal representations.

Antiquities.

The Government of Greece furnished the central group in the collection, containing ancient Greek art and archæology chronologically arranged in connection with exhibits from Assyria, Egypt, and Rome. Russia exhibited illustrations of the habits and costumes of the various classes of her peoples. Spain had collections from the Madrid Museum. Japan, Palestine, Africa, the West Indies, the Argentine Republic, Paraguay, and Mexico were all represented. British Guiana contributed a very interesting collection of native jars, spears, articles of dress, and the fibres and palm-leaves used by the aborigines for their houses. Some of the warlike plumes were very beautiful. There were also some cases filled with stuffed but unmounted birds of lovely plumage. The native drums, with the heads made of wild hog or peccary skin, were also shown.

The Charnay collection, exhibited by the Minister of Public Instruction of France, contained remarkable representations and models of bas-reliefs, fragments of temples, sculptured inscriptions from temples. The "Paroi interieur d'une salle du jeu de paume avec essai de reproduction de peinture murale d'après les manuscrits Mayas et Astecs" was a very beautiful example of this large collection. Some of these wall sections, as well as the Yucatan mural specimens, were brilliantly coloured and appeared to me very like Egyptian work of the same character.

Perhaps the series of exhibits which awakened the highest curiosity and interest were those of the prehistoric American races. Exhumed from mounds which have remained undisturbed for untold ages, the large collection of relics, revealing the past, unravelling long-buried secrets of domestic life, business relations, and exhibiting even from the mouth of the grave, on the stone sepulchre, the fact of prehistoric heroism were very instructive. The fashions of the day, the industries, the favourite foods were all shown; what the primitive man bartered, and how he warred; how he worshipped, and what; how he lived; stories of his travels, where and how he summered and wintered; all these and many other particulars of prehistoric life as man lived it, enjoyed and employed it, were told in the exhibits presented in this section. Professor Putnam, one of the Harvard professors, in charge of this department, took a deep and practical interest in this collection.

It is believed that the most ancient evidences of man on the American continent were found in Ohio. The archæological exhibit of this State, largely collected by Warren K. Moorehead, abounded with specimens of the mound-builder, the prehistoric man of the continent and his works. Time allows no estimate of the age when he peopled the Muskingum and other valleys of the State, planted and harvested his corn, worked in his flint quarries, and bartered his skilfully wrought arrow-heads, stone-knives, and even copper utensils and ornaments with his less skilful neighbour for such raw material as he could make of avail.

Of the ancient races of America, the Aztecs of Mexico, the Chimus and Incas of Peru, and the Indians of North America, we have historical accounts and traditional stories. Among the Indians of all the continent there are supposed to be surviving descendants even at this day. Of the cliff-dwellers there are traditions; and the mesa homes of the Zuni, Moqui, and other Pueblo Indians of the far southwest are so like the abandoned villages of Mancos Canyon and other
Arizona

Arizona sites of the cliff-dweller's habitations that these peaceable husbandmen and farmers may possibly have been their descendants. But of the mound-builders there remains nothing to tell the story of their life and manners but their homes, the tumuli from which they are exhumed, together with relics of their domestic and economic life and intercourse with other people, of whose existence nothing is known, except by inference from what the mound-builders have left. In the Ohio collection of these pre-historic people who inhabited the Ohio, Mississippi, and Missouri valleys, there were skeletons well preserved, battle-axes of stone, spear and arrow heads, pottery and weapons made of copper, and ornaments of the same metal. Two kinds of graves have been found, and were here reproduced. One was that of a well-preserved skeleton found in a stone grave—a grave scooped out of the earth, and lined on the bottom and sides with stone flags, and covered with stone, as was the well-known custom in eastern countries. The other grave was the reproduction of the pit in the tumulus or mound, in which the true mound-builder was buried. A great necropolis of the mound-builders belongs to the "Hopewell Group," at Anderson, Ross County, Ohio; and here and elsewhere these cemeteries of the past have been explored, and hundreds upon hundreds of graves have been opened. The skeletons are found prone and in a sitting posture, and each grave has been made the depository of weapons, ornaments, and pottery. That religiously the mound-builder, primitive as he may have been, and slowly passing from the stone to the bronze age, had an idea of or a belief in the hereafter is evidenced by the fact that the pottery contained food to last him on his journey, that his weapons were buried with him to be handy in case of an emergency, and that his ornaments decked him to play his part in the new life beyond the grave. That he had traffic with other people is proved by the fact that splendid specimens of obsidian, spear-heads, arrows, daggers, and knives are found in the Ohio graves, while no ledge from which this hard crystal stone, so useful to the mound-builder, is found nearer the Muskingum Valley than the Yellow-stone Valley of Montana. That they sold corn or some other commodity susceptible of growth in the fertile valley of the Ohio is proved by the copper weapons, utensils, and ornaments they had, which must have been procured from nomads of Michigan, or by expeditions sent out to get it. Their religious life also, as well as their commercial intercourse with other people, is proved by the altars found. That they were warlike—perpetually at war—is demonstrated by the weapons found and the rude earthworks that were thrown up for protection among great areas of country which had salient points. These were marked by mounds for "conning towers," though their mounds ordinarily were the pyramids in which they entombed their dead. Distinction of rank and caste occurred among the mound-builders as it does among men to-day. A skull pierced by an arrow-head told of a heroic death. Like a Spartan of old, the warrior returned on his shield rather than without it. In one grave the skull of a skeleton, prone and stretched out to the full length of a tall and massive man, was found surmounted by a head-dress, a helmet of copper, from the crown of which rose two antlers fashioned out of copper. A chief, or perhaps a king, was disturbed when the sleep of this massively-framed man was broken. There were long-headed and short-headed men in those days among the toilers of the mound-builders, and in those primitive times the long-headed man was inferior to the short-headed. But a full account of these peculiar people and their relics will be found in Mr. Moorehead's works entitled "Fort Ancient, Ohio," and "Primitive Man, Ohio," both of which were shown with the relics.

In addition to the relics from Ohio there was a large collection of arrow-heads, bronze weapons, spears, and axes from the mounds of Michigan, as well as a large collection of ancient pottery from mounds in Arkansas.

Ancient Life in South America.

Lying speechless, in an adjoining section, some ancient American people eloquently presented their story—a history antedating Columbus, and which was centuries old when Pizarro first fought the Incas of Peru. This collection of Peruvian antiquities was one of the largest and most complete among the various and curious exhibits which Professor Putnam had gathered from all parts of the world. There was a ghastliness about the display: the reproduction of an ancient necropolis, peopled by the very men, women, and children who were laid therein ages and ages for their last rest. The bodies, mummies, wrapped and unwrapped, and parchment skin-covered bones were placed, surrounded by pottery, ornaments, and weapons, just as they were found in the ancient Peruvian cemetery.

Peruvian Cemetery.

The necropolis of Ancon, Peru, is one of the most famous in America, both for its vast area and the good state of preservation of the contents of the graves. The burying-ground is on the rainless desert coast, 22 miles north-west of Lima. The surface is uneven and covered with a layer of sand about 2 feet deep. Beneath this is a hard cement-like gravel (the original ocean bottom). Where this gravel has been disturbed it remains loose, because it has not been subjected to the same conditions it underwent in geologic times. The graves are generally at a depth of 6 feet, although they have been found to be over 20 feet deep. There is no ridge or mound to mark the grave, nor do they occur at regular intervals; they must be discovered by means of a steel rod, which may be easily thrust into the loose gravel found in the graves. Two facts account for the almost perfect preservation of the contents of the graves: it seldom rains in the coast of Peru, and the gravel contains large quantities of saline material. The body is usually found in a sitting posture, with knees drawn up to the chin, and hands placed over the face. It is wrapped in various garments, and cotton is usually found over the face and breast. There was a large exhibit fenced in representing this cemetery and the contents. In addition to the bodies, which lay as found in their original position, there were clay vessels and calabashes containing food often found inside the wrappings of cloth, the whole made into a bundle and tied with rope or wrapped in a matting made with rushes. The bundles were sometimes further decorated by a false head placed over the real one. These false heads were made of various plants sewn up in a sack on which were placed eyes of shell, nose of wood, ear ornaments, straw headbands, and feather plumes. At the sides and in front of the bundle were placed vessels of food—maize, beans, fish, crabs, and various kinds of fruit; work-baskets containing hand-looms, cotton, wool, spindles, tubes of paint, &c.; agricultural implements, war clubs or sceptres, clay or wooden images, painted tablets, and other articles. There were two of these enclosures exhibited, containing graves from different parts of Ancon, and showing many different styles of burial. The graves shown did not occupy their original relative positions, but from want of space were placed much closer than they occur at Ancon. The ridges of gravel individualised the graves, and, as exhibited, often two or more bodies were found together. The skulls, the long bones, cloth, &c., lying loosely on the sand in the exhibit gave some idea of the extent of the surface of the Ancon graveyard, for thousands of graves have been despoiled by relic-hunters and the contents scattered about. The mummies and the relics were wonderful spoils, and were deprived of their outer rope-bound rush covering, and were swathed in vari-coloured blankets and richly-figured cotton-cloth, and, strange as it may appear, the red, white, and black of the blanket stripes were as bright as if the robe had just been taken from the loom. Beside each mummy were earthen jars and bowls, and the corn in the vessels was well preserved, while the skeletons of the animals intended to feed the traveller on his long journey were so intact that the animal could be reproduced. Dried
fruits

fruits, too, and the rinds of pumpkins were shown, while about every corpse there were tablets evidently bearing the epitaph of the dead, or telling in a heraldic way some deed or service of the long-departed one. These tablets, too, were not of enduring bronze (though copper ornaments were found in nearly every grave), nor was the history or the biography of the long-sleeping occupant of the grave wrought in marble. The tablets were of cloth, stretched over short willow or reed wands, and figures and cunieforn characters were painted on the cloth. Colouring and figures remained undimmed and unworn, though they, along with the body, have been earth-covered for ages. The antiquity of the necropolis cannot be estimated. It had been used by the Incas for thousands of years before Pizarro first saw it, for it was densely populated then; and since then it has only been spoiled for the sake of the gold it was hoped was treasured with the dead. Whole families are found together, probably taken off by an epidemic. Wrapped up, the knee against the chin and the arms plaited about the body, the mummy looked like a rope-bound bale of old rags. Unwrapped, the mummy was a fleshless yet skin-covered skeleton, and the hair was seen to have adhered to the skull in all its plentifulness. The bodies were tattooed, and beads and copper ear-rings (a pound and a half in weight each) were found to have been the fashion among the Incas women long before the Spaniards desecrated their graves in their mad search for gold. Sacrificial altars, stones, and weapons were found, but these last not so plentiful, showing that the Incas were peaceably disposed, or had nobody to fight before the Spaniards came.

Ecuador Cemetery.

Next to this cemetery were other relics of kindred people, who were interred on the island of La Plata, off the coast of Ecuador. The exhumations here consisted of mummies, cased like the Ancon dead, yet wrapped differently, though crushed into a sitting posture, just as the others were. The pottery of these people showed a high degree of ceramic art, while the copper, gold, and silver ornaments, heads, and idols exhumed displayed fine and skilful workmanship. Sombre or ghoulish as was the appearance of these dead, and the property of which their graves have been robbed, there was a valuable lesson taught by their examination. And when we compare these ancient American methods of burying the dead with that of still older Americans, and that of other countries, there seems a similarity that makes man akin the world over, ever since the music of the spheres was first heard.

The Cliff-dwellers.

The Cliff-dwellers buried their dead as did these people and the Aztecs. They mummied their dead, swathed them in cotton cloth, wrapped a feather robe about them, and twined over all a burlap covering, rope-bound and tightened. An Egyptian mummy is not unlike the American antique, excepting that it is fresher and a little more gorgeously got up and painted, because the embalmer's art had been improved upon in the modern days of Egypt far beyond the crude methods of the old-time American undertaker.

It would appear, therefore, that throughout all these burials, even down to the days of ancient Greece, when sculpture flourished as an art never since equalled, the despoiled tombs showed the conception of immortality. The dead king of the mound-builders was put into his grave armed cap-a-pie to combat such unknown enemies as he might encounter, and he was provided with food to strengthen him that he might not be caught unprepared. The Incas went away provisioned and armed; the Cliff-dweller was given a proper send off by his friends; the Egyptian was loaded with treasures to appease Osiris; and over in the Greek section it was shown that the Greek pugilist took his cestus along with him and a cruse of oil to limber up his muscles if he got into a pugilistic encounter in the brimstone country of Hades.

Yucatan

Yucatan Ruins.

Consul Thompson, of Yucatan, came specially to Chicago to arrange the exhibits he had collected among the ancient ruins of Yucatan, in which was shown the peculiar architecture of the people who lived in that country in the remote past. Tropical plants from Yucatan were brought and artistically arranged over and about these ruins. The structures reproduced were the protal from the ruined group of the Labna; the straight arch of the Uxmal, reproduced from the east façade of the so-called House of the Governor; the Serpent House; the west section, north wing, of the House of the Nuns; south-east corner, east wing, House of the Nuns,—all ruins of Uxmal. In addition to these were two monoliths and a collection of scriptural stones of scientific value. There were also casts from moulds, several monoliths or idols from the pre-historic city of Capan. The casts were taken by the Peabody Museum expedition.*

Pre-historic Designs of America.

A paper was read at one of the meetings of the World's Congress Auxiliary during the currency of the Exposition, by Miss V. V. Dodge, of Washington, D.C., one of the best-known American archæologists, who had just returned from a journey of discovery extending over several years in South America, where she had made many wonderful discoveries relating to the art of old pre-historic races. Pre-historic designs of America are of some interest in this connection. Miss Dodge's address was, in part, as follows:—

“As we pass into the charmed circle in which the artist conjures, we enter a fairy realm that has its own laws, its own usages. This is particularly true of the pre-historic artists of America, either of the southern or northern continent. Before the wealth of their productions we may well be awed and scarce know from what nation to gather. We have already proved with what freedom of thought and what originality of conception they lived and wrought. Note the infinite grace and variety of the races who peopled this latitude. From the burial-mounds of warriors come graven trophies and vessels placed there for the long journey to that far country. From the lone skeleton in armour on the bleak New England coast, whom Longfellow immortalised, to the tenants of those graves built in the shadow of the Cumberland—graves laid of stone, like unto the one over which Mary and Martha wept—to the unparalleled revelations which have opened for us within the boundaries of Ohio, all of which are abundant proof of the supremacy of the pre-historic mind in design.

“That most beautiful and historic valley in Ohio, the Muskingum, has opened up to us the art that neither Phidias nor Michael Angelo would have disclaimed. No history recounts the customs of this pre-historic race, their lives or the day of their doom; but their grave yields up after thousands of years such handicraft that tell us mutely much of the story of their lives. The renaissance yields nothing more graceful than the decorations on pre-historic clays and medals. The conception is vigorous. Some, it is true, are wrought in the image of primitive things, while many others reveal the elaborateness of the far East.

“In the south of our Continent, even to Panama itself, another conception reigned, a magnificence of architecture and design; of carving, sculpture, design, painting, and graving that is a proof of the original genius of these skilled artisans. In the pottery everywhere the mark of individuality shows itself, duplicated designs being unknown, proving that there was no such things as moulds used in the construction of their works of art. Realistic in some examples, pre-historic designs diverge into most lovely decorative effects, and all are fruitful for further consideration.

“Whether these designs had their birth in an Asiatic home before Babylon, as is declared, or in our own Continent wholly and originally, we can only conjecture by the types of ornamentation and mythological symbols. Whatever may have been the arts of our Continent, they were made in a new spirit, a creation bearing a strength and nobility that we must admire. In colossal figures, in idols, in adornment, in weapons, in utilitarian lines, in carving, in relief, and so on through the long catalogue of their works, there is no servility, no mere copying that would point to Nineveh, or Egypt, or to any land. The designs of America combine the delights of the arts of Araby, of Persia, of Egypt, and of other lands, but it is only a suggestion of these. A virile individuality reigns through them all. An element of splendid possibility comes to us out of the years and ages. Human faces and heads, animals of ages long past, as well as familiar designs of birds, flowers, the forms of rivers and seas, all combined with every form in nature to serve the artist of those pre-historic times. On these are founded conventionalisms really excellent and adaptable to many purposes.

“Of

* A full account of these relics will be found in Squire's work on Peru, and in the Report of the Smithsonian Institution for 1888.

"Of the uses of colour these races knew all, but time with its relentless hand has destroyed the first glory. Bits of colour on the walls and pavements of palaces show a refinement of tone that Turner or Paul Veronese would not have ignored. The pink and madder of the ancient walls are not the taste of a crude mind. The Assyrians, with their famed dyes, did not excel the black and red and white combinations of colours and design that the mummies of the South American pre-historic tribes were wrapped in. Even the Tyrian purples have been rivalled in our own borders. The colour secrets of our continent were not those of a barbarous or inartistic race.

In ecclesiastical design the archæology of America is rich. From the most insignificant mound of that chain trending north-east in our Republic to the mighty pyramidal structures or temples of the tropics of America we can decipher the forms of vessels, ornaments, signs, and even the belief in the immortal life. These things reveal to us the high ideal toward which our far predecessors wrought. Nor Roman, nor Greek, nor Mohammedan, nor Buddhist has a richer symbolism than that by which the belief of pre-historic Americans is revealed in their designs. There are conceptions fitting the impressive pomp of processional days. There were those of sacrifice, and on this they felt deeply, and wrought their images with great feeling. Long before Vincennes or any of the famous wares of Europe were known, America had clays wrought into such artistic shapes that we would do well to copy. Out of these pre-historic treasures let us take the special jewels that will reflect light on a new school in our own land, that shall be a copy of no other nation's thought. Many there are who disdain these precious inheritances of archæology. Murillo, Raphael, and Rubens they hold only worth their worship. The artist who will to-day go back to the fountain of pre-historic American art will reap the richest reward.

It was my good fortune in hunting for the typical American designs for my collection to watch an Isleta silversmith at work upon an ornamental band, wrought in relief in a most exquisite manner known only to him. Every square was worthy of Cellini. There were incomparable little figures joined by slender bands of graven silver. When I asked him where the designs came from, he said "Ah, from my fathers. They got it from the rain and the clouds. Each of us adds to it." This was the simple effort of the untutored to tell me that out of the mists of ages from pre-historic times his people had inherited that beautiful design.

Among the relics of American antiquity I have noted a stately design which would be adaptable to architectural forms and is of great strength and beauty. It is a procession of animals, bordered on either side with an intricate design of horns, locked and interlocked. It is unique. The altar carvings of Guatemala, the wondrous fronts of the palaces of the kings in Central America, the arches, the interior decorations, the plaques with their star-like edges in sharp relief and cameo effects, are all adaptable to the ceramic art, and to all art applicable in painting and sculpture. The pieces from the mounds of the north and the plains of Peru are highly adaptable shapes. Of the little that remains of the proud races who peopled our land we must acknowledge skill and genius. They sprang from the gods. They were great in their choice of simple truth. I urged their designs as a foundation, an element for a future school of American art. We need inspirations, desire something born of ourselves. We should perpetuate our American inheritances. We should build and mould for ourselves out of our own nationality. We must not be confounded with any other school. Let us rise to new things out of these old. Ruskin has told us all success depends upon knowing what to gather. Let us then be wise in our day.

SANITATION EXHIBITS.

The south-eastern end of the floor space of the building was occupied by apparatus for sanitation, disinfection, &c. Here also were large collections of anatomical models of various kinds, and collections of surgical instruments, showing the most recent advances of science in this direction. Near these were various booths containing the ivory points and the apparatus used in the operation of vaccination. The booth of the Lancaster U. S. farms contained a large collection of points loaded with heifer vaccine virus, and similar quill slips (the price of each being 10 for \$1 each) and lymph tubes (stated to be sold for \$2 each) and tablets or crusts (for \$1.50 each). There were also a number of interesting photographs showing the methods in use on the farms where the heifers are inoculated, and some coloured paintings representing the pock in various stages both on the teats of the heifers and the hands of operatives.

The western portion of the south end of the floor space was devoted to exhibits of the various departments of charity and correction. A remarkable series of charts was placed on the screen of one of the courts with circles divided into sections variously coloured representing the proportional numbers of the defective, the dependent, and

and the delinquent classes in the United States, for 1890, from the eleventh census. These representations showed, in variously-coloured sections, the habits, education, marital relation, and groups of crimes, distinguishing between native and foreign born persons. In the case of prisoners there was in the special chart representing this subject distinctions drawn as to the groups of crimes occurring in foreign-born, native, white, and coloured prisoners according to the population of the State. The classes of crimes were represented on these charts by differently coloured proportional parts as crimes against property, against the person, against society, against the government, and miscellaneous. The sentences of prisoners were similarly represented by large circles containing, as before, differently coloured sectors, showing the proportion of sentences in classes as of under one year from one to five years, over five years, for life, death sentences, and were divided also as occurring in the case of native white, foreign born, and coloured prisoners.

Similar particulars, in like form, were shown with regard to benevolent institutions, juvenile reformatories, asylums for idiots and the insane—and the whole series was most complete, and conveyed to the sight as well as to the mind correct relative information on all these subjects. There were also in the neighbourhood practical illustrations of the prison cells and other matters illustrating prison life. Amongst the various curious exhibits in this section was the original electrocuting chair, the first application of electricity to the purpose of capital punishment, in which the murderer Kemmler was executed at New York. At first this chair was open to the public, but with that infatuation which seems to be popular everywhere, so many people rushed to sit in this murderous apparatus and to remove portions as mementoes of their visit, that it was found necessary to put a fence round it to exclude the public.

Identification by the Fingers.

In the Department of Charities and Correction, in the Anthropological Building, there was a very excellent representation of the Bertillon system of identification of criminals. As is well known, the French system so classifies anthropometrical methods of record that each case falls into its own natural group. As a supplementary aid to this system a method of identification advocated by Francis Galton received attention. By means of it finger-prints are classified in a similar manner to the records of the Bertillon system. The test of the efficiency of the system lies, first, in the certainty with which different (instructed) persons assign the same index letters to the same set of prints, however indifferently printed; and, secondly, in the degree to which the sets are differentiated by their classification. One of the most extraordinary points about Mr. Galton's system was the unique and remarkable ability afforded by the finger-prints to the observer of determining the individual, irrespective of his age and growth, whether the clear impression, taken at different dates, were or were not made by the same finger. The result depends not on the general pattern of the print, which is the basis of classification, but upon the numerous forks and other details in the ridges composing the patterns. Mr. Galton is of opinion that no matter how early in life the first impression of a finger-tip with fully formed markings may be taken, and how late the second impression may be obtained, the similarity between them will not only be decipherable but unmistakable. The simplicity of the process of taking the impressions and the small equipment necessary are points very much in its favour. There is no undressing required, and nothing else of a humiliating character to be undergone during the brief act of making the prints.

Representation

Representation of the Games of Various Peoples.

At the northern boundary of this section there were a number of cases filled with the games of the principal countries of the world, which were for the most part exhibited by the University of Pennsylvania. These consisted of pyramids, wooden draughtsmen from Bavaria (18th century) and from Poland, ivory draughts from Canton, China, chess from various countries, European and Oriental curling, croquet, marbles, polo, baseball, quoits, lacrosse, jackstones, tops, puzzles, tip-cat, cricket, golf, football, bowls, and other games from all countries, with descriptions of games written and printed, and practical illustrations of every kind, as well as text-books of various languages on the subject. Another case contained the game of Eckha, strategy, Kerion, and other similar games. The ancient Greek games as represented on the vase paintings of Dactylon-Epallage (finger changing) were shown. There were also gambling-sticks from Alaska, fantan and other Chinese games and lotteries. A most interesting case contained a large number of exhibits showing the evolutions of the playing card, both Chinese and European. In another case were shown the dice and dominoes, ancient and modern. The University of Pennsylvania exhibited its publications on the subject, as did the Numismatic and Antiquarian Society of Pennsylvania.

Folk-lore of China.

A special feature of the folk-lore exhibit was the collection illustrative of the life and customs of the Chinese in the United States, made by the Archæological Museum of the University of Pennsylvania. The collection embraced shrines, religious and ceremonial objects, charms and amulets, implements for fortune-telling, musical instruments, games and amusements, utensils for writing, account books, scales and measures, implements used in the shop, cooking utensils and table furniture, articles of dress and adornment—everything, in fact, that is peculiar to these interesting people in the various settlements they form in this country.

North American Indians.

There was a very fine exhibit representing the Indians of Northern America and their modes of life. Least familiar, and, therefore, most interesting, to many were the articles brought from the aboriginal tribes on the Pacific Coast from Puget Sound to Alaska, including the model of the village of Skidgate, showing all its houses and their totem poles, already referred to, and a collection of "sure enough" totem poles from Alaska, with displays of the Thinkit art of carving the grotesque and grinning countenances used as ornaments to the building erections. There were collected on the banks of the lagoon, near the Ethnological Building, camps of aboriginal people from different sections of North America. Maine sent several families of civilised Penobscot Indians. New York was represented by an Iroquois village, with different styles of bark houses, including the long house and the palisade house. Canada contributed several families of Creeks living in bark wigwams. A skin tent was inhabited by an Esquimaux family. All these brought their boats, which were shown on the water near by. Among the other features of this locality were a mat and a bark house of the Winnebagoes of Wisconsin, skin tents, hogans, and other habitations of the Apaches and Navajos, a wooden house and totem poles from Vancouver Island, thatched house from British Guiana, inhabited by Arawak and Savannah Indians, and a pioneer house.

Mexican

Mexican Exhibits.

In the Mexican Court there was a model of Teocalli, the principal temple of the city of Mexico, on a scale of one centimetre to the metre, representing it as it was before the conquest. On the flat roof of the great edifice were shown some of the ancient religious ceremonies of the sun-worshippers, as well as a representation of the sacrificial rites and the mode of disposal of the dead. Another excellent model represented the meeting of Montezuma, Emperor of the Aztecs, and Fernando Cortez, at his entrance into the city of Mexico, while a third represented Cortez receiving Cecanthemoc as a prisoner in one of the great flat-roofed buildings of the period. The famous Mayer Stone of Mexico was also shown, and books explaining its symbolism, published by Dulan & Co., of Soho, London. There was also the large and splendid work of Antonio Penafiel, "Monumentos del arte Mexicano," published at Berlin by Ascher & Co.

Palæontological Exhibits.

The large and extensive galleries of the building contained most interesting displays, and were always filled with crowds of visitors, whose attention had been specially attracted when on the floor space by the display of immense fossil remains and animals shown by the celebrated American firm, Ward & Co. The south-east and half of the west galleries were filled with Natural History exhibits, including stuffed birds and animals, birds' eggs, fossils, and taxidermic work. The largest and most splendid collection was that of Ward, of Rochester, N.Y. It contained among the exhibits Palæontological and Natural History exhibits of all kinds, collections of minerals, ærolites, and geological specimens. In fact every form of past and present life was exhibited in the collection evenly and comprehensively through the entire course of life on our planet; and, in order to render it complete, where natural specimens were not obtainable, casts, accurately made, were provided. Very remarkable were the restorations of the immense animals of the Miocene Period, such as the Colosohelys Atlas, &c. There was shown the actual skeleton on the Mastodon Giganteus, of the Quaternary Period, from Michigan, and the Megacerus Hibernicus, of the Pleistocene Period, from Limerick, Ireland, and the Hydrosaurus Foulkii, an immense fossil reptile, from the Upper Cretaceous, of New Jersey. There was also shown the Mammoth (*Elephas Primogenius*), which was a reconstruction upon the bony skeleton (one entire natural tusk was present in the specimen) found in a deposit of the Quaternary Age, near Stuttgart, Wurtemberg, and preserved in the Royal Natural History Museum of that city. The outer covering (skin and hair) was copied from the great Siberian Mammoth in the Museum of the Imperial Academy of St. Petersburg. I ought to state that the bones used for this reconstruction were those of an individual of extraordinary size, a mammoth among mammoths, and hence this specimen was regarded as one-fourth larger than the average size typical mammoth.

Nevada Prehistoric Footprints.

Perhaps nothing shown in this department was more interesting than the prehistoric footprints reproduced from the quarry of the Nevada State Prison, at Carson, Nevada. The prison is situated at the north end of a low ridge of sandstone, the termination of a short spur of the Pine Nut Mountains, which is only three miles east of and parallel to the Sierra Nevada Mountains, and is placed at an altitude of 4,950 feet above sea-level. In quarrying the stone required for the penitentiary, at a locality about a mile and a half east of Carson, the capital of the State, where the foothills border the valley, there was found the bed of an ancient sea. In carrying out the work of quarrying there was found, overlapping the usual country rock, another
of

of grey slate colour, very similar to chalk in substance. The formation, probably in volcanic days, consisted of lake or sea-shore mud. How the Pliocene beach had piled on it a wall of rock 30 to 50 feet in thickness it would be difficult to tell, and still more difficult to explain the extraordinary impressions found under it. As soon as the overhanging rock was removed there were found the unmistakable footprints of man, of the mastodon, the wolf, the horse, and some extinct species of bird, very large in size, and divers other prehistoric remains. The most interesting track or print was that of a man, the footprints measuring no less than 18 inches in length by 8 inches in breadth. The age of the strata has never been fully ascertained with absolute certainty; the deposit is supposed to be either quaternary or upper Pleiocene for no true horse or elephant is found in the American Miocene (Joseph Leconte). As regards the elephant footprints, Professor H. W. Harkness says, "there is no doubt about their 'character.'" Portions of a tusk and fragments of teeth found in the sandstone resemble those of a mammoth, and make it probable that these were the footprints of the *Elephas Primogenius*. (C. Drayton Gibbes, C.E.) B. B. Redding asserts that the Carson footprints carry the mind back to the Glacial Period, and if it is ever proven they are human relics they will entirely upset all the scientific theories as to the age of man upon the earth. Professor Harkness, who has taken a deep interest in this matter, says, "that the only evidence that can be adduced in favour of an earlier age than the quaternary is the lithification of the strata—the partial, or in some cases of plants, the complete fossilisation of the organic remains and the tilting of the strata."

There was in this exhibit a very large plan, about 30 ft. x 10 ft., exhibiting the footprints and the marks, and a number of the actual specimens of the elephant's teeth, some of the stone with the original footprints, the jaw-bone of a horse, the original hip-bone of a mastodon, as well as a number of human relics found 18 feet under the sandstone. Several charts and diagrams, prepared by Charles Drayton Gibbes, C.E., represented the exact size, to scale, of the marks, the footprints, and the mammoth tracks.

Psychological Exhibits.

The north gallery contained a number of courts or bays devoted to anthropology, neurology, and psychology. Here skulls abounded, and casts of the head and features of the natives of every clime. There was also a very large collection of photographs illustrating Indian (American) life in all its various phases, as well as coloured cartoons showing the games and occupations of the race. In this section was a large collection of all the various instruments used for craniology, belonging to the University of Chicago. Head spanners were shown by the Scientific Instrument Society of Cambridge, England. On the walls were tabular statements noting the various scientific classifications of the different heads of different peoples, the length and the breadth index, and the facial index, as well as the connection between stature and the length of the head, and a vast amount of similar information relative to cranial development. Models of the brain were exhibited by Professor Cunningham, of Dublin, and others, exhibiting the localization of the motor region of the cerebrum, the weight of the brain, its structure, its development and its pathology. The organs of sense were also fully represented. Illustrations of the latest discoveries in these various departments were made by models and charts, chiefly given as the result of French and German research.

The psychological laboratory was under the direction of Professor Joseph Jastrow, of the University of Wisconsin. The strictly psychological apparatus was very complete, and was contributed by a
number

number of American and European Universities. The exhibit made in the section of Psychology was contained in two rooms, one of which was devoted to a collection of apparatus used in the experimental study of the mental phenomena and the other was arranged as a laboratory. Modern psychology comprises several divisions and makes use of many methods. The main divisions of this interesting study may be enumerated as experimental psychology, including the study of sensation and movement of the relations between body and mind, of the forms of judgment, distinctions, memory, attention, association, and all other elements of the mental faculty. Comparative psychology embraces a study of animal life, development of the mental powers in childhood, variation of thought, and culture in different stages of civilisation. Abnormal psychology may be characterised as the study of the different forms and degrees of divergence from normal mental manifestations, including the study of illusions, hypnotism, sense defects, mental defects, &c. These divisions of psychology necessarily overlap, some being characterised by method and others by subject matter, and serve merely to indicate the general nature of the subject. The science also has very intimate and practical relations to education, medicine, and a general guidance to thought and action. It has special relations to anthropology, which, as the science of man, necessarily deals with the human mind. In the working laboratory at the Fair such tests and experiments as were most in line with modern anthropometry have received special attention. The tests made by Professor Jastrow and his assistants covered a wide range of mental and physical real conditions. The great object was to obtain a series of normals of sense capacity, &c., by which a man's position as compared with that of his fellows could be determined, so that the order of development might be shown, and, on a basis of this, average questions of growth and divergence from the normal could be determined.

The number of people who applied at the laboratory and offered themselves as subjects for testing, depositing therefor a nominal fee for examination, proved that a very considerable percentage of mankind are anxious to know something about themselves. The blank which the applicant for test was required to fill up provided in the first group for data of a personal character, all of which had a direct bearing on the value of the final deduction. The basic information thus required included the applicant's age in years and months, his birthplace, and also that of his father and mother; his general health, past and present; his occupation, as well as that of his father; the educational institution at which the applicant was in attendance or at which he had completed his studies, and whether he was his mother's first, second, third, or subsequent child. These questions were all supposed to have a bearing on the question at issue.

The various tests were divided into five different groups, and when the investigator had gone through all of them there was very little left in regard to his personal history required to be known as to his judgment in the matter of lengths, weights, and surfaces, accuracy and equality of movement, accuracy of aim, sight, memory, sensitiveness to pain, and in fact his quickness of perception in a dozen different ways. The first test consisted in the application of a kinesiometer, an instrument for determining the sense of movement upon the skin. With this the smallest perceptible differences of movement were determined. Another instrument measured the time necessary for impressions to announce themselves, while the compass *æsthesiometer* determined the distance at which the two points of the kinesiometer felt as one. The pressure was made on the inner surface of the index finger, because the sense of touch is more highly developed at this point than elsewhere on the surface of the body. The normal distance at which distances are noticed is one-twelfth of an inch. On the

the back of the neck, for instance, the points must be 2 inches apart before the subject could tell whether one or two points were applied. The next was a pressure-test to determine sensibility to pain, the lower limit being the one desired. In this case the fore-finger was placed in a tube to keep it immovable, and pressure was applied by means of a spring. In men the normal was 6.6 kilograms, or about 14 lb., and in women 5.2 kilograms, or 11 lb. The subject was next tested by being required to arrange five small boxes in regular order according to their weight. These boxes were in two series, coarse and fine, the ration of the first being 1.15, and the latter 1.30. The percentage of persons making no errors in the lifting test was sixty-five. The touch was further tested by passing the finger over small coils of wire of varying size.

Another test determined the equality of movements. On a strip of white paper 15 inches long the subject was asked to make five dots equidistant. In this equality of movement test the average deviation was 10.4 per cent. Accuracy of aim was tested by attempting to strike a designated spot with a lead pencil, the point of which was secured by a disc 2 inches in diameter. In this test the normal average of correctness was 4.8. One of the optical tests consisted in the reproduction of lengths, the subject was shown (separately), three blocks on which there were lines of different lengths. After looking at each block he undertook to reproduce the line on a paper before him. In the reproduction of the short lines the normal average was 25.6, two-thirds of those tested failing between 22.5 and 29.5. The normal average for the middle lengths was 49.7, and for the long lines 76.2. The lines were afterwards reproduced from memory, the normal average on this test being on the short line 27.2, and on the middle line 50.4, and on the long line 76.7. Accuracy of movement under the guidance of the eye was also included in this test. A sheet of white paper about 14 inches square was provided. The centre of the paper was indicated, and exactly opposite the middle point on the edges of this sheet were four small crosses. The effort in this case was to draw a straight line from the centre of the sheet to the designated point on the circumference. Rapidity of motion and right and left handedness were determined by an apparatus attached to a wall which consisted simply of a plate of ebony 4 inches wide and $2\frac{1}{2}$ feet long, having an indicated centre on either side of which were the movable upright strips which moved simultaneously to the right and left. A scale at the back, not visible when the test is made, determined the correctness of optical judgment. Another test of the quick perceptive faculty lay in one's ability to correctly indicate by a pencil mark the number of similar printed characters in a sheet containing 215 characters resembling each other just sufficiently to make one hesitate a moment and refer to a guide line at the top of the sheet. The percentage was strictly determined by placing over the marked sheet a skeleton from which the correct figures, as they appeared at different places, had been cut out. A somewhat similar test consisted in looking at a series of circles, very slightly open at different positions, some at the top, others at the bottom or sides; and reproducing them as nearly as possible from memory. Quickness and accuracy of eyesight were tested by a special apparatus, and were used in connection with the special training which usually precedes pugilistic and similar matches. At this point the examination ran into a colour test, in which a large black disc was used, containing twenty-eight patches of colour consecutively numbered. In the centre of the disc was a circular opening. A smaller disc underneath showed the same colours lettered instead of numbered. If the subject of the test was colour-blind he was very apt to insist that "A" on one wheel matched with twenty-eight on the other. The first was a very pronounced green and the other a subdued grey. In the matter of determining colours it was found that women make a better average than

than men. As a result of the experiments the department had no accurate figures on the averages, but it was stated that all the colours had been frequently matched correctly in one minute.

The central idea of the fourth group was the measurement of the quickness of the mental process. The right hand was placed over a telegraph key. As soon after the left hand was touched with any substance so that the subject could determine the sensation he struck the key with the forefinger of his right hand. The time necessary for the nervous impulse to travel up the right arm was announced to the brain and in turn was transmitted down the left arm averaging $\frac{1.5}{100}$ of a second. Ear perceptions or reactions were taken by striking a bell, while a dropped shutter furnished a similar test to the eyes. Time in these instances was measured by the distance through which a hand had turned, and its amount was read off directly from graduations on the dial in hundredths of a second. The next test was that of the combined faculties of memory and association, the object being to secure a pure sense memory. A straight line was drawn, and after a lapse of about two minutes the subject reproduced it as nearly as possible. The memory span, or extent of memory, was determined by the number of words one was able to recall after reading them as they appeared for a moment in an opening behind which a printed list of words passed. There were nine words in the series, and the average man could remember but five or six of them. The last test was a complex one, and required the association of words.

A large number of curious and interesting instruments, which were not brought into requisition in the tests ordinarily conducted at the Fair, were shown in cases in one of the rooms. There was a peecimeter by which the sensibility to form and colour in different portions of the retina was mapped out. The subject looked with one eye at a brass button, termed a fixation point. While staring at this point he attended, in indirect vision, to a pair of points or patch of colour held in a slide. By a movement of rack and pinion this test object was moved along the arm, and the arm itself moved about the central point. In this way all the meridians of the eye could be examined, and the result automatically registered. A photometer was used in studying the sensibility to intensities of light. There was a large number of tests also for the colour sense, one of which consisted of a series of wheels with attachments for changing the proportion of colours while the disc was in motion. For the same purpose a set of ground glasses covering coloured ones were used. Another test for colour-blindness was a series of black letters printed on coloured paper. When these were covered with tissue paper only the complementary colours showed, and the person afflicted with colour-blindness could not see these letters, although they were distinct to the normal eye.

One of the most ingenious pieces of mechanism was employed for testing the sense of hearing, and for determining the appreciation of the difference in musical pitch. The sound was produced by a closed organ pipe, the pitch of which was varied by changing its length. An automatic arrangement was adopted by which the sound was continued during one second, then there was silence during another second, then sound was produced during a third second. During the interval of silence the length of the organ pipe admitted of being varied by a known amount. The instrument was used in the following manner:— A scale was adjusted to fix the amount of movement that could be given to the sliding plug in the organ pipe. This allowed two notes to be sounded, differing by any number of hundredths of a semitone. When the scale was at zero the note sounded was 1,024 single vibrations per second, and when at a hundred it was 966.45 single vibrations per second. That is, each division on the scale corresponded to a change of 0.575 complete vibrations per second. If a person to be tested could, after several trials, distinguish the notes either by saying they

they differed or by knowing which was the sharper, the interval between the two notes was reduced. As will clearly be observed, the practical application of all these experiments was directly educational, and there can be no doubt that the science of education is, to a large extent, founded on psychology.

At the north-east corner of the gallery the Boston Normal School of Gymnastics displayed a very curious series of charts containing statistics, the result of actual examination of the weight, height, and age of boys and girls in the Boston schools, together with the length of the head, its breadth, the breadth of the face, and the proportion of the breadth of the face to that of the head in school children (boys and girls) of Massachusetts and Toronto and of St. Louis. These experiments were made on a large scale for the purpose of making a relative comparison in regard to the physical development of school children of various cities with that of the average American child.

There was also a development booth, in which were models, life-size, of the average American student, and a number of charts exhibiting the system of measurement tests adopted by Harvard University.

Out-door Exhibits.

To complete the representation of anthropology there was an out-door exhibit composed of live Indians from the northern portion of Vancouver Island, a few from the Iroquois tribe, an Esquimaux family, three families from Penobscot, with their wigwams, and also Navajos and Apaches. The mat house of the Winnebago, the buffalo hide tepee of the Sioux, the sod house of the Omaha, and several other types of habitations were set up on the grounds. There were representatives of the Flatheads, Blackfeet, Pen de Oreille, Nez Percés, and Tootenai, all of whom appeared in their tepees. From South America three tribes from British Guiana. All these tribes were engaged in their native manufactures of pottery-making, basket-making, and other occupations illustrative of their customs.

The Count Rumford Kitchen.

The Count Rumford Kitchen at the Fair was a little unpretentious cottage, very near the south door of the Anthropological Building. Benjamin Thompson, the "benefactor of humanity," was born in Massachusetts in 1753, studied medicine upon arriving at manhood, and devoted his life to scientific and economical cookery and the invention of stoves and ranges for cooking with the best utilisation of heat and the production of the best flavours, as well as to the combination of materials and method of preparation which would give the most wholesome and palatable food for the least service. For his services to mankind in bringing all known science to bear upon the problem of feeding the poor of Munich at the least cost he received the title of count, and chose the name of his New Hampshire home, Rumford (now Concord), for his title.

The Rumford Kitchen, therefore, was an application of the principles of chemistry to the science of cooking, and was an exhibit of the Massachusetts Board of World's Fair managers in connection with the bureau of hygiene and sanitation. The exhibit consisted, in part, of samples of food served at the tables to illustrate the effects of cooking by the methods used, samples of food prepared for the very sick, *menus* giving the composition and food value of the dishes thus cooked and served, charts and diagrams illustrating methods of teaching important facts in connection with food, and a kitchen laboratory table with indispensable apparatus. Samples of this scientific cooking were served daily from 12 to 3, but nothing was cooked for
the

the sake of being sold, as the enterprise was wholly a scientific and educational one. Ten standard luncheons were served—for example, one consisting of baked beans, brown bread, roll, butter, and apple sauce; another of escalloped fish, rolls or bread, butter, and baked apples; another of beef, broth, rolls or bread, butter, and gingerbread. The bill of fare gave the number of ounces and grams of each portion served, its food value in grams of proteid, fat, and carbo-hydrates, and its calories. An astonishing showing on the same bill of fare was the actual cost of the raw materials of these ten standard luncheons, at a fair market price, averaging about one farthing for each luncheon.

The cooking here was a revelation. But a comparatively small portion was served; but after one had eaten his appetite was satisfied, and he felt as if he had risen from a satisfactory dinner—the best possible proof of the claims of scientific cooking. Everything was delicious, and it was served in an atmosphere of genuine courtesy and old-time hospitality, which fully compensated for the cramped quarters of the little kitchen and its out-of-the-way location. The walls were covered with pungent mottoes pertaining to the science of eating and of cooking. The Boston ladies in charge cared for the patronage only of those who were honestly interested in the science of healthful and economical cookery and were seekers after knowledge. Probably no exhibit of the Fair was of greater practical value to mankind, or of greater interest to the masses, than the modest little Rumford Kitchen.

As a branch of this department the contents of the Midway Plaisance were catalogued.

It would occupy too much time and space to refer to all the curious representatives contained in this by-show of the Exhibition; in one word, it was a great national promenade, and in its space the world at large was represented in miniature. As a branch of ethnology it was perhaps the most popular portion of the Exhibition. It contained many characteristic illustrations of the life and customs of various countries—as for example, the Irish industries exhibit, under the patronage of Lady Aberdeen, with Blarney Castle for its prominent feature; the Irish Village and Donegal Castle, of Mrs. Hart; the Japanese Bazaar; Dutch Settlement; the Panorama of the Bernese Alps; the Javanese Village; Original Vienna Bakery; the German Village; the Turkish Village; Street in Cairo; Egyptian Temple; Persian Palace; Moorish Palace; Model of the Cathedral of St. Peter; Vienna Café; Algerian and Tunisian Village; East Indian Bazaar; Volcano of Kilauea; Austrian Village; and Old Vienna; Chinese Theatre; Dahomey Village; Lapland Village; Hungarian Café, and many others.

The Convent of "La Rabida."

The full-sized model of the Convent of La Rabida, near Palos, in Spain, was an historic lesson as well as a beautiful feature of the Fair. As is well known, Columbus was sheltered in this convent before his departure for the west of discovery. The building was filled with the relics of Columbus, gathered from all the countries of the world in which he had sojourned, and these were considered of so valuable a nature, and in the case of many which had been lent were surrounded with such injunctions as to their security from their owners, that the building was placed under the special police protection of the United States Government. Within the building were found the tombstone of Columbus, and the gates around the tomb in *fac simile*. There was also the room in which he rested at the invitation of the head of the order. On the upper floors were the cells of monks, now occupied during the currency of the Fair by the guardsmen. To give them an ancient look sulphur and charcoal had been burned, and the walls and ceilings were begrimed with smoke. In the centre of monastery was the walled-in courtyard, in which the monks sat and rested safe from all

THE "SANTA MARIA"—FULL-SIZE MODEL OF COLUMBUS' FLAGSHIP.

all intrusion from the outside world. Those who wished to follow the fortunes of Columbus could in this building observe a vast number of articles bearing on the geographical knowledge of the day, as well as on the science of navigation. Maps, charts, and globes, nautical and astronomical instruments, and models of the vessels of the period, were exhibited.

The histories of the discoveries in America by the Norsemen, Welshmen, and Phœnicians preceding the era of Columbus, was illustrated. Relics of the court of Ferdinand and Isabella, including portraits, autographs, and other remembrances of the personages who aided Columbus, manuscripts, printed volumes, charts, maps, armours and weapons of the times, and oil paintings of Pedro Gonzalez de Mendoza, Grand Cardinal of Spain, who introduced Columbus to the Queen, and of Juan Perez de Marchenta, Prior of the Convent of Santa Maria de La Rabida, who did so much to help the sailor, were hung upon the walls. A model of the house in which it is said Columbus was born, and a number of portraits of Columbus, the authenticity of which, however, could not be guaranteed, were exhibited. An assortment of articles used by Columbus for barter with the natives, such as beads, coins, metals, knives, cloths, mirrors, and nails, were there, proving that the discoverer was something of a trader.

In the same way pictures representing the reception at the Spanish Court, and the scene on his return from his first voyage, were presented, as well as the representation of his return from the third voyage in the Letters, which he said he would preserve as the relics and memorials of the record of his services. Relics of Columbus and his family, consisting of his armour, equipment, autograph letters, and the early publications relating to him and his works, as well as the original authority under which he sailed forth in quest of the Indies, and the will of Queen Isabella in the original, were also shown.

In the lagoon adjoining the convent, after their arrival from Spain, the full-sized models of the Columbus Caravels, consisting of the "Santa Maria," the "Nina," and the "Pinta" were moored; these models were built at the conjoined expense of the Spanish and American Governments, and formed an interesting supplement to La Rabida and its treasures.

Forestry Building and Exhibits

Description of the Building.

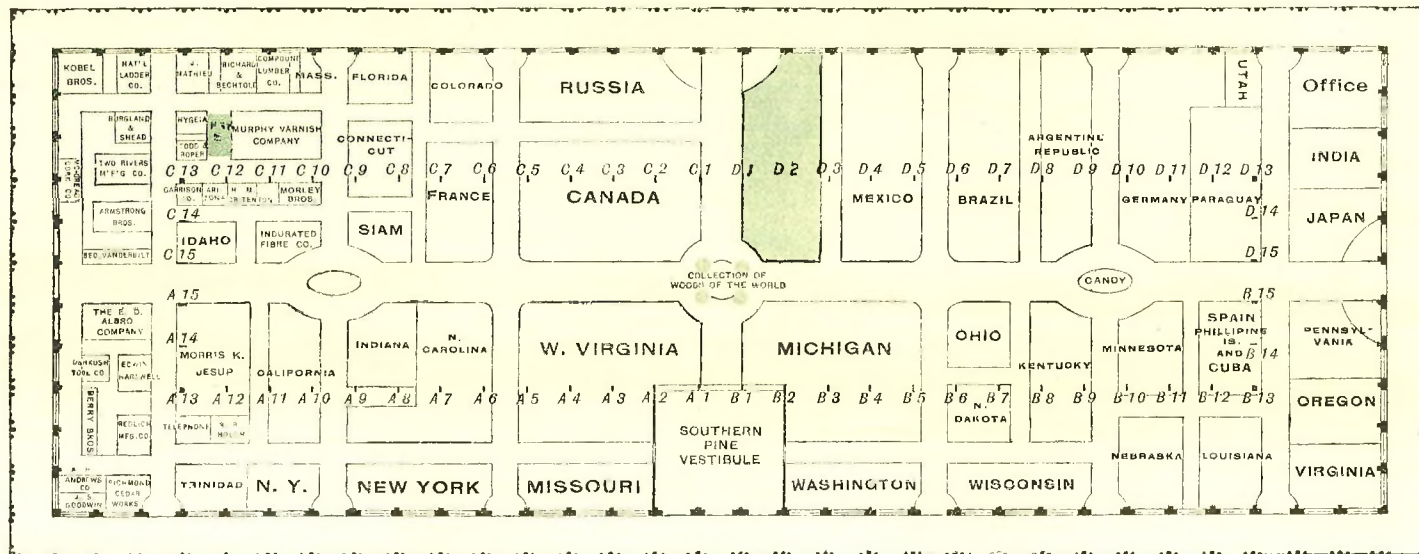

THE peculiarity of the Forestry Building consisted in the fact that it was entirely constructed of wood, the fastenings of the timbers and other structural portions not being of iron, as usual, but of wood. Round about the building was a colonnade, composed of tree trunks sent from almost every State in the Union. The vestibule at the main eastern entrance was of very handsome appearance and spacious dimensions, and was constructed of yellow pine beautifully polished. The building was situated at the south-eastern portion of the grounds. In dimensions it was 200 feet by 500 feet, with a central height of 60 feet. Its side walls, window frames, and roofs, being all of wood, it presented a very rustic and unique appearance. Four hundred trees are native to America, and specimens of most of these were employed in the colonnade just referred to, and formed of themselves a remarkable exhibit. The exhibits comprised in Group 19 of the Official Catalogue, which were contained in this building, embraced a variety of forest products, including samples of wood and timber, ornamental woods, dye wood, barks and vegetable substances, gums and resins, medicinal roots and herbs, wood-pulp, paper and wooden ware, seed collections, statistics of the lumber trade and of Forestry, &c., the whole being of great interest, and nearly every section being fully represented. Among the many innovations introduced in exposition methods at this World's Fair the idea of presenting forestry exhibits in an individual building, and of making that subject a separate class, stands without a parallel. At previous International expositions, forestry exhibits have consisted largely of specimens of curious woods of little interest, except to those practically acquainted with the subject, and even such exhibits have heretofore been engulfed in the infinities of agricultural departments. There could be no doubt in the mind of any thoughtful visitor that the innovation adopted in this case was of great practical value, more especially to those interested in the timber trade of the world. The comparisons exhibited between the timbers of the various countries of the world by the presentation so fully made in this building was of special interest. Many of the courts were beautifully arranged, and their distinctive exhibits most instructive, both from a scientific and a utilitarian standpoint. On the Wooded Island, but connected with this department, there was a typical American log cabin, contributed by the State of Michigan, furnished and prepared in a characteristic manner, and New South Wales, in the same locality and near it, erected its bark hut. It was one of the rules of this department that no finished wood products—only the raw material—should be exhibited in this building. When it was considered desirable to show the special uses or adaptations of certain kinds of wood, these could only be shown by pieces of disjointed furniture or other partially finished product.

New South Wales Court.

Our space in this department contained 3,000 feet, and was well situated in the centre of the west side of the building, bounded by the main aisle on the east, and with the principal western entrance to the building at the south-west corner. The space of Mexico was situated
to

INTERIOR SECTIONAL VIEW, NEW SOUTH WALES COURTS, FORESTRY BUILDING.

to the north of us, and the allotments of Canada and Russia to the south. Our court was a leading feature of the department. The logs of timber sent from Sydney in the rough were all sawn up at the saw-mill on the grounds into large planks, and used as a wall for the court, the outside of the wall being planed quite smooth and polished in a most beautiful manner, showing the grain and texture of the wood, by the Murphy Varnishing Co. of Chicago, while the interior was left merely planed and smoothed without polish, so as to exhibit the natural section of the wood. The show of timbers, thus exhibited, was most remarkable, and drew forth the highest encomiums from the experts. The inside of the court was decorated with the photos of the New South Wales timber trees. A division ran through the centre of the court, and on tables and trophies were placed the resins, gums, wattle-barks, and similar exhibits. The dried botanical specimens of plants were placed near the trees to which they belonged. The gunstocks made of New South Wales timbers, highly polished in part, showed to great advantage. The shingles were placed on a piece of roofing to show clearly how they were used. A trophy of the wooden blocks used for street paving was made, and the collection of timbers was placed so as to catch the eye of every visitor. The seeds and seed-vessels of timber trees and shrubs were placed on tables made for them, and the various barks forwarded for this department were supplemented by a portion of the collection from the Technological Museum in order to complete the educational character of the whole exhibit. The bean-tree door was made a portion of the front wall of the court, to show this variety of timber in its finished state. It looked very handsome after treatment by the Murphy Varnish Co. Our representative photos of forest trees attracted universal attention, and on the whole this court was one which greatly surprised the American and Canadian visitors, in view of the fact that the principal portion of the timber of their countries is of the soft-wooded character. I anticipate that the advertisement by our exhibit in this section will in the near future originate important trade relations between America and Australia for this abundant product of our country.

I obtained a special space in the building for the large block of cedar, part of the surface of which I had planed and smoothed and then polished to exhibit the grain of the wood.

The bark hut sent by the Commission, as I have already stated, was placed on the wooded island, at its southern end, a privilege granted at my request. In its immediate vicinity was the hunter's log-cabin of America, a roadway and shrubbery separating them. As illustrations of the early habitations of the settlers of both countries, and as a marked contrast to each other, they attracted considerable attention.

In the centre of the Forestry Building there was a large and attractive trophy of selected specimens of timbers of all the best kinds exhibited. In the middle of the trophy was a large section of a Californian red-wood log, 14 feet in diameter. On either side of this were two Japanese bamboo trunks, their tapering ends reaching to the roof of the building and placed crosswise on the red-wood slab. These were flanked on either side by great slabs of spotted gum and rose-wood—half polished and half merely smoothed—from New South Wales. Arranged on the front of the trophy were sections of plain and polished specimens of the woods of Argentine, Canada, Brazil, Mexico, Trinidad, Siam, and Russia, as well as those of Oregon, West Virginia, Minnesota, Illinois, Missouri, and other States. A conspicuous object in the trophy was the celebrated axe of the Hon. William Ewart Gladstone.

The Booth of Michigan, like most of the United States Courts, was a very handsome one. In it there was a very useful table containing a large amount of information on the lumber trade of the States.

The

The following particulars from it, with reference to the United States generally, conveyed, in brief compass, a useful summary:—

VALUE of annual Forestry product of the United States by groups, Census of 1890:—

White Pine Group—Mich., Wis., Minn.	\$115,699,014
Eastern Group—Me., N.H., Vt., Mass, R.I., N.T., N.I., Pa., Del.	62,087,984
Hard Pine Group—Md., Va., N.C., S.C., Ca., Fla., All., Miss, La., Tex., Ark., Mo.	54,747,266
Central Group—Ohio, Ind., W. Va., Ky., Tenn.	49,433,293
Pacific Coast—Cal., Wash., Org.	24,192,367
Atlantic States and Territories	16,974,095
Total product for United States	\$323,134,019

Michigan leads all other States in value of forest products. Michigan, Minnesota, and Wisconsin furnish one third of the country's output. Michigan alone one fifth; she leads all the States in both pine and hardwood products.

There was a large and valuable collection of seeds and medicinal plants in glass jars in the North Carolina exhibit. There was also, in this court, the largest and most interesting collection to be seen in the building of enlarged photographs, something like those of New South Wales, but a little smaller, and by a different process, illustrating the forest and large trees of the State.

The largest plank in the world was exhibited by a lumber firm. It came from Humboldt County, Cal. Its dimensions were 16 ft. 5 in. wide, and 12 ft. 9 in. long, by 5 in. thick.

A booth built of cork, and exhibiting cork in all its various and numberless forms and applications, was shown by the Armstrong-Gilbert Cork Company.

Some remarkable fine and valuable exhibits of timber were shown in the south verandah of the building. The first was an immense log of mahogany from Mexico, about 41 feet in length and 42 inches square, and contained 5,986 superficial feet, and was valued at £250. The other was a walnut log from Kansas cut in April, 1892. The main trunk of the tree from which it was cut was 48 feet in diameter at the base and 48 inches at the top. This log was valued at £200.

Roadway Construction.

In connection with this Department it was originally intended to have a practical demonstration of the various styles of construction of roadways used in different countries in order to exhibit the material and methods employed, and a strip of ground at the north-east corner of the Ethnological Building was devoted to this purpose. The Commission in Sydney sent over several thousand of our wooden blocks for this purpose, and I caused them to be laid down in the approved plan and according to specification. Beside the roadway was placed a large section of this roadway on a stand, so that it could not be overlooked by the passer-by, exhibiting the various layers, &c., of the roadway, and in the adjoining wall was placed a large distinctive signboard, coloured blue and white lettering, announcing that this was a specimen of the roadways laid in Sydney, New South Wales, the metropolis of Australia, and in all the principal cities of the Australian colonies. As soon as the road was constructed I took the opportunity of writing to His Honor the Mayor of Chicago and the Council of that city, calling attention to the importance of this matter in the interest of the ratepayers, and in view of the wretched character of the streets there and in America, taken generally. As a matter of fact the soft woods, although sometimes so used, of America are unfit for the purpose, and both our sleepers (called "ties" here) exhibited in the Forestry Building and in the Transportation Building were a

source

source of surprise. It was only after careful and critical examination, supplemented by the certificate on the sleepers and the evidence of the pamphlet on timbers containing the statement of the results of the testing examinations made by Professor Warren, that the hardness and durability vouched for was properly appreciated.

Polishing and Varnishing of Wood.

Elsewhere I have referred to the fact that an American Varnish Company polished our timbers with very successful and very surprising results. It is a curious and interesting fact that the method of polishing employed in the United States and that which obtains in Europe, are quite different from each other. In the United States the material used is varnish, which is put on the wood to be polished with a brush in successive coats until the pores of the wood have been thoroughly filled. The varnish, when sufficiently dried, is then (in first-class work) rubbed to a smooth surface with pumice stone and water, and brought to a bright polish by rubbing it with the palm of the hand. In European countries the process is different. The workman uses gum shellac dissolved in alcohol and polishes the wood by rubbing the liquid shellac into the pores with a pad made of cotton or soft woollen rags. Under these circumstances the question is, not as to which workman does the best work but rather which method produces the best results. The exhibits furnished an excellent test of this question. For weeks previous to the opening of the Fair, and up to its close, the exhibits of fancy woods used in furniture of all kinds, in musical instruments, in the construction of passenger coaches, and the interior finishing of houses was exposed to every change of temperature, to heat and cold, to dampness and to dryness, and to all those atmospheric conditions to which a wood polish is peculiarly susceptible. In fact the polished woods, as exhibited at the Fair, were subjected to a severer test during the six months the exhibits were on the Fair grounds than would be imposed during a period of several years when housed in private dwellings, the purpose for which the majority of them were intended. Consequently only those exhibits which possessed the requisite qualities of good material and good workmanship stood the strain, and the difference in the methods used in America and in Europe was brought out in a singular and striking manner.

In the work of polishing fancy woods the first principle is that the wood shall be properly seasoned, and that the pores of the wood to be polished shall be thoroughly and completely filled with the material used in the polishing. Unless this is done, atmospheric conditions affect the wood—it shrinks and expands with changes of temperature—and, as a consequence, the polish cracks and scales and gradually disappears. I have made a comparison of this class of work in the two styles of finish, taking as examples of the American work the exhibit of the Brunswick and Balke Co., in fixtures and billiard-tables; the furniture and pianos of the collective exhibit of the Grand Rapids Firm, and several other pianoforte firms, in all of which there was shown careful and excellent workmanship, and compared them with the exhibit of the London and North-western Railway Co., an exhibit containing, perhaps, the best polishing work on the natural wood, shown by any European country of the Exhibition, and as far as my judgment would lead me to form an opinion I am inclined to believe that for appearance and permanence of results the American was the superior article.

I have been informed that in the best classes of varnish used in the United States kauri gum is largely used, and it is considered to be a great improvement to add gum copal; a mixture of one part of copal to six of kauri is a favourite one with polishers.

Woman's Building and Exhibits.

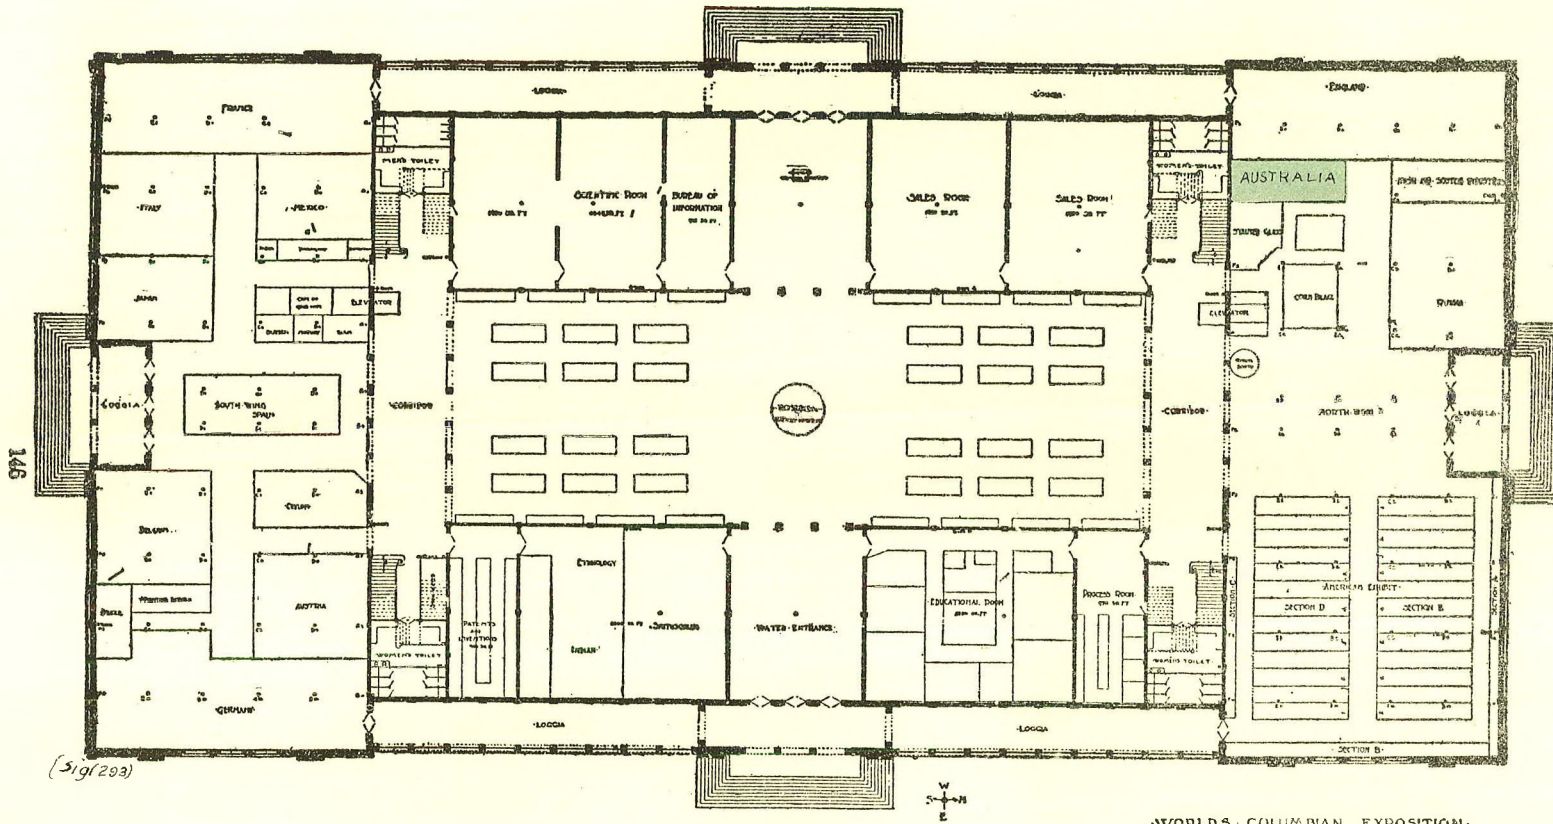

THIS was the second time only in the history of exhibitions in which a large building was set apart for the exhibits of woman's work, the first instance having occurred at the Philadelphia Centennial Exposition of 1876. The building was situated on the north-east corner of the lagoon and opposite to the entrance of the Midway Plaisance. The architecture was of a somewhat more severe style than that of the other Exhibition buildings. The architect was a woman, Miss Sophia S. Hayden, of Boston, Mass. The building covered an area of 400 feet in length by 200 feet in width, and was in the style of the Italian Renaissance, consisting chiefly of two rectangular wings at each end, connected by longitudinal galleries, covered by a pitched roof. In the front between the two wings there was a colonnade with open arches supported by pillars. The chief entrance was in the centre, fronting the lagoon, and was approached from the water by a broad flight of steps. The view of this stately building seen from the water was impressive in the extreme. Few, judging by conventional standards, would have supposed the design to have sprung from a woman's brain. Conventionality, however, would be at fault, for women have as fine a sense of symmetry and the value of proportion as men, whilst their artistic perception is beyond question. It is only because they have lacked technical instruction that they have not produced any school of fame, a fact strongly supported by the competition for the Woman's Building at the World's Fair. "Designs," we are told, "were invited from women architects, and the result was awaited with somewhat uncertain expectancy. Women were not known in this craft, and the President of the Board of Directors confessed an apprehensive sinking of the heart when summoned to assist the Chief of Construction in examining the plans submitted. There were some thirteen of them. Some were poor whilst some were excellent, and the principal difficulty was to decide which was best. To three of the designs prizes were awarded, and then, after the award was made, the interesting fact was disclosed that all the plans were the work of young girls, ranging in age from 20 to 29. Miss Sophia Hayden, of Boston, won the first prize, and was at once summoned to Chicago to perfect and elaborate the design."

Paintings and Decorations.

At the end of the Gallery of Honor were two mural paintings, the one representing modern women and the other primitive women. On each side of the main walls were two panel paintings, and these, like the former, were by women artists. The drapings between the panels and the end paintings were of gold-coloured cloth and formed an effective background for the canvas. A broad gold frieze surrounded the gallery, and on the panels between the arches were inscribed the names of famous women, from the earliest Bible heroines to the latest modern belles. The ceilings of the library and the carvings about the cases and friezes were all done by women. The pediment and statues on the roof line were by Miss Alice Rideout, of California. The first group represented women's virtues; the central figure typified women's spirituality, with the pelican—which symbolises love and sacrifice—at her feet. A nun, laying her jewels on the altar, typified sacrifice and "charity" to the left of "virtue." The second group represented
woman

WOMAN'S BUILDING.

146

(519/293)

--PLAN OF FIRST FLOOR--

WORLD'S COLUMBIAN EXPOSITION
WOMAN'S BUILDING

woman as the genius of civilization, with a figure at her right representing a student; on the left was a woman groping for the light, as yet in mental darkness. At the feet of the central figure was the bird of Minerva, the owl representing wisdom. The pediment represented women's work in the progress of civilisation, and the figures typified charity, beneficence, literature, art, and home life.

The interior arrangement of the building comprised a series of spacious galleries running round the four sides at the height of above 25 feet above the ground. The galleries were divided into a number of courts devoted to different sections of industries in which women are more especially engaged or interested. The rotunda was 70 feet by 65 feet, reaching through the height of the building and covered with a skylight. On the roof of the pavilion were open areas, covered with Oriental awnings, one of which served as a *café* and the other as a tea garden. These resorts were very popular and highly appreciated, especially by the ladies.

While a selected class of exhibits was placed in this building its main purpose was to provide accommodation to the lectures, assemblages, and official meetings of the lady managers and other similar purposes. The general exhibits of women's work were placed throughout the departmental buildings, but small Special Courts were provided here for foreign countries and some of the United States in which to exhibit their special women's industries; and in the Great Hall space was provided for a large and valuable display of fine art pictures by women artists of England, France, America, and other countries.

The floor space of the building was occupied by about forty cases, in which were displayed the choicest examples of women's work of various countries. The north and south wings of the building were appropriated to the special exhibits from foreign Governments and from America, which latter country occupied the eastern portion of the north wing.

There were two sale-rooms provided for the disposal of all articles not catalogued in the north-west portion of the building, and these were daily thronged with persons wishing to obtain souvenirs of various kinds. Further south were rooms provided for the Bureau of Information and for scientific purposes. The Board-room and the offices of the lady managers were placed in the south-east corner of the gallery, and in these rooms were many works of art, open to the public when not officially in use. The Organisation room occupied the remainder of the south gallery, and in it there were more than fifty philanthropic and religious societies, church and educational establishments located. In this room was a large display of the statistics of the societies and similar matters. Other rooms in the gallery were provided for the British Nursing exhibit, for Records, for the New York Library, and for Committee purposes. It would be impossible to give a full list of the decoration and furniture of these rooms, which in some cases were not only beautiful and useful but also characteristic either of periods or of the peculiarities of States. One example will suffice: In the room furnished and decorated by the women of Cincinnati there was a splendid show of the fine porcelains of that State; beautiful carved bookcases and cabinets were placed about the room; massively carved chairs, upholstered with soft silks, and divans of leather, helped to complete that long parlour. The parti-colour of the side walls was a dull, soft shade of terra cotta, which was varied as it reached the wide frieze, which was a charming conceit of bunches of crush roses. Below the frieze was a conventionalised border of "buckeye." The walls were hung with oils, water-colours, and engravings. The decoration of the porcelains in this showing was exclusively painted over the glaze, with the exception
of

of a few specimens in the historical collection, which were under glaze. These porcelains were considered the best in the country. The scope of these artistic decorations was broad and comprehensive; good colours had been used and laid on with judgment. Vitrified crayon work was exhibited by the Cincinnati Pottery Club. The gold work was also excellent. In the display were many lovely dinner sets. One set of plates was especially fine. It was in highly luminous porcelain, with a border of metallic green, picked out with gold. Another set of plates in portraiture decoration. Among the subjects were Madame Lamballe, Madame de Montespan, Charlotte Corday, and Madame de Grigan. In the same room there was a case of daintily decorated glass; it followed in embellishment the Rouen, Persian, Egyptian, Japanese, faience, and rococo styles. Etching on metal was another of the exhibits of these clever women. Beautiful art needlework, ranking among the oldest accomplishments of women, is one of the pleasantest still to attribute to her, and it will always remain a fascinating branch of the accomplishments of a gentlewoman. The delicate designs and exquisite textiles used by the women of Cincinnati in their needlework were very beautiful. Artistic wood-carving by American women was first cleverly done by these women of the buckeye State. Their schools have had far-reaching influence, and women from all parts of the United States have received instructions in them.

The Record rooms were filled with interesting statistics of the progress of woman throughout the world. The library contained most of the books and literary work exhibited in this building. A very interesting portion of the gallery was the model kitchen in the north-west corner, where daily lectures in the art of cooking were delivered. In the Assembly room of the gallery lectures on all kinds of subjects were given by women almost daily on all kinds of subjects during the Exposition. Dressing and other official rooms were located in the east gallery. The furniture and decorations of the State rooms were contributions from the women of the different States, one room, however, being decorated by Japan. The general public were admitted to the entertainments held in several of these rooms, and no fee was charged for admission under any circumstances.

New South Wales Court.

Our court in this building contained 384 superficial feet of floor space, with 1,200 feet of wall space, and was situated in the north-east corner, adjoining the space of Great Britain. From the peculiar position and size of the court, as well as from the peculiar views of the lady managers as to decoration, &c., I had some difficulty in arranging the numerous exhibits sent by the Ladies' Committee in Sydney. Finally, I made two walls 11 feet high to bound the sides of the court and to provide as much available screen space as possible. Two decorated moulded pillars, festooned with cloth of our national colour, were placed at the entrance of the front end of these walls, and about them were hung trophies of our flags, and a coat of arms with a small stuffed kangaroo on either side. The name New South Wales, both on the side, front, and at the back of the court, was emblazoned in silver letters on a blue ground, and various trophies of flags were placed at the back of the court, sufficiently high to catch the eye of the visitor and attract his attention. Three pyramidal cases with glass sides were placed lengthwise in the centre of the court. Two tables of half-oval shape were placed against the walls on either side in the centre of the court, and the whole of the back wall was covered with a glass-fronted case on a table and reaching to the height of the court, so as to exhibit without handling the dresses and fur exhibits. I was thus enabled to place under glass all the small and the valuable articles. Amongst the exhibits the needlework, embroidery, and fancy work formed an attractive and
 much

NEW SOUTH WALES WOMAN'S WORK EXHIBITS.

much admired exhibit. The taste and skill exhibited in the hand-painted screens, the fans and china, emu mats, the beautiful fur cloaks, rugs and muffs, extracted commendatory remarks from the crowds of fair visitors from all parts of the world. The exhibit of cow and calf and others of a similar kind were much admired, not only for the exquisite modelling but also for the artistic finish in the application of the natural hair. There was also great attention paid to the stuffed birds and animals, and, in fact, to every exhibit in this court. Lady Abbott's exhibit of Australian woods I placed in the Forestry Building, as well as that of Mrs. Kelly, on account of want of space and in order that these exhibits might be more completely brought under the notice of visitors and the Awards Jury. The excellent exhibits of invalid mattresses of Mrs. Guille and Miss Fox Harding were for like reasons placed in the Manufactures Court.

General Description of Exhibits.

The exhibits in the Woman's Building were not only numerous but in some cases priceless in value and exquisite in beauty. Many Royal families sent the personal work of the ladies of their families and heirlooms (in the form of laces, silks, silver and gold ware, and jewellery) which had been in their possession for centuries.

British Exhibits.

In the British Court work of members of the Royal Family were exhibited; six original sketches from nature by Her Majesty were exhibited in a frame. A Welsh girl was employed weaving in one section, and a Scotch woman in another. There was a large number of specimens of women's work in various handicrafts, consisting of cameos, carvings in wood and ivory, designs, fan-painting, goldsmith's work, leather-work, marqueterie, modelling, repoussé work, upholstery, lace, both of English and Irish make, and an immense number of specimens of needlework of various kinds. The exhibit of the Baroness Burdett Coutts contained representations of the charitable work of that lady, together with type-written reports on the philanthropic work of women, classified under the following subject headings:—Childhood; Girlhood; Women; Help for Poor Ladies; Home Mission Work; Amelioration of the condition of the Working Classes; Women as Poor Law Guardians; Working Guilds and Work Societies; Blind, Deaf and Dumb, and care of the Helpless; Nursing; Work among British Soldiers and Sailors; Technical and other Educational Work; Philanthropic Work of Women in Ireland, and Philanthropic Work in the Colonies and abroad.

There was also a large number of models and specimens of handicraft work from the English Ladies' village classes, and specimens of work from various industrial institutions affiliated to the society for promoting female welfare. The Irish Industries Association and the Scottish Home Industries Association also had a large representation, as had the Women's Industries from North and South Wales. The court contained a very large and most interesting series of portraits of eminent British women, classified according to the periods of history, as Mediæval, Tudor, Civil wars, and early half of the sixteenth century, pioneers in philanthropy and general advancement of women, pioneers in education, in science, history, general literature, poetry, fiction, the drama and music, and in art, and in a central group Her Majesty, as taken in 1837 and 1887, and as Princess Victoria in 1830, was shown, together with the Empress Frederick, the Princess Alice, and the Princess Christian.

A large number of the famous Windsor tapestries were on exhibition at the Woman's Building—114 in all. They came from the rooms of the Royal Windsor tapestry works, which were started in 1876, with the late Duke of Albany as president. The aim of the management was to combine the broad effect of the "Arras work," or style

style of the old Flemish school, with the delicate detail and fine elaboration of the Gobelins, and in this endeavour it is regarded as having been fairly successful. Among the earliest productions were the panels illustrating the "Merry Wives of Windsor," from designs of E. M. Ward, R.A. These panels, it is said, obtained marked distinction at the Paris Exposition. Her Majesty the Queen has purchased a number of Windsor tapestries, among them "The Idylls of the King," while Mr. Vanderbilt's house in New York is decorated with a series of panels illustrating English sports and pastimes.

After the death of the Duke of Albany the presidency was accepted by the Prince of Wales; but owing to the cost of production of these tapestries the limited demand for them, and the absence of all subsidy from the British Government, the works became unremunerative, and had to be closed. The principal artists and workmen of the Windsor tapestries were French refugees from the Gobelin and Beauvais manufactories, who fled to England during the Franco-Prussian war.

Unfortunately for a proper appreciation and true criticism of these tapestries, they were hung too high on the walls of the Woman's Building, and the light fell on them so poorly as to make it next to impossible to get a clear and comprehensive view of them. However there were two panels, one representing a "Boar Hunt" and the other a "Stag Hunt," each 9 feet by 11 feet 7 inches, designed by E. M. Ward, R.A., which were splendid pieces of tapestry, full of vigour and expression and worthy the highest commendation. Besides the above there were a suite of tapestry coverings of charming design and beautiful execution, for five armchairs and eight small chairs, which would make a set of furniture fit for the palace of an Emperor.

Windsor tapestries are thoroughly English in conception and execution, and are in marked contrast to the French style. French tapestries are light and airy and full of brightness, while the English are heavy in design and quiet, almost sombre in colour, yet not without an excellency of their own. The widely different temperaments of the two races find expression even in their tapestries.

The Royal School of Art needlework at Kensington had on exhibition a large collection of choice and artistic work, conspicuous among which were panels of pale fawn satin, exquisitely embroidered after the French school, with Louis XVI bows, scattered over with flowers in delicate tints, and handsomely mounted in gilt. Similar to this was a Louis XV screen, also decorated with flowers and bows, but of another design. A bed-spread of cream silk had a Florentine pattern of roses and tulips, outlined with gold thread. There was also a Bible which formerly belonged to Queen Elizabeth, and now owned by Queen Victoria, covered in red plush, and decorated with Tudor roses, in gold bullion, with leaves in shaded green silk, the design of the border being partly wrought in seed pearls. This was quite a gem in itself, and deserved special mention for its beautiful design and execution.

Russian Exhibits.

Russia had no woven tapestries, but its embroidery works were both abundant and choice. The Imperial Ladies' Committee exhibited many beautiful specimens of women's work. The show excelled chiefly in bullion work; a magnificent and remarkable specimen of this latter style consists of a dress designed by the Duchess of Moscow. It was a white satin dress with yellow brocaded train, worked in silver and pearls, and bordered with white ostrich feathers—the design was massive, and would at least take six pages to carry it. The other was a purple violet robe, completely covered with bullion embroidery, and was remarkable for the quantity of work and richness of design. Many shades of gold and quite a variety of stitches were used.

French

French Exhibits.

The exhibit of France was an excellent one. There was a large and beautiful collection of Sèvres work by women, chiefly from the celebrated national manufactory at Sèvres. There were many reproductions of costumes of periods in France by dressed dolls with exquisite work. Fans, embroideries, artificial flowers, gloves, screens, statuary and painting, and a number of articles of similar character, were shown in addition. The Liberal Arts were numerous, containing representations of nursing and hospital work; exhibits from the various charitable and philanthropic societies of France, school work from all the leading ladies' schools of Paris, illuminated missals and manuscripts. A large number of these exhibits were installed in the record room of the west wing of the west gallery of the building, and consisted of the statistics of the various societies of France for charitable purposes, as well as collections of musical compositions by women.

Japanese Women's Work.

The women's work of Japan was represented in its court by many exhibits of the Japanese Ladies' Committee, consisting principally of silk in the raw and worked conditions; of which a beautiful exhibit was that of the figured silk fabrics, lent by the household of Her Majesty the Empress Dowager of Japan, as well as lovely silk braid made by the ladies of the Court. Embroidered panels and pictures and beautiful feather work were also shown. The characteristic chrysanthemum was also a feature, and there was a poem composed and written by Her Majesty the Empress, as well as manuscripts in the handwriting of Court ladies and the Japanese Ladies' Committee.

In the Japanese Court was a woman's boudoir, showing the surroundings of a Japanese woman in her house. Her wardrobe was conveniently hung on a rack in the room, the dress hanging on the upper bar of the rack and the sash on the lower. Adjoining the boudoir was a study or reception room, with the customary mat in the centre of the room, on which were placed musical instruments and little low reading tables, as well as a brazier for fire.

German Exhibits.

In the German Court the bent ironwork made by the women of Germany, one of whom sat at a table and manufactured it before the wondering eyes of the visitors, was exhibited in hanging lamps, candle-holders, inkstands, &c. In one corner was a beautifully mounted lyre, unstrung, the centre filled with swinging leaves, containing photographs of the noted women musicians of Germany. There was a fine embroidered wall hanging done in long stitch representing "Louis XI of France receiving a Hunting Party," after John Eyk; designs and colours chosen by Barbara Wolf, and executed in the art school of Frl. Torres. This beautiful and artistic work took years to accomplish. A portierre by the same artist, renaissance style, is remarkably good and deserving of the highest praise. A table-cover in macrame work, by Frau Gerson, is a fine and striking illustration of macrame embroidery, and comes from the school of art of the Lette-Verein. The school of industry of Reydt and the school of art needlework of Reutlingen have many exquisite pieces on exhibition. But what is most worthy of note is the system of teaching in these schools. Children are given instructions from the age of 6 to 14, and the work is graduated during those years from the simplest sewing to the most exquisite embroidery.

Spanish

Spanish and Other Exhibits.

In the Spanish Court were wonderful priestly vestments, embroidered with gold and jewels. A representation of the cathedral, where the King attends Divine worship, was shown worked in fine thread embroidery, of most delicate pattern. Pillow lace-work was shown, in process of making, with the bobbins hanging to the pillow, as if the worker had just left off work. There were also wonderful medallions, embroidered with the priest thread, made by Spanish women, showing the features distinctly, just as if they were cut in marble.

Ceylon's exhibit here, as elsewhere, throughout all the places where it was represented, was Tea, Tea, Tea.

In the Siamese, Norwegian, Swedish, and Danish sections splendid examples of needlework and embroidery characteristic of these countries were shown, many of them historically interesting.

The exhibit of Mexican embroidery was very large and very fine. Its drawn work was superior to any of its kind, with the exception of the Turkish women's "Yassap Work." There was also a number of pieces of photo-needle work which show remarkable artistic ability, in fact there was nothing like them in any other part of the Fair. The work is done with black sewing silk, on a white silk ground, and the stitches are so fine as not to be discerned with the eye. Among these pieces of photo-needle work were portraits of Presidents Carnot and Diaz and fac-similes of the World's Fair Buildings.

The shading in these photo-needle pictures was as fine and artistic as that we see in photo-gravures or steel engravings.

The exhibits of the women of the United States were very excellent and the decorative art schools of the different States were well represented, but "the Society of Associated Artists of New York," managed by Mrs. Candace Wheeler, deserve special mention. Three panels, "Psyche," "The Fighting Dragons," and "Twilight" were exquisite gems, splendid in design and superb in execution.

The exhibition of embroideries by the Turkish Compassionate Fund was one of the features of the Building. The special branches of the work were draperies for various sorts of house decorations — hand embroideries, ball dresses, worked on foundations of crêpe de Chine, mousseline, chiffon and other gauzy materials, doylies that look like frost work, with the faintest tinge of colour in green and gold, and pink and gold.

The different stitches used in these embroideries were the Yassap, or drawn thread work; the Tsmidt, or surface stitch; the Gaelzed, a stitch similar to the Tsmidt, but done on both sides; the Dival, or raised gold work, and the Souzeni, or chain stitch, similar to the old tambour work. These different embroideries are done by Mahomedan women. The only ornamental work done by Christians is the raised Armenia work. This work, like that of the Tsmidt, is capable of beautiful artistic effects in colouring and design, the only difference being that it is raised work, while the Tsmidt is flat or surface work.

Fans.

The most interesting collection of fans in the Exposition was that placed in the Woman's Building by the women of New York. It might justly be called a historical record of this light implement used for giving motion to the air. There were in this display of feminine possessions fans of modern French workmanship, Italian decorated kid leaf, with sticks carved by the hand of a Chinese, also solid ivory examples relieved by an infoliate design in gold to ornament the top of the sticks. A fan shown was said to be the one presented

presented to the wife of Alexander I of Russia as a bridal gift. One old Chinese specimen was in ivory with silver filagree work outlined in enamelled colours. An excellent and unusual fan was Spanish in its decoration and was called a mourning fan. It was in tones of gray and black. A pen and ink drawing of the battle of the Amazons was skilfully done on vellum and arranged into a fan. There were in the same collection carved fans in the time of the first Empire, Directoire, Vernese, Martin painting on ivory; fans painted in the days of Louis XVI, and many lovely examples in horn, shell, and lace. The fans from Paris were exquisitely lovely, especially those painted on skin. The varieties of designs were endless and they were mounted or unmounted. One dainty unmounted example showed a pretty woman sitting on a stile; her arms filled with spring flowers. At her feet was Cupid with his offering of roses.

Lace.

I have already referred to various forms of woman's art in textile work, but the collections of lace, &c., were so full of beautiful specimens and so extensive, that further reference to this subject may be made, founded on the remarks of a very able expert.

The authentic date of lacemaking is not known, but examples made in the thirteenth and fourteenth centuries are still found in public collections. In the sixteenth century lace was known in Italy as "punto a maglia quadra" and in France as "laciis." The patterns then were stiff and only geometrical, a kind of design traced to Grecian origin and taken from Greece to Italy. When the making of lace was fairly established in Venice the designs quickly grew in beauty and variety of pattern and complexity of stitch. The making of the important variety of Venetian needle-point attained unqualified perfection in the middle of the sixteenth century.

Italy's display of lace, in the Woman's Building, was the largest. It was composed of ancient and modern examples. There were in it complete sets of antique bobbins to illustrate the making of pillow-lace, and needles and threads showing the way in which the early "punto in aria" (needle-point) was made. The revival of this industry at Burano (and the exquisite specimens sent from there to the World's Fair) proves conclusively that the artisans of Italy have not lost their delicate execution. Some of the heavier pieces of Venetian point resembled fine bits of carving in ivory: some of the old patterns, geometrical in design, were like the intricate weavings of a spider's web. In laces of a flat character the brides (links) were interspersed between the various details of the patterns with exquisite skill. The examples of "rose point," "caterpillar," and bone point and the bold designs done in relief were very lovely. All sorts of minute embellishments, like little knots and stars, were used; specimens in a honeycomb pattern, which was much used in the seventeenth century, were interesting bits of that time. The delicate Venetian point, which is made with a ground of meshes, and usually known as "Point de Venise à réseau," is very beautiful. There was a flounce of Venetian point, made in the seventeenth century, in this showing that was a superb example of the work then accomplished. The baptismal veil of Queen Caroline of Naples was the most exquisite example of lace shown by the Italians. The modern pieces of guipure were excellent; also the bits of veticella and Spanish of the sixteenth century, in which the heraldic arms of Charles V were intricately wrought into the webby meshes.

The brilliant French artisans are never disappointing, either in their handicrafts or in their arrangement of them. Their collection of laces, both in the Liberal Arts Building and in the Woman's Building,

adds

adds one more proof of the artistic ability of these clever people. Lacemaking was introduced into France by the Venetians and it attained its greatest excellence there in the early days of the Renaissance, through the great and untiring efforts and influence of Louis XIV's minister, Colbert. Even the earlier specimens of "Points de France," or Alençon, were more fanciful and floral in their designs than the Venetians. The French laces resemble the foam that floats on the crest of a wave; they are so soft and filmy that their existence seems necessarily transient, but on the contrary they are enduring. Alençon and Point d'Argentine are very like Point de Venise. They have the hexagonal brides which distinguish that lace from Italy. Almost every variety of needle or pillow lace ever made is woven in France in perfection. A lovely example was in old Gênois. It represented the crowning of the virgin; the relief effect in this piece was exquisite. A most beautiful flounce of artistic guipure, a design of the eighteenth century, was perhaps the most effective large piece of lace shown. The Flemish point in the pattern known as Louis XIII, and the babe's lace of Louis XIV, were incomparably charming. Valenciennes, which was made in perfection during the reign of Louis Philippe, were well represented. This variety of lace is essentially French, and has a cobweb delicacy which is exquisite. A perfect piece of Robat Angleterris Point of the seventeenth century was displayed; and two figures of angels, in Colbert Point, which were masterpieces of lace workmanship.

The making of this delicate and beautiful article by the women of Belgium is an old inheritance, for the invention of pillow lace is said to have existed in Flanders as early as 1495. The Belgians have imbibed the brilliancy and daring of their lacework from the French, and in the making of the Valenciennes pattern are equal to them. A dress of Point d'Angleterre shown by them was masterful. In many examples the coats of arms of the different provinces of Belgium were wrought. A quaint and lovely veil of the virgin, made in the last century, had woven in its viseaux or meshes a lovely Flemish design. These people work garlands of fine flowers exquisitely; in fact their lace can be easily distinguished from that of other countries by this peculiarity. The showing was composed of beautiful specimens of Mechlin, round point, Point de Bruges, Duchesse, Point Appliqué, and the beautiful lace called Dentelle Louis XV.

The Irish laces in Jackson Park were extremely beautiful. The display of them was one of the most comprehensive shown in the building. The Irish point does not equal in fineness of texture the laces made in other countries. The Honiton made by the Irish is exquisite. Their crochet lace, both in cotton and silk, is beautiful. Examples of Carrickmacross, Limerick, and other laces found in handkerchiefs, fans, and trimming laces were very pretty.

Spain is considered a lace-making country and no doubt a great deal of lace is now made in Spanish convents, but it has no distinctive character. The Point d'Espagne made in the seventeenth century was much esteemed by the Spanish, and was much used in France. No lace pattern books have been found in Spanish publication—the patterns followed by them were either Venetian, French, or Flemish. The silk pillow laces and "blondes" shown in the Woman's Building by the Spaniards were daintily attractive. There were examples of Malta thick pillow lace shown, chiefly in geometrical designs, in which circles, wheels, and radiations of shapes resembling grains of wheat were a principal feature.

The unusually large display of modern hand made laces at the Fair proves conclusively that the machine-made laces, which for a time threatened the existence of real laces, have now to some extent been abandoned.

Of

Of all the collections of laces in the Woman's Building, the one that was the recipient of the greatest admiration was that made and lent by the women of New York. It would be impossible to state the monetary value of this massing of beautiful laces. In one corner was arranged a valuable lot of laces or darned netting made between the years 1468 and 1576. The oakleaf and geometrical designs were to be found among them; also, the favorite embellishment of the Paschal Lamb. Many pieces of punto tirato or drawn work, punto tagliato or cutwork, and rectecella were shown, both in the white and with yellow and red silk and linen threads introduced. Beautiful examples of Venetian laces were in the collection; also lovely bits of Point de France, guipure de Flandres, Brabant, Spanish blondes, Mechlin, Lille, Tondren, Valenciennes and American, all of which were deeply interesting. One unfinished piece of darned lace was the work of Susannah Vaughn, and was accomplished in the year 1730. A cobweb-like handkerchief was made by Elizabeth Brinkerhoff, of Albany. All the examples of American lace told historically interesting stories.

NURSING EXHIBITS.

Nursing being essentially woman's work, part of the required space was provided for the purpose in the Woman's Building, and over the door of an attractive room in the first gallery, the sign "British Nursing Exhibit," told where England, the "pioneer" in this particular field of work, had her very complete display.

The room, which was arranged under the supervision of two celebrated English nurses, contained many glass-cases which were filled with models of almost all appliances needed in hospital or any other kind of nursing. Models of beds were shown, with newest improvements, for the treatment of various injuries. Also the latest ideas of instruments, surgical dressings, bandages, and all articles needed for operation. One case showed the most recent mode of treating medical patients. In this was a model of a portable bath which could be wheeled and raised to the level of any bed; also one great improvement in hospital work, not shown anywhere else in any exhibit, of every utensil needed in the treatment of typhoid fever. Each article was clearly marked in large letters "typhoid," thus doing away with the danger of having it used for any other patient.

There was noticed also a watch, with a strongly magnifying crystal, for use in a dimly-lighted room, besides many other useful articles for the sick, such as modern medicine glasses, droppers, measures, &c.

Another case contains the outfits for the different English district nurses. Especially interesting is that shown by the Queen Victoria Jubilee District Nurse Association, which society was founded from the pennies collected by the poor women of England during Her Majesty's jubilee year.

One very large case shows between sixty and seventy dolls, dressed (very prettily the greater part of them) in the indoor and outdoor uniforms of all the larger hospitals in England. In connection with this was a model nurse's trunk and a display of sanitary and ventilated clothing.

In the English exhibit was also a cabinet containing many interesting mementoes, such as a case of medals presented to different nurses for bravery in war time, and the pincushion, scissors, chain, and other souvenirs of the celebrated Sister Dora. Sister Dora's picture, with that of Elizabeth Fry, Florence Nightingale, and many famous heads of English training schools hung on the wall of the room, in company with portraits of Queen Victoria and other English-women of high rank interested in the encouragement of the profession of nursing.

The

The Woman's Building contained, also, that portion of the very large American nursing exhibit sent by the hospitals and charities of New York, Brooklyn, and Philadelphia. The most noticeable part of this display was a fine model, shown by the Presbyterian Hospital of New York, representing a ward furnished with every necessary appliance in the latest antiseptic style. It contained six white-painted iron beds, each so arranged as to present a very perfect object lesson, for the treatment of various injuries and diseases, the methods of dressing and bandaging wounds, of lifting a fever patient into a portable bath, and of using a steam inhaler for diphtheria, with an exactness of detail which made this display one of the most perfect in the whole nursing exhibit.

Bellevue Hospital's Exhibit.

Bellevue Hospital of New York shows a model of a bed and a doll dressed in the uniform of a nurse, with a label pinned to its apron, on which is written "I am the grandmother of all," Bellevue being the pioneer training school in America. The Mount Sinai and New York hospitals both showed many photographs of the interior and exterior of their buildings, with groups of the nurses at work in the wards. Besides models of hospital beds there were several of special methods of preparing such surgical dressing and medical supplies as splints and pneumonia jackets; also dolls dressed in the uniforms of nurses. The rest of the New York hospitals showed only photographs.

CHILDREN'S BUILDING.

A large building, called the Children's Building, was provided under the auspices of the Board of Lady Managers, which was truly an educational exhibit. One object lesson was to be found in the crèche or nursery, a department provided for the reception of babies and young children, by means of which parents were enabled to visit the Exposition without being encumbered by their little ones, and I can state from personal observation that it was well patronised. On an average 50 to 60 little ones were received daily for this kind of protection, and the room was found inadequate for all the applications made. Many mothers who visited the Fair office to check-in their babies were obliged to turn away in disappointment, and a sign, "No more children received to-day," was affixed to the office-door by the matron not unfrequently.

Twenty-five cents was the modest fee charged by the managers of the crèche for the care of a child daily, and in addition the little one was fed bountifully in the nursery dining-room, morning and afternoon. Sterilised milk was the diet for babies in arms, while the older children were given plain, wholesome food that included all the staple necessaries of life. The meals were nicely served on low tables, at which the little ones sat supremely happy, and feeling far more comfortable than if they were being dragged about in the hot sun to look at a lot of buildings and exhibits in which they took not the slightest interest.

The greatest attention was paid to the reception of the children. The secretary of the crèche entered on her register—first, the child's name, permanent residence of the parents, temporary home while in Chicago, occupation or profession of the father, and brief description of the little one's clothing. A round (brass) numbered check was then handed the parents, or whoever brought the child, and a correspondingly-numbered check was attached to the dress of the youngster, generally at the back under the collar, where it could not easily be detached. A third check was placed with the child's outer clothing. It was almost impossible to mix the babies up, and the mother had no timidity about leaving her baby on this account.

When

When the crèche was ready for the reception of the little ones the windows opening into the body of the building from the nursery were besieged by crowds of curious visitors, who took keen delight in watching the children at play.

It is almost unnecessary to state that the 25 cents fee charged for the care of a child by no means reimbursed the management for the expense incurred in maintaining its obligations. Nor was such return contemplated. The crèche at the Fair was not a money-making venture; it was an object lesson for the study of thinking people. The hope was entertained that its teachings would so impress the many thousands who became interested in the crèche that on returning to their widely-scattered homes the desire to establish like institutions would be so firmly inculcated that useful results might follow.

The crèche, in the Children's Building at the Fair Grounds, occupied the entire west wing on the ground floor, and consisted of office, nursery, children's playroom, dining-room, kitchen, laundry, and drying-room. Numerous closets and retiring-rooms were arranged for sanitary convenience, and the entire wing was well ventilated by large low windows that flooded the rooms with light, and admitted plenty of fresh air. On the second floor, in the south-west corner, was the Kindergarten portion of the crèche, where the older children were taken every morning to be pleasantly instructed and entertained. The airy room contained all the best appliances known to Kindergarten work, and the children thoroughly enjoyed the morning hours passed in this attractive retreat.

On the ground floor admission to the nursery was gained from the office at the north entrance, where the matron's assistant sat with her register to receive the children. Babies of two years and under were retained in the large nursery adjoining the office, where numerous pretty white and gold cribs were arranged around the walls. In the centre of the room was an enclosure known as the pound, where the good wide-awake babies sat upon a soft mattress, furnished with a white coverlet, and smiled and crowed at the youngsters. In spite of several loud-keyed infants, who refused to be consoled by doses of sterilized milk, half-a-dozen babies slept peacefully in adjacent cribs with just as much comfort as if they were alone. Baby-jumpers, dolls, and rubber balls were in evidence to amuse the tiny occupants of the cots, and the trim appearance of the competent maids lent additional attractiveness to the scene.

In the playroom beyond upward of forty children had a good old time under the watchful eyes of three or four rosy-cheeked lasses in white caps and aprons. Toys of all descriptions littered the floor, while small chairs and tables flourished everywhere. Bright pictures, calculated to please the infantile mind, adorned the walls, and smiling faces largely predominated. Only one or two tearful visages were to be seen in the room, and these were due to temper, so the maid in charge declared. Half-a-dozen little girls had a tea-party in one corner, a buffalo-bill show was improvised by four young ruffians in another, and bull-fights, horse manœuvres, ball-playing, racing, singing, shouting, laughing, and block building elsewhere proved the merit of the venture.

Viewed as a public convenience the crèche was a great success, and represented a great underlying principle. Of the fifty-seven babies and children gathered in the nursery on the occasion of my visit only six were permanent residents of Chicago, the remainder came from all parts of the Union, and, with only two exceptions, all seemed very happy in their temporary quarters.

The World's Fair Hospital.

THE Medical Bureau and Emergency Hospital was one of the few places of interest in Jackson Park that was not open to general inspection. It was not a public exhibit, so to speak. If a visitor got inside the hospital he or she had to come in an ambulance wagon or under escort of a Columbian guard. It was cool and breezy; its main corridors and reception parlors were decorated with potted flowers and vines; cool rattan furniture greeted the eye on every hand, and in two of the larger apartments were long rows of brass cots clad with snow-white linen. Flitting about the halls were quiet and soft-stepping nurses in cool linen garments and snow-white caps. There was an air of stillness about the whole place which invited rest and conduced to peace of mind.

The Medical Bureau and Hospital were established by the World's Fair managers to supply quick and prompt medical attention to all who might need it among the vast throngs who entered the gates. When large gatherings of people assembled there was plenty to do in the Medical Bureau. The world's Fair Hospital was especially designed for prompt but temporary attention. It was not intended for cases involving serious work of physicians, nor was it established with a view to continued treatment; it was simply a place for the application of quick remedies for immediate relief. Of course patients not fit to be removed were kept there until they could be taken elsewhere.

The hospital was situated in the southern end of what was known as the Service Building. Entrance was obtained through the main gateway opposite Festival Hall, thence through a wide court to the southward, where, through a doorway decorated with potted plants, one was ushered into the corridors of the cool retreat. There were four or five reception-rooms divided by a wide hall-way running the length of the wing; at either end of the main hall-way were the two wards, each fitted with twenty-four brass beds. Both these wards were models of cleanliness, and were very inviting to the eye. In the corridor between the two hospital wards were the officers and consulting rooms of the physicians, a ladies' reception-room and parlour, a diet kitchen in which was a gas range, two pretty cooks ready at any moment to supply any article of diet that might be ordered for the sick. In the kitchen was a dainty china closet filled with blue china, a neat little refrigerator always filled with ice and cooling drinks on ice, and all, of course, delightfully sweet and clean. Then there was a surgeon's operating-room provided with a large glass table, a splendid glass case of surgical instruments, and every other appliance that could be needed in a surgical emergency.

Sanitation System of the Exposition.

The Engle Crematory.

THE sanitation system adopted at Jackson Park was one of some interest to our municipal authorities in Australia. When the plans for the World's Columbian Exposition were made, and it was found that about 600 acres were to be occupied with buildings which would be thronged with multitudes of people for six months of the summer season, it became apparent that one of the most serious questions was that of sanitation. The situation to be met was that of a concourse of strangers to the city amounting, practically, to an improvised city or encampment of at least about 80,000 inhabitants, including constant residents to the number of 20,000, and a possible average of ten times that number of visitors every day during the season, besides the extensive live stock exhibit, from all which extensive concourse of men and animal the excreta, refuse, and garbage of every kind resulting from their presence and sustenance on the grounds must daily be received and disposed of, entirely within the crowded space of the Fair, there being no legitimate outlet on land or water, nor any aid to be obtained from the city for such purposes. The plan adopted reflected the highest credit on the ability and good judgment of the authorities. The solution of the problem may be expressed in the one word "fire"; and the scientific principle of duplex combustion, as adopted in the Engle Cremator, after an exhaustive and impartial comparison of all the various systems of garbage disposal, was employed for the purpose. A contract was made with the Engle Sanitary and Crematory Company, of Des Moines and New York, for the erection of two garbage cremators, guaranteed to destroy utterly 100 tons per day of garbage, miscellaneous combustible waste, sewage sludge, and stable refuse. At the same time the "Shone Hydro-Pneumatic" system of sewerage was adopted in connection with all the larger buildings of the Exposition to convey the sewage from the closets and drains and to deliver it in the form of compressed precipitates to the cremators.

The furnaces covered a space of ground, including the chimney, 42 feet long by 18 feet wide. There were two furnaces placed back to back, with a brick stack 50 feet high. They were surrounded by platforms with inclined approaches, which allowed the collection carts to discharge their loads directly upon iron slopes leading down to the feeding-holes of the furnaces. The furnaces and slopes were covered with a protecting house, 45 feet square, of corrugated iron, with large doors on each side admitting the collection carts for the deposit of garbage. All of the waste collected was discharged within this covering house. There were four feeding-holes for each furnace, connecting at the bottom of the iron slopes, through which the garbage was discharged, with the interior of the furnaces. The capacity of the slopes was 20 tons, which was equal to the capacity of each furnace for one charge. The garbage was received inside the furnaces on grates made of interlocked fire-clay brick, through the spaces of which the ashes passed into the lower chamber.

The fuel (as required to be used on the Exposition grounds) was crude petroleum oil, which was conveyed through three burners, two of which, for the initial fire, were placed at the rear or stack end of the furnace, and one, for the secondary or perfecting furnace, at the front extremity. The form of the hydrocarbon burner adopted was the "S.C.T. Burner," largely used by the Standard Oil Co. for the production of large temperatures at their pumping stations. Air for atomising the

the oil was driven from a Root Positive Blower by an electric motor of twelve Kilo-watt power. The pressure of only 8 oz. of air to the square inch furnished the best result for the combustion of the oil. The flame from the rear or initial burners passed over and through the garbage, swiftly licking up its moisture and volatilising and inflaming its combustible elements. This blazing mixture of gases, vapour, and smoke then entered the flame of the second burner at the other extremity of the chamber, turning downward into a return flue beneath the grating, through which the whole product, in a state of perfected combustion, was driven back to the smoke stack, filling the space beneath the grating and the entire mass of garbage upon it with all-consuming heat. Every particle of the vapours, smoke, and gases was annihilated before reaching the outlet, and issued only in an aerial residuum, thin, colourless, odourless, and innocuous as the atmosphere itself, in which it is dissipated unperceived. This operation was maintained continuously without limit of time, the charging and removal of ashes being carried on without interference with the work of combustion.

In the earlier weeks of the Fair the daily collection of waste was about 15 tons, which was destroyed in about six hours' time by one furnace, using only about one-third of the capacity of one furnace, and that for about one-fourth of each day, although the sewage sludge and garbage often contained 20 to 50 per cent. of liquid, which required a degree of heat realised from no other principles of combustion to overpower it with the unimpeded swiftness witnessed in the work of the Engle Cremator. When the furnace was first fired the three burners quickly raised the temperature to a height in which the material to be consumed was compelled largely to sustain its own combustion, aided only thereafter by two burners with the smallest amount of oil which could be used. The labour employed was that of three men running the furnaces, while others subsequently removed the ashes.

The Engle Cremators were placed in the extreme south-east portion of the Exposition grounds, within 100 yards of the power-house of the intramural railroad, within 150 yards of the forestry exhibit, and 120 yards from the sewage cleansing works. Thus to destroy dangerous and offensive waste in great quantities, in the immediate neighbourhood of the Exposition buildings, under the noses of multitudes of people, under the critical observation of sanitary officials, engineers, and experts perfectly familiar with all forms of furnaces and modes of combustion, and to perform this work in a manner universally satisfactory and beyond criticism, entirely sanitary, speedy, economical, thorough, and pleasant, was undoubtedly the most exacting test and the most conclusive demonstration of the supreme advantage and utility of the destruction of waste by fire that has ever been seen in America or any other country.

In the city of Chicago the dust and dirt bins placed in the lanes at the rear of the residences are divided into two portions, the one containing dry refuse, the other moist. These are cleared away as provided by the municipal authorities, and carted to distant parts of the city for filling in or similar modes of disposal. Last year the Mayor gave instructions for the employment of a number of travelling cremators, as they were termed, in which was burned the refuse of the district, and these cremators moved about whilst performing their work in the district. Just before I left Chicago the establishment of a large fixed cremator was determined on, and the following article from the *Chicago Tribune*, 22nd December, 1893, will be found interesting in this connection:—

TO BURN THE GARBAGE OF THE CITY OF CHICAGO.

THE new garbage crematory erected near the intersection of Huron-street and the river commenced operations on 22nd November, 1893. It is estimated to consume 100 tons per twenty-four hours, or about one-fifth of the quantity of garbage now produced

produced in the city. It will do this with the use of 500 gallons of petroleum, costing little more than \$8 per diem, and the labour of three shifts of seven men in each. The estimated cost of the reduction in labour and material is 47 cents per ton, and the city will pay 70 cents per ton for all that is consumed while the test is in progress. There should be a considerable saving in the cost of transporting the garbage, which is paid for by the city, owing to the much smaller distance the stuff must be carried to the crematory as compared with the ordinary dump.

The new apparatus promises well. It is said to generate a heat sufficient to melt down scraps of iron and glass, while a supplementary furnace consumes the smoke and stench. Its merits as compared with the perambulating crematory have to be decided by actual trial. It is claimed to be capable of producing a far greater degree of heat than the perambulator can do, and therefore more completely reduces the material submitted to its action. Hence it is preferred for its avoidance of emissions of smoke and stench. But it is feared the cartage accompaniment may be far from agreeable. The long line of garbage waggons passing through streets and alleys will be both unsightly and unsavory, and in the latter respect may be a terrible nuisance to thousands of citizens. On the other hand it is claimed for the perambulator that while it emits some smoke and stench the discomfort caused by it in any one spot is of short duration, as the machine can go through a whole block in about twelve minutes, after which the place is free till the next visit. Of course it has the advantage of taking up the garbage directly from the boxes into which it has been emptied by residents, and thus does away with the nuisance of the garbage waggon, which takes the freshly stirred up stuff long distances through densely populated sections to poison the air all around. The perambulators are proved capable of doing good work, and it is claimed they can do the same amount of cremation at less cost than needed by the stationary crematory. This fact is cited as sufficient reason why the contractors are "down on it." If the perambulator were adopted their occupation would be gone.

A great reform will have been achieved if the garbage of the city is disposed of by burning instead of being dumped all around us to fester and rot near residences of the people. The fact that the persons thus afflicted under the old time arrangement belong to the poorer classes does not mitigate the wrong. They are entitled to protection from nuisances originated by others as well as are the richer members of the community, and the latter are in danger in case of disease breaking out amongst those directly exposed to the contagion. So either method will be a vast improvement on present conditions, but both should be watched carefully by persons competent to judge, and the best chosen in the interest of all the people, since all have to pay their share of the cost. If after careful examination it be found that the perambulator is preferable on the whole to the stationary crematory no opposition by contractors should be allowed to stand in the way of its adoption for every ward in the city. The fact that those gentlemen get a large share of the million dollars appropriated yearly for the removal of filth may form a strong argument with them, but it should be of no force with the great majority, those who foot the bills.

Meeting of World's Congress Auxiliary.

THE World's Congress Auxiliary, as I have already stated in an earlier part of this Report, held its various meetings during the currency of the Exposition, in the Art Palace on the lake front, in the city of Chicago. The Government of the United States, recognising in the congress auxiliary the proper agency to conduct great international conventions, invited other nations to send as representatives their most eminent men and women in the various departments of human progress. Unprepared discussion or miscellaneous debate would obviously have been inconsistent with a plan of which the chief object was to procure the maturest thought of the world on all the great questions of the age, in a form best adapted to universal publication. The time at disposal, after the delivery of a discourse, was therefore given to the most eminent persons present, who spoke at the call of the presiding officer. The summaries of progress presented and the problems of the age stated in the congress were not to be submitted to the vote of those who happen to be present, but will be offered for subsequent deliberate examination by the enlightened minds of all countries, for unrestricted discussion in the forum, the pulpit and the public press, and finally for the impartial judgment of that exalted public opinion which expresses the concensus of such minds. With this end in view, remarks of leaders, in elucidation of a subject, took the place of ordinary debate.

The World's congresses were held, as I have stated, in the permanent memorial Art Palace on the lake front, that use being granted for the gift of \$200,000 by the Exposition company to the art enterprise. The building had two large lecture-halls, each capable of seating 3,000 persons, and twenty smaller rooms to accommodate from 300 to 700 each. It was thus possible to have two general and twenty special conventions in session at the same time.

This undertaking was of a most elaborate and extensive character, and a distinct assignment of subjects was provided for different periods, as follows :—

MAY.

- I. Woman's Progress,
- II. The Public Press.
- III. Medicine and Surgery.

JUNE.

- IV. Temperance.
- V. Moral and Social Reform.
- VI. Commerce and Finance.

JULY.

- VII. Music.
- VIII. Literature.
- IX. Education.

AUGUST.

- X. Engineering.
- XI. Art, Architecture, etc.
- XII. Government, Law Reform, Political Science, etc.
- XIII. General Department.
- XIV. Science and Philosophy.

SEPTEMBER.

- XV. Labour.
- XVI. Religion, Missions, and Church Societies.
- XVII. Sunday Rest.

OCTOBER.

- XVIII. Public Health.
- XIX. Agriculture.

The ambitious aim of the promoters of these congresses was a presentation of the intellectual and moral and religious progress by the World at large, and the assistance of men, recognised as leaders in the several departments of human knowledge, was asked for, in order to give practical effect to the proceedings. In Appendix O will be found the general programme of this department of the World's C. E.

Several papers written by persons in New South Wales were read at these congresses, and I prepared several also, for the information of those attending the meetings, on subjects connected with our country's history and resources. As far as my other engagements would permit, I attended some of those congresses, and was impressed by the enthusiasm of many of those taking part in the proceedings. Many of them were very largely attended and others but sparsely. As a matter of fact it required very attractive matter to allure the public to congresses on abstract matters, in view of the wonderful objective and highly picturesque rival installed at Jackson Park. It seemed to me, also, that in order to produce a completely satisfactory result from the congresses their number might have been greatly reduced without any loss of efficiency, and that the selection of persons who prepared the papers read and participated in the discussions might on many occasions have been characterised by a fuller possession of the qualifications of speakers clothed with responsibility, sound judgment, and defined learning.

The number of sessions of these congresses that will be ultimately successful and useful to the world at large, or that shall have provided some advance in our knowledge of their special subjects, will certainly not be as extensive as the official programme. Certain of them, however, will certainly be of public advantage, such as the engineering, the electrical, and other similar congresses, and the papers read and the opinions given by the eminent men who took part in them when published will be interesting and beneficial. I have already quoted from some of the papers read in the course of this Report, and when ultimately a judiciously collected publication of the proceedings is made, a much larger value will attach to the work performed than could possibly be the case during the actual course of the congresses, when, in consequence of the large numbers of persons present and the necessarily rapid consideration of papers, dealing in some cases with questions of supreme importance, requiring mature and deliberate thought, it was impossible to estimate aright, either the true value of the theories and principles enunciated or the relative importance of questions treated in the various congresses.

Special Items of Interest in connection with closing of Exposition and New South Wales Courts.

Closing Day of the Exposition.

THE Exposition closed, as appointed, on 31st October. A very extensive programme had been prepared for the celebration of this event; but a great calamity intervened. Instead of the closing day being marked by rejoicing and the great enthusiasm characteristic of such occasions, there was sorrow and sadness at the final meeting in the Great Music Hall, in consequence of the death of the Mayor of the city of Chicago, Carter Harrison, one of the most vigorous and enthusiastic projectors of the Exposition, by the hand of an assassin. A short address by President Palmer and prayer completed the proceedings on the occasion.

Attendance at the Exposition.

THE attendance at the World's Columbian Exposition, although not so great as was originally estimated, was very remarkable. There can be no doubt that it would have been much greater had it not been for unforeseen circumstances. Not only had Chicago at the commencement to experience the long and bitter struggle for the honour of celebrating the Columbian anniversary, as I have already stated in an early part of this Report, but it had, subsequently, to sustain the envy of the unsuccessful cities—a jealousy which only subsided when the hour of triumph for Chicago and America had arrived—as well as the unjust and damaging criticisms of the Eastern press (especially of New York), only too readily adopted and endorsed by European newspapers and circulated all the world over in the most unfavourable form. The silver crisis in the United States, the war of tariffs, the financial difficulties of the country (for these were not confined to Australia, but were simultaneously very widespread in the United States), and the high rates for railway carriage to Chicago in the early months of the Fair, as well as the wretched weather in the months of April and May, all added to the difficulties of the matter. Yet all these difficulties were surmounted, and the indomitable energy of Chicago was crowned by a success which was undoubtedly as complete as it was well deserved.

The number of visitors present on the opening day was 137,557. On the 4th July (Independence Day) the attendance numbered 330,542; but the most remarkable total was that of Chicago Day, when 761,942 persons passed the turnstiles, and of this number 683,742 were paying adults and 33,139 children, 45,061 being admitted free, and the money taken on this day was not far short of 375,000 dollars. This was the highest total hitherto reached at any Exhibition. The greatest day at the Great Paris Exposition of 1889 was little more than half of this number—397,000; while at the Philadelphia Centennial Celebration Exhibition the highest total was about 275,000. During Chicago week the attendance approximated $2\frac{1}{4}$ millions, and the sum taken as entrance fees was about 2,050,000 dollars. The paid admission exceeded 100,000 on 92 days; 200,000 on 24 days—once in July, once in August, four times

times in September, and eighteen times in October; while 300,000 was exceeded on four occasions—on the first three days of Chicago week, October 9th, 10th, and 11th, and on Thursday, the 19th of the same month.

The attendance and its growth will be observed in the following table:—

	Total Paying.	Grand Total.	Per Day.
May	1,050,037	1,531,984	54,714
June	2,675,113	3,577,834	119,271
July	2,760,263	3,977,502	132,583
August	3,515,493	4,687,708	151,216
September	4,659,871	5,808,942	193,631
October	6,816,435	7,945,430	264,849
Total	21,477,212	27,529,400	153,800

The average daily total was 153,800—and this includes Sundays, when the attendance usually was very small indeed.

The only other Exhibition with which comparison can be made in this respect is that of the Paris Exposition of 1889. It must be remembered, however, that the Paris Exposition was open for two days longer than the World's Columbian Exposition, and that on Sunday the visitors to the French Exposition were usually more numerous on that day than on week days. At the French Exposition there were about 600,000 more visitors than to the American one, but this is more than accounted for by the circumstances just referred to.

In this comparison some consideration must be given to the entrance fee. At Chicago each of the 20 $\frac{1}{4}$ millions of adult-paying visitors had to pay 50 cents, or 2s., while the 1 $\frac{1}{3}$ million children paid 25 cents for admission; the only concession made occurred during the Chicago week, when school-children were given a holiday and the charge was reduced to 10 cents for children under 18 years of age. During this week 316,066 children visited the Fair. At Paris, on the other hand, the visitors paid a nominal sum of 1 franc each in the daytime and 2 francs in the evening. Owing, however, to the peculiar lottery system adopted in Paris, the entrance cost on an average not more than 5d. in the morning and 10d. in the evening; in fact, on account of the great supply of tickets, the price fell even below this, and on one occasion the entrance fee was as low as 2 $\frac{1}{2}$ d.

As has been said, at the World's Columbian Exposition 20 $\frac{1}{4}$ million adults each paid 50 cents, representing about £2,314,924, and 1 $\frac{1}{3}$ million children each paid 25 cents, equalling £69,681; while the children who attended during the week ending 21st October paid only 10 cents each, equal to £6,585. So that the entrance receipts amounted to £2,391,190.

The sum obtained from various concessions helped also to swell the income. These were estimated to amount to over £800,000, as compared with about £160,000 received from the same source in Paris in 1889. The total receipts at the latest date of information was about 5 $\frac{3}{4}$ million pounds, while the expenditure was put at nearly 6 $\frac{1}{4}$ million pounds.

The

The following table supplies interesting particulars in connection with some of the leading International Exhibitions:—

Held in.	Year.	Acres of Build-ings.	Days.	Attendance.		Cost.	Receipts.	Exhib-itors.
				Total.	Daily.			
London ...	1851	21	144	6,039,195	41,952	\$ 1,460,000	\$ 1,780,000	13,937

New South Wales Awards.

IN Appendix AA will be found the revised list of awards to New South Wales, numbering over 800. The results thus obtained, and deservedly obtained, by our exhibits, has never before been equalled. When the diplomas issued by the United States authorities are received, particulars of the reason for award and degree of excellence by the expert judges will be found inserted for the information of exhibitors and the public.

The medals and diplomas will, in due time, be forwarded by the Government of the United States to the Honorable the Colonial Secretary for distribution.

Seizure of Exhibits by Sells Brothers.

ON Thursday, 2nd November, 1893, three days after the closing of the Exhibition, the Sheriff of Chicago attached the gold and other mineral specimens belonging to the Government of New South Wales, at the instance of Sells Brothers and another, circus proprietors, of Ohio. It was stated by the Sheriff that 100,000 dollars security had been given by these persons in connection with a claim for 50,000 dollars in the action Sells Brothers and another against the Province of New South Wales for certain alleged injuries to their horses, &c., three or four years ago, while the circus was in operation in New South Wales. The Sheriff served on me a writ of summons as a witness in the case, and the day for the trial was stated to be 4th December proximo, in the Superior Court of Cook County, Chicago.

The facts of the case were cabled to Sydney to Sir George R. Dibbs, Premier, and subsequently I had the assistance and advice of Director-General Davis, the United States Attorney (Mr. Walker), the British Consul at Chicago (Colonel Sadler), the Collector of Customs at Chicago (Mr. Clarke), and, lastly, the British Ambassador at Washington (Sir Julian Pauncefote). The case gave me considerable anxiety, as I anticipated detention in Chicago in consequence of the proverbial delays connected with procedure in American Law Courts. The New South Wales Government finally gave instructions to Mr. Walker to proceed with the removal of the injunction obtained in the case as to removal and sale of the attached exhibits as a preliminary measure, and at this stage the Judge gave an opinion against Sells Brothers, declaring that "no action of a citizen could lie against a friendly

friendly power." Against this decision Sells Brothers appealed; but in the meantime, under legal advice and with the official sanction of the United States Customs' authorities, I sent the exhibits to Sir Saul Samuel, our Agent-General in London, so that they might be forwarded to Sydney, with all the precautions as to safety and insurance adopted when they were forwarded to Chicago. The curious part of the case was that the officials of the Court in Chicago continued to watch the safe in which the gold specimens were kept for security for some time after their removal, unconscious of their disappearance.

I may state that this procedure of Sells Brothers was regarded generally with extreme displeasure in the United States, and every assistance and sympathy under the circumstances was afforded me by the officials, the public, and the press.

Visits of New South Wales Commissioners and Others.

DURING the currency of the Exposition several members of the Sydney Commission visited Chicago. There were present at the opening of the Exposition Messrs. Skarrett and James Martin and Miss Windeyer. At a later period Mr. Joseph Marks, Mr. Peabody of Boston, Dr. Carl Fischer and Mr. Saddington of Sydney, and Sir Roderick Cameron of New York, visited the Exposition. Mr. Skarrett rendered most valuable practical assistance in the arrangement of the wool fleeces and otherwise, during the time he remained in Chicago. Dr. Fischer assisted us with advice regarding the placing of our fine art exhibits. I regret to state that this gentleman, after a very short illness, died at Chicago on the 21st June. Every respect was paid to his memory; the flags of Australia House and of all the foreign buildings in the neighbourhood were lowered half-mast, from the time of his death till after his funeral, at which I and several members of the New South Wales staff attended. Dr. Fischer was buried at Oakwood Cemetery, Chicago, a short distance south of the Exposition. Miss Windeyer, as I have stated elsewhere, was, on my recommendation, appointed a judge in the artistic section of the manufactures exhibits, and in this and in various other ways rendered very valuable service during her stay in Chicago. Lord Jersey visited the Exposition in June, 1893, and was good enough to accompany me through our various courts. His lordship expressed himself as highly gratified with the display of our country, and the satisfactory impression we had created in Chicago and the United States. Our visitors' books in Australia House and in the various courts contained the names of a vast number of visitors from all parts of the World, as well as a number of Australian visitors from all the colonies. As far as I am aware, every attention was paid to these visitors as soon as they introduced themselves at Australia House or our various courts in the Exhibition.

The New South Wales Officials.

It affords me great pleasure to place on record the high appreciation of the services rendered by the various members of the official staff engaged in the work of our representation at the World's Columbian Exposition. Every officer during the whole course of the exhibition acted to my satisfaction in the various departments, and all were animated with an anxious desire to promote the best interests of our country.

Mr. Hudson, as general superintendent, supervised our traffic arrangements, both on their arrival and their return, and assisted materially in the installation, more particularly of the heavy exhibits, where his great practical experience was found of special value. In the arrangement of the courts under his charge, and more especially in the display of our timbers in the Forestry Building, his work was very

very successful. Mr. Pugh's display of our wines, our pictures, our fish and our ethnological exhibits, evinced remarkably good taste. Mr. Carne, from his long experience in exhibition work, made undoubtedly the best and most impressive display of our mineral resources ever produced. Mr. Bruce's labours with the wool exhibits were rewarded by a show unrivalled in the exhibition. Mr. Terry, both in the Liberal Arts and the Manufactures Department, gave me great satisfaction by his continuous and enthusiastic labours for successful results: As accountant and clerk, Mr. McGuinness was painstaking, reliable, and punctual. To my private secretary, Mr. H. J. Renwick, I am indebted for much of the information contained in this report. The assistants in the various courts, whose names and duties will be found elsewhere, were remarkable for their good conduct. I am pleased to report that during the whole course of the exhibition, notwithstanding the excitement and temptation of the occasion, I had no reason, in any single case, to find fault with the conduct or the observance of the rules by these gentlemen.

One painful circumstance must be placed on record. I refer to the death of Mr. Thos. Ford, assistant to Mr. Carne, in the Mines Court. Mr. Ford, in the early stages, rendered great assistance in the display of the mineral exhibits, and subsequently, from his long experience at various Exhibitions, was enabled to give valuable and reliable information to visitors of the court, and perform services of various kinds on behalf of our representation. His death was a serious loss to us. Every respect was paid to his memory, and he was buried in a grave adjoining that in which we had placed the remains of Dr. Fischer a few weeks previously.

Harmonious Co-operation of Commission in Sydney.

It is a matter of supreme satisfaction to me that the harmonious and mutual action taken on behalf of the country by the Commission and myself has never, on any single occasion, been disturbed.

The work of this Commission was unquestionably the most arduous ever undertaken on behalf of our country, and the excellent results obtained were due in no small measure to the continued and well directed efforts of the various committees appointed for the purpose.

I consider it proper here to acknowledge the invaluable services rendered to the Commission by Mr. Secretary Cumming, who has also rendered me great assistance by correcting the proofs of this report as it has passed through the press.

Dr. Fischer and Mr. Ford.

THE deaths of these gentlemen afforded me an opportunity of observing the practice adopted in the larger American cities in connection with the interment of strangers. In both these cases the corpse was removed to an undertaker's establishment; in the one case, from the hotel, at which death had occurred, and the other from the hospital. Provision is made at these establishments for placing the body on ice for preservation until the desires of the relatives as to the mode of interment and ultimate disposal are ascertained. Facilities for embalming the body in various ways are provided. The coffin has its cover or lid in two sections, and the upper one is not fastened down till the friends up till the last moment have had an opportunity of seeing the face of the deceased person. A large room, in which the funeral service can be performed, is attached to the establishment; and here the friends can meet and observe the usual service for the dead. As it is not the universal custom to have services for the dead at the grave, the advantages of this provision must be obvious. At the grave the coffin or casket is placed in a plain pine case, and contained

contained in this covering is lowered into the grave. Everything done in connection with this sad business is conducted in a very decent and decorous manner. In the case of the sudden death of visitors or of strangers the provision was most necessary and useful.

Contrast of this with Former Exhibitions.

FOR the first time in the history of Exhibitions an attempt was made at the Columbian Exhibition to provide a scientific classification of exhibits in departmental buildings independent of country. There were some few unimportant exceptions to this rule, but on the whole it was carried out as far as was possible. It would be difficult at this stage to give a decisive estimate of the value of this plan. To the visitor and to the critical inquirer, and perhaps as far as the production of comparative results is concerned, this system would appear to be a great advance on the arrangement whereby the exhibits of each country are distinctively displayed. In the case of countries showing a small number of exhibits it is a system attended with considerable disadvantage, such representation being completely overshadowed by the larger and more complete ones of countries possessing higher civilisation and greater resources. It also prevents the presentation of the aggregate exhibits of a country, and thus shuts out of view its special characteristics. But for the purpose of the special inquirer and for the promotion of critical investigation it is undoubtedly the best system. In all probability the final outcome of this special classification, in view of the extension of civilisation, will lead to Exhibitions of a special nature. In fact the Fisheries Exhibition and the Mineral Exhibition held in London, and similar special Exhibitions held elsewhere, are practical illustrations of this conclusion.

Another question that arises in connection with this Exhibition is, as to whether the great size of the World's Fair, or of any succeeding large Exhibition is not likely to cause failure, to a large extent at any rate, in the general results which ought to accrue from them. Since the inauguration of Exhibitions the advances of knowledge of all kinds of all the races of mankind have become so extensive, the range of the sciences and the arts so advanced, and the progress of civilisation so universal that in order to obtain anything like an adequate representation great expanses of space are necessary, and, as a consequence, immense and imposing buildings demanded. But the resources and powers of the individual are strictly limited. It was impossible, for instance, in the case of the White City of great distances for any individual to grasp completely even any one great section of the whole. With the unrevealed possibilities of the future before us how much more difficult must such a task become. Confined to a single object, the matter, although in some branches even then not divested of difficulty, becomes somewhat more easy of solution.

Position of New South Wales at Chicago.

AT this Exhibition New South Wales occupied a unique position. Represented as our country has been—and well represented—at former Exhibitions, she never before occupied such a distinguished place as at this great World's Fair. In the midst of the greatest Exhibition the World has ever seen, among the most complete representations of the World, New South Wales appeared in her proper rôle, as the mother Colony and the gracious standard-bearer of Australia and the South Seas. As was confessed by every visitor, the exhibits were worthy of her great resources and representative of her advancement in education, science, and art. Her flag floated on the great buildings and over her special State building; her beautiful national blue colour on the walls of the spaces throughout the departments attracted attention
and

and made the visitor conscious of her presence; and her early presence at the Exposition, her extensive presentation, and her characteristic and well-arranged courts were the theme of universal commendation.

As a British Commissioner has said: "Many of the colonies of the British Empire helped to make good the deficiencies of the mother country, and two of them, New South Wales and Canada, may be deservedly accorded places in the foremost rank among the nations which exhibited. No such opportunity has previously been afforded for British colonies, rising rapidly into the importance of rich and powerful nations, to show to the World the extent and variety of their resources. In almost every department the distant Colony of New South Wales has been conspicuous; in more than once her exhibits occupied a front rank. New South Wales must occupy a leading position in the future records of the World's Columbian Exposition, the exhibits in her numerous courts having been both actually and by comparison of the first order."

One effect was produced by our display: The people of the United States are of a most inquisitive nature, and the large display we made, especially in our natural products, led to inquiries by visitors on almost every subject connected with the exhibits. Foreigners, also, from the great nations of Europe and elsewhere examined our representation. Australia was to most of these a *terra incognita*, and the name of New South Wales was, on our first appearance in Chicago, imagined to be representative of some portion of Great Britain. The remembrance, however, of the existence of Indians, as our aborigines were called, in our country rather confused this generalisation. Before the conclusion of the Fair, New South Wales and Sydney (generally spelt "Sidney" up to this time) were well known. Outside of the exhibits of our natural resources two things greatly assisted the general effect of our representation. The large number of enlarged photographs representing our scenery, our great public works, our hospitals, our schools, trade and commerce, our architecture and our social life, was a most important factor as an educational medium, and I must confess that had I not been an eye-witness of the effect of these photographs I could not have believed in its great importance. The constant expression was one of surprise that such things could possibly be in a country so remote and of which so little up to that time was known by the average American citizen or the foreign visitor. The fact that these representations were photographs, and not mere pictures of the cunning artist's imagination, was a matter which appealed at once to the observer, and took away all hesitancy as to the credibility and accuracy of that which was represented. The other great factor was the pamphlets and other literary matter forwarded for distribution. It often appeared to me that these were perhaps the most useful of all our exhibits. There was a steady and constant demand for all these pamphlets, not only from the general public but also from learned men of all countries. They have now been distributed not only in the United States but in nearly every civilised country of the World by the accredited representatives of these countries at the Exhibition, to whom collected sets were sent for that purpose.

Every great newspaper represented (foreign and American) received some of them in Chicago. Long after the White City has been reconverted into Jackson Park, and its great palaces have passed away, these publications in public libraries, and in the studies of the literary men, and of the reading public, will remain a permanent legacy of our representation at the World's Columbian Exposition. No country at the Fair had such a collection of useful literary matter, and it was universally allowed that our catalogue, with its bold clear type, its lucid explanations, its comprehensive index of the exhibits, and its general information, was not surpassed by any other.

Australia

ART GALLERY, HALL OF "AUSTRALIA" HOUSE, NEW SOUTH WALES ADMINISTRATION BUILDING.

HALL, "AUSTRALIA HOUSE," NEW SOUTH WALES ADMINISTRATIVE BUILDING.

NEW SOUTH WALES GOVERNMENT BUILDING, "AUSTRALIA HOUSE."

Australia House.

THE provision of our Administration Building was, I clearly foresaw from the first, an absolute necessity. Our country made its arrangements for space, for reasons I need not now enter into, at so late a date after the official announcements of allotment that, notwithstanding the extra space granted afterwards at my personal request, I was quite certain some provision of this kind would be necessary not only for exhibits but for official purposes. Independently altogether of this reason I found that if we were to hold a distinctive position at the Exhibition; and if New South Wales was to occupy its proper place among other countries, a State or Government building would be required. The only difficulty in the way was the necessity of adhering to the principle of economy, and especially of endeavouring to keep within the amount that had been resolved upon as our limit of expenditure. All these purposes were subserved by Australia House. There the New South Wales flag floated from morning till night; there all visitors from Australia were welcomed; there all the official business was transacted; there were stored surplus exhibits and other matters; there was placed in the great hall the principal portion of our Fine Arts exhibits. Thousands visited the building every day, and the visitors' book contained the names of many of the most distinguished visitors, and was filled with commendatory remarks on the exhibits of New South Wales throughout the buildings. In the hall of the building, as in all our various courts, was a placard announcing where our exhibits were to be found in the various buildings.

The building was 60 feet by 60 feet, and had garden ground around it grassed and planted. Its cost was only about \$5,000, and altogether it looked as well and was much more useful than many other similar buildings, but none were so reasonable in cost; in fact some buildings of the same kind, certainly not more imposing, cost as much as the whole of the Parliamentary vote for the New South Wales Commission.

Australia House was classical in design and ornamentation. It covered an area of 4,320 square feet, being 60 feet by 60 feet in exterior dimensions, with a portico 12 feet wide extending across the front. There was a flight of three steps leading to this portico, and extending across the front and ends of the same. The roof of this portico was supported by six Doric columns, 2 ft. 6 in. in diameter, and 20 feet high, with a cornice frieze and balustrade extending round the entire building. At each of the corners was a large Doric pilaster, corresponding to the columns of the portico. The entrance was at the centre of the portico front. All mouldings had moulded architraves and cornices, and each window had a pair of moulded modillions under it. The exterior of the building was staff. The central portion was occupied by a hall 30 feet in width, and extending the entire depth of the building. In the centre was a polygonal dome 30 feet in diameter, the top being 40 feet from the floor. This dome added to the effect, to the light and ventilation of the whole, and was covered on the interior with ornamental staff. Arranged on three sides of the main hall were the offices of the legation, eight in number.

Effect of the New South Wales Representation.

At this Exhibition the New South Wales Commission was acknowledged as a distinct national commission. In view of the future this was an important matter. Two circumstances already alluded to in this Report—the insertion of the name of our country among those of the great nations of the World on the entablature round the

the interior of the dome of the Administration Building, and the placing of the Sydney time on one of the great clocks, showing the hour of the day in the frieze of the railway station waiting-room—show the tendency in this direction; and many other circumstances of similar character occurred during the currency of the Exposition.

A fact frequently referred to by the American press, and one of great importance, was that as a Colony we represented all Australia, none of the other Colonies of Australia being officially present. During the course of the Exhibition, day after day, the cables containing the news of the various stages of the great bank failures in Australia were printed in the newspapers of America; but the great and unrivalled display of natural resources was pointed out by the American press as conclusive proof that, notwithstanding the financial disaster, a country possessing such resources would soon recover itself. Our wool, our minerals, our timbers, our wines, and then the exhibits illustrating our progress in arts and civilisation and our industrial and educational advance, all told their own tale to even the untutored observer.

But after all, the question may be asked as to what direct advantages will accrue to New South Wales for the money expended in the Colony's participation in the Exposition. While it may be allowed that our expenditure was greatly less than that of other countries, whose display could not rival our own, what are the direct benefits derived from the outlay? The question is a reasonable one, and the answer not far to seek. At the World's Columbian Exposition, the grandest ever yet created, in the midst of all the greatest nations of the world, New South Wales has established a reputation as the greatest wool-producing country in the world, and her show of wool has undoubtedly attracted the attention of all those who are in favour of a repeal of the wool duties in force. Those who were indifferent on the subject have had their views strengthened, and many of those who had no conception of the real nature of our staple, the desirableness of introducing it direct into the American market, have conceded that this wool exhibit was the greatest object lesson on the subject of "Free Wool," America has ever had—and it must bear fruit in the near future in the form of a great outlet for our staple.

The Timber resources have been shown in a most convincing manner and the contrast between the soft American timbers and the hardwoods of Australia so exhibited that the need for an exchange of products of this class between the two countries has been fully recognised. The wooden block road we constructed was a practical exemplification of the matter, and attracted the attention of men who are fully alive to the importance of the subject. Our minerals, an unrivalled exhibit, were the subject of much attention. In fact the attention of capitalists, contractors, and others from all parts of the world has been drawn specially to these matters, and I have had innumerable inquiries on all these subjects.

There are many other matters which might be referred to in this connection. I shall only mention one. In the near future the severities of the M'Kinley tariff must be removed—this both Republican and Democrat seem to be agreed upon. Our country is only three or four weeks distance by steam from America. Germany, which is half that distance, in order to produce an effective result, spent several millions sterling on its exhibit; and other countries, still more remote, spent large sums for the same purpose. In view of the closer relations anticipated, surely it was well worth our while to spend the comparatively small sum we disbursed to effect the impression we created, and to strengthen and consolidate any recognition heretofore existing as to our character and our great natural resources. Within the last few months additional reason from this standpoint has been provided by the establishment of the new steamship line from
Sydney

Sydney to England, *via* Vancouver; and I know that the interest manifested in our commercial resources and the desire for closer commercial intercourse was greatly forwarded by our country's representation at the World's Columbian Exposition.

Departure of the Executive Commissioner from Chicago.

THE numerous formalities connected with the repacking of our exhibits, to be forwarded to London for the New South Wales Court in the Imperial Institute, and to be returned to Sydney, having been arranged, and as soon as the railway cars were prepared for loading, under the supervision of the General Superintendent, I left Chicago after a residence there of nearly eleven months, during which long period I was only absent two days from the Exposition on account of illness. I visited Washington in order to make myself assured that our list of awards was quite correct, and at the Bureau of Awards, already located in that city, I had the opportunity of finally revising the official list. Several of the nations represented at the Exposition had appointed agents to watch their interests in this matter at Washington, but I believe my visit accomplished all that was necessary on our behalf in this matter. Whilst in Washington I had the advantage of a long conversation with Mr. Wilson, Chairman of the Tariff Committee of the House of Representatives, on the subject of the remission of the duties on wool, as provided for in the new bill, and left with that gentleman a memorandum on the subject, prepared by Mr. Bruce, Chief Inspector of Stock for New South Wales.

On my arrival in London I visited the Imperial Institute in company with Sir S. Samuel, Agent-General for New South Wales, and met there the various officials of the Institute, and conversed with them as to the reasonableness of obtaining increased space for our valuable exhibits from Chicago. The space granted to New South Wales in the Imperial Institute appeared to me very inadequate. As a member of the Council of the Institute Sir S. Samuel undertook to represent this matter more fully to the authorities.

Conclusion.

IN now bringing my labours to a close, and resigning my office as Executive Commissioner to this greatest of all Exhibitions, an office which has engaged my time and ability from October, 1891, I trust that my endeavours, honestly made in the interest of New South Wales and of Australia, have been of some advantage, and that ultimately practical results will follow the splendid representation our country has made at the World's Columbian Exposition.

I have the honor to be,
Your Excellency's obedient Servant,
ARTHUR RENWICK.

APPENDIX A.

Executive Commissioner's Commission.

VICTORIA, by the Grace of God, of the United Kingdom of Great Britain and Ireland,
Queen, Defender of the Faith, and so forth.

To Our Trusty and Well-beloved—

The Honorable ARTHUR RENWICK, "Abbotsford," Five Dock, near Sydney, in Our
Colony of New South Wales, M.D., F.R.C.S. Edin., and a Member of the Legislative
Council of Our said Colony,—

GREETING :

WHEREAS, by an Instrument under the Great Seal of Our said Colony of New South
Wales, bearing date the twenty-eighth day of September last, We did appoint certain
Commissioners for Our said Colony, in connection with the World's Columbian
Exposition, to be held in the City of Chicago, in the United States of America, in the
year one thousand eight hundred and ninety-three, to which Exposition divers of Our
subjects in Our said Colony of New South Wales propose to transmit various articles,
the produce or manufacture thereof: And whereas it has appeared to us to be
expedient to appoint an Executive Commissioner, to act on behalf of Our said Colony
of New South Wales, in all things connected with the said Exhibition, in conjunction
with the said Commissioners, or such other Commissioners as may hereafter be appointed:
Now therefore know you, that We, of Our especial grace, have thought fit to appoint,
and do hereby appoint you to be Our Executive Commissioner for Our said Colony of New
South Wales, at the World's Columbian Exposition, to be held in the City of Chicago,
in 1893, with full power to arrange for the fitting up and preparing the New South
Wales Court at the said Exposition; and to receive and superintend and direct the
unpacking and placing of all properties and articles whatsoever, which Our Commission,
sitting in Sydney, may send and transmit as Exhibits from the said Colony of New South
Wales. We further enjoin you in all your proceedings, wherever it may be necessary for
the public interest, to act in communication and harmony with Our Commission aforesaid.
And further, that you use your utmost diligence and care in all matters connected with
the arrangement and display therein of all such articles, and their subsequent disposal
in Chicago, or their retransmission to New South Wales, as circumstances may require.

In testimony whereof, We have caused these Our Letters to be made Patent, and
the Great Seal of Our said Colony of New South Wales to be hereunto affixed.

Witness, Our Right Trusty and Right Well-beloved Cousin and Councillor,
VICTOR ALBERT GEORGE, EARL OF JERSEY, Knight Grand Cross of Our
Most Distinguished Order of Saint Michael and Saint George, Our Governor
and Commander-in-Chief of Our said Colony of New South Wales and its
(L.S.) dependencies, at Government House, Sydney, in New South Wales aforesaid,
this sixteenth day of October, in the fifty-fifth year of Our reign, and in the
Year of Our Lord one thousand eight hundred and ninety-one.

JERSEY.

By His Excellency's Command,
HENRY PARKES.

APPENDIX B.

Commissions of Foreign Countries in the United States.

 Mr. Jacinto Lopez, 2244, Michigan Avenue, Chicago.

Special Delegate—

- Dr. A. Ernst, 2949, Groveland Avenue, Chicago.

Counsellors—

- Dr. Francisco E. Bustamante, E.E. and M.P., 1400, Massachusetts Avenue, Washington, D.C.
 Dr. H. Rivero Saldivia, Consul-General, 18, Broadway, New York.

Commissioners ad honorem—

- Mr. J. A. Sanchez, 22, State-street, New York.
 Mr. A. S. Baker, 18, Broadway, New York.
 Mr. Manuel Cadenas, 53, William-street, New York.
 Mr. Luis E. Forsyth, Clarendon Hotel, New York.

APPENDIX C.

Dedication Ceremonies.

(21st October, 1892.)

THE PROCESSION FROM LAKE FRONT, ALONG MICHIGAN AVENUE
TO JACKSON PARK.

THE procession was composed as follows :—

1. Joint Committee on ceremonies of the World's Columbian Commission and the World's Columbian Exposition.
2. The Director-General of the World's Columbian Exposition, and the President of the Centennial Commission of 1876, at Philadelphia, and the Director-General thereof.
3. The President of the World's Columbian Commission, and the President of the World's Columbian Exposition.
4. The Vice-President of the United States, and the Vice-President of the World's Columbian Commission, and the Vice-President of the World's Columbian Exposition.
5. The Secretary of State and the Secretary of the Treasury.
6. The Secretary of War and the Attorney-General of the United States.
7. The Postmaster-General and the Secretary of the Navy.
8. The Secretary of the Interior and the Secretary of Agriculture.
9. The Diplomatic Corps.
10. The Supreme Court of the United States.
11. The Speaker of the House of Representatives and the Mayor of Chicago.
12. Ex-President Hayes; escort, John Sherman, Lyman J. Gage, Ex-President of the World's Columbian Exposition.
13. Ex-Secretary Thomas F. Bayard and W. T. Baker, Ex-President of the World's Columbian Exposition.
14. The Senate of the United States, headed by the President *pro tem*.
15. The House of Representatives.
16. The Army of the United States.
17. The Navy of the United States.
18. The Governors and their staffs of the States and Territories of the United States.
19. Ex-Cabinet Officers.
20. The Orators and Chaplains.
21. Commissioners of Foreign Governments to the World's Columbian Exposition.
22. Consuls for Foreign Governments.
23. The World's Columbian Commissioners, headed by the second, third, fourth, and fifth Vice-Presidents thereof.
24. The Board of Lady Managers, headed by the President thereof.
25. One woman to represent each one of the thirteen original States.
26. Board of Directors of the World's Columbian Exposition, headed by the second Vice-President thereof and the Director of Works.
27. Presidents and Executive Commissioners State World's Fair Boards.
28. Board of Management United States Government Exhibits.
29. The Department Chiefs.
30. The Staff Officers of the Director of Works.
31. The City Council of Chicago.

United States Cavalry and Light Artillery served as escort, while mounted troops acted as special cohorts for Governors of States and Territories and their staffs, stationed at their immediate rear. The procession moved south on Michigan Avenue to Twenty-ninth-street, where it was joined by Vice-President Morton, who, in the absence of President Harrison, assumed the post of honor. The march continued on to Thirty-fifth-street; thence east to Grand Boulevard; thence south to Washington Park, where a halt was made and a re-form was effected in the line, it being doubled, to avoid too great a prolongation of the procession by the addition of the militia held in readiness at that point.

Brigades of the National and State troops fell in line and passed in review, finishing in the position of escort with Vice-President Morton in command. While these manœuvres were in progress the commander's salute was fired, rendering the scene impressive and warlike. The march was resumed *via* Fifty-seventh-street, and continued on to the Exposition grounds; thence to the Manufactures and Liberal Arts building.

The pageant evoked hearty cheers all along the line of march, the last notes of one section of spectators being caught up and hurried on by another, the transmission being almost unbroken along the way. The vociferous greetings were graciously acknowledged by the doffing of hats by the dignitaries to whom the applause was addressed. The acknowledgment came, not as the stilted courtesy of sovereigns but as an exchange of salutation between friends and fellow men.

As the pageant neared the exposition grounds the national salute was fired from a battery near the lake. The troops, upon their arrival at their destination, were assigned position while the occupants of the carriages mounted the platform.

PROGRAMME

PROGRAMME OF THE EXERCISES.

“Columbian March”—composed by Prof. J. K. Paine, of Cambridge.
 Prayer by Bishop Charles H. Fowler, D.D., LL.D., of California.
 Introductory address by the Director-General.
 Address of welcome and tender of the Freedom of the City of Chicago by Hempstead Washburne, Mayor.
 Selected recitations from the Dedicatory Ode, written by Miss Harriett Monroe, of Chicago; Music by G. W. Chadwick, of Boston; reading by Mrs. Sarah C. LeMoyne.
 Presentation by the Director of Works of the Master Artists of the World's Columbian Exposition, and award to them of special commemorative medals.
 Chorus—“The Heavens are Telling”—Haydn.
 Address—“Work of the Board of Lady Managers”—Mrs. Potter Palmer, President.
 Tender of the buildings on behalf of the World's Columbian Exposition by the President thereof to the President of the World's Columbian Commission.
 Presentation of the buildings by the President of World's Columbian Commission to the Vice-President of the United States for dedication.
 Dedication of the buildings by the Vice-President of the United States.
 “Hallelujah Chorus” from the “Messiah”—Handel.
 Dedicatory oration—Henry Watterson, of Kentucky.
 “Star Spangled Banner” and “Hail Columbia,” with full chorus and orchestral accompaniment.
 Columbia oration, Chauncey M. Depew, of New York.
 Prayer by His Eminence, Cardinal James Gibbons, Archbishop of Baltimore.
 Chorus, “In Praise of God,” Beethoven.
 Benediction by Rev. H. C. McCook, of Philadelphia.
 National Salute.

The large audience sat throughout the exercises without apparent fatigue, unless they grew tired in contributing to the great applause that followed each number. The participants in the exercises felt an inspiration which only such an audience and such an occasion can give, and this lent additional vigour and enthusiasm to their contributions.

Five thousand sweet-voiced children warbled soul-stirring choruses from a beautifully decorated platform at the extreme south end of the great Auditorium. The girls clad in fluffy gowns of the national colors won the plaudits of the admiring hosts gathered to witness the ceremonies from the commencement to the end.

Huge pots of sweet-scented flowers surrounded the platform and the children were lost sight of at some points, the rose bushes screening them from the gaze of the audience. Not once did the little ones falter, and their voices rang through the building high above the tumult of the troops without. An excellent orchestra of fifty instruments accompanied the youthful warblers, and the World's Fair Chorus was pronounced one of the greatest successes of the occasion.

After the opening march BISHOP CHARLES H. FOWLER, D.D., of California, offered the following prayer:

Almighty God, our heavenly Father, Thou art the one true God, eternal, immortal, invisible, blessed over all for evermore. We come before Thee to worship Thee, to render unto Thee thanks-giving, to confess our helplessness, and to invoke Thy blessing upon us. Thou art God. Thou hast created all things. Thou hast made the world and all things therein. Thou art Lord of heaven and earth. Thou hast made of one blood all nations of men, for to dwell on all the face of the earth, and hath determined the times before appointed and the bounds of their habitation. As a people whom Thou hast exalted, we worship Thee. Before the majesty of Thy power and the all-consuming glory of Thy presence, angels and archangels veil their faces. Thrones and dominions and principalities and powers prostrate themselves. Yet we, the members of a fallen race, children of a wayward family, urged by our dire necessities, encouraged by Thine unbreakable promises, emboldened by Thine infinite love, inspired by Thy life-giving spirit, and sheltered by the all-sufficient atonement, press our way up to the very steps of Thy throne and worship Thee, because Thou hast told us that in spite of our littleness, and in spite of our sinfulness, we may come, in the way Thou hast appointed, with boldness, even to the mercy-seat. * * *

We thank Thee for the revelation of Thyself in Thy Son to take away all sin, in Thy spirit to quicken every virtue, in Thy word to dispel every superstition, in Thy providence to protect from every peril.

We thank Thee especially for Thy favouring providence, which has ordered the unfolding of our history as a people and the shaping of our destiny as a nation. Thou didst keep this new world in the thick clouds that surround Thy purposes and didst reserve it for the high honours of Thy maturing kingdom. In the fulness of time Thou didst bring it to the knowledge of men by the wisdom and prowess and faith of Thy servant Columbus. Thou didst so inspire his mind and direct his thought by signs on the surface of the sea and by the flight of birds through the depths of the air, that the southern continent of the western hemisphere was open to southern Europe, and this northern continent was preserved for another people and another destiny. Thus Thou didst launch upon the tide of history in the two continents of the new world two new and great and mutually helpful nations. We thank Thee for Thy favouring providence. * * *

O Almighty God, we are gathered here within these walls and within these gates, from our national capital and from every city and section of our wide domain and from all the lands of the earth, to acknowledge Thee, and in Thy name, and in the name of the Government of the United States, and in the name of the people of the United States, to dedicate these buildings and these grounds to the uses and purposes of the World's Columbian Exposition. We pray Thy blessing upon this undertaking that it may bring glory to Thy name and benedictions to mankind.

Now, O Lord, our Father, we pray Thy blessing upon this multitude. In Thy great mercy forgive the sins of each of us and bless us with eternal salvation. As this assembly will scatter and soon be gone, may each one be ready to stand in that great assembly which shall gather before Thy throne and be permitted to hear the supreme sentence: “Well done, enter Thou into the joy of thy Lord.”

And unto Thee, our God and our Father, through Him who is the friend of sinners, will we, with the angels that stand about the throne, ascribe “blessing and glory and wisdom and thanks-giving and honour and power and might for ever and ever. Amen.”

When

When Bishop Fowler had closed his eloquent prayer and the orchestra had made the immense building echo again and again with the strains of beautiful music, DIRECTOR-GENERAL GEORGE R. DAVIS, as master of ceremonies of the dedicatory services, made the introductory address, telling of the cause and the aims and objects of the Columbian Exposition. His address was as follows:—

LADIES AND GENTLEMEN:—By virtue of my official position it is my pleasurable duty to present the noted personages who, at this hour, in their several functions, are to contribute to the exercises with which we here dedicate the grounds and buildings of the World's Columbian Exposition.

In a presence so vast, on an occasion so pre-eminent in the progress of universal affairs, I am moved by emotions that can sweep a human heart but once in life. Awe overmasters inspiration, and both are lost in gratitude that I am permitted to inaugurate these ceremonies.

The citizens of our common country may be pardoned the pride and satisfaction with which we study the historic steps by which our people have been led to their present exalted position.

Of the great nations of the world, the United States is the youngest; our resources are equal to those of any other nation. Our 60,000,000 people are among the most intelligent, cultured, happy, and prosperous of mankind. But what we are and what we possess as a nation is not ours by purchase, nor by conquest, but by virtue of the rich heritage that was spread out beneath the sun and stars, beneath the storms and rains and dews, beneath the frosts and snows, ages before a David, a Homer, or a Virgil sang, or before Italy's humble and immortal son had dreamed his dream of discovery. This rich heritage is ours not by our own might, not even by our own discovery, but ours by the gift of the Infinite. It is fitting that, on the threshold of another century, we reverently pause in the presence of the world, and with confession and supplication, with thanksgiving and devotedness, with praise and adoration, acknowledge our dependence on the Creator of the universe, the God of nations, the Father of mankind.

Nature has given us a virgin soil of incomparable richness and variety. Our climate is so diversified that all the fruits of tree and vine ripen under our autumnal skies.

The great seas that form our boundaries, and with their ebb and flow bathe our shores, are rich with all the treasures of the deep.

The granite vaults of our mountain chains are stored with untold mineral wealth.

In the prodigality of nature bountiful provision has been made for our multiplying people, and in times of emergency from our great abundance we may succour and comfort the distressed and afflicted of other lands.

A single century has placed this people side by side with the oldest and most advanced nations of the world,—nations with a history of a thousand years.

But in the midst of our rejoicing no American citizen should forget our national starting-point, and the quality of the manhood on which was laid the very foundation of our government. Our fathers were born under foreign flags. The very best brain and nerve and muscle and conscience of the older governments found their way to this western continent. Our ancestors had the map of the world before them; what wonder that they chose this land for their descendants! Over the very cradle of our national infancy stood the spirit and form of the completed civilization of other lands, and the birth-cries of the republic rang out over the world with a voice as strong as a giant of a thousand years. From the morning of our history the subjects of all nations have flocked to our shores and have entered into our national life and joined in the upbuilding of our institutions. They have spaded and planted, they have sown and gathered, they have wrought and builded, and to-day, everywhere over all this land, may be seen the products and results of this toil, constituting our national prosperity, promoting our national growth. To all of such the doors of the nation are ever open.

The World's Columbian Exposition is the natural outgrowth of this nation's place in history. Our continent, discovered by Christopher Columbus, whose spirits were revived as his cause was espoused by the generous-hearted Queen of Spain, has, throughout all the years from that time to this, been a haven to all who saw here the promise of requited toil, of liberty and of peace.

The ceaseless, resistless march of civilization westward, ever westward, has reached and passed the great lakes of North America, and has founded on their farthest shore the greatest city of modern times. Chicago, the peerless, has been selected for the great celebration which to-day gives new fire to progress, and sheds its light upon ages yet to come. Established in the heart of this continent, her pulse throbs with the quickening current of our national life. And that this city was selected as the scene of this great commemorative festival was the natural outgrowth of predestined events. Here all nations are to meet in peaceful, laudable emulation on the fields of art, science, and industry, on the fields of research, invention, and industry, on the fields of research, invention, and scholarship, and to learn the universal value of the discovery we commemorate; to learn, as could be learned in no other way, the nearness of man to man, the fatherhood of God, and the brotherhood of the human race.

This, ladies and gentlemen, is the exalted purpose of the World's Columbian Exposition. May it be fruitful of its aim and of peace for ever to all the nations of the earth.

When Colonel Davis had concluded his address he introduced MAYOR HEMPSTEAD WASHBURN, who tendered the freedom of the city to the guests in the following words:—

MR. PRESIDENT, REPRESENTATIVES OF FOREIGN GOVERNMENTS, LADIES AND GENTLEMEN: This day is dedicated by the American people to one whose name is indissolubly linked with that of our continent. This day shall add new glories to him whose prophetic vision beheld in the stars which guided his audacious voyage a new world and a new hope for the peoples of the earth. The four centuries passing in review have witnessed the settlement of a newly-discovered continent, the founding of many nations and the establishment in this country of more than sixty millions of people whose wonderful material prosperity, high intelligence, political institutions, and glorious history have excited the interest and admiration of the civilized world. These centuries have evolved the liberty-loving American people who are gathered here to-day. We have with us the pioneer bearing in his person the freedom of his western home—the ageing veteran, whom all nations honor, without whose valour government, liberty, and patriotism would be but idle words. We have with us builders of cities, founders of States, dwellers in the forests, tillers of the soil, the mechanic and the artisan, and noble women, daughters of the republic, not less in patriotism and deserved esteem than those who seem to play the larger part in building up a State.

There are gathered here our President and stately senate, our grave and learned judges, our Congress and our States, that all mankind may know this is a nation's holiday and a people's tribute to him whose dauntless courage and unwavering faith impelled him to traverse undismayed the unsailed waste of waters, and whose first prayer upon a waiting continent was saluted on its course by that banner which knows no creed, no faith, no nation—that ensign which has represented peace, progress, and humanity for nineteen hundred years—the Holy banner of the Cross.

Those

Those foreign nations which have contributed so much to our growth will here learn wherein our strength lies—that it is not in standing armies—not in heredity or birth—not even in our fertile valleys—not in our commerce or our wealth—but that we have built and are building upon the everlasting rock of individual character and intelligence, seeking to secure an education for every man, woman, and child over whom floats the stars and stripes, that emblem which signifies our government and our people.

That flag guards to-day 21,500,000 school children, of a country not yet four centuries old, and who outnumber nearly four times the population of Spain in 1492.

This is our hope in the future—the anchor of the republic—and a rainbow of promise for the centuries yet to come. As a mark of public gratitude it was decided to carry down into history through this celebration the appreciation of this people for him before whose name we all bow to-day.

You, sirs, who are the chosen representatives of our people—you into whose keeping we intrust our property and our rights—you whose every act becomes a link in that long chain of history which spans four hundred years without a break, and whose every link signifies a struggle and victory for man—you who represent that last and most perfect experiment of human government have by your official acts honoured this young city with your choice as the most fitting place to mark this country's dawn. She accepts the sacred trust with rivalry towards none and fellowship for all. She stands ready to fulfil the pledges she has made. She needs no orator to speak her merits, no poet to sing her glories. She typifies the civilisation of this continent and this age; she has no hoary locks; no crumbling ruins; the gray-haired sire who saw her birth to-day holds on high his prattling grandchild to see the nations of the earth within her gates.

Over the very spot whereon we stand, within the memory of men still young, the wild fowl winged their migratory flight. Less than a century ago the site of this young city was unknown; to-day a million and a half people support her honour, enterprise, and thrift. Her annual commerce of one billion and a half tells the eloquent story of her material greatness. Her liberality to all nations and all creeds is boundless, broad as humanity, and high as the dome of heaven. "Rule Britannia," the "Marseillaise," "Die Wacht am Rhein," and every folk-song of the older world has drifted over the Atlantic's stormy waves, and as each echo, growing fainter with advancing leagues, has reached this spot, it has been merged into that one grand chorus, "My country, 'tis of thee, sweet land of liberty, of thee I sing."

This, sirs, is the American city of your choice; her gates are open, her people at your service. To you and those you represent we offer greeting, hospitality, and love.

To the old world, whose representatives grace this occasion, whose governments are in full accord with this enterprise so full of meaning to them and to us, to that old world whose children braved unruly seas and treacherous storms to found a new state in an unknown land, we give greeting, too, as children greet a parent in some new home.

We are proud of its ancestry, for it is our own. We glory in its history, for it was our ancestral blood which inscribed its rolls of honour, and if to-day these distinguished men of more distinguished lands behold any spirit, thing, or ambition which excites their praise, it is but the outcropping of the Roman courage on a new continent in a later age.

Welcome to you men of older civilizations to this young city, whose most ancient landmark was built within the span of a present life. Our hospitalities and our welcome we now extend without reserve, without regard to nationality, creed, or race.

When Mayor Washburne had finished his address of welcome Mrs. SARAH C. LE MOYNE, of New York, read in a beautiful pure voice, selections from the "Commemoration Dedicatory Ode," written for the great occasion by Miss Harriet Monroe, of Chicago. Those parts of the ode printed in italic were set to music by George W. Chadwick, the celebrated composer of Boston. The ode complete is as follows:—

Columbia! on thy brow are dewy flowers
 Plucked from wide prairies and from mighty hills.
 Lo! toward this day have led the steadfast hours.
 Now to thy hope the world its beaker fills.
 The old earth hears a song of blessed themes
 And lifts her head from a deep couch of dreams,
 Her queenly nations, elder-born of Time,
 Troop from high thrones to hear.
 Clasp thy strong hands, tread with the paths sublime,
 Lovingly bend the ear.
 Spain, in the broided robes of chivalry,
 Comes with slow foot and inward-brooding eyes.
 Bow to her banner! 'twas the first to rise
 Out of the dark for thee.
 And England, royal mother, whose right hand
 Moulds nations, whose white feet the ocean tread,
 Lays down her sword on thy beloved strand
 To bless thy wreathed head;
 Hearing in thine her voice, bidding thy soul
 Fulfil her dreams, the foremost at the goal.
 And France, who once thy fainting form upbore,
 Brings beauty now where strength she brought of yore.
 France, the swift-footed, who with thee
 Gazed in the eyes of Liberty,
 And loved the dark no more.
 Around the peopled world
 Bright banners are unfurled.
 The long procession winds from shore to shore.
 The Norseman sails
 Through icy gales
 To the green Vineland of his long-ago.
 Russia rides down from realms of sun and snow.
 Germany casts afar
 Her iron robes of war,
 And strikes her harp with thy triumphal song.
 Italy opens wide her epic scroll,
 In bright hues blazoned, with great deeds writ long,
 And bids thee win the kingdom of the soul.
 And the calm Orient, wise with many days,
 From hoary Palestine to sweet Japan
 Salutes thy conquering youth;
 Bidding thee hush while all the nations praise,
 Know, though the world endure but for a span,
 Deathless is truth.

Lo!

Lo ! unto these the ever-living Past
 Ushers a mighty pageant, bids arise
 Dead centuries, freighted with visions vast,
 Blowing dim mists into the Future's eyes.
 Their song is all of thee,
 Daughter of mystery.
 Alone ! Alone !
 Behind wide walls of sea !
 And never a ship has flown
 A prisoned world to free.
 Fair is the sunny day
 On mountain and lake and stream,
 Yet wild men starve and slay,
 And the young earth lies adream,
 Long have the dumb years passed with vacant eyes,
 Bearing rich gifts for nations throned afar,
 Guarding thy soul inviolate as a star,
 Leaving thee safe with God till man grow wise.
 At last one patient heart is born
 Fearless of ignorance and scorn.
 is strong youth wasteth at thy sealed gate—
 Kings will not open to the untrod path,
 His hope grows sere while all the angels wait,
 The prophet bows under the dull world's wrath,
 Until a woman fair
 As morning lilies are
 Brings him a jewelled key—
 And lo ! a world is free.
 Wide swings the portal never touched before,
 Strange luring winds blow from an unseen shore,
 Towards dreams that cannot fail
 He bids the three ships sail,
 While man's new song of hope rings out against the gal

*Over the wide unknown,
 Far to the shores of Ind,
 On through the dark alone,
 Like a feather blown by the wind ;
 Into the west away,
 Sped by the breath of God,
 Seeking the clearer day
 Where only his feet have trod ;
 From the past to the future we sail ;
 We slip from the leash of kings.
 Hail ! spirit of freedom—hail !
 Unfurl thine impalpable wings !
 Receive us, protect us, and bless
 Thy knights who brave all for thee.
 Though death be thy soft caress,
 By that touch shall our souls be free.
 Onward and ever on,
 Till the voice of despair is stilled,
 Till the haven of peace is won,
 And the purpose of God fulfilled.*

O strange, divine surprise !
 Out of the dark, man strives to rise,
 And struggles inch by inch with toil and tear ;
 Till, lo ! God stoops from his supernal spheres,
 And bares the glory of his face.
 Then darkness flees afar,
 This earth becomes a star—
 Man leaps up to the lofty place.
 We ask a little—all is given,
 We seek a lamp—God grants us heaven.
 So those who dared to pass beyond the pale,
 For an idea tempting the shrouded seas,
 Sought but Cathay. God bade their faith preva
 To find a world—blessed his purposes !
 The hero knew not what a virgin soul
 Laughed through glad eyes when at her feet he
 The gaudy trappings of man's masquerade.
 She who had dwelt in forests, heard the roll
 Of lakes down-thundering to the sea,
 Beheld from gleaming mountain heights
 Two oceans playing with the lights
 Of eve and morn—ah ! what would she
 With all the out-worn pageantry
 Of purple robes and heavy mace and crown ?
 Smiling she casts them down,
 Unfit her young austerity
 Of hair unbound and strong limbs bare and brown.

Yet they who dare arise
 And meet her stainless eyes
 Forget old loves, though crowned queens these be.
 And whither her winged feet fare
 They follow though death be there—
 So sweet, so fleet, so goddess-pure is she.
 Her voice is like deep rivers, that do flow
 Through forests bending low.
 Her step is softest moonlight, that doth force
 The ocean to its course.
 Gentle her smile, for something in man's face,
 World-worn, time-weary, furrowed deep with tears
 Thrills her chaste heart with a more tender grace.

Softly

Softly she smooths the wrinkles from his brow,
 Wrought by the baleful years,
 Smiles sunshine on the hoar head, whispers low
 New charges from the awakened will of truth—
 Words all of fire, that thrill his soul with youth.
 Not with his brother is man's battle here.
 The challenge of the earth, that Adam heard,
 His love austere breathes in his eager ear.
 And lo! the knight who warred at love's command.
 And scarred the face of Europe, sheaths his sword,
 Hearing from untaught lips a nobler word,
 Taking new weapons from an unstained hand.
 With axe and oar, with mallet and with spade,
 She bids the hero conquer, unafraid
 Though cloud-veiled Titans be his lordly foes—
 Spirits of earth and air, whose wars brook no repose.
 For from far-away mountain and plain,
 From the shores of the sunset sea,
 The unwearying rulers complain, complain,
 And throng from the wastes to defend their reign—
 Their threatened majesty.
 The low praries that lie abloom
 Sigh out to the summer air :
 Shall our dark soil be the tomb
 Of the flowers that rise so fair ?
 Shall we yield to man's disdain,
 And nourish his golden grain ?
 We will freeze and burn and snare.
 Ah ! bid him beware ! beware !
 And the forests, heavy and dark and deep,
 With the shadows of shrouded years,
 In a murmurous voice, out of age-long sleep,
 Ask the winds : What creature rude
 Would storm our solitude ?
 Hath his soul no fears, no tears ?

The prone rivers lift up their snow-crowned heads,
 Arise in wrath from their rock-hewn beds,
 And roar : We will ravage and drown
 Ere we float his white ships down.
 And the lakes from a mist
 Of amethyst
 Call the storm-clouds down, and grow ashen and brown.
 And all the four winds wail :
 Our gales shall make them quail.
 By blinding snow, by burning sun
 His strength shall be undone.
 Then men in league with these—
 Brothers of wind and waste—
 Hew barbs of flint, and darkly haste
 From sheltering tents and trees ;
 And mutter : Away ! away !
 Ye children of white-browed day !
 Who dares profane our wild gods' reign
 We torture and trap and slay.

Child of the light, the shadows fall in vain,
 Herald of God, in vain the powers conspire,
 Armed with truth's holy cross, faith's sacred fire,
 Though often vanquished, he shall rise again,
 Nor rest till the wild lords of earth and air
 Bow to his will, his burdens glad to bear,
 The angels leave him not through the long strife,
 But sing large annals of their own wide life,
 Luring him on to freedom. On that field,
 From giants won, shall man be slave to man ?

*Lo! clan on clan,
 The embattled nations gather to be one,
 Clasp hands as brothers 'neath Columbia's shield,
 Upraise her banner to the shining sun.
 Along her blessed shore
 One heart, one song, one dream—
 Man shall be free forevermore,
 And love shall be supreme.*

When dreaming kings, at odds with swift-paced time
 Would strike that banner down,
 A nobler knight than ever writ or rhyme
 With fame's bright wreath did crown
 Through armed hosts bore it till it floated high
 Beyond the clouds, a light that cannot die !
 Ah, hero of a younger race !
 Great builder of a temple new !
 Ruler, who sought no lordly place !
 Warrior, who sheathed the sword he drew !
 Lover of men, who saw afar
 A world unmarred by want or war,
 Who knew the path and yet forebore
 To tread, till all men should implore ;
 Who saw the light and led the way
 Where the gray world might greet the day ;
 Father and leader, prophet sure,
 Whose will in vast works shall endure,
 How shall we praise him on this day of days,
 Great son of fame who has no need of praise ?

How shall we praise him? Open wide the doors
 Of the fair temple whose broad base he laid.
 Through its white halls a shadowy cavalcade
 Of heroes moves o'er unresounding floors—
 Men whose brawned arms upraised these columns high,
 And reared the towers that vanish in the sky—
 The strong who, having wrought, can never die.

And lo! leading a blessed host comes one
 Who held a warring nation to his heart;
 Who knew love's agony, but had no part
 In love's delight; whose mighty task was done
 Through blood and tears that we might walk in joy.
 And this day's rapture own no sad alloy.
 Around him heirs of bliss, whose bright brows wear
 Palm leaves amid their laurels ever fair.
 Gaily they come, as though the drum
 Beat out the call their glad hearts knew so well.
 Brothers once more, dear as of yore,
 Who in a noble conquest nobly fell.
 Their blood washed pure yon banner in the sky,
 And quenched the brands laid 'neath these arches high;
 The brave who, having fought, can never die.

Then surging through the vastness rise once more
 The aureoled heirs of light, who onward bore
 Through darksome times and trackless realms of ruth
 The flag of beauty and the torch of truth.
 They tore the mask from the foul face of wrong;
 Even to God's mysteries they dared aspire;
 High in the choir they lit yon altar fire,
 And filled these aisles with colour and with song:
 The ever-young, the unfallen, wreathing for time
 Fresh garlands of the seeming-vanished years;
 Faces long luminous, remote, sublime,
 And shining brows still dewy with our tears.
 Back with the old glad smile comes one we knew—
 We bade him rear our house of joy to-day.
 But beauty opened wide her starry way,
 And he passed on. Bright champions of the true,
 Soldiers of peace, seers, singers ever blest—
 From the wide ether of a loftier quest
 Their winged soul throng our rites to glorify—
 The wise who, having known, can never die.

Strange splendors stream the vaulted aisles along—
 To these we loved celestial rapture clings.
 And music, born on rhythm of rising wings,
 Floats from the living dead, whose breath is song.
 Columbia, my country, dost thou hear?
 Ah! dost thou hear the songs unheard of time
 Hark! for their passion trembles at thine ear.
 Hush! for thy soul must heed their call sublime.
 Across wide seas, unswept by earthly sails,
 Those strange sounds draw thee on, for thou shalt be
 Leader of nations through the autumnal gales
 That wait to mock the strong and wreck the free.
 Dearer, more radiant than of yore,
 Against the dark I see thee rise;
 Thy young smile spurns the guarded shore
 And braves the shadowed ominous skies.
 And still that conquering smile who see
 Pledge love, life, service all to thee.
 The years have brought thee robes most fair—
 The rich processional years—
 And filleted thy shining hair,
 And zoned thy waistcoat with jewels rare,
 And whispered in thine ears
 Strange secrets of God's wondrous ways,
 Long hid from human awe and praise.

For lo! the living God doth bare his arm.
 No more he makes his house of clouds and gloom.
 Lightly the shuttles move within his loom;
 Unveiled his thunder leaps to meet the storm.
 From God's right hand man takes the powers that sway
 A universe of stars.
 He bows them down; he bids them go or stay;
 He tames them for his wars.
 He scans the burning paces of the sun,
 And names the invisible orbs whose courses run
 Through the dim deeps of space.
 He sees in dew upon a rose impearled
 The swarming legions of a monad world
 Begin life's upward race.
 Voices of hope he hears
 Long dumb to his despair,
 And dreams of golden years
 Meet for a world so fair.

For now Democracy doth wake and rise
 From the sweet sloth of youth.
 By storms made strong, by many dreams made wise,
 He clasps the hand of Truth.
 Through the armed nations lies his path of peace,
 The open book of knowledge in his hand.

Food to the starving, to the oppressed release,
 And love to all he bears from land to land.
 Before his march the barriers fall,
 The laws grow gentle at his call.
 His glowing breath blows far away
 The fogs that veil the coming day,
 That wondrous day—

When earth shall sing as through the blue she rolls
 Laden with joy for all her thronging souls.
 Then shall want's call to sin resound no more
 Across her teeming fields. And pain shall sleep,
 Soothed by brave science with her magic lore,
 And war no more shall bid the nations weep.
 Then the worn chains shall slip from man's desire,
 And ever higher and higher
 His swift foot shall aspire ;
 Still deeper and more deep
 His soul its watch shall keep,
 Till love shall make the world a holy place,
 Where knowledge dares unveil God's very face.

Not yet the angels hear life's last sweet song.
 Music unutterably pure and strong
 From earth shall rise to haunt the peopled skies
 When the long march of time,
 Patient in birth and death, in growth and blight,
 Shall lead man up to happy realms of light
 Unto his goal sublime.

*Columbia ! Men behold thee rise
 A goddess from the misty sea.
 Lady of joy, sent from the skies,
 The nations worshipped thee.
 Thy brows were flushed with dawn's first light ;
 By foamy waves with stars bedight
 Thy blue robe floated free.*

*Now let the sun ride high o'erhead,
 Driving the day from shore to shore.
 His burning tread we do not dread,
 For thou art evermore
 Lady of love whose smile shall bless,
 Whom brave deeds win to tenderness,
 Whose tears the lost restore.*

*Lady of hope thou art. We wait
 With courage thy serene command.
 Through unknown seas, toward undreamed fate,
 We ask thy guiding hand.
 On ! Though sails quiver in the gale !—
 Thou at the helm, we cannot fail.
 On to God's time-veiled strand !*

*Lady of beauty ! thou shalt win
 Glory and power and length of days.
 The sun and moon shall be thy kin,
 The stars shall sing thy praise.
 All hail ! we bring the vows most sweet
 To strew before thy winged feet.
 Now onward be thy ways !*

PRESIDENT HIGINBOTHAM was brief but very eloquent in his acceptance of the buildings from the architects who designed them, and in bestowing upon them the medals which are to serve as a mark of appreciation of the great work these masters have done, he said :—

MR. BURNHAM AND GENTLEMEN :—It becomes my agreeable duty, on behalf of the board of directors of the World's Columbian Exposition, to receive from you these buildings, which represent your thought, skill, and labour, as master artists of construction. It is difficult to command language fully adequate to express our satisfaction with your achievements. We have observed with admiration the rapid development of your plans, until there stand before us to-day structures that represent the ripest wisdom of the ages.

Never before have men brought to their task greater knowledge, higher aims or more resolute purpose. Never before have such magnificent fruits been the result of thought and toil. The earth and all it contains have been subservient to your will. You have pursued your work loyally, heroically, and with an unselfish devotion that commands the applause of the world. Your country and the nations of the earth will join us in congratulating you upon the splendid issue of your plans and undertakings.

We accept these buildings from you, exulting in the belief that these beautiful structures furnish proof to the world that, with all our material growth and prosperity since the Columbian discovery of America, we have not neglected those civilising arts which minister to a people's refinement, and become the chief glory of the nation.

“Peace hath her victories,
 No less renowned than war.”

In this exposition, one of the adorning victories of our age of peace, you take conspicuous part, and the work accomplished reflects, and will continue to reflect, honour alike upon yourselves and upon your country.

In recognition of your faithful and efficient services, and in order to commemorate more substantially than by mere words the successful termination of your great work as master artists of construction, the Board of Directors has issued this medal, which I have the honour to present to you. A simple token it is, which finds its real and abiding value not in its intrinsic worth but rather in the high merit which receives and the grateful appreciation which bestows it.

After

After the echoes of the grand chorus of Haydn's "The Heavens are Telling" had died out of the great building, MRS. POTTER PALMER, President of the Board of Lady Managers, who has sometimes been called "The Queen of the Fair," told in a characteristically modest address of the work of the remarkable body of women whose doings she has directed. She said:—

Official representation for women, upon so important an occasion as the present, is unprecedented. It seems peculiarly appropriate that this honour should have been accorded our sex when celebrating the great deeds of Columbus, who, inspired though his visions may have been, yet required the aid of an Isabella to transform them into realities.

The visible evidences of the progress made since the discovery of this great continent will be collected six months hence in these stately buildings now to be dedicated.

The magnificent material exhibit, the import of which will presently be eloquently described by our orators, will not, however, so vividly represent the great advance of modern thought as does the fact that man's "silent partner" has been invited by the Government to leave her retirement to assist in conducting a great national enterprise. The provision of the Act of Congress that the Board of Lady Managers appoint a jury of her peers to pass judgment upon woman's works adds to the significance of the innovation, for never before was it thought necessary to apply this fundamental principle of justice to our sex.

Realising the seriousness of the responsibilities devolving upon it, and inspired by a sense of the nobility of its mission, the Board has, from the time of its organisation, attempted most thoroughly and conscientiously to carry out the intentions of Congress.

It has been able to broaden the scope of its work and extend its influence through the co-operation and assistance so generously furnished by the Columbian Commission and the Board of Directors of the Exposition. The latter took the initiative in making an appropriation for the woman's building, and in allowing the Board to call attention to the recent work of women in new fields by selecting from their own sex the architects, decorators, sculptors, and painters to create both the building and its adornments.

Rivalling the generosity of the directors, the National Commission has honoured the Board of Lady Managers by putting into its hands all the interests of women in connection with the Exposition, as well as the entire control of the woman's building.

In order the more efficiently to perform the important functions assigned it, the Board hastened to secure necessary co-operation. At its request women were made members of the World's Fair Boards of almost every state and territory of the union. Inspired by the success at home, it had the courage to attempt to extend the benefits it had received to the women of other countries. It officially invited all foreign Governments, which had decided to participate in the Exposition, to appoint committees of women to co-operate with it. The active help given by the Department of State was invaluable in promoting this plan, the success of which has been notable, for we now have under the patronage of royalty, or the heads of Government, committees composed of the most influential, intellectual, and practical women in France, England, Germany, Austria, Russia, Italy, Holland, Belgium, Sweden, Norway, Portugal, Japan, Siam, Algeria, Cape Colony, Ceylon, Brazil, the Argentine Republic, Cuba, Mexico, and Nicaragua, and although committees have not yet been announced, favourable responses have been received from Spain, Columbia, Ecuador, Venezuela, Panama, and the Sandwich Islands.

No organisation comparable to this has ever before existed among women. It is official, acting under Government authority, and sustained by Government funds. It is so far reaching that it encircles the globe.

Without touching upon politics, suffrage, or other irrelevant issues, this unique organisation of women for women will devote itself to the promotion of their industrial interests. It will address itself to the formation of a public sentiment, which will favour woman's industrial equality, and her receiving just compensation for services rendered. It will try to secure for her work the consideration and respect which it deserves, and establish her importance as an economic factor. To this end it will endeavour to obtain and install in these buildings exhibits showing the value of her contributions to the industries, sciences, and arts, as well as statistics giving the proportionate amount of her work in every country.

Of all the changes that have resulted from the great ingenuity and inventiveness of the race there is none that equals in importance to woman the application of machinery to the performance of the never-ending tasks that have previously been hers. The removal from the household to the various factories where such work is now done, of spinning, carding, dyeing, knitting, the weaving of textile fabrics, sewing, the cutting and making of garments and many other laborious occupations has enabled her to lift her eyes from the drudgery that has oppressed her since prehistoric days.

The result is that women as a sex have been liberated. They now have time to think, to be educated, to plan and pursue careers of their own choosing. Consider the value to the race of one-half of its members being enabled to throw aside the intolerable bondage of ignorance that has always weighed them down! See the innumerable technical, professional, and art schools, academies and colleges that have been suddenly called into existence by the unwonted demand! It is only about one hundred years since girls were first permitted to attend the free schools of Boston. They were then allowed to take the places of boys for whom the schools were instituted, during the season when the latter were helping to gather in the harvest.

It is not strange that woman is drinking deeply of the long-denied fountain of knowledge. She had been told, until she almost believed it, by her physician, that she was too delicate and nervous an organization to endure the application and mental strain of the school-room—by the scientist that the quality of the gray matter of her brain would not enable her to grasp the exact sciences, and that its peculiar convolutions made it impossible for her to follow a logical proposition from premise to conclusion—by her anxious parents that there was nothing that a man so abominated as a learned woman, nothing so unlovely as a blue-stocking—and yet she comes smiling from her curriculum with her honors fresh upon her, healthy and wise, forcing us to acknowledge that she is more than ever attractive, companionable and useful.

What is to be done with this strong, self-poised creature of glowing imagination and high ideals, who evidently intends as a natural and inherent right, to pursue her self-development in her chosen line of work? Is the world ready to give her industrial and intellectual independence, and open all doors before her? The human race is not so rich in talent, genius, and useful creature energy that it can afford to allow any considerable proportion of these valuable attributes to be wasted or unproductive, even though they be possessed by woman.

The sex which numbers more than one-half of the population of the world is forced to enter the keen competition of life with many disadvantages, both real and factitious. Are the legitimate compensation and honors that should come as the result of ability and merit to be denied on the untenable ground of sex aristocracy?

We are told by scientists that the educated eye and ear of to-day are capable of detecting subtle harmonies and delicate gradations of sound and colour that were imperceptible to our ancestors; that artists and musicians will consequently never reach the last possible combination of tones, or of tints, because their fields will widen before them, disclosing, constantly, new beauties and attractions. We cannot doubt that human intelligence will gain as much by development; that it will vibrate with new power because of the uplifting of one-half of its members—and of that half, which is, perhaps, conceded to be the more moral, sympathetic and imaginative—from darkness into light.

As a result of the freedom and training now granted them we may confidently await, not a renaissance, but the first blooming of the perfect flower of womanhood. After centuries of careful pruning into conventional shapes, to meet the requirements of an artificial standard, the shears and props have been thrown away. We shall learn by watching the beauty and the vigour of the natural growth in the open air and sunshine, how artificial and false was the ideal we had previously cherished. Our efforts to frustrate nature will seem grotesque, for she may always be trusted to preserve her types. Our utmost hope is that woman may become a more congenial companion and fit partner for her illustrious mate, whose destiny she has shared during the centuries.

We are proud that the statesmen of our own great country have been the first to see beneath the surface and to understand that the old order of things has passed away and that new methods must be inaugurated. We wish to express our thanks to the Congress of the United States for having made this great step forward, and also for having subsequently approved and indorsed the plans of the board of lady managers, as was manifested by their liberal appropriation for carrying them out.

We most heartily appreciate the assistance given us by the President of the United States, the Department of State and our foreign ministers. We hope to have occasion to thank all of the other great departments of the Government before we finish our work.

Even more important than the discovery of Columbus, which we are gathered together to celebrate, is the fact that the general Government has just discovered woman. It has sent out a flash-light from its heights, so inaccessible to us, which we shall answer by a return signal when the Exposition is opened. What will be its next message to us?

Then PRESIDENT HIGINBOTHAM, on behalf of the board of directors, tendered to the national commission the grounds and building upon which so much of Chicago's energy has been expended, at the same time offering thanks to the many sources of help in bringing the enterprise to its present condition. His address to President T. W. Palmer and the national commission was as follows:—

But yesterday these surrounding acres composed a dismal morass—a resting place for the wild fowls in their migratory flight. To-day they stand transformed by art and science into a beauty and grandeur unrivalled by any other spot on earth.

Herein we behold a miniature representation of that marvellous material development and that unprecedented growth of national greatness which, since the day of Columbus, have characterised the history of this new world.

The idle boy, strolling along the shore of this inland sea, carelessly threw a pebble into the blue waters. From that centre of agitation there spread the circling wave, which fainter and still fainter grew, until lost at last in the distant calm. Not so did the great thought come and vanish which has culminated in these preparations for the World's Columbian Exposition. It was not the suggestive impulse of any single brain or locality that originated this noble enterprise. From many minds and many localities there seemed to come, spontaneously and in unison, the suggestions for a Columbian celebration. Those individual and local sentiments did not die out like the waves, but in an inverse ratio grew more and more powerful, until they mingled and culminated in the grand and universal resolve of the American people, "It shall be done."

To-day, sir, on behalf of the board of directors, representing the citizens of Chicago, to me has been assigned the pleasant duty of presenting to the World's Columbian Commission these buildings, for dedication to the uses of the World's Columbian Exposition, in celebration of the four hundredth anniversary of the discovery of America.

In viewing the work thus far accomplished we gladly acknowledge ourselves debtors to the patriotic pride of our fellow citizens throughout the land; to the kindly interest manifested by the President of the United States; to the generosity of the Congress; to the hearty sympathy of the civilized nations of the earth and to the efficient co-operation of the honorable commission which you represent.

The citizens of Chicago have cherished the ambition to furnish the facilities for the exposition, which, in character, should assume a national and international importance. They entertain the pleasing hope that they have not come short of the nation's demand and of the world's expectation. Permit us, sir, to believe that it was not a narrow ambition, born of local pride and selfishness, that asked for the location of the World's Columbian Exposition at Chicago. Rather let it justly be said that it was in view of the fact that 25,000,000 of people live within a radius of 500 miles of Chicago, and that standing here, so near the centre of population, Chicago would be accessible to a larger number of American people, who are the creators of our wealth and prosperity, than would any other city on the continent. The citizens of Chicago have been actuated by the most patriotic sentiments in asking for the location of the exposition at this place. Animated by the most public spirited motives, they have made such preparations for the exposition as we trust you cannot but look upon with satisfaction.

The fidelity and remarkable skill of the master artists of construction must be a justification for the pride with which we point to the structures which rise about us in such graceful and magnificent proportions. In furnishing grounds and buildings which should meet the modern demand for utility and scientific adaptation, we have not done violence, let us hope, to that growing love for the beautiful which gratifies the eye and educates the taste. Nature, science, and art have been called upon to contribute their richest gifts to make these grounds and buildings worthy of your acceptance.

The board of directors now beg leave to tender to the World's Columbian Commission and to the nation these buildings, in fulfilment of Chicago's pledge and in honor of the great event we celebrate.

When President Higinbotham had finished his address surrendering control of the buildings on behalf of the local organization, the World's Columbian Exposition, to the World's Columbian Commission, PRESIDENT PALMER made his brief address, in which he accepted the grand product of Chicago's labour and asked the Vice-President to "dedicate these buildings and grounds to humanity." PRESIDENT PALMER's address was as follows:—

When a structure designed for a beneficent purpose has reached completion and is about to be devoted to its object, it is deemed fitting, in accordance with a custom which sprang from the aspirations of man, and which has received the sanction of successive generations, that its intent and aim shall be declared amid imposing ceremonies, and the good will of the present and the blessing of the future invoked upon it.

If this occasion shall have as one of its results the inauguration of another festal day to enlarge the too meagre calendar of our people, the world will be richer thereby, and a name which has been hitherto held in vague and careless remembrance will be made a vital and elevating force to mankind.

Anniversaries are the punctuations of history. They are the emphases given to events, not by the song of the poet, or the pen of the rhetorician, but by the common acclaim of mankind. They are the monuments of the heroes and the saviours of the race. They are the Memmons which fill the heart with promise, the eye with gladness, and the ear with song.

The teacher of Socrates, when dying, was asked what he wished for a monument. He answered, "Give the boys a holiday."

It

It was a happy thought to have linked with the achievements of Columbus and Pinzon, which doubled the area of the habitable globe, an undertaking whereby we hope to illustrate the fact that they also made possible more than a duplication of blessings to mankind.

As these great men died ignorant of the magnitude of their work, may we not hope that this exposition will accomplish a greater good than will be revealed to us of to-day, be its outcome never so brilliant? May we not hope that lessons here learned, transmitted to the future, will be potent forces long after the multitudes which will throng these aisles shall have measured their span and faded away?

Four hundred years ago to-day Rodrigo de Triana, from the prow of the "Pinta," cried, "Land!" That cry marked the commencement of an era wherein has been condensed more of good import to the race than any other. To-day, at the flood-time of that era, we are reminded of what the cry involved, and of how much there is yet to do to give it its fullest significance.

There are no more continents to discover, but there is much to do to make both hemispheres the home of intelligence, virtue, and consequent happiness. To that end no one material thing can contribute more than expositions to which are invited, in a fraternal spirit, all nations, tribes, and peoples, where each shall give and receive according to their respective capacities.

The foundations of civilisation have been laid. Universal enlightenment, now acknowledged as the safe substructure of every State, receives an added impulse from the commingling of peoples and the fraternisation of races, such as are ushered in by the pageant of to-day.

Hitherto the work of the National Commission and of the Exposition Company has been on different but convergent lines; to-day the roads unite, and it may not be amiss at this time to speak of the work already done. Two years ago the ground on which we stand was a weary waste of sand-dunes and quagmires, a home for wild fowl and aquatic plants. Under skilled artists, supplemented by intelligence, force, industry, and money, this waste has been changed by the magic hand of labour to its present attractive proportions. I do not speak of this work as an artist but as one of the great body of laymen whom it is the high calling of art to uplift. To me it seems that, if these buildings should never be occupied, if the exhibits should never come to attract and educate, if our people could only look upon these walls, towers, avenues, and lagoons, a result would be accomplished by the influence diffused well worth all the cost.

Of the Commission and its agencies, its director-general and the heads of its departments, its agents and envoys, I, although a part of that national organisation, may be permitted to speak. Called together by the President two years ago, its organic law difficult of construction, with room for honest and yet contradictory opinions, it has striven honestly, patriotically, and diligently to do its whole duty. Through its agencies it has reached to the uttermost parts of the earth to gather in all that could contribute to make this not only the museum of the savant and the well read but the kindergarten of child and sage.

The National Commission will, in due time, take appropriate action touching the formal acceptance of the buildings provided under their direction by the World's Columbian Exposition Company for this national and international fair, and to you, Mr. President, as the highest representative of the nation, is assigned the honor of dedicating them to the purposes determined and declared by the Congress of the United States.

In behalf of the men and women who have devoted themselves to this great work, of the rich who have given of their abundance, and the poor who have given of their necessities; in behalf of the architects who have given to their ideals a local habitation and a name, and the artists who have brought hither the three graces of modern life—form, colour, and melody—to decorate and inspire; of the workmen who have prepared the grounds and reared the walls; in behalf of the chiefs who have organised the work of the exhibitors; in behalf of the city of Chicago, which has munificently voted aid; of the Congress, which has generously given of the national moneys; in behalf of the World's Columbian Commission, the World's Columbian Exposition Company and the board of lady managers, I ask you to dedicate these buildings and grounds to humanity, to the end that all men and women of every clime may feel that the evidence of material progress which may here meet the eye is good only so far as it may promote that higher life which is the true aim of civilisation—that the evidences of wealth here exhibited and the stimulus herein given to industry are good only so far as they may extend the area of human happiness.

Then VICE-PRESIDENT MORTON, in response to the request of President Palmer, "dedicated the fair to humanity" in an eloquent speech, which was as follows:—

MR. PRESIDENT,—Deep indeed must be the sorrow which prohibits the President of the United States from being the central figure in these ceremonials. Realising from these sumptuous, surroundings the extent of design, the adequacy of execution, and the vastness of results, we may well imagine how ardently he has aspired to be officially and personally connected with this great work, so linked to the past and to the present of America. With what eloquent words he would have spoken of the heroic achievements and radiant future of his beloved country! While profoundly anguished in his most tender earthly affection, he would not have us delay or falter in these dedicatory services, and we can only offer to support his courage by a profound and universal sympathy.

I am not here to recount the wonderful story of this city's rise and advancement, of the matchless courage of her people, of her second birth out of the ashes of the most notable conflagration of modern times, nor the eminent position she has conquered in commerce, in manufactures, in science, and in the arts.

These are known of all men who keep pace with the world's progress.

I am here in behalf of the Government of the United States, in behalf of all the people, to bid all hail to Chicago, all hail to the Columbian Exposition.

From the St. Lawrence to the Gulf, and from the peerless cosmopolitan capital by the sea to the Golden Gate of California, there is no longer a rival city to Chicago, except to emulate her in promoting the success of this work.

New York has signalised the opening of the new era by a commemorative function, instructive to the student, encouraging to the philanthropist, and admonitory to the forces arrayed against liberty.

Her houses of worship, without distinction of creed, have voiced their thanks to Almighty God for religious freedom; her children, to the number of five and twenty thousand, have marched under the inspiration of a light far broader than Columbus, with all his thirst for knowledge, enjoyed at the University of Pavia; and for three successive days and nights processional progresses on land and water, aided by Spain and Italy and France, saluted the memory of the great pilot with the fruits of the great discovery in a pageant more brilliant than that at Barcelona, when, upon a throne of Persian fabrics, Ferdinand and Isabella disregarded the etiquette of Castile and Arragon, received him standing, attended by the most splendid court of Christendom.

And what a spectacle is presented to us here! As we gaze upon these munificent erections, with their columns and arches, their entablatures and adornments, when we consider their beauty and rapidity of realisation, they would seem to be evoked at a wizard's touch of Aladdin's lamp.

Praise for the organisation and accomplishment for the architect and builder, for the artist and artisan, may not now detain me, for in the year to come in the mouths of all men it will be unstinted.

These are worthy shrines to record the achievements of the two Americas, and to place them side by side with the arts and industries of the elder world, to the end that we may be stimulated and encouraged to new endeavours. Columbus is not in chains, nor are Columbian ideas in fetters. I see him, as in the great picture under the dome of the capitol, with kneeling figures about him, betokening no longer the contrition of his followers, but the homage of mankind, with erect form and lofty mien animating these children of a new world to higher facts and bolder theories.

We

We may not now anticipate the character and value of our national exhibit. Rather may we modestly anticipate that a conservative award will be made by the world's criticism to a young nation eagerly listening to a beckoning future, within whose limits the lightning was first plucked from heaven at the will of man, where the expansive power of steam was first compelled to transport mankind and merchandise over the waterways of the world, where the implements of agriculture and handicraft have been so perfected as to lighten the burdens of toil, and where the subtle forces of nature, acting through the telegraph and telephone, are daily startling the world by victories over matter which in the days of Columbus might have been reckoned among the miracles.

We can safely predict, however, those who will come from the near and distant regions of our country, and who will themselves make part of the national exhibit. We shall see the descendants of the loyal cavaliers of Virginia, of the pilgrim fathers of New England, of the sturdy Hollanders who in 1624 bought the twenty-two thousand acres of the island of Manhattan for the sum of \$24, of the adherents of the old Christian faith who found a resting place in Baltimore, of the Quakers and Palatine Germans who settled in Pennsylvania and New Jersey, of the Huguenots who fled from the revocation of the edict of Nantes to the banks of the Hudson in the North and those of the Cooper and Ashley Rivers in the South, of the refugees in Georgia, from Salzburg, and in North Carolina of Charles Edward's Highlanders. With them also we shall have in person or in their sons, the thousands of others from many climes, who, with moderate fortunes, have joined their future to that of the great Republic, or who with sinewy arms have opened our waterways and bulid our ironways.

We trust that from the lands beyond the seas many will come to engage in fraternal competition, or to point us to more excellent standards. If they shall find little in our product to excite their admiration, we shall welcome them to the atmosphere of the New World, where some of the best efforts have been made in the cause of freedom and progress by Washington and Franklin and Lafayette; by Agassiz and Lincoln and Grant; by Bolivar and Juarez and Toussaint L'Ouverture; by Fulton and Morse and Edison.

Columbus lived in the age of great events. When he was a child in 1440 printing was first done with movable types; seven years later the Vatican Library, the great fountain of learning, was founded by Nicholas the Fifth, and 1455 is given as the probable date of the Mazarine Bible, the earliest printed book known. It was not until a hundred years after the discovery that Galileo, pointing his little telescope to the sky, found the satellites of Jupiter, and was hailed as the Columbus of the heavens.

His character was complex as was that of many of the men of his time who made their mark in history. But his character and attainments are to be estimated by those of his contemporaries, and not by other standards. Deeply read in mathematical science, he was certainly the best geographer of his time. I believe, with Castelar, that he was sincerely religious, but his sincerity did not prevent his indulging in dreams. He projected, as the eloquent Spanish orator says, the purchase of the holy places of Jerusalem, in the event of his finding seas of pearls, cities of gold, streets paved with sapphires, mountains of emeralds, and rivers of diamonds. How remote, and yet how marvellous, has been the realization! Two products of the southern continent which he touched and brought into the world's economy have proved of inestimable value to the race, far beyond what the imagined wealth of the Indies could buy.

The potato, brought by the Spaniards from what is now the Republic of Ecuador, in the beginning of the century following the discovery, has proved, next to the principal cereals, to be the most valuable of all plants for human food. It has sensibly increased the wealth of nations and added immeasurably to the welfare of the people. More certain than other crops, and having little to fear from storm or drought, it is hailed as an effectual barrier against the recurrence of famines.

Nor was the other product of less importance to mankind. Peruvian bark comes from a tree of spontaneous growth in Peru, and many other parts of South America. It received its botanical name from the wife of a Spanish viceroy, liberated from an intermittent fever by its use. Its most important base, quinine, has come to be regarded, as nearly as may be, as a specific for that disease and also for the preservation of health in certain latitudes, so that no vessel would dare to approach the east or west coast of Africa without a supply, and parts of our own land would be made partially desolate by its disappearance. No words that I could use could magnify the blessings brought to mankind by these two individuals of the vegetable kingdom from the shores of the new world.

Limited time for preparation does not permit me to speak authoritatively of the progress and proud position of our sister republics and of the Dominion of Canada to demonstrate the moral and material fruits of the great discovery. Concerning ourselves the statistics are familiar and constitute a marvel. One of the States recently admitted, the State of Montana, is larger than the Empire of Turkey.

We are near the beginning of another century, and if no serious change occurs in our present growth, in the year 1935, in the lifetime of many now in manhood, the English speaking republicans of America will number more than 180,000,000. And for them, John Bright, in a burst of impassioned eloquence, predicts one people, one language, one law, and one faith; and all over the wide continent, the home of freedom and a refuge for the oppressed of every race and every clime.

The transcendent feature in the character of Columbus was his faith. That sustained him in days of trial and darkness, and finally gave him the great discovery. Like him let us have faith in our future. To insure that future the fountains must be kept pure, public integrity must be preserved. While we reverence what Garibaldi and Victor Emmanuel fought for, the union of peoples, we must secure above all else what Steuben and Kosciusko aided our fathers to establish—liberty regulated by law.

If the time should ever come when men trifle with the public conscience let me predict the patriotic action of the republic in the language of Milton:

"Methinks I see in my mind a noble and puissant nation rousing herself like a strong man after sleep, and shaking her invincible locks; methinks I see her as an eagle mewing her mighty youth, and kindling her undazzled eyes at the full midday beam; purging and unscaling her long abused sight at the fountain itself of heavenly radiance; while the whole noise of timorous and flocking birds, with those also that love the twilight, flutter about, amazed at what she means."

Mr. President, in the name of the Government of the United States, I hereby dedicate these buildings and their appurtenances, intended by the Congress of the United States for the use of the World's Columbian Exposition, to the world's progress in art, in science, in agriculture, and in manufactures. I dedicate them to humanity.

God save the United States of America.

Then HENRY WATTERSON, the Son of the "Star-Eyed Goddess," one of Kentucky's most eloquent orators and a favourite in the heart of this nation, arose amid a storm of welcoming applause to deliver the dedicatory oration. He said:

Among the wonders of creative and constructive genius in course of preparation for this festival of the nations, whose formal and official inauguration has brought us together, will presently be witnessed upon the margin of the inter-ocean, which gives to this noble and beautiful city the character and rank of a maritime metropolis, a spectatorium, wherein the Columbian epic will be told with realistic effects surpassing the most splendid and impressive achievements of the modern stage. No one who has had the good fortune to see the models of this extraordinary work of art can have failed to be moved by the union which it embodies of the antique in history and the current in life and thought, as, beginning with the weird mendicant fainting upon the hillside of Santa Rabida, it traces the strange adventures of the Genoese seer from the royal camp of Santa Fé to the sunny coasts of the Isles of Inde; through

through the weary watches of the endless night, whose sentinel stars seemed set to mock but not to guide; through the trackless and shoreless wastes of the mystic sea spread day by day to bear upon every rise and fall of its heaving bosom the death of fair, fond hopes, the birth of fantastic fears; the peerless and thrilling revelation, and all that has followed to the very moment that beholds us here, citizens, freemen, equal shareholders in the miracle of American civilization and development. Is there one among us who does not thank his Maker that he has lived to join in this universal celebration, this jubilee of mankind?

I am appalled when I reflect upon the portent and meaning of the proclamation which has been delivered in our presence. The painter employed by the king's command to render to the eye some particular exploit of the people or the throne knows in advance precisely what he has to do; his canvas is measured, his colours are blended, and with the steady and sure hand of the master he proceeds, touch upon touch, to body forth the forms of things known and visible. Who shall measure the canvas or blend the colours that are to bring to the mind's eye of the present the scenes of the past in American glory? Who shall dare to attempt to summon the dead to life and out of the tomb of the ages recall the tones of the martyrs and heroes whose voices, though silent for ever, yet speak to us in all that we are as a nation, in all that we do as men and women?

We look before and after, and we see through the half-drawn folds of Time as through the solemn archways of some grand cathedral the long procession pass, as silent and as real as a dream; the caravels, tossing upon Atlantic billows, have their sails refilled from the East and bear away to the West; the land is reached, and fulfilled is the vision whose actualities are to be gathered by other hands than his who planned the voyage and steered the bark of discovery; the long-sought, golden day has come to Spain at last, and Castilian conquests tread one upon another fast enough to pile up perpetual power and riches.

But even as simple justice was denied Columbus was lasting tenure denied the Spaniard.

We look again, and we see in the far north-east the old world struggle between the French and English transferred to the new, ending in the tragedy upon the heights above Quebec; we see the sturdy Puritans in bell-crowned hats and sable garments assail in unequal battle the savage and the elements, overcoming both to rise against a mightier foe; we see the gay, but dauntless cavaliers, to the southward, join hands with the Roundheads in holy rebellion. And, lo, down from the green-walled hills of New England, out of the swamps of the Carolinas, come, faintly to the ear like far away forest leaves stirred to music by autumn winds, the drum taps of the revolution; the tramp of the minute men, Israel Putnam riding before; the hoof beats of Sumter's horse galloping to the front; the thunder of Stark's guns in spirit battle; the gleam of Marion's watch fires in ghostly bivouac; and there, there in serried, saint-like ranks on fame's eternal camping-ground, stand—

—"The old Continentals,
In their ragged regimentals,
Yielding not,"

as, amid the singing of angels in heaven, the scene is shut out from our mortal vision by proud and happy tears.

We see the rise of the young republic; and the gentlemen in knee-breeches and powdered wigs who signed the declaration, and the gentlemen in knee-breeches and powdered wigs who made the constitution. We see the little nation menaced from without. We see the riflemen in hunting shirt and buckskin swarm from the cabin in the wilderness to the rescue of country and home; and our hearts swell to a second and final decree of independence won by the prowess and valour of American arms upon the land and sea.

And then, and then—since there is no life of nations or of men without its shadow and its sorrow—there comes a day when the spirits of the fathers no longer walk upon the battlements of freedom; and all is dark; and all seems lost, save liberty and honour, and, praise God, our blessed union. With these surviving, who shall marvel at what we see to-day; this land filled with the treasures of earth; this city, snatched from the ashes, to rise again in splendour and renown, passing the mind to preconceive?

Truly, out of trial comes the strength of man, out of disaster comes the glory of the state!

We are met this day to honor the memory of Christopher Columbus, to celebrate the four hundredth annual return of the year of his transcendent achievement, and with fitting rites to dedicate to America and the universe a concrete exposition of the world's progress between 1492 and 1892. No twenty centuries can be compared with those four centuries, either in importance or in interest; as no previous ceremonial can be compared with this in its wide significance and reach; because, since the advent of the Son of God, no event has had so great an influence upon human affairs as the discovery of the western hemisphere. Each of the centuries that have intervened marks many revolutions. The merest catalogue would crowd a thousand pages. The story of the least of the nations would fill a volume. In what I have to say upon this occasion, therefore, I shall confine myself to our own; and in speaking of the United States of America, I propose rather to dwell upon our character as a people, and our reciprocal obligations and duties as an aggregation of communities, held together by a fixed constitution, and charged with the custody of a union upon whose preservation and perpetuation in its original spirit and purpose the future of free, popular government depends, than to enter into a dissertation upon abstract principles, or to undertake a historic essay. We are a plain, practical people. We are a race of inventors and workers—not of poets and artists. We have led the world's movement—not its thought. Our deeds are to be found not upon frescoed walls or in ample libraries, but in the machine-shop, where the spindles sing and the looms thunder; on the open plain, where the steam-plough, the reaper and the mower contend with one another in friendly war against the obdurances of nature; in the magic of electricity as it penetrates the darkest caverns with its irresistible power and light. Let us consider ourselves and our conditions, as far as we are able, with a candour untinged by cynicism and a confidence having no air of assurance.

A better opportunity could not be desired for a study of our peculiarities than is furnished by the present moment.

We are in the midst of the quadrennial period established for the selection of a chief magistrate. Each citizen has his right of choice, each has his right to vote and to have his vote freely cast and fairly counted. Whenever this right is assailed for any cause wrong is done and evil must follow, first to the whole country, which has an interest in all its parts, but most to the community immediately involved, which must actually drink of the cup that has contained the poison and cannot escape its infection.

The abridgment of the right of suffrage, however, is very nearly proportioned to the ignorance or indifference of the parties concerned by it, and, there is good reason to hope that, with the expanding intelligence of the masses and the growing enlightenment of the times, this particular form of corruption in elections will be reduced below the danger line.

To that end, as in all other good ends, the moderation of public sentiment must ever be our chief reliance; for when men are forced by the general desire for truth, and the light which our modern vehicles of information throw upon truth, to discuss public questions for truth's sake, when it becomes the plain interest of public men, as it is their plain duty, to do this, and when, above all, friends and neighbours cease to love one another less because of individual differences of opinion about public affairs, the struggle for unfair advantage will be relegated to those who either have no character to lose or none to seek.

It is admitted on all sides that the current presidential campaign is freer from excitement and tumult than was ever known before, and it is argued from this circumstance that we are traversing the epoch of the commonplace. If this be so, thank God for it! We have had full enough of the dramatic

dramatic and sensational, and need a season of mediocrity and repose. But may we not ascribe the rational way in which the people are going about their business to larger knowledge and experience and a fairer spirit than have hitherto marked our party contentions?

Parties are as essential to free government as oxygen to the atmosphere or sunshine to vegetation. And party spirit is inseparable from party organism. To the extent that it is tempered by good sense and good feeling, by love of country and integrity of purpose, it is a supreme virtue; and there should be no gag short of a decent regard for the sensibilities of others put upon its freedom and plainness of utterance. Otherwise, the limpid pool of democracy would stagnate and we should have a republic only in name. But we should never cease to be admonished by the warning words of the Father of his country against the excess of party spirit, re-enforced as they are by the experience of a century of party warfare; a warfare happily culminating in the complete triumph of American principles, but brought many times dangerously near to the annihilation of all that was great and noble in the national life.

Sursum Corda. We have in our own time seen the republic survive an irrepressible conflict, sown in the blood and marrow of the social order. We have seen the federal union, not too strongly put together in the first place, come out of a great war of sections stronger than when it went into it, its faith renewed, its credit rehabilitated and its flag saluted with love and homage by 60,000,000 of God-fearing men and women, thoroughly reconciled and homogeneous. We have seen the federal constitution outlast the strain not merely of a reconstructory ordeal and a presidential impeachment, but a disputed count of the electoral vote, and a congressional dead-lock and an extra-constitutional tribunal, yet standing firm against the assaults of its enemies, while yielding itself with admirable flexibility to the needs of the country and the time. And finally, we saw the gigantic fabric of the federal government transferred from hands that had held it a quarter of a century to other hands, without a protest, although so close was the poll in the final count that a single blanket might have covered both contestants for the chief magisterial office. With such a record behind us who shall be afraid of the future.

The young manhood of the country may take this lesson from those of us who lived through times that did, indeed, try men's souls—when, pressed down from day to day by awful responsibilities and suspense, each night brought a terror with every thought of the morrow, and when, look where we would, there were light and hope nowhere—that God reigns and wills, and that this fair land is, and has always been, in his own keeping.

The curse of slavery is dead. It was a joint heritage of woe, to be wiped out and expiated in blood and flame. The mirage of the confederacy has vanished. It was essentially bucolic, a vision of Arcadie, the dream of a most attractive economic fallacy. The Constitution is no longer a rope of sand. The exact relation of the States to the federal government, left open to double construction by the authors of our organic being, because they could not agree among themselves, and union was the paramount object, has been clearly and definitely fixed by the three last amendments to the original chart, which constitute the real treaty of peace between the North and the South and seal our bonds as a nation for ever.

The Republic represents at last the letter and the spirit of the sublime declaration. The fetters that bound her to the earth are burst asunder. The rags that degraded her beauty are cast aside. Like the enchanted princess in the legend, clad in spotless raiment and wearing a crown of living light, she steps in the perfection of her maturity upon the scene of this, the latest and proudest of her victories, to bid a welcome to the world!

Need I pursue the theme? This vast assemblage speaks with a resonance and meaning which words can never reach. It speaks from the fields that are blessed by the never-failing water of the Kennebec and from the farms that sprinkle the valley of the Connecticut with mimic principalities more potent and lasting than the real; it speaks in the whirr of the mills of Pennsylvania and in the ring of the wood-cutter's axe from the forests of the lake peninsulas; it speaks from the great plantations of the South and West, teeming with staples that insure us wealth and power and stability, yea, and from the mines and forests and quarries of Michigan and Wisconsin, of Alabama and Georgia, of Tennessee and Kentucky, far away to the regions of silver and gold, that have linked the Colorado and the Rio Grande in close embrace and annihilated time and space between the Atlantic and the Pacific; it speaks in one word from the hearthstone in Iowa and Illinois, from the home in Mississippi and Arkansas, from the hearts of seventy millions of fearless, freeborn men and women, and that one word is "Union!"

There is no geography in American manhood. There are no sections to American fraternity. It needs but six weeks to change a Vermonter into a Texan and there never has been a time when upon the battle-field or the frontier puritan and cavalier were not convertible terms, having in the beginning a common origin and so diffused and diluted on American soil as no longer to possess a local habitation or nativity except in the national unit.

The men who planted the signals of American civilization upon that sacred rock by Plymouth Bay were Englishmen, and so were the men who struck the coast a little lower down, calling their haven of rest after the great republican commoner and founding by Hampton roads a race of heroes and statesmen, the mention of whose names brings a thrill to every heart. The South claims Lincoln, the immortal, for its own; the North has no right to reject Stonewall Jackson, the one typical puritan soldier of the war, for its own. Nor will it. The time is coming, is almost here, when hanging above many a mantel-board in fair New England—glorifying many a cottage in the sunny South—shall be seen bound together, in everlasting love and honor, two cross-swords carried to battle respectively by the grandfather who wore the blue, and the grandfather who wore the gray.

I cannot trust myself to proceed. We have come here not so much to recall by-gone sorrows and glories as to bask in the sunshine of present prosperity and happiness, to interchange patriotic greetings and indulge good auguries, and, above all, to meet upon the threshold the stranger within our gate, not as a foreigner, but as a guest and friend, for whom nothing that we have is too good.

From wheresoever he cometh we welcome him with all our hearts—the son of the Rhone and the Garonne, our God-mother, France, to whom we owe so much, he shall be our Lafayette; the son of the Rhine and the Moselle, he shall be our Goethe and our Wagner; the son of the Campagna and the Vesuvian bay, he shall be our Michael Angelo and our Garibaldi; the son of Arragon and the Indies, he shall be our Christopher Columbus, fitly honored at last throughout the world.

Our good cousin of England needs no words of special civility and courtesy from us. For him the latch-string is ever on the outer side; though whether it be or not we are sure that he will enter and make himself at home. A common language enables us to do full justice to one another at the festive board or in the arena of debate, warning both of us in equal tones against further parley on the field of arms.

All nations and all creeds be welcome here: from the Bosphorus and the Black Sea, the Viennese woods and the Danubian plains; from Holland dyke to Alpine crag; from Belgrade and Calcutta, and round to China seas and the busy marts of Japan, the isles of the Pacific, and the far away capes of Africa—Armenian, Christian, and Jew—the American, loving no country except his own, but loving all mankind as his brother, bids you enter and fear not; bids you partake of these fruits of 400 years of American civilization and development, and behold these trophies of 100 years of American independence and freedom.

At this moment, in every part of the American union, the children are taking up the wondrous tale of the discovery, and from Boston to Galveston, from the little log school-house in the wilderness to the towering academy in the city and the town, may be witnessed the unprecedented spectacle of a powerful nation captured by an army of lilliputians, of embryo men and women, of topling boys and girls

girls and tiny elves scarce big enough to lisp the numbers of the national anthem ; scarce strong enough to lift the miniature flags that make of arid street and autumn wood an emblematic garden, to gladden the sight, and to glorify the red, white, and blue. See

“ Our young barbarians all at play,”

for better than these we have nothing to exhibit. They, indeed, are our crown jewels ; the truest, though the inevitable, offsprings of our civilization and development ; the representatives of a manhood vitalised and invigorated by toil and care, of a womanhood elevated and inspired by liberty and education. God bless the children and their mothers. God bless our country's flag. And God be with us now and ever, God in the roof-tree's shade, and God on the highway, God in the winds and waves, and God in all our hearts.

The roar of applause that broke from the vast gathering of people in recognition of those two magnificent national airs, “ Star Spangled Banner” and “ Hail Columbia,” had not died away when CHAUNCEY M. DEPEW, the gifted Gotham orator, rose to deliver the Columbian oration. That applause broke forth again at Mr. Depew's appearance, and swelled to a thunderous ovation. The address was brilliant, like everything else of Depew's. It was as follows :—

This day belongs not to America but to the world. The results of the event it commemorates are the heritage of the peoples of every race and clime. We celebrate the emancipation of man. The preparation was the work of almost countless centuries, the realisation was the revelation of one. The Cross on Calvary was hope ; the cross raised on San Salvador was opportunity. But for the first Columbus would never have sailed ; but for the second there would have been no place for the planting, the nurture and the expansion of civil and religious liberty. Ancient history is a dreary record of unstable civilizations. Each reached its zenith of material splendor and perished. The Assyrian, Persian, Egyptian, Grecian, and Roman empires were proofs of the possibilities and limitations of man for conquest and intellectual development. Their destruction involved a sum of misery and relapse which made their creation rather a curse than a blessing. Force was the factor in the government of the world when Christ was born, and force was the sole source and exercise of authority, both by Church and State when Columbus sailed from Palos. The wise men travelled from the east towards the west under the guidance of the star of Bethlehem. The spirit of the equality of all men before God and the law moved westward from Calvary with its revolutionary influence upon old institutions to the Atlantic Ocean. Columbus carried it westward across the seas. The emigrants from England, Ireland, Scotland, and Wales, from Germany and Holland, from Sweden and Denmark, from France and Italy have, under its guidance and inspiration, moved west and again west, building states and founding cities, until the Pacific limited their march. The exhibition of arts and sciences, of industries, and inventions, of education and civilisation, which the Republic of the United States will here present, and to which, through its Chief Magistrate, it invites all nations, condenses and displays the flower and fruitage of this transcendent miracle. * * *

Fifty years before Columbus sailed from Palos, Gutenberg and Faust had forged the hammer which was to break the bonds of superstition, and open the prison doors of the mind. They had invented the printing press and movable types. The prior adoption of a cheap process for the manufacture of paper at once utilised the press. Its first service, like all its succeeding efforts, was for the people. The universities and the school men, the privileged and the learned few of that age, were longing for the revelation and preservation of the classic treasures of antiquity, hidden, and yet insecure in monastic cells and libraries. But the first-born of the marvellous creation of these primitive printers of Mayence was the printed Bible. * * *

God always has in training some commanding genius for the control of great crises in the affairs of nations and of peoples. The number of these leaders are less than the centuries, but their lives are the history of human progress. Though Cæsar and Charlemagne, and Hildebrand, and Luther, and William the Conqueror, and Oliver Cromwell, and all the epoch makers prepared Europe for the event, and contributed to the result, the lights which illumine our firmament to-day are Columbus the discoverer, Washington the founder, and Lincoln the saviour.

Neither realism nor romance furnishes a more striking and picturesque figure than that of Christopher Columbus. The mystery about his origin heightens the charm of his story. That he came from among the toilers of his time is in harmony with the struggles of our period. Forty-four authentic portraits of him are descended to us, and no two of them are the counterfeits of the same person. Each represents a character as distinct as its canvas. Strength and weakness, intellectuality, and stupidity, high moral purpose and brutal ferocity, purity and licentiousness, the dreamer and the miser, the pirate and the puritan, are the types from which we may select our hero. We dismiss the painter, and piercing with the clarified vision of the dawn of the twentieth century the veil of 400 years, we construct our Columbus.

The perils of the sea in his youth upon the rich argosies of Genoa, or in the service of the licensed rovers who made him their prey, had developed a skilful navigator and intrepid mariner. They had given him a glimpse of the possibilities of the unknown, beyond the highways of travel, which roused an unquenchable thirst for adventure and research. The study of the narratives of previous explorers and diligent questionings of the daring spirits who had ventured far toward the fabled West gradually evolved a theory, which became in his mind so fixed a fact that he could inspire others with his own passionate beliefs. The words “ that is a lie,” written by him on the margin of nearly every page of a volume of the travels of Marco Polo, which is still to be found in a Genoese library, illustrates the scepticism of his beginning and the first vision of the new world, the fulfilment of his faith.

To secure the means to test the truth of his speculations this poor and unknown dreamer must win the support of kings and overcome the hostility of the church. He never doubted his ability to do both, though he knew of no man living who was so great in power, or lineage, or learning that he could accomplish either. Unaided and alone he succeeded in arousing the jealousies of sovereigns and dividing the councils of the ecclesiastics. “ I will command your fleet and discover for you new realms, but only on condition that you confer on me hereditary nobility, the admiralty of the ocean and the vice-royalty and one-tenth the revenues of the new world,” were his haughty terms to King John of Portugal. After ten years of disappointment and poverty, subsisting most of the time upon the charity of the enlightened monk of the Convent of Rabida, who was his unfaltering friend, he stood before the throne of Ferdinand and Isabella, and, rising to imperial dignity in his rags, embodied the same royal conditions in his petition. * * *

It was a happy omen of the position which woman was to hold in America that the only person who comprehended the majestic scope of his plans and the invincible qualities of his genius was the able and gracious Queen of Castille. Isabella alone of all the dignitaries of that age shares with Columbus the honors of his great achievement. She arrayed her kingdom and her private fortunes behind the enthusiasm of this mystic mariner, and posterity pays homage to her wisdom and faith.

The overthrow of the Mahomedan power in Spain would have been a forgotten scene, in one of the innumerable acts in the grand drama of history, had not Isabella conferred immortality upon herself, her husband, and their dual Crown by her recognition of Columbus. The devout spirit of the Queen, and the high purpose of the explorer inspired the voyage, subdued the mutinous crew, and prevailed over the raging storms. They covered, with the divine radiance of religion and humanity, the degrading search for gold and the horrors of its quest, which filled the first century of conquest with every form of lust and greed. * * *

The

The rulers of the old world began by partitioning the new. To them the discovery was expansion of empire, and grandeur to the throne. Vast territories, whose properties and possibilities were little understood, and whose extent was greater than the kingdoms of the sovereigns, were the gifts to court favourites and the prizes of royal approval. But individual intelligence and independent conscience found here haven and refuge. They were the passengers upon the caravels of Columbus, and he was unconsciously making for the port of civil and religious liberty.

The nations of Europe were so completely absorbed in dynastic difficulties and devastating wars, with diplomacy and ambitions, that they neither heeded nor heard of the growing democratic spirit and intelligence in their American colonies. To them these provinces were sources of revenue, and they never dreamed that they were also schools of liberty.

The northern continent was divided between England, France, and Spain, and the southern between Spain and Portugal. France wanting the capacity for colonisation, which still characterises her, gave up her western possessions, and left the English, who have the genius of universal empire, masters of North America. The development of the experiment in the English domain makes this day memorable. It is due to the wisdom and courage, the faith and virtue of the inhabitants of this territory, that government of the people, for the people, and by the people, was inaugurated, and has become a triumphant success. The puritan settled in New England, and the cavalier in the South. They represent the opposites of spiritual and temporal life and opinions. The processes of liberty liberalised the one and elevated the other. Washington and Adams were the new types. Their union in a common cause gave the world a republic both stable and free. It possessed conservatism without bigotry, and liberty without license. It founded institutions strong enough to resist revolution and elastic enough for indefinite extension to meet the requirements in government of ever enlarging areas of population, and the needs of progress and growth.

The "Mayflower" with the pilgrims, and a Dutch ship laden with African slaves, were on the ocean at the same time, the one sailing for Massachusetts and the other for Virginia. This company of saints and first cargo of slaves represented the forces which were to peril and rescue free government. The slaver was the product of the commercial spirit of Great Britain, and the greed of the time to stimulate production in the colonies. The men who wrote in the cabin of the "Mayflower" the first charter of freedom, a government of just and equal laws, were a little band of protestants against every form of injustice and tyranny. The leaven of their principles made possible the declaration of independence, liberated the slaves, and founded the free commonwealths which form the Republic of the United States. * * *

The time has arrived for both a closer union and greater distance between the old world and the new. The former indiscriminate welcome to our prairies, and the present invitation to these palaces of art and industry mark the passing period. Unwatched and unhealthy immigration can no longer be permitted to our shores. We must have a national quarantine against disease, pauperism, and crime. We do not want candidates for our hospitals, our poor-houses, or our gaols. We cannot admit those who come to undermine our institutions and subvert our laws. But we will gladly throw wide our gates for, and receive with open arms, those who by intelligence and virtue, by thrift and loyalty, are worthy of receiving the equal advantages of the priceless gift of American citizenship. The spirit and object of this Exhibition are peace and kinship.

Three millions of Germans, who are among the best citizens of the republic, send greeting to the fatherland their pride in its glorious history, its ripe literature, its traditions and associations. Irish, equal in number to those who still remain upon the Emerald Isle, who have illustrated their devotion to their adopted country on many a battle field fighting for the Union and its perpetuity, have rather intensified than diminished their love for the land of the shamrock, and their sympathy with the aspirations of their brethren at home. The Italian, the Spaniard, and the Frenchman, the Norwegian, the Swede and the Dane, the English, the Scotch, and the Welsh, are none the less loyal and devoted Americans, because in this congress of their kin the tendrils of affection draw them closer to the hills and valleys, the legends and the loves associated with their youth.

The grandeur and beauty of this spectacle are the eloquent witnesses of peace and progress. The Parthenon and the cathedral exhausted the genius of the ancients, and the skill of the mediæval architects, in housing the statue or spirit of Deity. In their ruins or their antiquity they are mute protests against the merciless enmity of nations which forced art to flee to the altar for protection. The United States welcome the sister republics of the southern and northern continents and the nations and peoples of Europe and Asia, of Africa and Australia, with the products of their lands, of their skill and of their industry, to this city of yesterday, yet clothed with royal splendour as the queen of the great lakes. The artists and architects of the country have been bidden to design and erect the buildings which shall fitly illustrate the height of our civilization and the breadth of our hospitality. The peace of the world permits and protects their efforts in utilising their powers for man's temporal welfare. The result is this park of palaces. The originality and boldness of their conceptions and the magnitude and harmony of their creations are the contributions of America to the oldest of the arts and the cordial bidding of America to the peoples of the earth to come and bring the fruitage of their age to the boundless opportunities of this unparalleled exhibition.

If interest in the affairs of this world are vouchsafed to those who have gone before, the spirit of Columbus hovers over us to day. Only by celestial intelligence can it grasp the full significance of this spectacle and ceremonial.

All hail Columbus, discoverer, dreamer, hero and apostle. We here, of every race and country, recognise the horizon which bounded his vision and the infinite scope of his genius. The voice of gratitude and praise for all the blessings which have been showered upon mankind by his adventure is limited to no language, but is uttered in every tongue. Neither marble nor brass can fitly form his statue. Continents are his monuments, and unnumbered millions, past, present, and to come, who enjoy in their liberties and their happiness, the fruits of his faith, will reverently guard and preserve, from century to century, his name and fame.

To bring the magnificent exercises of the day up to a fitting close and to prepare all for the musical praise of God and the benediction that were to follow, **CARDINAL GIBBONS** offered up the following eloquent prayer of thankfulness and hope:—

We are assembled, O Lord, in Thy name to celebrate with grateful homage the four hundredth anniversary of the discovery of this continent.

We adore Thy wisdom in choosing for this providential mission Thy servant Columbus, who united to the skill and daring of a navigator the zeal of an apostle, and who was not only impelled by the desire of enriching his sovereign with the wealth of new dominions, but was inspired with the sublime ambition of carrying the light of the Gospel to a people buried in the darkness of idolatry.

Whilst the land which gave birth to Columbus and the land from which he set forth on his voyage of exploration through hitherto unknown seas are resounding with Divine praise, it is meet and just that we give special thanks to Thee, since we have a share in that earthly heritage which his indomitable spirit purchased for us and for thousands unnumbered of the human family. For where blessings abound gratitude should superabound. And if Columbus poured forth hymns of thanksgiving to Thee when a new world first dawned upon his vision, though, like Israel's leader, he was not destined to abide in the promised land, how much greater should be our sense of devout gratitude, since, like the children of Israel, we enjoy the fruit of his labours and victory.

But not for this earthly inheritance only do we thank Thee, but still more for the precious boon of constitutional freedom which we possess: for even this favoured land of ours would be to us a dry and barren waste if it were not moistened by the dew of liberty. We humbly implore Thee to
continue

continue to bless our beloved country and her cherished institutions, and we solemnly vow, in this vast assembly and in the name of our fellow citizens, to exert all our power in preserving this legacy unimpaired and in transmitting it as a priceless heirloom to succeeding generations.

We pray Thee, O God of might, wisdom, and justice, through whom authority is rightly administered, laws are enacted, and judgment decreed, to assist with Thy Holy Spirit of counsel and fortitude the President of these United States, that his administration may be conducted in righteousness and be eminently useful to Thy people over whom he presides, by encouraging due respect for virtue and religion and by a faithful execution of the laws in justice and mercy.

Vouchsafe, O Lord, to bless the labours of the President and Directors of the World's Columbian Exposition, that it may redound to the increased prosperity and development of this young and flourishing metropolis.

May the new life and growth which it will impart to this throbbing centre of trade pulsate and be felt even to the farthest extremity of the land, and may the many streams of industry converging from every quarter of the globe in this great heart of Illinois, flow back with increased abundance into every artery of the commercial world. May this international exposition contribute to the promotion of the liberal arts, science, useful knowledge, and industrial pursuits.

As 1,900 years ago men assembled in Jerusalem from various portions of the old world to hear from the lips of thy apostles "the wonderful works of God," so shall we soon behold men assembled here from Europe, Asia, Africa, and Australia, from the islands of the Atlantic and the Pacific, as well as from all parts of the American Continent, to contemplate the wonderful works of man—of man created to Thine image and likeness, of man endowed with Divine intelligence, of man, the productions of whose genius manifest Thy wisdom and creative power not less clearly than "the heavens which declare Thy glory, and the firmament which showeth forth the works of Thy hands." And as every contemplative being and student of nature "finds tongues in trees, books in the running brooks, and sermons in stones," and rises from nature to nature's God, so will he devoutly rise from the contemplation of those works of human skill to the admiration of Thee, the Uncreated Architect. For every artist and man of genius who will exhibit his works within these inclosures must say, with the royal prophet, "Thy hands, O God, have made and fashioned me," and with Bezaleel, who framed the ancient Tabernacle, he must confess that Thy spirit lightened his understanding, and guided his hands.

Grant, O Lord, that this pacific reunion of the world's representatives may be instrumental in bringing together in closer ties of friendship and brotherly love all the empires and commonwealths of the globe. May it help to break down the wall of dissension and jealousy that divides race from race, nation from nation, and people from people, by proclaiming the sublime lesson of the fatherhood of God, and the brotherhood of Christ. May the goodwill and fellowship which will be fostered in this hospitable city among the delegates of the powers be extended to the Governments which they represent. May the family of nations become so closely identified in their interests by social and commercial relations that when one nation is visited by any public calamity, all the others will be aroused to sympathy, and be ready, if necessary, to stretch out a helping hand to the suffering member.

Arise, O God, in Thy might, and hasten the day when the reign of the Prince of Peace will be firmly established on the earth, when the spirit of the Gospel will so far sway the minds and hearts of rulers that the clash of war will be silenced for ever by the cheerful hum of industry, that standing armies will surrender to permanent courts of arbitration, that contests will be carried on in the Cabinet instead of the battle-field, and decided by the pen instead of the sword.

Finally, we pray that under thy superintending providence that "reacheth from end to end mightily, and ordereth all things sweetly," this Columbian exposition, like the voyage of Columbus, may result in accomplishing a Divine as well as a human mission. May it exert a wholesome influence on the moral and religious as well as on the social and material world. May it promote the glory of God, as well as the peace and temporal prosperity of man. May it redound to the development of Christian faith and Christian principles, and may the queen of commerce, in her triumphant progress throughout the world, be at the same time the handmaid of religion and of Christian civilization to the nations of the earth.

At the close of Cardinal Gibbons' prayer the chorus sang "In Praise of God," after which the Rev. H. C. McCook, of Philadelphia, pronounced the Benediction. This ended, the National salute was fired, and the great dedication exercises closed.

APPENDIX D.

Proceedings at the Inauguration of the World's Congress Auxiliary

(Held at the Auditorium, Chicago, on 21st October, 1892).

ORDER OF EXERCISES.

THE Programme, which began at 8 o'clock and finished before 10, was as follows:—

Organ—Festival Overture, on the Choral, "A Strong Castle is our Lord" (Nicolai-Liszt), Clarence Eddy.

The Opening Invocation—Rev. John Henry Barrows, Chairman of the General Committee of the Auxiliary on Religious Congresses.

The Welcome—Charles C. Bonney, President of the World's Congress Auxiliary.

The Woman's Branch Greeting—Mrs. Potter Palmer, President of the Woman's Branch of the World's Congress Auxiliary.

Salutation in honor of Queen Isabella—Mrs. Charles Henrotin, Vice-President of the Woman's Branch of the Auxiliary.

Introduction of the Orator.

The Oration—"The World's Congresses of 1893." His Grace the Most Reverend John Ireland, Archbishop of St. Paul.

"America,"—Sung by the Audience, led by E. R. Sharpe.

The Closing Invocation—Dr. William R. Harper, President of the University of Chicago, Chairman of the World's Congress Committee on Higher Education.

Organ—Triumphal March (Dudley Buck), Clarence Eddy.

Festival Overture: "A Strong Castle is our God."

Opening Prayer by Rev. John Henry Barrows.

PRESIDENT BONNEY'S Address of Welcome:—

The World's Congress Auxiliary salutes and welcomes this magnificent audience assembled to witness the inaugural ceremonies of the intellectual and moral exposition of the progress of mankind to be made in the World's Congresses of 1893. The greeting on behalf of the Woman's Branch of the Auxiliary will be given by its President, Mrs. Potter Palmer.

MRS. POTTER PALMER'S Welcome from the Woman's Branch:—

The Woman's Branch of the World's Congress Auxiliary, representing the marvellous progress of Woman during the last four centuries, unites most cordially in this greeting, and sends congratulations to the leaders of that progress in all enlightened lands. The salutation in honor of Queen Isabella will be given by Mrs. Charles Henrotin, Vice-President of the Woman's Branch of the World's Congress Auxiliary.

The Salutation in honor of Queen Isabella, by Mrs. HENROTIN, was simple and dignified, albeit the salutation was not long. She said:—

The assistance which Columbus received from Queen Isabella enabled him to discover and reveal the American continents. The aid which enlightened womanhood, the queen of this new age, now offers to all men, will enable them, especially the toiling millions, to find in their own countries new worlds of intellectual and moral enjoyment, enhanced material prosperity, improved social conditions, and the rich fruitage of resulting peace.

The Orator of the evening, JOHN IRELAND, Archbishop of St. Paul, was introduced by PRESIDENT BONNEY, amid a tumultuous wave of applause. In introducing Archbishop Ireland, PRESIDENT BONNEY said:—

The Government of the United States has recognised the World's Congress Auxiliary as the proper agency to arrange and conduct a series of International Congresses to be held in connection with the World's Columbian Exposition of 1893, and has invited the Governments of other countries to send delegates to all or any of these Congresses, in addition to those who will attend as the representatives of the institutions and societies of participating peoples. It was, therefore, thought that the dedication ceremonies of the World's Columbian Exposition would be incomplete without a proper presentation of the plans and purposes of the World's Congress Auxiliary, the progress made, and the success assured. The Auxiliary, therefore sought, for such presentation, an orator equal to the occasion, and whose name would command attention in the old world as well as in the new. Such an orator it found in the Most Rev. John Ireland, Archbishop of St. Paul, who will now deliver the oration on the World's Congresses of 1893.

ARCHBISHOP IRELAND spoke as follows:—

The greatest of things is mind. Mind, conscious, intelligent, potent to put into action, thought, and wish, differentiates itself absolutely from matter, rises above it to immeasurable heights, dominates and moves the unthinking world. Mind is the causative power in all orderly results. Without it there is nothing or there is aimless movement and chaos. The universe is the product of the supreme mind—God incarnate. Within the universe there is created mind—man. Whatever, outside the workings of the first cause, comes in the universe of beauty, goodness, and progress, comes through man. He is, within the limit of God's creation, a second creator. The manifestations of mind in men are of varied measures. The degree of mind lifts man above man—the higher the mind the greater and the nobler the man.

Through

Through scenes of past ages, over which fancy delights to hover amid Columbian celebrations—Cordova's court, the hillside of La Rabida, Palos Harbour, or savage Guanabani—one object more than aught else obtains attention. We seek it out; we fix upon it the soul's eager eye. It is the figure of Christopher Columbus. The picture, Columbus unseen, whatever the remaining forms, whatever the colouring, is incomplete, meaningless; the spirit is absent; it is void of inspiration. Columbus is the mind, creating, directing the scenes, bringing into them motive and purpose, producing and co-ordinating results. All else in the scenes has value so far as it responds to the thoughts of Columbus, so far as it aids him to execute his plans. The queenly and generous Isabella, the patient and farseeing Juan Perez de Marchena, claim our esteem because mind in them understood and followed superior mind in Columbus.

In all places, in all occurrences, the sublime, the worshipful power is mind. Man, mind, incorporate, is the greatest being in the universe. The men among men, mind towering above common mind, are the worthiest of all objects of vision and study.

This day 400 years ago America first unfolded to the eyes of civilized races her beauty and her wealth. Fraught, indeed, with solemn meaning for the whole world of men was the occurrence. Few expressions recorded in story revealed great things coming as did the world which, rising in swelling choruses, rent the air above the decks of the weary and wave-beaten caravals of the admiral of the seas—land! land! The new land was in sight, so fruitful in resources, so pregnant in possibilities. A new world was given to human longings, to human action; a new era dawned for mankind, a marvellous epoch of human progress. Since the preaching of the Christian religion nothing has happened of such great import for the human race as the discovery of America. What has occurred during the last four centuries abundantly proves the assertion. What will occur in the future will set it out in yet clearer light. With much reason America and her sister continents keep sacred the Centennial Anniversary.

The solemn commemoration of the discovery of America has been allotted to the United States. It was the right and the duty of the first nation of the continent to charge itself with the gracious task. She, as none other, is the giant daughter of the progress of the age; she, as none other, has the power to command the splendours which should mark the commemoration. She has inaugurated the exposition of Chicago. Proper, too, was it that among the cities of the United States, Chicago be the chosen one within whose portals the exposition be enthroned. Chicago, fifty years ago the prairie village, the stupendous city of the present time, is the world's object lesson of progress. The monarch of our inland seas, the central city of the nation, she exhibits to the visitor the fulness of growth with which the United States has been blessed. Almost half-way across the continent, commanding the highways of nations, the mart in which meet for mutual exchange the offerings of Europe and Asia, Chicago forebodes the mighty destiny of the United States—to sit among all earth's nations the admired queen, the arbiter in the arts of peace and civilization of their destinies, the magnet in resistless attraction knitting all people into one harmonious and indestructible brotherhood.

The Exposition will show forth the results of the discovery of Columbus. In this wise he is honored. What Columbus gave to the world was not only the America of 1492—America, however, rich in hidden treasures, tranquil and undisturbed in nature's sleep. He gave the America of 1892—the America which his achievement made possible. He gave, in large measurement, modern progress amid all nations. America, be large-hearted in thy justice to Columbus. What thou art and what thou hast, be it all spread out to the wondering gaze of the world. Call thou upon all nations to unite with thee in praising him who was a universal benefactor, and to unroll, also, upon thy banquet-tables their choicest gifts—these and thy own, the ripest fruits of human progress, a bounteous feast for the human mind, the like of which was never set before men.

The Exposition will bring to the memory of Columbus yet higher honour. The dawn which on that memorable discovery day purpled the sails of the Santa Maria, the Nina, and the Pinta, and diffused joy untold into the souls of Columbus and his mariners was the harbinger to the world of a magnificent era of progress. What, then, should be the record told in future history of our commemorative celebration? This, and this above all else, that it did beget another era of progress for the world, distancing the previous era, so much more deeply marked in intensity and in results, that it began its course upon the higher plane to which the thinkers and toilers of 400 years had lifted mankind. This we shall do if we, in the magnitude and wisdom of our work, respond to the expectations of nations and to the plannings of the all-ruling Providence, who, in our case, as in that of Columbus, never puts before men great opportunities without demanding that fullest profit be made of them.

The Exposition of Chicago must be surpassingly great. Be there nothing wanting in it that thought or skill, wealth or courage, can bring hither. The Exposition commemorates a great event. It represents a great age in the life of humanity—it presages a greater age which is to be. To the greatness of the Exposition is pledged the honour of a great nation, and of its greatness a great city stands the sponsor.

Jackson Park, the pride to-day of Chicago, upon whose buildings, vast and stately, the majesty of the nation descended this morning in dedicatory services, tells the resolve to redeem all promises, to realise all hopes. Hither shall be brought the product of labour and art, the treasures of earth and sea, the inventions of this wondrously inventive century, the fruits of learning and genius. The entire globe is astir in preparation to fill to repletion the palaces we have erected. The invitation has gone out to the world in all the fulness and warmth of the heart of this Republic, and the nations of the earth have hearkened to it as they never did before to a voice calling men to an exposition. The best that America can bring, the best the world owns shall soon be in Jackson Park.

What may be added? I will give reply. What is there more important, more precious, than matter, and all the forms with which matter may be invested? Is there not mind? What is there greater than all the results of the thought, the labour of man? Is there not man himself, the designer, the maker of his works? Bring hither, then, mind. Bring men—not merely the millions, anxious to see and to learn. These do we need—they do not suffice. Bring the men whom the millions desire to contemplate, and from whom they may receive valued lessons. Bring the thinkers, the workers, the scholars, the apostles of action, who have rendered possible or have produced the marvels which will be housed in Jackson Park, whose dreams make toward the building up of humanity, whose arms reach out to the improvement of men along the lines of human progress. Let us have the Columbuses of our time. Let us have Parliaments of the leaders of men convoked from all lands under the sun. In this manner is your Exposition complete in all its parts, truly representative of the age, and truly great. You have matter and men; you have the works and the workers. In men far more than in matter you have the highest products of progress. There is progress only when men grow. In men you have the potent means to determine the progress of the future. God has made men the agents of progress.

I am stating the purpose of the world's Auxiliary Congress of the World's Columbian Exposition.

The organisation known as the auxiliary congress is an integral part of the Columbian Exposition, whose directors authorize and support it. It has received from the United States Government recognition and approval. Its special mission is to organise and cause to be held, during the several months allotted to the Exposition, international conventions of the scholars and workers of the world along all the lines of human progress in the various departments of civilised life, and in this way present, through the living voice of the chief actors, clear and comprehensive statements of the questions in all the fields of activity which vex to-day the souls of men. The idea is truly grand, and most important results must follow from the successful carrying out of it. All countries are asked to send to Chicago their best and most attractive minds. The several conventions, or congresses, will bring into actual contact the leaders in the several departments of thought. The thinking world will be

be under our eyes ; the whole trend of modern activity will be under our touch. What schools for learners ! What workshops of new ideas, where mind in friction with mind provokes unto higher flights and rises into broader vistas of truth !

The president of the auxiliary is the Hon. Charles C. Bonney. The name gives warrant that all shall be done to assure success which high intellect, intense honesty of purpose, and strictest devotion to duty can do. He is seconded in his work by a body of able directors. Each broad department of thought is, under their guidance, intrusted to a commission of chosen men, whose duty it becomes to prepare the plan of work, to awaken public interest, to solicit counsel from men of note the world over. In each department there will be held as many congresses as there may be traced out leading subdivisions of the general subject, and for each congress there is appointed a special commission, who will give to its organisation their immediate attention.

I instance the department of education : There is the general commission on education—and co-operating with it there are the special commissions on higher education, public instruction, public instruction in music, the instruction of the blind, the deaf and dumb, and the feeble-minded, &c. Furthermore, and I call particular attention to this feature, the aid of woman is sought ; the importance of her work is recognised. There is the woman's department of the congress auxiliary, a general commission, and commissions corresponding to all the proposed congresses into which woman's work may appropriately enter.

The world's congresses will be held in the permanent memorial art palace erected in Lake Front Park. Complete reports of all deliberations will be published in memorial volumes at the expense and under the direction of the United States Government. Already arrangements are being made for the holding of over 100 congresses under charge of the various departments into which the work of the congress auxiliary has been organised. For some congresses, in view of the nature of the subjects to be discussed, the attendance will probably not range above the hundreds. In the greater number it will go far upward in the thousands, and in congresses of departments of education, of temperance, religion, &c., &c., we are assured that the audience will not be under 50,000. The work already done, the promises given, the preparations made, the adhesions from people in America and in transatlantic countries, allow no doubt of the triumphant outcome of the world's congress auxiliary.

The congress auxiliary, the controlling idea of which is to bring together men working for men, puts forth in clear outlines the high purpose of the whole Exposition and invests it with meaning and dignity.

Expositions are held as indications of progress and as stimulants to its continuous growth. But what is progress ? Its chief seat is not in matter. It is not in the changes of forms to which matter may be subjected. Matter is not an end to itself. It has no consciousness of its conditions. No benefit, no enjoyment comes to it, whatever be the uses to which it is put, or the shapings or the colourings which may be impressed upon it. Progress is in man. It is the growth of man in the faculties and powers of his being, in his empire over inanimate and irrational creation. Man alone progresses, for man alone is intelligent and conscious.

God's aim in his workings through nature was man. The earth was created to prepare for him a dwelling-place. It was endowed with vernal fecundity to provide him with nutriment and to give delectation to his senses. The atmosphere was tempered to man's physical life. The firmament was spread to light his footsteps and to draw his soul into supernal contemplation. All these things were made for man and were given to man. "Fill the earth and subdue it," said the Lord, "and rule over the fishes of the sea and fowls of the earth, and all living creatures that move upon the earth."

"The meaning of creation," it has been well said, "is not understood until dust stands erect in a living man." The law of nature endures. Man must remain the monarch of nature ; the purpose of nature and of all its forces must be the service of man—the betterment and elevation of man. There is no other value than this in material things. To rate man inferior to matter is the reversal of the divine ordering of the universe.

Be there as much as there may the development of nature's forces and the harnessing of them to the chariots of science and industry. Be there searchings into the abyssal secrets of the earth, sea, and sky. Be there trade and commerce. But, throughout, be the aim to build up man into a higher manhood, into a more intelligent, a better, and a happier being.

Be it always man who is progressing. Man not growing, nothing has been accomplished ; man deteriorating, there is evil done. Perish trade and commerce if thereby man is lessened in his sense of righteousness and the fibre of his heart is hardened. Perish the most ingenious machinery if its conscienceless wheels in their merciless rotations annihilate the purity and happiness of human souls. Labour is a curse if man is thereby made the slave of matter and assimilated to matter. The wealth of nations is a blasphemy thrown into the face of the Creator, if riches lead to selfishness and narrow-mindedness in the possessors and the accumulation thereof condemns the multitude to misery and sin. Man is the precious being ; man must be saved and lifted upward ; the progress of man is the sole progress. Nor by man must we be allowed to understand a few men here and there amid the masses of their fellows. The few may have grown to mountain heights ; if the many dwell in the darkened valleys of suffering and of soul-wreckage, man has not progressed. God has not care of the few ; He has care for all. For the benefit of all has He swung the earth into space and lit above it His fiery orbs. Progress through the whole human family is the progress which God wills and which we should name progress.

There is danger lest expositions where all is wood and marble, gold and silver, machinery and cereals, where matter alone feasts the eye and speaks to the soul, silently teach false lessons of progress. All is well with the world, it might seem, if matter is improved. Men seek matter and admire matter. Matter, then, is the all-important. The tendency of the times is already more materialistic than its well-wishers desire. Nothing should be done to accelerate it. There is need to repeat aloud the poet's warning :

"Ill fares the land, to hastening ills a prey,
Where wealth accumulates and men decay."

This is the mission of the congress auxiliary. It will put into the foreground man as the chief factor and first fruit of civilisation and progress. Its programmes of studies will bring out in clearest light his grandeur and final destiny.

The plans of the congress auxiliary are most comprehensive. They extend along all the lines of the growth of man.

There are the departments of agriculture, engineering, commerce, and finance, &c., in which his relations to matter receive due consideration. Man lives upon the earth, derives hence his subsistence, and in subjecting it to his service he enlarges by exercise the powers of his soul. Far be it from us not to recognise as vital elements in progress, and as strong evidences of it, the triumphs of mind over things.

The marvels of physical and mechanical sciences, in which the age glorifies itself ; its surprising inventions, enabling us to dominate more completely over nature and to yoke its subtlest forces to our industrial chariots ; its vast discoveries, opening up to our gaze the surface of the globe, revealing to us the entrails of earth and the remote regions of ethereal space—we admire and praise. God gave to us the material universe that we study it and use it. Material progress is no less within the lines of His supreme law than progress moral and spiritual. The whole man must grow, and grow in all directions. I am as impatient with the narrowness which limits him in one direction as with that which limits him in another. The sole lesson which I inculcate is that the earth is the footstool of man, and that material progress in its grandest flights fails unless man retains throughout his higher nature and is made by it a greater and a better being.

The

The interests of man's mind are cared for in the departments of education, science, and philosophy, literature, the public press, &c. Man is primarily an intelligence. His other operations depend upon and follow from his knowing. Without knowledge the darkening clouds of barbarism never rend over the face of a people. There is no progress without it in material things, and none in other realms of human aspiration. And as progress must reach over the whole human family, so knowledge, however varied in degrees, must be universal in its diffusion.

The moral life of man wells up in the heart, beneath the vivifying dews of Divine grace. Into this inner sanctuary congresses have little access. Yet it is well that the importance of the moral life of the individual and of society be emphasised; for righteousness and well doing are the vital conditions of healthfulness in body and in soul. Congresses give aid by directing outside social currents, the influences for which make strongly for good or evil. Hence, we have the department of moral and social reform, including congresses on charity, philanthropy, prevention, reform, &c., and the department of temperance, marshalling into mutual counselling the devoted legions of men and women who are giving battle to a giant evil of the times.

The department of government deals with all the complex problems which the proper regulation of man's social interests suggests. We will have congresses on municipal and national administrations, international law, peace arbitration, the several divisions of jurisprudence and practical government, &c. Government is necessary that men may abide together in peace and derive from their relations with one another help in their labour of self-development. Government is the means, not the end: the means to the elevation of the many, not to the few. The congresses of this department will be most serviceable in the progressive march of humanity.

In the strugglings of men to subsist and to rise, success is measured out in unequal degrees. This is a natural necessity. None, however, live for themselves; all are members of the human family, and the Divine Master intended for all a sufficiency of the things of earth and of the means, moral and physical, to attain to the stature of physical and moral manhood. The department of labour will discuss the intricate and pressing questions arising from the relations of labour to capital, of employee to employer—maintaining the rights of all, prescribing the duties of all, and guarding over all for their protection the reign of social order.

The health of the body of man is entrusted to the department of medicine. Man, in the fulfilment of his destiny, can neglect neither body nor soul. Be there a healthful body to house a healthful soul.

There are, too, the departments of art, music, architecture, &c. The instinct of the beautiful is deeply embedded in man: it must be satisfied. The beautiful is the reflection of elevated regions, unperceived by sense, the native home of the soul. Man expands beneath its sunshine, and is preserved by it from the hardening impress which comes towards him from the dreary drudgery of his strugglings with matter.

There is the department of woman's progress, providing for a general congress of representative women of all countries. At the same time, as I have already stated, there is in connection with each congress organised in the several departments of the congress auxiliary, wherever the mind, heart, and finger of woman may be invited to give aid, a woman's committee, for the purpose of obtaining the co-operation of women in the work of human progress. At no previous world's congress was there the marked recognition of women which the Columbian auxiliary accords her. In this recognition we rejoice. It is a noticeable token and promise of progress for woman herself and for the world at large. Woman for her own good has been too dependent upon the stronger sex, and in the battling for better things in the life of humanity we cannot longer afford to keep off the open field the deep charity and exhaustless energy of woman's soul. Columbus could not have succeeded without the practical patronage of Isabella. Be Isabella honoured in the Columbian exposition by America's generous recognition of woman's sphere.

Finally, there is the Department of Religion, crowning the work of other departments, and perfuming them with the fragrance of Heaven. Sublime the thought to have the proclamation go out from the great exposition that God reigns, and that man is his servant, that all progress begins and ends with him who is the alpha and omega of all things.

Religion is at home amid Parliaments of men working for progress in men. There is no progress deserving the name where no provision exists for the growth of man's spiritual nature. Nor can labourers in the field of progress afford to overlook the powerful aid which comes from religion to progress in the moral and social spheres. Without God's love inspiring and God's justice rewarding, men's hearts are warped, souls are chilled, enthusiasm is transient sentiment. The fatal enemy of the spirit of sacrifice and of self-control, from which springs all moral and social progress, is the cold positivism which unbeliefs seeks to substitute for the religion of a living God. Positivism is despair and practical pessimism. England's lamented laureate wrote lines of which all feel the truth:—

"Why should we bear with an hour of torture, a moment of pain,
If every man die for ever, if all his griefs are in vain,
And the homeless planet at length will be wheeled through the silence of space,
Motherless evermore of an ever-vanishing race?"

Religion is the eternal fount of hope, and hope it is which sustains man and his strugglings, and impels him to deeds of virtue and of valour. Positivism can never be the creed of a progressive people. It is not the creed of the Congress Auxiliary of the Columbus exposition.

Exception has been taken to religious congresses on the ground that on so many points there will be no harmony of thought and that truth will suffer by the juxtaposition of error. There is no force in the remark. The vital primordial truths regarding the supreme God will be confessed by all. The proclamation of these truths will be a great gain. Beyond this, those who believe they possess the truth need not fear. Truth should not be timid. Rather should she court publicity on this as on all other occasions, in order that she be known and loved. There shall be no discussions, no controversies. The purpose shall be to show forth in methods of peace, what are the professions of faith and the religious works of the world at the present time. From the plans of the Department of Religion of the Congress Auxiliary nought but good results can follow.

Through its varied departments the congress auxiliary unrolls its chart of progress for the building up of the whole man. Its convention halls will be workshops in which earnest men seek to purify and to fashion humanity according to high ideals. In convoking men to its gatherings it convokes them to the noblest of tasks—that of working for fellow-man. God works for man; the divine purpose in the creation and the preservation of the universe is man. We become Godlike in action when we work for man. God must ever be the supreme end of our willing and our doing, but outside the worship due immediately to His Majesty, he has determined that we reach him through our fellow-beings. God's manifestation of his eternal mind, Christianity, makes work for humanity a fundamental principle of religion. "Amen, amen, I say to you, as long as you did it to one of these, my least brethren, you did it to me."

The lines of work which Christ prescribes in favour of man are not merely those relating to the spiritual life; they are those, also, relating to the life of the body—the feeding of the hungry, the clothing of the naked, the solacing of the captive, the healing of the crushed and suffering heart. God's sweet religion is wherever work is done for man's welfare—wherever humanity is benefited and lifted upward, were it only by the width of a hair of the head. There is religion within cathedral walls, where God is spoken to and loved; there is religion in the wheat-field, where clay and air combine to produce food for man; there is religion in the factory, where matter is turned into new forms for man's comfort; there is religion in the sanctuary of philosopher and writer, dreaming of new upliftings

upliftings for the race, and oh ! there is religion when the weary one is comforted, the outcast saved, and the hand of the hungering filled with bread. There is religion wherever there is work for man ; religion expands her heavenly wings over all the palaces of your great exposition.

Nor by any manner of means is working for men the hopeless task that pessimists would fain proclaim it to be. Progress is the law of nature and the law of nature's God. Since the Creator has bestowed upon us faculties capable of expansion it must be His will that we draw into action their latent forces. Since He subjected to us the earth, it must be His will that we take possession of it and assert our mastership of its every part. Powers lying dormant and idle find no favour in God's eyes. Progress is the continuity of creation ; to arrest it, through malice or indolence, is a crime against Creator and creature. Christ's Gospel is throughout a gospel of progress. It announces that all things should be put to profit and increase ; the talent wrapped up in a napkin, not made to fructify, draws down upon its possessor the ire of the Master. The parable of the talent rather primarily applies to progress in material things. History is the witness that humanity under Christ's touch was impelled into moral and spiritual progress with such might that centuries do not still the sublime vibration. The pessimist who stands idly by, uttering words of discouragement, reads not nature's lessons in the brightness of its morning sun, or in the richness of its autumnal fruitage ; he reads not in his Bible the Divine lessons of mercy and grace. There shall always be in limited humanity sin and misery, suffering and death. But evil may be lessened, and good may be increased, and this is progress. I will never believe that good must necessarily yield to evil, that the devil is stronger than God, and hence I shall never cease to put my hope in the progress of humanity.

The history of humanity is a history of progress. A narrow survey of the scene will not always bring out this important truth. There are in the tide of progress backward currents and tortuous windings. We must consider the general movement of which the trend ceases not to toward higher planes.

“ Forward, then ; but still remember how the course of time will swerve,
Crook and turn upon itself in many a backward streaming curve.”

Disguised in a rhythm of rise and decline, of ebb and flow, of growth and decay, the progress of humanity continues, and the hopes of the workers in the cause of humanity obtain their rewards

“ Through the ages one increasing purpose runs,
And the thoughts of men are widening with the process of the suns.”

The effect of the work of our congresses will be to give a marked impetus to the forward stream of progress. Their deliberations will provide the charts for the march of future generations.

The congresses organised by the congress auxiliary will not be meetings of pleasure or friendship ; they will be solemn conventions of earnest men and women, working with mind and heart for progress, comparing together their observations and conclusions, drawing from contact with one another light and heat, and when separating more firmly resolved than before to labour for fellow men.

The time is most auspicious. Manifestly we live in one of those momentous cycles of history when humanity is casting around for new pathways and girding itself for unusual manifestations of its energies. How much has been done since the days of Columbus ! Much more will be done in the new period, whose approach already brightens the landscape.

Ours is an age of unrest, of searchings and dreamings. Past achievements have but whetted the appetite. We are to-day less satisfied with inventions and discoveries than we were when the steamship and the railroad car were mere experiments. Science is more restless in its inquiries into cause and effect than when it made its first step beyond the borderland of guessings. Signal victories in the extension of popular rights and of individual liberty, the elevation of the masses, the enlargement of the sphere of woman, make known how much more may be obtained and awaken new and untried ambitions.

Another feature of the age is its questioning spirit, its tireless inquisitiveness. It puts all things to the test ; it peers into the heights and depths, so as to arrive at the real facts, the ultimate foundations, content to repose itself upon nothing else. No possibilities escape the vision and no difficulties affright the heart of man. He is emboldened by the past and enriched with its accumulated treasures of knowledge and experience. Never was humanity so daring as it is to-day, never so ready to leave far behind the pillars of Hercules and steer its ships over undiscovered seas.

I would remark, too, the universality of its energies and labours. The manifestations of the age can be reduced to no single force or trait. All the diverse energies of preceding ages combine in it and many others born of itself. All forces, physical, scientific, social, moral, are evoked, and all are challenged to show their best results.

The age is ready for great feats. If we are the loyal workers of progress our lines are, indeed, cast amid hopeful surroundings.

The future ! What will it be ? Material progress, no doubt, will continue onward with ever-increasing velocity. The wildest dreams, scarcely, I believe, foreshadow the realities—nothing need be unexpected. The travellers to the Columbian Exposition a hundred years hence will, perhaps, birdlike, sail through the air, journeying in a half-dozen hours from the Atlantic coast to the city of the north-west on the banks of the Mississippi. More unlikely would the prophecy of travel by rail, or steam, or electricity have seemed to our forefathers one century ago.

I trust in Providence and in humanity, and I have confidence that the moral and social forces which now so profoundly agitate the world will work into an increase of goodness and happiness among men. Much will depend upon the intelligence and zeal of those whom position and talent have made the leaders of thought and action. Seldom in all history did such deep responsibilities rest upon the leaders of their fellows as there do to-day. Scarcely ever was humanity pregnant with such momentous possibilities ; scarcely ever were similar opportunities offered to accomplish great things.

The future will bring no millennium. There will be no rosebush without thorns ; no day without the nearness of evening shades ; no life without the menace of death. There will be inequalities among men, and passions will disturb the peace of souls. But I do believe there will be more mercy in the world, more justice, more righteousness. There will be more respect for manhood, more liberty for the individual. The brotherhood of men will be more widely recognised, and its lessons more faithfully practised. Servitude and oppression will be banished, even from the darkest thickets of African forests. The boon of civilisation will reach all races of the human family. Civil and political liberty will speed across all seas and oceans. Nations will see in one another assemblies of brothers, and peaceful arbitration will, in settlement of disagreements, take the place of the murderous sword. Brute force will more and more yield before reason ; mind will more and more assert itself over matter and over passion. All this will not come to pass without delays and backward movements, without reactions and repressions, but the victory will be for truth and justice.

The atmosphere of the day is chilled with the spirit of unbelief. Need we fear for religion ? It is as if we asked : Need we fear for eternal truth, for the reign of the Almighty ? Unbelief is but a passing wave. The material and scientific progress of the age has begotten an over-estimate of nature, and draws a film over eyes which would seek the supernatural. The realities of the supernatural and man's profound need of them endure, and his reason will not lose sight of them. The protest against unbelief will bring religion into bolder relief, and the widening thoughts of men along other lines of progress will prove more clearly that religion is the need of all progress—a God is the need of all being.

Toward a future, as I briefly sketch it, will tend the labours of the Congress Auxiliary.

In the course of history Providence selected now one nation, now another, to be the guide and exemplar of humanity's progress. At the opening of the Christian era mighty Rome led the vanguard. Iberia rose up the mistress of the times, when America was to be born into the family of civilised peoples. The great era, the like of which has not been seen, is now dawning upon the horizon. Which will be Providence's chosen nation to guide now the destinies of mankind?

The noble nation is before my soul's vision. Giant in stature, comely in every feature, buoyant in the freshness of morning youth, matronly in prudent stepping, the ethereal breezes of liberty waving with loving touch her tresses—she is—no one seeing her doubts—the queen, the conqueror, the mistress, the teacher of coming ages. To her keeping the Creator has intrusted a great continent, whose shores two oceans lave, rich in all nature's gifts, embosoming precious and useful minerals, fertile in soil, salubrious in air, beauteous in vesture. For long centuries had he held in reserve this region of his predilection, awaiting the propitious moment in humanity's evolutions to bestow it on men when men were worthy to possess it. Her children have come from all countries, bearing with them the ripest fruit of thought, labour, and experience. Adding thereto high inspirations and generous impulses they have built up a new world of humanity. This world embodies the hopes, the ambitions, the dreamings of humanity's priests and seers. To its daring in the race of progress, to its offerings at the shrine of liberty there seems to be no limit; and yet prosperity, order, peace, spread over its vast area their sheltering wings.

The nation of the future! need I name it? Your hearts quiver loving it.

“My country, 'tis of thee
Sweet land of liberty,
Of thee I sing.”

We commemorate the discovery of America, 400 years ago. Behold the crowning gift to humanity from Columbus, whose caravels ploughed ocean's uncertain billows in search of a great land, and from the all-ruling Providence whose wisdom and mercy inspired and guided the immortal Genoese mariner—the United States of America.

When the long-continued applause following Archbishop Ireland's oration had subsided, Mr. Bonney announced that owing to unforeseen circumstances Vice-President Morton was unable to be present. The hymn “America” was sung by the audience, led by E. R. Sharpe, the 3,000 people in the hall rising to their feet. When the last notes had died away Dr. William R. Harper, President of the Chicago University, invoked the Divine blessing, and the audience left the hall accompanied by the strains of Dudley Buck's grand triumphal march.

APPENDIX E.

Act of Congress Creating the World's Columbian
Commission.

AN ACT to provide for celebrating the four hundredth anniversary of the discovery of America by Christopher Columbus by holding an international exhibition of arts, industries, manufactures, and the products of the soil, mine, and sea, in the City of Chicago, in the State of Illinois.

WHEREAS it is fit and appropriate that the four hundredth anniversary of the discovery of America be commemorated by an exhibition of the resources of the United States of America, their development, and of the progress of civilisation in the New World ; and

Whereas such an exhibition should be of a national and international character, so that not only the people of our Union and this Continent, but those of all nations as well, can participate, and should therefore have the sanction of the Congress of the United States ; therefore

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That an exhibition of arts, industries, manufactures, and products of the soil, mine, and sea shall be inaugurated in the year eighteen hundred and ninety-two, in the City of Chicago, in the State of Illinois, as hereinafter provided.

Section 2. That a Commission, to consist of two Commissioners from each State and Territory of the United States and from the District of Columbia and eight Commissioners-at-Large, is hereby constituted to be designated as the World's Columbian Commission.

Section 3. That said Commissioners, two from each State and Territory, shall be appointed within thirty days from the passage of this Act by the President of the United States, on the nomination of the Governors of the States and Territories, respectively, and by the President eight Commissioners-at-Large and two from the District of Columbia ; and in the same manner and within the same time there shall be appointed two alternate Commissioners from each State and Territory of the United States and the District of Columbia and eight alternate Commissioners-at-Large, who shall assume and perform the duties of such Commissioner or Commissioners as may be unable to attend the meetings of the said Commission ; and in such nominations and appointments each of the two leading political parties shall be equally represented. Vacancies in the Commission nominated by the Governors of the several States and Territories, respectively, and also vacancies in the Commission-at-Large and from the District of Columbia may be filled in the same manner and under the same conditions as provided herein for their original appointment.

Section 4. That the Secretary of State of the United States shall, immediately after the passage of this Act, notify the Governors of the several States and Territories, respectively, thereof and request such nominations to be made. The Commissioners so appointed shall be called together by the Secretary of State of the United States in the City of Chicago, by notice to the Commissioners, as soon as convenient after the appointment of said Commissioners, and within thirty days thereafter. The said Commissioners, at said first meeting, shall organise by the election of such officers and the appointment of such Committee as they may deem expedient, and for this purpose the Commissioners present at said meeting shall constitute a quorum.

Section 5. That said Commission be empowered in its discretion to accept for the purposes of the World's Columbian Exposition such site as may be selected and offered and such plans and specifications of buildings to be erected for such purpose at the expense of and tendered by the corporation organised under the laws of the State of Illinois, known as "The World's Exposition of eighteen hundred and ninety-two." Provided, that said site so tendered and the buildings proposed to be erected thereon shall be deemed by said Commission adequate to the purposes of said Exposition : And provided, that said Commission shall be satisfied that the said corporation has an actual *bona fide* and valid subscription to its capital stock which will secure the payment of at least five millions of dollars, of which not less than five hundred thousand dollars shall have been paid in, and that the further sum of five million dollars, making in all ten million dollars, will be provided by said corporation in ample time for its needful use during the prosecution of the work for the complete preparation for said Exposition.

Section 6. That the said Commission shall allot space for exhibitors, prepare a classification of exhibits, determine the plan and scope of the Exposition, and shall appoint all judges and examiners of the Exposition, award all premiums, if any, and generally have charge of all intercourse with the exhibitors and the representatives of foreign nations. And said Commission is authorised and required to appoint a Board
of

of Lady Managers of such number and to perform such duties as may be prescribed by said Commission. Said Board may appoint one or more members of all committees authorised to award prizes for exhibits which may be produced in whole or in part by female labour.

Section 7. That after the plans for said Exposition shall be prepared by said corporation, and approved by said Commission, the rules and regulations of said corporation governing rates for entrance and admission fees, or otherwise affecting the rights, privileges, or interests of the exhibitors or of the public, shall be fixed or established by said corporation, subject, however, to such modification, if any, as may be imposed by a majority of said Commissioners.

Section 8. That the President is hereby empowered and directed to hold a naval review in New York Harbour, in April, eighteen hundred and ninety-three, and to extend to foreign nations an invitation to send ships of war to join the United States Navy in rendezvous at Hampton Roads, and proceed thence to said review.

Section 9. That said Commission shall provide for the dedication of the buildings of the World's Columbian Exposition in said City of Chicago on the twelfth day of October, eighteen hundred and ninety-two, with appropriate ceremonies, and said Exposition shall be open to visitors not later than the first day of May, eighteen hundred and ninety-three, and shall be closed at such time as the Commission may determine, but not later than the thirtieth day of October thereafter.

Section 10. That whenever the President of the United States shall be notified by the Commission that provision has been made for grounds and buildings for the uses herein provided for, and there has also been filed with him by the said corporation, known as "The World's Exposition of eighteen hundred and ninety-two," satisfactory proof that a sum not less than ten million dollars, to be used and expended for the purposes of the Exposition herein authorised, has in fact been raised or provided for by subscription or other legally binding means, he shall be authorised, through the Department of State, to make proclamation of the same, setting forth the time at which the Exposition will open and close, and the place at which it will be held; and he shall communicate to the diplomatic representatives of foreign nations copies of the same, together with such regulations as may be adopted by the Commission, for publication in their respective countries, and he shall, in behalf of the Government and people, invite foreign nations to take part in the said Exposition and appoint representatives thereto.

Section 11. That all articles which shall be imported from foreign countries for the sole purpose of exhibition at said Exposition, upon which there shall be a tariff or customs duty, shall be admitted free of payment of duty, customs fees, or charges under such regulations as the Secretary of the Treasury shall prescribe; but it shall be lawful at any time during the exhibition to sell for delivery at the close of the Exposition any goods or property imported for and actually on exhibition in the Exposition buildings or on its grounds, subject to such regulations for the security of the revenue and for the collection of the import duties as the Secretary of the Treasury shall prescribe: Provided that all such articles when sold or withdrawn for consumption in the United States shall be subject to the duty, if any, imposed upon such articles by the revenue laws in force at the date of importation, and all penalties prescribed by law shall be applied and enforced against such articles, and against the persons who may be guilty of any illegal sale or withdrawal.

Section 12. That the sum of twenty thousand dollars, or as much thereof as may be necessary, be, and the same is hereby appropriated, out of any moneys in the Treasury not otherwise appropriated, for the remainder of the present fiscal year and for the fiscal year ending June thirtieth, eighteen hundred and ninety-one, to be expended under the direction of the Secretary of the Treasury for purposes connected with the admission of foreign goods to said Exhibition.

Section 13. That it shall be the duty of the Commission to make report, from time to time, to the President of the United States of the progress of the work, and, in a final report, present a full exhibit of the results of the Exposition.

Section 14. That the Commission hereby authorised shall exist no longer than until the first day of January, eighteen hundred and ninety-eight.

Section 15. That the United States shall not in any manner, nor under any circumstances, be liable for any of the acts, doings, proceedings, or representations of the said corporation organised under the laws of the State of Illinois, its officers, agents, servants, or employees, or any of them, or for the service, salaries, labour, or wages of said officers, agents, servants, or employees, or any of them, or for any subscriptions to the capital stock, or for any certificates of stock, bonds, mortgages, or obligations of any kind issued by said corporation, or for any debts, liabilities, or expenses of any kind whatever attending such corporation or accruing by reason of the same.

Section 16. That there shall be exhibited at said Exposition, by the Government of the United States, from its Executive Departments, the Smithsonian Institution, the United States Fish Commission, and the National Museum, such articles and materials as illustrate the function and administrative faculty of the Government in time of peace and its resources as a war power, tending to demonstrate the nature of our institutions, and their adaptation to the wants of the people; and to secure a complete and harmonious arrangement of such a Government exhibit, a Board shall be created to be charged with the selection, preparation, arrangement, safe-keeping, and exhibition of such articles and materials as the heads of several departments and the Directors of the Smithsonian Institution and National Museum may respectively decide shall be embraced in said Government exhibit. The President may also designate additional articles for exhibition. Such Board shall be composed of one person to be named by the head of each Executive Department, and one by the Directors of the Smithsonian Institution and National

National Museum, and one by the Fish Commission, such selections to be approved by the President of the United States. The President shall name the Chairman of said Board, and the Board itself shall select such other officers as it may deem necessary.

That the Secretary of the Treasury is hereby authorised and directed to place on exhibition, upon such grounds as shall be allotted for the purpose, one of the life-saving stations authorised to be constructed on the coast of the United States by existing law, and to cause the same to be fully equipped with all apparatus, furniture, and appliances now in use in all life-saving stations in the United States, said building and apparatus to be removed at the close of the Exhibition and re-erected at the place now authorised by law.

Section 17. That the Secretary of the Treasury shall cause a suitable building or buildings to be erected on the site selected for the World's Columbian Exposition for the Government exhibits as provided in this Act, and he is hereby authorised and directed to contract therefor in the same manner and under the same regulations as for other public buildings of the United States; but the contracts for said building or buildings shall not exceed the sum of four hundred thousand dollars, and for the remainder of the fiscal year and for the fiscal year ending thirtieth June, eighteen hundred and ninety-one, there is hereby appropriated for said building or buildings, out of any money in the Treasury not otherwise appropriated, the sum of one hundred thousand dollars. The Secretary of the Treasury shall cause the said building or buildings to be constructed, as far as possible, of iron, steel, and glass, or of such other material as may be taken out and sold to the best advantage, and he is authorised and required to dispose of such building or buildings or the material composing the same, at the close of the Exposition, giving preference to the city of Chicago, or to the said World's Exposition of eighteen hundred and ninety-two, to purchase the same at an appraised value to be ascertained in such manner as he may determine.

Section 18. That for the purpose of paying the expenses of transportation, care, and custody of exhibits by the Government, and the maintenance of the building or buildings hereinbefore provided for, and the safe return of articles belonging to the said Government exhibit, and for the expenses of the Commission created by this Act, and other contingent expenses, to be approved by the Secretary of the Treasury, upon itemised accounts and vouchers, there is hereby appropriated for the remainder of this fiscal year and for the fiscal year ending thirtieth June, eighteen hundred and ninety-one, out of any money in the Treasury not otherwise appropriated, the sum of two hundred thousand dollars, or so much thereof as may be necessary: Provided that the United States shall not be liable, on account of the erection of buildings, expenses of the Commission or any of its officers or employees, or on account of any expenses incident to or growing out of said Exposition, for a sum exceeding in the aggregate one million five hundred thousand dollars.

Section 19. That the Commissioners and alternate Commissioners appointed under this Act shall not be entitled to any compensation for their services out of the Treasury of the United States, except their actual expenses for transportation and the sum of six dollars per day for subsistence for each day they are necessarily absent from their homes on the business of said Commission. The officers of said Commission shall receive such compensation as may be fixed by said Commission, subject to the approval of the Secretary of the Treasury, which shall be paid out of the sums appropriated by Congress in aid of such Exposition.

Section 20. That nothing in this Act shall be so construed as to create any liability of the United States, direct or indirect, for any debt or obligation incurred, nor for any claim for aid or pecuniary assistance from Congress or the Treasury of the United States in support or liquidation of any debts or obligations created by said Commission in excess of the appropriations made by Congress therefor.

Section 21. That nothing in this Act shall be so construed as to override or interfere with the laws of any State, and all contracts made in any State for the purposes of the Exhibition shall be subject to the laws thereof.

Section 22. That no member of said Commission, whether an officer or otherwise, shall be personally liable for any debt or obligation which may be created or incurred by the said Commission.

Approved, 25th April, 1890.

APPENDIX F.

Customs Regulations.

THE following Regulations were issued by the Secretary of the United States Treasury, under date 5th November, 1891:—

1. It is the purpose of this Department to secure expedition and security to all articles imported for exhibition at the Chicago Exposition, without the exaction of customs duties, fees, or charges, and to arrange the proceedings on entry so as to afford the utmost convenience and despatch.

2. In order to obtain the benefits of this arrangement, every package destined for the Exposition should have affixed to it by the foreign shipper one or more labels representing the flag of the country to which it belongs. This label should be about 8 by 12 inches in size, and should bear across the face, in plain black letters, the inscription "Exposition at Chicago."

All packages should be plainly marked, as follows:—

- (1) "Collector of Customs, Chicago."
- (2) "Exhibits for Columbian Exposition."
- (3) Name of consignee or agent at the port of first arrival in the United States.
- (4) The shipping marks and numbers of the exhibitor.
- (5) Name and address of the exhibitor.

3. Every foreign exhibitor will prepare, in duplicate, a statement in the form of an invoice, which shall show the name of the exhibitor, the marks and numbers of the packages, with a description of their contents and a declaration of the quantity and the market value of each separate kind thereof in the country of production. This statement must be signed by the exhibitor, but will require no further verification. One of the invoices will be transmitted by mail to the Collector of Customs at Chicago, and the other to the consignee of the goods at the port of first arrival.

4. As a matter of convenience it is recommended that all packages intended for the Exposition shall be consigned to an agent or forwarder, or commissioner at the port of first arrival, who will attend to customs business incident to the transfer of packages from the importing vessel to a bonded route for transportation to Chicago.

All of the bonded transportation lines will discharge their freight at stations in Chicago to be arranged within the Exposition grounds, and packages marked as suggested in article 2 may be taken to their respective divisions as soon as they have been identified by the Customs officers.

5. *List of Companies, bonded for the transportation of Merchandise to Chicago, without appraisalment.*

6. The consignee of the merchandise at the first port of arrival must present at the Custom-house the invoice above described, with a bill of lading and an entry in duplicate made out upon the special form to be provided for this purpose by the Treasury Department, which shall show the name of the foreign shipper or owner, the name of the importing vessel, the marks and numbers of the packages, with a statement of the nature of their contents and of their foreign value, as declared in the invoice. The entry must also indicate the bonded route by which the goods are to be transported to Chicago, and must be signed by the consignee. No other declaration will be required. The goods will be consigned, on the customs entry, to "Collector of Customs, Chicago," and there need be no computation of duties upon this entry, but the amount charged against the bond of the transportation company shall be double the invoice value.

7. The collector will thereupon issue a special permit bearing the words, "Chicago Exposition," authorising the transfer of the goods from the ship to the bonded railroad for transportation to Chicago, and will record and file one of the entries in his office and send the other by mail, with the invoice, to the collector at Chicago.

8. The permit will be taken by the agent or consignee to the inspector on board the importing vessel, who will thereupon send the goods, by a cartman duly licensed, to be delivered under the supervision of a Customs' officer to the transportation company.

9. The consignee will also prepare a manifest of the goods, which, after being duly certified, will be handed to the conductor of the car carrying the same, and a duplicate copy must be sent by mail to the Collector of Customs at Chicago. Upon arrival at Chicago of any car containing such articles, the conductor or agent of the railroad company

company will report such arrival by the presentation of the manifest to the Customs' officer designated to receive it, who shall compare the same with the copy received by mail, and superintend the opening of the car, taking care to identify the packages by marks and numbers as described in the manifest. In case of the non-receipt of the manifests, the unloading of cars need not, for that reason, be delayed, but the invoice may be used to identify the packages.

10. Articles sent by foreign Governments to the Exposition, which are used solely for Government purposes, and are not intended for sale, will be admitted to entry at the exterior port of arrival on certificates of the proper foreign commissioner, without the production of invoice. But it is desired that the estimated value of each package shall be stated on the certificate or the bill of lading, in order that the pecuniary responsibility of the transportation company may be fixed.

11. These regulations will also apply to goods sent to the Exposition from foreign contiguous territory. All articles destined for the Exposition arriving from Canada on through cars under consular seal, and articles which are sent direct by vessel from any foreign port to Chicago, must be consigned by the foreign shipper to the "Collector of Customs" at that port, and on entry being made, as in the case of goods arriving at the seaboard, a permit will be issued for the transfer of the goods directly to the Exposition grounds.

12. The buildings and spaces set apart for the purposes of the Exposition are constituted "constructive bonded warehouses and yards," and all foreign articles placed therein under the supervision of the Customs' officers, and which have been specially imported for exhibition therein, will be treated the same as merchandise in bond. No warehouse entry will be required at Chicago in order to obtain entrance for such goods, but the latter will be kept under Customs' supervision in accordance with the general regulations governing merchandise in bonded warehouses, except as herein otherwise provided for. The collector at Chicago will keep a special record, in the form of a warehouse ledger, of every invoice, assigning serial numbers to the same in order of their reception, and the transportation entry received from the collector at the port of arrival will be considered the warehouse entry.

13. After the packages have been placed in the respective positions assigned to them by the officers of the Exposition, they will be opened by an officer of the Customs, who shall primarily identify the contents with the invoice only as to quantity and character. Due examination of the contents and appraisement of values will be subsequently made by the appraiser, who shall be furnished with the invoice of the articles to be appraised, and shall endorse his report of appraisement upon such invoice in like manner as if such articles were regularly entered for consumption or warehouse. The entry will then be liquidated, the full amount of duties ascertained, and the whole transaction entered upon the prescribed record. All the proceedings relating to the examination, appraisement, and liquidation shall be the same as on ordinary importations.

14. As, under the United States tariff, the cost of packages is made a part of the dutiable value of imported goods, the empty boxes, barrels, and casks from which imported articles have been taken in order to be displayed should be carefully preserved so as to be repacked for exportation at the close of the Exposition. Dutiable packing cases not exported will be subject to the payment of duty.

15. Packages containing articles imported for gratuitous distribution, or for actual use and consumption in restaurants, refreshment-rooms, &c., must be regularly entered for consumption, and duty paid thereon before being delivered by the Customs officers.

16. The articles, after having been received in the Exposition, will remain under the custody of the Customs officers, and must not be removed from the place assigned without a permit from the Collector of Customs or the officer who may be designated by him to grant such permit. In no case shall such articles be released from the custody of the Customs officers unless the same shall have been regularly withdrawn for consumption, for warehouse, or for export.

The requisite number of Customs inspectors will be stationed at every place containing foreign exhibits, each of whom will be placed in charge of a section, which shall be numbered and designated as a Customs Division.

A list of the articles entered for exhibit in his section will be furnished to each of such inspectors, who shall retain a copy thereof, certify the original, and transmit it to the Collector.

17. Sales may be made, during the Exposition, of articles imported for exhibition, but deliveries of the same will be allowed only at the close of the Exposition. For this purpose a regular withdrawal as from bond will be required, and duty must be paid according to law. In case the articles are sold for delivery at some port other than Chicago, a withdrawal may be made for transportation and rewarehouse, duty to be paid at the place of destination. Any exhibitor of articles which shall be sold may authorize withdrawal of the same by the purchaser, such authority to be contained in a written notice to the Collector at Chicago. After the filing of such notice the person specified in the same shall be recognised as entitled to all the rights and subject to all the liabilities of the original importer.

18. Withdrawal from bond cannot be made for less than one entire package, but in case of accidental damage or destruction it is not intended to assess duties upon such articles as shall not have entered into actual consumption in this country. On
articles

articles which shall have suffered diminution or deterioration from incidental handling and necessary exposure, the duty, if paid, will be assessed according to the appraised value at the time of withdrawal for consumption.

19. At the close of the Exposition all goods intended for exportation will be transported in bond to the seaboard or exterior port, and exported there from under the general regulations for immediate export in bond, as modified by special regulations to be in due time provided.

20. Any exhibitor who may import merchandise in excess of that which he desires to place on view in the Exposition may make regular warehouse entry of the same on its arrival at Chicago, whereupon it shall be taken to a United States bonded warehouse and stored without payment of duty, subject to the regulations provided for bonded goods.

Withdrawals of merchandise stored under these conditions, if made for the purpose of placing the same within the Exposition, will be treated under the provisions for entry on arrival at first port of entry, and no duty will be required to be paid. Such merchandise must be delivered at the Exposition in charge of a Customs' officer.

Should any merchandise be abandoned by the owner at the close of the Exposition, it will be placed in a general order warehouse for twelve months, and, if then unclaimed, will be sold for account of the owner.

21. The privileges granted by virtue of these regulations are intended solely for the benefit of exhibitors at the World's Columbian Exposition, and with the view of relieving them, so far as practicable, of delays and vexations in connection with the customs business pertaining to their importations.

Any attempt to take advantage of these regulations in order to evade the tariff laws of the United States will subject the offender to all the penalties prescribed by those laws, including confiscation of goods and fine and imprisonment.

22. The regulations issued by this Department on January 7, 1891, are hereby revoked, and the foregoing adopted in lieu thereof.

CHARLES FOSTER,
Secretary.

APPENDIX G.

General Regulations for Foreign Exhibitors.

(Issued by the Director-General of the Exhibition.)

1. The Exhibition will be held on the shore of Lake Michigan, in the city of Chicago, and will be opened on the 1st day of May, 1893, and closed on the 30th day of October following.

2. All Governments have been invited to appoint commissions for the purpose of organising their departments of the Exhibition. The Director-General should be notified of the appointment of such foreign commissions as soon as the appointment is made.

Diagrams of the buildings and grounds will be furnished to the foreign commissions on or before 1st January, 1892, indicating the localities to be occupied by each nation, subject, however, to revision and readjustment.

3. Applications for space and negotiations relative thereto must be conducted with the commission of the country where the article is produced.

4. Foreign commissions are requested to notify the Director-General not later than 1st June, 1892, whether they desire any increase or diminution of the space offered them, and the amount.

5. Before 1st November, 1892, the foreign commissions must furnish the Director-General with approximate plans showing the manner of allotting the space assigned to them, and also with lists of their exhibitors and other information necessary for the preparation of the official catalogue.

Products brought into the United States at the ports of Portland (Maine), Boston, New York, Philadelphia, Baltimore, Tampa, New Orleans, San Francisco, Wilmington, Portland (Oregon), Port Townsend (Wash.), Seattle (Wash.), Tacoma (Wash.), and Chicago (Ill.), or at any other port of entry intended for display at the International Exhibition, will be allowed to go forward to the Exhibition buildings, under proper supervision of Customs' officers, without examination at such ports of original entry, and at the close of the Exhibition will be allowed to go forward to the port from which they are to be exported. No duties will be levied upon such goods, unless entered for consumption in the United States.

6. The transportation, receiving, unpacking, and arranging of the products for exhibition will be at the expense of the exhibitor.

7. The installation of heavy articles requiring special foundations or adjustment, should, by special arrangement, begin as soon as the progress of the work upon the buildings will permit. The general reception of articles at the Exhibition buildings will commence on 1st November, 1892, and no articles will be admitted after 10th April, 1893.

8. Space assigned to foreign commissions, and not occupied on the 10th day of April, 1893, will revert to the Director-General for reassignment.

9. If products are intended for competition it must be so stated by the exhibitor; if not, they will be excluded from the examination by the international juries.

10. An Official Catalogue will be published in English, French, German, and Spanish. The sale of catalogues is reserved to the World's Columbian Exposition.

The twelve departments of the classification which will determine the relative location of articles in the Exhibition—except in such collective exhibits as may receive special sanction—also the arrangement of names in the catalogue, are as follows:—

- A. Agriculture, Forest Products, Forestry, Machinery, and Appliances.
- B. Viticulture, Horticulture, Floriculture.
- C. Live Stock: Domestic and Wild Animals.
- D. Fish, Fisheries, Fish Products, and Apparatus for Fishing.
- E. Mines, Mining, and Metallurgy.
- F. Machinery.
- G. Transportation: Railways, Vessels, Vehicles.
- H. Manufactures.
- J. Electricity.
- K. Fine Arts: Pictorial, Plastic, and Decorative.
- L. Liberal Arts: Education, Engineering, Public Works, Architecture, Music, and the Drama.
- M. Ethnology, Archæology, Progress of Labour and Invention, Isolated and Collective Exhibits.

11. Foreign commissions may publish catalogues of their respective sections.

12. Exhibitors will not be charged for space.

A limited quantity of steam and water power will be supplied gratuitously. The quantity of each will be settled definitely at the time of the allotment of space. Any power required by the exhibitor in excess of that allowed will be furnished by the World's Columbian Exposition at a fixed price. Demands for such excess of power must also be settled at the time of the allotment of space.

13.

13. Exhibitors must provide, at their own cost, all show-cases, shelving, counters, fittings, &c., which they may require, and all countershafts, with their pulleys, belting, &c., for the transmission of power from the main shafts in the building where the exhibit is located. All arrangements of articles and decorations must be in conformity with the general plan adopted by the Director-General.

The World's Columbian Exposition will take precautions for the safe preservation of all objects in the Exhibition; but it will in no way be responsible for damage or loss of any kind, or for accidents by fire or otherwise, however originating.

14. Favourable facilities will be arranged by which exhibitors or foreign commissions may insure their own goods.

Foreign commissions may employ watchmen of their own choice to guard their goods during the hours the Exhibition is open to the public, subject to the rules and regulations of the Exposition.

15. Foreign commissions, or such agents as they may designate, shall be responsible for the receiving, unpacking, and arrangement of objects, as well as for the removal at the close of the Exposition; but no person shall be permitted to act as such agent until he can give to the Director-General written evidence of his having been approved by the proper commission.

16. Each package must be addressed "To the Commission (name of country) at the World's Columbian Exposition, Chicago, United States of America," and should have at least two labels affixed to different but not opposite sides of each case, and give the following information:—

17. (1) The country from which it comes; (2) name of firm or of the exhibitor; (3) residence of the exhibitor; (4) department to which objects belong; (5) total number of packages sent by that exhibitor; (6) serial number of that particular package.

18. Within each package should be a list of all objects.

19. If no authorised person is at hand to receive goods on their arrival at the Exposition buildings they will be removed, without delay, and stored at the risk and cost of whomsoever it may concern.

20. Articles that are in any way dangerous or offensive, also patent nostrums and empirical preparations, whose ingredients are concealed, will not be admitted.

21. The removal of goods on exhibition will not be permitted prior to the close of the Exhibition.

22. Sketches, drawings, photographs, or other reproductions of articles exhibited will only be allowed upon the joint assent of the exhibitor and the Director-General; but views of portions of the building may be made upon the Director-General's sanction.

23. Immediately after the close of the Exhibition, exhibitors shall remove their effects, and complete such removal before 1st January, 1894; goods then remaining will be removed and sold for expenses, or otherwise disposed of under the direction of the World's Columbian Exposition.

24. Each person who becomes an exhibitor thereby acknowledges and agrees to be governed by the rules and regulations established for the government of the Exhibition.

Special regulations will be issued concerning the exhibition of fine arts, awards, the organisation of the international juries, and sales of special articles within the buildings, and on other points not touched upon in these preliminary instructions.

25. All communications concerning the Exhibition will be addressed to the Director-General, World's Columbian Exposition, Chicago, Illinois, U.S.A.

The management reserves the right to explain or amend these regulations, whenever it may be deemed necessary for the interest of the Exhibition.

GEORGE R. DAVIS,
Director-General.

APPENDIX GA.

Traffic Department: Information for Foreign Exhibitors.

ARRANGEMENTS WITH TRANSPORTATION COMPANIES.

(1) The Freight Traffic Associations of this country, of which the leading transportation lines are members, have uniformly adopted a tariff of full rates on the forward journey (no charge to be less than for 100 lb. at the class rates applicable thereto, nor less than 25 cents), granting free return of exhibits to all seaboard ports, provided ownership remains unchanged. This arrangement, however, does not apply to horses and other fancy animals returned to Atlantic seaboard ports, on which no reduced rates will be made in either direction.

The following is the schedule of standard class rates in effect at the present time (July, 1892) between the principal seaboard ports and Chicago:—

CLASS RATES—in cents per 100 lb.

From	1st class.	2nd class.	3rd class.	4th class.	5th class.	6th class.	A class.	B class.	C class.	D class.	E class.
New York	75	65	50	35	30	25
Boston, Mass.	75	65	50	35	30	25
Philadelphia, Pa.	69	59	43	33	28	23
Baltimore, Md.	67	57	47	32	27	22
Portland, Me.	75	65	50	35	30	25
Newport News, Va.	59	51	43	29	25	20
Norfolk, Va.	59	51	43	29	25	20
Montreal, Can.	65	57	44	31	26	22
Tampa, Fla.	227	196	168	149	128	104	86	67	69	49	106
Mobile, Ala.	100	85	73	55	46	40	30	31	30	25	33
New Orleans, La.	100	85	73	55	46	40	30	31	30	25	33
Galveston, Tex.	140	116	97	80	65	...	69	63	59	52	44
San Francisco, Cal.	390	340	270	210	185	...	190	170	135	120	110
Portland, Ore.	390	340	270	210	185	...	190	170	135	120	110
Pt. Townsend, Wash. ...	390	340	270	210	185	...	190	170	135	120	110
Tacoma, Wash.	390	340	270	210	185	...	190	170	135	120	110
Vancouver, B.C.	390	340	270	210	185	...	190	170	135	120	110

(a) The inland classifications of articles can be obtained from the agents of steamship lines running to the United States, and from the agents of American railways in foreign countries.

(b) The class rates quoted, will, it is believed, cover such exhibits as are not of a particularly high grade. Fine goods, such as cabinets or show-cases, baskets, furniture, wax figures, fur goods, plate or mirror glass, which are classified from one and one-half to double first-class, are charged for at proportionately higher rates than those scheduled.

(c) Exceptionally fine, expensive, or fragile foreign exhibits, such as paintings, pictures, statuary, jewellery, gold and silver ware, and bric-a-brac, will not be accepted for transportation by the railroad companies, but should be delivered to the express companies for carriage.

(d) To the foregoing class rates there must be added 6 cents per 100 lb., with a minimum of 50 cents for any single shipment from one consignor to one consignee. This is a terminal charge made by the Exposition management covering the switching

switching of exhibits into the Exposition grounds from the points of intersection with railroads entering the grounds, and the placing of them on or adjacent to the spaces allotted.

This charge of 6 cents per 100 lb. is made in each direction, and will apply with the minimum aforesaid.

(2) PREPAYMENT OF FREIGHT CHARGES—HOW TO OBTAIN RATES.

(a) Freight charges on exhibits, including the terminal charge, must be prepaid at point of foreign origin or at the American port of first arrival. The goods must be delivered at the Exposition clear of all charges incident to their transportation. No transportation or other charges will be advanced by the Exposition management.

(b) The rates for transporting goods to the Exposition grounds at Chicago may be obtained from the transportation companies at points where goods are first offered for shipment. The foregoing arrangements for reduced rates do not in any way alter or affect the carriers' freight classifications nor their conditions for receiving and transporting goods, nor change in any way the rules of such companies, except to require the prepayment of freight and terminal charges.

(3) THROUGH BILLS OF LADING—NOTIFICATION OF SHIPMENT.

(a) Bills of lading covering exhibits must show the precise routes by which such exhibits are to be transported, specifying in detail every carrier from starting-points to the Exposition, in order that exhibited articles entitled to free return may be returned by the exact routes first used.

(b) On exhibits which are or are not covered by through bills of lading from foreign ports there will be no charge for transfer at seaboard points (except that on heavy or bulky articles exceeding 3 tons each in weight, the extra cost of handling will be charged for in both directions under special agreements to be made in advance through the railroad foreign freight agents or authorised representatives of the steamship companies abroad).

NOTE.—Exhibits from Australian and New Zealand ports arriving at the port of San Francisco will be subject to a transfer charge from steamer to rail and *vice versa*, of 1 dollar per ton, with a minimum of 1 dollar 50 cents for any single shipment.

(c) Two copies of each bill of lading must be sent by the shipper to the Director-General, World's Columbian Exposition, Chicago. Letters of advice should also be forwarded, giving information of the shipments made and full particulars in regard to articles of extraordinary dimensions or excessive weight.

(4) EXHIBITS BY EXPRESS.

The Express Companies are bonded transportation lines from the following ports:—

(Ports and Express Companies enumerated, and the various rates to be charged stated.)

(5.) CUSTOMS REGULATIONS—HOW TO CONSIGN EXHIBITS.

The Customs Regulations, issued by the Secretary of the Treasury of the United States, 5th November, 1891, require every foreign exhibitor to procure in duplicate a statement in the form of an invoice, which shall show the name of the exhibitor, the marks and numbers of the packages, with a description of their contents and a declaration of the quantity and the market value of each separate kind thereof in the country of production. This statement must be signed by the exhibitor, but will require no consular verification. One copy of this statement or invoice will be transmitted by mail to the Collector of Customs at Chicago, and the other to the consignee of the goods at the American port of first arrival, and should be forwarded by the steamer carrying the goods or by the one preceding it, otherwise the goods will be sent to the warehouse and storage and other charges incurred. In the circular referred to above it is provided that "articles imported from foreign countries for the sole purpose of exhibition at the said Exposition, upon which there should be a tariff or customs duty, will be admitted free of payment of duty or charges." Agents or forwarders to whom exhibits are consigned at port of entry will be expected to take prompt action in looking to the immediate transportation of said exhibits under bond to Chicago. The compensation or fees of such forwarders is a matter which must be arranged between the exhibitor or owner and the forwarder. If either of the following transportation or express companies named are selected as forwarders, no charge will be made by such company for the preparation of necessary papers at port of entry.

The companies bonded for the immediate transportation of merchandise (exhibits) to Chicago, together with the names of the agents of the respective companies to whom goods should be consigned and invoices sent, are:—

(Here the names of Ports, Companies, and Agents.)

The Exposition grounds and buildings thereon will be treated as bonded warehouses. If no authorised person is at hand to take charge of the goods within a reasonable time after their arrival at the Exposition they will be removed and stored at the cost and risk of whomsoever it may concern.

The Director-General will decide what goods shall be accepted as exhibits; any foreign articles not so accepted will be treated as dutiable merchandise and stored in warehouse within Exposition grounds, and may be withdrawn upon payment of duties and charges at any time.

(6)

(6) REMOVAL OF GOODS.

The Exposition will close on the 30th of October, 1893. The removal of exhibits will not be permitted prior to that date, and must be completed before January 1st, 1894. In the event of the exhibits not having changed ownership during the Exposition, and being therefore entitled to free return, a certificate to this effect will be issued on application to the proper officer of the Exposition. Such certificates, together with paid freight bills or the original Bills of Lading and releases, showing that the exhibit paid full rates on the forward journey, will, on presentation to the Joint Railroad Agent at Jackson Park (World's Fair Grounds), entitle exhibits to free transportation to the seaboard port over the same routes first used. No charges will be advanced on articles returned free, nor be allowed to follow the goods. Certificates and releases, which must be obtained by the exhibitor, must be attached to manifests. Persons accompanying exhibits which are returned free will be charged fare. On returned exhibits prepayment at Chicago will be required of the 6 cents per 100 lb. terminal charge thereat, and also a charge of 5 cents per 100 lb., with a minimum of 1 dollar for any single shipment not exceeding 3 tons, this charge being for transfer at the seaboard to steamer. On articles each exceeding 3 tons in weight, the extra cost of handling will be charged for under special agreement to be made in advance as set forth in paragraph 3, section B.

Approved:—

HARLOW N. HIGINBOTHAM, President, World's Columbian Exposition.

APPENDIX H.

Proceedings at the Opening of the World's Columbian
Exposition.

(1st May, 1893.)

Music by Orchestra—"Grand Columbian March." John R. Paine.

Prayer by REV. W. H. MILBURN, Chaplain to Congress.

Poem—Written for the occasion by W. A. CROFFUTT, of Washington D.C., read
by MISS COUTHONY, attired in Spanish costume. The poem is as follows:—

THE PROPHECY.

Sadly Columbus watched the nascent moon
Drown in the gloomy ocean's western deeps.
Strange birds that day had fluttered in the sails
And strange flowers floated 'round the wandering keel,
And yet no land. And now, when through the dark
The Santa Maria leaped before the gale
And angry billows tossed the caravels
As to destruction, Gomezrascon came
With Capt. Pinzon through the frenzied seas
And to the Admiral brought a parchment scroll,
Saying: "Good master, read this writing here—
An earnest prayer it is from all on board.
The crew would fain turn back in utter fear;
No longer to the Pole the compass points;
Into the zenith crops the northern star.
You saw but yester eve an albatross
Drop dead on deck beneath the flying scud;
The Devil's wind blows madly from the east
Into the land of Nowhere, and the sea
Keeps sucking us adown the maelstrom's maw.
Francisco says the edge of earth is near
And off to Erebus we slide unhelmed.
Last Sunday night Diego saw a witch
Dragging the Nina by her forechains west
And wildly dancing on a dolphin's back;
And as she danced the brightest star in Heaven
Slipped from its leash and sprang into the sea,
Like Lucifer, and left a trail of blood.
I pray thee, Master, turn again to Spain, obedient to the omens, or
perchance,
The terror-stricken crew to escape their doom,
May mutiny and———"
"Gomezrascon, peace,"
Exclaimed the Admiral; "Thou has said enough;
Now, prithee, leave me; I would be alone."
Then eagerly Columbus sought a sign
In sea and sky and in his lonely heart;
Finding, instead of presages of hope,
The black and ominous portents of despair.
As thus he mused he paced the after-deck
And gazed upon the luminous waves astern.
Strange life was in the phosphorescent foam,
And through the goblin glow there came and went,
Like elfin shadows on an opal sea,
Prophetic pictures of the land he sought.
He saw the end of his victorious quest;
He saw ablaze on Isabella's breast,
A string of Antillean jewels rest—
The islands of the West.
He saw invading Plenty dispossess
Old Poverty; the land with bounty bless.
And through the wretched caverns of distress
Walk star-eyed Happiness.
He saw the Bourbon and Braganza prone,
For ancient error tardy to atone,
Giving the plundered people back their own
And flying from the throne.
He saw an Empire, radiant as the day,
Harnessed to law, but under Freedom's sway,
Proudly arise, resplendent in array,
To show the world the way.
He saw celestial Peace in mortal guise
And, filled with hope and thrilled with high surprise,
Lifting its tranquil forehead to the skies,
A vast Republic rise.

He

He saw, beyond the hills of golden corn,
Beyond the curve of Autumn's opulent horn
Ceres and Flora laughingly adorn
The bosom of the morn.

He saw a cloth of gold across the gloom,
An arabesque from evolution's loom,
And from the barren prairies' driven spume,
Imperial cities bloom.

He saw an iron dragon dashing forth
Along an iron thoroughfare—south, north,
East, west, uniting in beneficent girth
Remotest ends of earth.

He saw the lightning run an elfin race
Where trade, love, grief, and pleasure interlace,
And absent ones annihilate time and space,
Communing face to face.

He saw Relief through deadly dungeons grope ;
Foes turned to brothers, black despair to Hope,
And cannon rust upon the grass-grown slope
And rot the gallows' rope.

He saw the babes on labour's cottage floor ;
The bright walls hung with luxury more and more,
And comfort, radiant with abounding store,
Wave welcome at the door.

He saw the myriad spindles flutter round ;
The myriad mill-wheels shake the solid ground ;
The myriad homes where jocund joy is found,
And love is throned and crowned.

He saw exalted Ignorance under ban,
Though panoplied in force since time began,
And Science, consecrated, lead the van,
The providence of man.

The picture came and paled and passed away.
And then he said to Pinzon, in the gloom :
" Now, Martin, to thy waiting helm again.
Haste to the Pinta ; westward keep the prow,
For I have had a vision full of light.
Keep her prow westward in the sunset's wake,
From this hour hence, and let no man look back."

Music—Overture, "Rienzi"—Wagner.

Address of the DIRECTOR-GENERAL, as follows :—

The dedication of these grounds and buildings for the purpose of an international exhibition took place 21st October, at which time they were accepted for the objects to which they were destined by the action of the Congress of the United States. This is not the time nor the place, neither will it be expected of me, to give a comprehensive *résumé* of the strenuous efforts which have been put forth to complete the work to which we invite your inspection to-day. I may be permitted, however, to say a word in praise of, and in gratitude to my co-officers and official staff, who form the great organisation which made this consummation possible.

This Exposition is not the conception of any single mind, it is not the result of any single effort, but it is the grandest conception of all the minds, and the best obtainable result of all the efforts put forth by all the people who have in any manner contributed to its creation. The great commanding agencies through which the Government has authorised this great work to proceed are : The National Commission, consisting of 108 men and their alternates, selected from the several States and territories, presided over by the Hon. Thomas W. Palmer, of Michigan ; the corporation of the State of Illinois, known as the World's Columbian Exposition, consisting of forty-five directors, presided over by H. N. Higinbotham, of Chicago ; and the Board of Lady Managers, consisting of 115 women and their alternates—selected from the several States—presided over by Mrs. Potter Palmer, of Chicago. To these great agencies, wisely selected by Congress, each performing its special function, the gratitude of the people of this country, and the cordial recognition of all these friendly foreign representatives are due.

To perfect from these agencies an efficient organisation was our first duty, and it was successfully accomplished, at the outset through committees, subsequently by great executive departments ; and through these departments the systematic, vigorous, and effective work has progressed. Through the Department of Administration, the Department of Finance, the Department of Works, and the great Exhibit Departments, the plan and scope of a grand international exposition have been worked worked out.

The Department of Finance, composed of members of the Illinois corporation, has, with a disinterestedness remarkable, with courage undaunted, successfully financed the Exposition, and has provided for the great work upward of 20,000,000 dollars. The Department of Works, and its many bureaus of artists, architects, engineers, and builders, have transformed these grounds which, twenty-one months ago, were an unsightly, uninviting, and unoccupied stretch of landscape, into the beauty and splendor of to-day. They have conspicuously performed their functions, and these grand avenues, these Venetian waterways, the finished landscapes, the fountains, and sculptures, and colonnades, and these grand palaces stand out as a monument to their genius and their skill, supplemented by the labour of that great army of skilled artizans and workmen, all citizens of this republic.

The chiefs of the great departments who have exploited this mighty enterprise, and gathered here the exhibits forming the picture that is set in this magnificent frame, have confirmed the wisdom of their selection. No State or territory of the Union has escaped their voices ; no land on the globe that has a language but has been visited, and the invitation of the President of the United States personally presented. Fortunately, at the inception of this enterprise our Government was, and still is, at peace with the whole world. Commissioners were sent to Europe, to Asia, to Australia, British North America, and to the islands of the seas, so that to-day the whole world knows and is familiar with the significance of the great peace festival we are about to inaugurate upon this campus, and all the nations join in celebrating the event which it commemorates.

This inclosure, containing nearly 700 acres, covered by more than 400 structures, from the small state pavilion, occupying an ordinary building site, to the colossal structure of the manufactures and liberal arts building, covering over 30 acres, is filled and crowded with a display of the achievements and products of the mind and hand of man such as has never before been presented to mortal vision.

The habits, customs, and life of the peoples of our own and foreign lands are shown in the variegated plaisance ; those stately buildings on the north are filled with the historical treasures and natural products of our several States. The artistic, characteristic, and beautiful edifices, the headquarters

quarters of foreign commissions, surrounding the Gallery of Fine Arts, which in itself will be an agreeable surprise to the American beholders, constitute the grand central zone of social and friendly amenities among the different peoples of the earth.

Surrounding this grand plaza where we stand, and reaching from the north pond to the extreme south, is the great mechanical, scientific, industrial, and agricultural exhibition of the resources and products of the world. These have been secured from the four quarters of the globe, and placed in systematic order under the supervision of these great departments, and while all the material upon the grounds is not yet in place I am gratified to be able to present to the President of the United States at this time the official catalogue containing a description, and the location of the exhibits of 4,000 participants in the Exposition. The number of exhibitors will exceed 60,000 when everything is in place.

The citizens of our country are proud, and always will be proud of the action of the Congress of the United States of America in authorising and directing this celebration to take place, for the appropriation of more than \$5,000,000 in its aid, and for the unswerving support and encouragement of the officers of the Government.

To the States of the Union we are largely indebted for active and substantial support. A sum in excess of \$6,000,000 has been raised and expended by the states and territories for their official use in promoting their own interests conjointly with the general success of the exhibition.

To the foreign nations who have a representation upon these grounds never before witnessed at any exposition, as shown by the grand exhibits they have brought here, and the hundreds of official representatives of foreign Governments who are present on this occasion, we bow in grateful thanks. More than \$6,000,000 have been officially appropriated for these commissions in furtherance of their participation in the exposition. The great nations of Europe and their dependencies, are all represented upon these grounds. The Governments of Asia and of Africa, and the republics of the Western Hemisphere, with but few exceptions, are here represented.

To the citizens and corporation of the city of Chicago, who have furnished \$11,000,000 as a contribution, and in addition have lent the management \$5,000,000 more, are due the grateful acknowledgments of our own people, and of all the honoured guests who share with us the advantages of this great international festival.

To the tens of thousands of exhibitors who have contributed on a larger scale than all others combined, we are under the deepest obligations for their interest and co-operation. To the women of Chicago and our great land, whose prompt, spontaneous, and enthusiastic co-operation in our work turned the eyes of the world towards the exposition as towards a new star of the east—an inspiration for womanhood everywhere—we extend our cordial and unstinted recognition.

It is our hope that this great exposition may inaugurate a new era of moral and material progress, and our fervent aspiration that the association of the nations here may secure not only warmer and stronger friendships, but lasting peace throughout the world.

The grand concerted illustration of modern progress which is here presented for the encouragement of art, of science, of industry, of commerce, has necessitated an expenditure, including the outlay of our exhibitors, largely in excess of \$100,000,000. We have given it our constant thought, our most devoted service, our best energy; and now, in this central city of this great republic, on the continent discovered by Columbus, it only remains for you, Mr. President, if in your opinion the exposition here presented is commensurate in dignity with what the world should expect of our great country, to direct that it shall be open to the public, and when you touch this magic key the ponderous machinery will start in its revolutions, and the activities of this exposition will begin.

THE PRESIDENT OF THE UNITED STATES then spoke as follows:—

I am here to join my fellow citizens in the congratulations which befit this occasion. Surrounded by the stupendous results of American enterprise and activity, and in view of magnificent evidences of American skill and intelligence, we need not fear that these congratulations will be exaggerated. We stand to-day in the presence of the oldest nations of the world, and point to the great achievements we here exhibit, asking no allowance on the score of youth.

The enthusiasm with which we contemplate our work intensifies the warmth of the greeting we extend to those who have come from foreign lands to illustrate with us the growth and progress of human endeavour in the direction of a higher civilisation.

We who believe that popular education and the stimulation of the best impulses of our citizens lead the way to a realisation of the proud national destiny which our faith promises, gladly welcome the opportunity here afforded us to see the results accomplished by efforts which have been exerted longer than ours in the field of man's improvement, while in appreciative return we exhibit the unparalleled advancement and wonderful accomplishments of a young nation, and present the triumphs of a vigorous, self-reliant, and independent people. We have built these splendid edifices, but we have also built the magnificent fabric of a popular government, whose grand proportions are seen throughout the world. We have made and here gathered together objects of use and beauty, the products of American skill and invention. We have also made men who rule themselves.

It is an exalted mission in which we and our guests from other lands are engaged, and we co-operate in the inauguration of an enterprise devoted to human enlightenment; and in the undertaking we here enter upon we exemplify in the noblest sense the brotherhood of nations.

Let us hold fast to the meaning that underlies this ceremony, and let us not lose the impressiveness of this moment. As by a touch the machinery that gives life to this vast Exposition is now set in motion, so at the same instant let our hopes and aspirations awaken forces which in all time to come shall influence the welfare, the dignity, and the freedom of mankind.

The President then touched the key before him, and the band played "America," and the ceremony was brought to a close.

APPENDIX I.

Regulations governing Awards.

Rule I. Conformably to the determination of the Commission "awards shall be granted upon specific points of excellence or advancement formulated in words by a board of judges or examiners, who shall be competent experts."

Board of Judges.

Rule II. This board of judges, which shall be composed, so far as practicable, of competent experts, shall be divided into thirteen Committees, one of which shall be assigned to each of the thirteen great departments of the Exposition, as recognised by the classification adopted by the World's Columbian Commission; provided, however, that the Committees assigned to the Departments of Live Stock, Agriculture, and Horticulture shall be subdivided into such sub-Committees as the Executive Committee on Awards shall deem expedient, and each such sub-Committee shall perform the duties assigned to it by the Executive Committee on Awards. The number of judges composing this board, and each Committee thereof, shall hereafter be determined. There shall be one or more women judges upon all Committees authorised to award prizes for exhibits which may be produced in whole or in part by female labour; and the number of women upon such Committee shall be hereafter determined according to the method heretofore prescribed by said Commission, after conference with the President of the Board of Lady Managers and the Awards Committee thereof.

Individual Judges.

Rule III. The individual members of the said thirteen Committees shall be, so far as possible, competent experts, and shall perform such duties and examine such exhibits as shall be assigned them by the Executive Committee on Awards. Provided, however, that it shall be the right and duty of the Departmental Committee of each Department in every case where the character of the exhibit or the general interests involved be such as, in the judgment of a majority, to warrant and justify it, to notify the Executive Committee on Awards that there ought to be a Special Committee appointed to assist the individual judge in conducting the preliminary examination of a particular exhibit, and also indicating the number whereof such Special Committee shall consist, and thereupon the said Executive Committee on Awards shall, in every such case, promptly appoint such Special Committee; and in case the said Special Committee, or a majority thereof, shall be in accord with the conclusion of the individual judge, they shall endorse their approval on his report over their signatures; or in case the majority of such Special Committee shall disagree with the opinions of said individual judge, they shall make a report over their signatures of the result of their examination of such exhibit, and transmit the same to the Departmental Committee on Awards. There shall be a foreign representation upon each one of these thirteen Committees, and the number of foreign judges will be fixed when the character and extent of the participation of the various foreign nations shall have been ascertained.

Rule IV. Each Committee shall, at the call of the Executive Committee on Awards, organise by the election of a President, Vice-President, and Secretary, and shall keep a record of all returns and reports by the individual judges as hereinafter provided for.

Duties of Judges.

Rule V. It shall be the duty of each individual judge to make a report in writing, over his signature, of the result of the examination of each exhibit primarily examined by him, as each examination shall have been completed; and as to every exhibit so examined which he shall deem worthy of an award, he shall formulate in words the specific points of excellence or advancement disclosed thereby, and which, in his opinion, render it worthy of an award. Every report shall be submitted as soon as possible to the Committee of which such judge is a member, for a finding in the premises; and in every case where, by the vote of the majority of such Committee, it is determined that an exhibit is worthy of receiving an award, said Committee shall forthwith formulate in written words the specific points of excellence or advancement which, in its opinion, warrant the award, and transmit the same, certified by its President, or Vice-President, and Secretary, to the Executive Committee on Awards. And in case the finding of the Committee shall differ from the conclusion of the individual judge making the preliminary examination, either as to its being worthy of an award or as to the character of the points of excellence or advancement it possesses, it shall be so distinctly stated in the report of said Committee. In every case where the finding of the Departmental Committee coincides with the conclusion of the individual judge, the said Committee shall transmit with such finding the report of such individual judge to the Executive Committee on Awards; and in those cases where the finding of the Departmental Committee does not coincide with the conclusion of the individual judge, then the finding in each such case shall

shall be accompanied by the written report of one of its members who shall have examined the exhibit, formulating therein in words the specific points of excellence or advancement possessed by such exhibit. And in every case where the individual judge has been assisted by a Special Committee, as provided for in Rule III, and the majority of such Committee shall disagree with the conclusion of such individual judge, they shall likewise make a written report in the same manner and form as is provided to be made by the individual judge, and shall immediately transmit the same to the Committee of which they are members.

Rule VI. In every case where the finding of the Committee is not in accord with the conclusion of the individual judge, or of such assistant Special Committee, it shall be within the power of the Executive Committee on Awards, if in its judgment justice demands it, to refer the report back to the Committee of that department whence it emanated, with the direction to review and further consider the case, and report its finding under such review, without delay, to said Executive Committee on Awards, and such finding shall be conclusive.

Notice to Foreign Nations.

Rule VII. This Executive Committee on Awards shall communicate, through the Director-General of the World's Columbian Exposition, with the foreign Governments which have appointed commissions to represent them at the World's Columbian Exposition, or with the said commissions directly, stating the character of the awards, the grounds upon which they are to be granted, and the requirement that all judges shall be, so far as practicable, competent experts. And the foreign Governments shall be invited to recommend, previous to June 20, 1893, experts in the various departments, and from those named the Executive Committee on Awards may make selections. The especial attention of foreign Governments shall be called to the fact that there will be but one class or kind of medals, which will be made of bronze and be works of art, and be accompanied by parchment diplomas, on which shall be formulated the specific points of excellence presented by the exhibit receiving the award. Notice shall be given to all exhibitors, whether domestic or foreign, that the medals and diplomas to be awarded are by authority of the Congress of the United States, and are prepared by the Secretary of the United States Treasury.

Rule VIII. Should any exhibitor, domestic or foreign, become a judge under these rules, his or her exhibit shall be excluded from examination for award, but the Executive Committee on Awards may cause such exhibit to be examined, and a report thereon made to complete the history of the Exposition.

Right to examine Exhibits.

Rule IX. Any exhibitor may have his exhibit exempt from examination for award by notifying the Executive Committee on Awards; otherwise the Executive Committee on Awards shall have the right, through its regularly appointed judges, to examine every exhibit, domestic or foreign, whether presented by an individual, association of individuals, institution, Government, or department thereof.

Date of commencing work.

Rule X. The work of the judges shall commence not later than the 15th day of July, 1893, and shall progress uninterruptedly until the completion of the work assigned them, except in the Department of Live Stock, and in those departments where the nature of the exhibits requires renewal from time to time during the Exposition.

Rule XI. Upon the completion of the work of the judges, the results thereof shall be presented by the Executive Committee to the full Committee on Awards, which Committee shall in turn report to the World's Columbian Commission, or in its absence to the Board of Reference and Control, by whom the formal promulgation of the awards and the distribution of medals and diplomas shall be made with appropriate ceremonies.

Rule XII. In addition to the reports by the individual judges of the various exhibits, each of the thirteen Committees shall present a comprehensive report, signed by the President and Secretary, embodying the principal educational and interesting features of the groups and classes composing that department, accompanied by a list of exhibitors who have received awards, with the reports of the individual judges giving the reasons and considerations therefor, and this report shall be delivered to the Director-General, to be included in and to form part of the history of the Exposition; but this shall not be so construed as to prevent or interfere with the duty expected of each of the department chiefs to prepare and submit, as part of the official history of the Exposition a complete and comprehensive report of the work of his department.

Rule XIII. In the performance of the duties entrusted to the Executive Committee on Awards, any member thereof shall have the right to be present at the deliberations of the Committees herein provided for, and in all matters of review or other complication the said Executive Committee shall have the right to avail itself of the aid and service of any member or members of the Committee on Awards, and as well of the advice and assistance of any competent agency whose aid ought, in its best judgment, to be invoked.

GEORGE R. DAVIS, Director-General.

JOHN BOYD THACHER, Chairman, Executive Committee on Awards.

Administration Building, Exposition Grounds, Pavilion B, Chicago, June 8, 1893.

APPENDIX IA.

Rules Governing Awards : Cereals.

1. The examination of cereals will begin on or before 15th July.
2. The examination shall be conducted under the general rules herein laid down, in addition to which such special methods and rules as in the judgment of the expert, judges are required to make a thorough and practical examination of the different cereals, shall be adopted.
3. All grains produced by irrigation shall be passed upon separately from those produced under other conditions.
4. No grain or seeds shall be examined by the judges that are less than standard weight.
5. In the examination of grains which are used for food the following points shall be considered by the judge :—
 1. Weight.
 2. Yield.
 3. Whether true to name or variety.
 4. The early maturity of any grain shall be considered by the judges as a factor in determining the final award.
 5. In all cases where doubt exists as to the superiority of any sample under examination, the final result shall be made upon its value as a nutritive, this result to be obtained by chemical analysis.
 6. In all cases the statement of temperature and rain or snowfall should be given if possible, as they are valuable factors to be taken into consideration in the report of the judges.
 7. In addition to the above general rules the judges shall prepare and submit to the Chairman of the Executive Committee on awards, and the Chief of the Department of Agriculture, before beginning work, the special rules they will follow in examining cereals, fibres (animal and vegetable) and other raw products not contemplated by this memorandum.
 8. In examining oils, judges will consider absence of free acid, freedom from moisture and settlings, colour, and flavour.
 9. In examining seed products from cotton seed, thoroughness of decortication, freedom from hulls and lint, sweetness, and brightness in colour should be considered as prominent points in determining the award.
 10. In examining grass seeds and forage plants it will be necessary, in order that the judges may place a proper value upon the exhibit, to have with the exhibit a statement showing :—
 - a. The average acreage from which the exhibit was taken.
 - b. The character of soil where grown.
 - c. The average rainfall in locality where grown.

APPENDIX J.

American Patents.

THE following Act has been passed by the United States Congress :—

“AN ACT to protect foreign exhibitors at the World's Columbian Exposition from prosecution for exhibiting wares protected by American Patents and Trade-marks.”

Be it enacted by the Senate and House of Representatives of the United States of America, in Congress assembled : That no citizen of any other country shall be held liable for the infringement of any patent granted by the United States, or of any trade-mark or label registered in the United States, where the act complained of is or shall be performed in connection with the exhibition of any article or thing at the World's Columbian Exposition at Chicago.

Approved 6th April, 1892.

APPENDIX K.

Reports on Canadian Mode of Packing Fruit.

PACKING APPLES FOR DISTANT SHIPMENT.

Superintendent Canadian Fruit Exhibit, at the World's Columbian Exposition,

Dear Sir,

15 September, 1893.

In reply to your inquiry regarding the most approved method of packing apples for distant shipment, as practised by the best Canadian shippers, I give you the following notes:—

1. The most satisfactory package is the apple-barrel, the dimensions of which should be the same the world over, especially if they must compete in the same markets. Only clean, new barrels should be used, and these can be purchased with us at 25 dollars to 30 dollars per 100.

2. The method of packing is as follows:—Open the bottom end of the barrel; line the head with clean white paper; lay selected apples, fair samples of the contents of the barrel, stems down, against the head, in circular rows, till bottom is covered; then another layer to cover the openings left, stems the same; after this a basketful at a time may be emptied carefully in until the barrel is filled. The great point is to pack so closely that the fruit will not move about inside the package, when it is in transit, and, therefore, it is usual to set the barrel on a plank or on a floor, and after each basketful or two shake the barrel and settle the apples, also by hand into close juxtaposition. Fill to a couple of inches above the chime, and then press the tail end into place. This only bruises the bottom apples a little; the rest will be intact.

3. The best tool for pressing the head into its place, is the barrel header, which I have described as follows in *The Canadian Horticulturist*, September number for 1893.

"This barrel header works to perfection, and any blacksmith will make it for 75c. The part A A A is made of a small wagon tire with hinges at C C. D D are rods of half-inch round iron riveted to the frame 3 in. above the hinges on each side, but left to turn freely as a hinge. B is a piece of 2-in. plank nearly the size of the barrel head. Place the head on the fruit, then the header in position. Loosen the top hoops, bear down A to press the head in. Drive down the hoops and the head is in."

4. Careful selection is one of the most important elements of success. My own practice is to make one class of extra selected, which is fairly uniform in size and colour, and is free from blemishes. Then a class of selected, which lack in colour or uniformity. Then comes the second-class fruit which is blemished, and should be disposed of near home, either for cider or for evaporating.

5. When the barrels are filled, they should be well head-lined, and all hoops nailed in place; then the name and address of both consignor and consignee should be plainly stencilled upon the head end of the barrel.

In case of tender varieties for distant shipments, it sometimes pays to wrap the extra selected in tissue paper.

I am, &c.,

L. WOOLVERTON.

Hon. Dr. Renwick, Commissioner from New South Wales
to the World's Columbian Exposition.

THE

THE SHIPPING OF TENDER FRUITS.

Dear Sir,

In reply to your inquiry respecting the best method of shipping tender fruit, I would reply:—

1. Concerning the package.—For peaches and plums, choice samples going long distances, I would recommend the wooden crate as the most satisfactory. The size is as follows—length, 20 inches. Four pieces of $\frac{1}{2}$ inch stuff, 20 inches long and $5\frac{3}{4}$ inches wide, form the sides; and two pieces, each 4 inches wide, the top and bottom. These are nailed to two end pieces of half-inch lumber, each $4\frac{1}{2}$ inches by $11\frac{3}{4}$.

2. Packing.—To fill, remove the bottom so as to pack from the narrow side. Pack closely in rows, so that in opening and exposing for sale, they will present an even and attractive appearance. Fill an inch or two more than full, and press down so tightly that not one can move from its place, no matter how roughly handled. If the specimens are choice, each should be first wrapped in tissue paper, in order to preserve their delicate fresh appearance, and prevent rot from spreading from one to another on the journey.

3. Selection.—For peaches especially it pays to exercise the greatest care in selection. The best success is attained where fine red-checked, golden Crawford's can be found so uniform in size that a case may be filled with them, two deep, in regular layers. This package is suitable for peaches, plums, and pears; but for pears a bushel box is often used. Another very fine package for pears, if handled on the green side, is a keg holding seven-eighths of a bushel.

With all fruits the important point to overcome the difficulty of distant shipments and long exposure, next after tight and careful packing, is cold storage. Without this latter every other care is vain, for heat always hastens maturity.

Yours, &c.,

L. WOOLVERTON,

Superintendent Canadian Fruit Exhibit.

Hon. Dr. Renwick, Commissioner for New South Wales.

APPENDIX L.

Report on Smelting Process in Colorado, U.S.

REPORT UPON THE "PYRITIC" SMELTING PROCESS, AND A FEW
POINTS IN THE SILVER-LEAD SMELTING PRACTICE OF
COLORADO, U.S.A., AMERICA.(By G. E. JEWELL, B.S., late Chemist for the Pueblo Smelting and Refining Company, Colorado,
U.S.A.)Hon. Arthur Renwick, M.D., M.L.C., Executive Commissioner for N.S.W., Australia,
World's Columbian Exposition, Chicago, Illinois.

Sir, Colorado School of Mines, Golden, Colo. 9 October, 1893.

I have the honor to transmit to you herewith a report made at your request upon the new Pyritic Smelting Process, together with some notes upon a few recent points in the silver lead smelting practice of Colorado, with which are embodied descriptions and working drawings of a number of newly introduced metallurgical appliances.

I have, &c.,

G. E. JEWELL.

INTRODUCTION.

INTRODUCTION.

The smelting industry of Colorado is a very important one, and is, perhaps, second only to that of mining, upon which it, in some measure, depends. I say in some measure depends, because, although it is true that the ores must be mined before they can be smelted, it is none the less true that the extent to which the ores of the precious metals are produced from the mines, will bear a certain and positive relation to the capacity for their metallurgical treatment, possessed by the smelting works.

It will, therefore, be as well to regard these two industries as mutually dependent. If, then, we illustrate, by statistics, the amount of mineral handled in either of the operations of mining or smelting in this State, a very good idea of the magnitude of the other may be obtained therefrom.

I shall, for convenience sake, quote here a paragraph from the "Mineral resources of the United States" for the year 1891, which is as follows:—

"Colorado continues to lead as the greatest lead-smelting State. Returns from every works, which in some instances differ slightly from the published figures, show a total product of base bullion of 95,871 short* tons, which is equal to about 92,000 tons of refined lead.

All the companies reported the lead contents of "Mexican" ores smelted during the year 1891, the total reaching 4,259 short tons, thus showing that this supply constitutes a relatively unimportant addition to the ores of the State."

The same authority gives the production of copper for the nine years, 1883 to 1891 inclusive, as follows:—

Year 1883	1,152,652 lb.
" 1884	2,013,125 "
" 1885	1,146,460 "
" 1886	409,306 "
" 1887	2,012,027 "
" 1888	1,621,100 "
" 1889	1,170,053 "
" 1890	3,585,691 "
" 1891	6,336,878 "
				Total	19,447,292 lb.

and the gold and silver for the year 1891 is given as:—

Fine gold	222,525 oz., value	4,600,000 dollars.
Fine silver	21,160,000 "	27,358,384 "

The above figures give the State of Colorado the distinction of second rank in the production of gold, and first rank in the production of silver amongst the States of the Union.

I might in addition quote figures upon the production of ironstone and limestone, since these two bodies play an important part in smelting, but as the amount of those minerals which was actually used in silver-lead smelting is not tabulated, the publication of the total figures alone would be misleading.

From the above figures the magnitude of the silver-smelting operations in this State may be gathered, and it will readily be seen that, to adequately describe the processes involved in the treatment of the large masses of mineral from which the above-mentioned fine metals have been derived would, in the space allotted to this short report, be impossible.

I will, therefore, at the outset, disavow any intention of making this little paper a "complete" report upon the metallurgical practice of this section of America, either from the scientific or the purely practical standpoint. I have, indeed, disregarded the former aspect of this question almost entirely, and have introduced chemical formula in their symbolic form only where their presence was deemed necessary to the elucidation of some particular phase in the description of a process. There are so many text books published upon industrial chemistry and kindred branches, which give *in extenso* the whole range, as far as they have been determined, of blast and reverberatory furnace reactions, that they need not be repeated here.

The smelting practice has undergone many changes within the last ten years, many innovations have been introduced, some of which have proved themselves to be improvements, and have held their ground, whilst others have died a natural death, and have disappeared from practice; but their remains may still be seen among the lumber that has been allowed to accumulate about the works of some of the older companies, silent witnesses of the amount of experimenting that has been done in this line of research.

Although it has been said that a great many improvements have been made, none of them can be justly considered distinct inventions, but rather as alterations in the mechanical construction, and design of the various parts of the smelting appliances, and it is a noteworthy fact that those departures from the beaten track of German and Welsh practice, which have done most to advance the economy of argentiferous lead-smelting in Colorado, are those aiming directly at increased capacity, not of the works as a whole, by the multiplication of the furnaces, but by an increase in the size of the furnaces themselves, whereby a reduction in the labour charges has been effected, and more refractory ores successfully treated.

How

* 2,000 lb.

How great this increase in size has been may be well shown by comparing the area of a cross-section at the tuyeres of one of the furnaces in operation in Leadville ten years ago, with the area of the same section through one of the furnaces in operation to-day.

According to "Guyard," the furnaces in use at Leadville at that time were, with but few exceptions, of the circular type, the largest of which had at the tuyeres a diameter of 40 inches, which is equal to 1,256.6 square inches, and the capacity was from 18 to 20 tons per day of twenty-four hours.

The ordinary bullion furnace of the present time measures 96 inches x 36 inches in the crucible, which is equal to 3,456 square inches at the tuyeres, and has a capacity of from 70 to 90 tons in twenty-four hours, showing that in ten years the size of the stacks has been almost trebled, and the capacity nearly quadrupled.

Nor has this striving after increased capacity been confined to blast furnaces alone, Dr. Richard Pearce, of the "Argo" works, near Denver, has for several years been using reverberatory furnaces, which are still believed to be the largest in the world.

Next in importance in their bearing upon the economy of the process, come the various mechanical devices for the separation of matte from slag, the collection of flue-dust, and the condensation of the more subtle fume, and the extraction of the valuable metals from those two troublesome bye-products. After these come the artifices for the transportation, sampling, and general handling, of ores, mattes, slags, &c., &c., about the works, and in the minimising of labour in the roasting of ores, by the introduction of automatic furnaces.

Although the improvement in plant has done so much towards making smelting a profitable pursuit, and has enabled the metallurgist to treat successfully a class of ores, which a few years ago could not be handled, there are other factors whose influence in this direction must not be overlooked. Two very important ones are, firstly, the railroads; and secondly, the excellent system of public sampling, works for which purpose are established in most of the mining centres. The wonderful spread of the rails throughout the State, and the consequent increase of transportation facilities has perhaps done more than anything else in developing the mining and smelting industries.

I have in the following notes confined myself to what appear to be the most important of these points, and have endeavoured to make my descriptions of them sufficiently minute, without being too prolix, to be readily understood by practical men. And in order to remove all possible ambiguity I have appended scale and detail drawings of nearly all the machines described; these drawings have been prepared from the writer's notes, supplemented by data kindly furnished by the manufacturers of some of the furnaces described.

I should like to take this opportunity of thanking the following firms and individuals for assistance rendered:—The Colorado Iron Works, Denver; Messrs. Fraser and Chalmers, Chicago, Ill.; H. F. Brown, Esq., Chicago, patentee of the "Brown Horseshoe Roasting Furnace"; and to all others who have kindly rendered assistance.

CHAPTER I.—SAMPLING.

The sampling of ores, although an operation of the first importance, does not appear to have had as much attention paid to it as it seems to deserve. It is true that numerous schemes for the performance of this operation mechanically have, from time to time, been brought forward, and there has been an almost constant struggle on the part of the inventors and manufacturers of mechanical sampling machines to replace the old hand sampling methods by the machines in which they are most interested. Hand sampling still continues to hold its own in the works of some, if not in all, of the largest and most important of the smelting companies, and is generally considered more accurate and satisfactory; although somewhat more costly than any of the mechanical means put forward up to the present time, nevertheless, the machines of Bridgeman and of Brunton are gradually creeping into favour in other mining States.

Hand sampling.

Hand sampling by the various methods of quartering by split shovelling, fractional selection, channeling, coning, and reducing by halves with shovels, &c., differ so little with the locality in which they are practised, and are so universally known that a detail description of them need not be entered into. It will suffice to give a brief description of the method in most general use, that of coning and quartering, for obtaining the final sample.

The exact manner in which the hand sample is taken varies with the grade and nature of the ore. With low grade siliceous and oxidised basic ores it generally suffices to take during the unloading of the cars, every fourth, fifth, tenth, or twentieth shovelful, which is dumped into a bin or truck, and, if too coarse for the rolls, is conveyed to the crushers; after crushing, if the sample is too large, it may again be reduced in the same manner as when taking the first sample; it is then passed through the rolls and carefully mixed by coning, and further reduced by quartering. It is reconed and requartered as often as is necessary to reduce it to proper bulk, each operation of quartering results in the elimination of one-half of the sample. It is now passed through a grinder, or small mill, resembling that in which coffee is ground, until it will pass through an eighty-mesh sieve, after which coning and quartering is again resorted to. Finally the sample is divided into three portions, one of which is sent to the seller, another to the assay office, and the third is bottled, labelled, sealed, and preserved as umpire sample in case of disputes.

There

There are three cases in which the first sample is not taken by the fractional selection method, as given above; they are: 1st, when the ore is a sulphide; 2nd, when it contains scales or metallics; 3rd, when it is of exceptional richness. In the first and third case the entire parcel is treated as described above. In the second case it is usual to pulverise the entire lot after careful weighing, and sift it to remove the metallic particles, and the determination of values is made upon pulp and scales separately.

The moisture sample, however, is in any case taken as soon as the ore is received, and is quickly cut down, and the moisture determination made in the usual way.

Several tools have been patented which aim at shortening the time needed for quartering; while performing practically the thing, amongst these may be mentioned the split shovel, which resembles, both in its appearance and operation, the riffle of the assay office—

And the Brunton quartering shovel, which is about 10 inches wide, with its face divided into three compartments, the central one of which is just one-fourth of the whole, and is enclosed on three sides with raised strips, and has its open end situated at the front edge of the shovel. The other two compartments are enclosed on two sides only, both ends being open. The operation of this shovel is confined to the sampling of moderately fine ores only, and is as follows:—

The first stroke of the shovel into the ore fills the three compartments; it is then raised, and a sharp forward movement given to it in the direction of the rejected ore heap, which causes the contents of the two side compartments to slide backwards off the shovel; the ore in the central space, however, is retained by the third strip; the workman now turns towards the sample heap, and projects the selected portion on to it. The speed with which one man can quarter a 1-ton sample down to from 90 lb. to 100 lb. is variously estimated at from twenty to thirty minutes. The same work done by the coning and quartering method would occupy two men for from one and a half to one and three quarters of an hour for its completion. The results with the Brunton shovel are claimed to be quite accurate; but, notwithstanding the fact that many of its users speak very highly of it, it has not been generally adopted.

The split shovel has been very little used in this section, and need not be described further than to say that the assayer's riffle is a modification of it, which should render its form and the manner of using it clear.

It is not proposed to describe in detail the various mechanical sampling machines in use in different parts of Colorado, for, as has been said, they have not been generally adopted. In fact a trial given to them in certain of the smelting works has resulted in their rejection.

They may be divided into two classes, which are distinguishable from one another by the different principles upon which they are constructed. The first of these classes, comprises, amongst others, the machine known as the "pipe" sampler. It allows the ore, in a fine state of division, to fall through a pipe or chute in a continuous stream; at a point or points in this chute are situated stationary deflectors, so arranged that their positions may be altered so as to withdraw any desired part of the falling ore, which is deposited in the sample bin.

The machines comprised in the second class have a movable deflector, which is made to oscillate upon a hinge or similar device. Its oscillations are intermittent, and may be regulated so as to make any desired number of movements in a given time across the falling stream of ore, so as to abstract the entire stream for a certain time—that is, while the deflector is making the passage across the chute. As the frequency of these movements is arbitrary, any desired proportion of the whole may be taken for sample.

In plates 18 and 19 (figs. 64-66) will be found drawings in elevation, plan, and vertical section, of the sulphide sampling mill of the Arkansas Valley Smelting Works, at Leadville, which is, perhaps, one of the best designed and most complete mills in the State. The drawings are carefully made to quarter-inch scale. The principal dimensions and parts have been given in figures and letters, so that the drawings are self-explanatory, and the general arrangements of the mill may be readily understood.

CHAPTER II—ROASTING.

THE different methods of roasting ores which have been in use from time to time in Colorado, may be briefly summarised under the following heads:—

- (1) Heap or stall roasting, used chiefly for copper ores and mattes, but rarely for lead ores.
- (2) Kiln roasting, used more or less upon all kinds of sulphide ores, but more especially upon pyrite, in connection with the manufacture of sulphuric acid.
- (3) Reverberatory roasting-furnaces, which may be divided into two classes—
 - (3a) When they are hand stirred, and
 - (3b) When they are mechanically stirred.

Of the first two classes little need be said, as they have almost entirely disappeared from practice in this State. They are still in use to a limited extent at Argo, where the class of ores treated by the reverberatory matting plant in operation there, being chiefly copper ores, are quite suitable for that kind of roasting, but even there they are being replaced by reverberatory furnaces of the automatic type, class (3b), and no doubt will have disappeared altogether in a very few years.

The furnace in almost universal use in Colorado is the long hearth reverberatory calcining furnace, which is a modification of the German "Fortschaufelungsofen," and is figured in plate 17, figs. 58 to 63 inclusive. Figures 58 and 59 represent the furnace inside and end elevation respectively; figure 60 a vertical longitudinal section through the centre of the roasting and fusion hearths; figure 61 is a cross section through roasting

roasting hearth at the stirring doors; figure 62 is a horizontal section through the entire combination above the hearth; figure 63 is a cross-section through fusion hearth, showing the position of cooling flues.

This furnace is one of a battery of nine in operation at the works of the Arkansas Valley Smelting Company at Leadville, and may be taken as a first-class representative of this style of furnace (class 3a). It will be observed that a fusion hearth is attached to the delivery end of the roasting hearth proper. This piece of apparatus gives to the whole the appellation of "fusion" or "slagging" roaster.

It has recently been discovered that this fuse-box is best not attached to the main hearth, as it has been found advantageous to preserve the charge in a powdery or pulverulent condition up to the end of the roasting operation proper. This condition, owing to the greater surface exposed, renders the charge more accessible to the oxidising influences of the furnace. In the combined furnace this condition is very difficult to preserve, for in raising the heat to fuse the contents of the first hearth, a great deal too much heat escapes therefrom to the roaster, which results in the over-heating of the ore nearest to the slagger. In the case of lead ores this frequently leads to a semi-fused or pasty condition, which not only interferes with the completeness of the roast, but also increases the loss by volatilisation, owing to the charge being subjected to the fusion heat for nearly twice the proper length of time, and at the same time, through the agglomeration of the ore, renders its removal to the fuse-box more difficult. It is also probable that a greater loss, through the seepage of the fused galena into the brick-work of the much larger furnace, is endured thereby.

It is therefore better to conduct the roasting in a separate hearth, and to convey the fine calcines therefrom to the slagger, where the heat is raised and maintained, until the reaction between the basic and acidic constituents of the charge is completed. This results in the conversion of the roaster fines to a coherent or massive condition, which is the most suitable for their further treatment in the blast furnace. And through the reaction of the basic oxides with the unaltered sulphides, and, by the decomposition of sulphates, an additional 3 to 4 per cent. of sulphur is eliminated.

It is unfortunate for the economy of smelting (lead ores particularly) that the advantages of slagging roasting should be offset by so serious a disadvantage as that entailed by the very considerable loss by flue-dust and by volatilisation. Of course the greater part of the former is recovered from the dust chambers, but excepting where special and costly bag-houses, &c., are employed, very little, if any, of the latter is recovered. It is true that up to the present time no satisfactory method of filtering roaster fume has been devised, and bag-houses are only mentioned in this connection, because of a conviction on the writer's part that before long some means of handling these corrosive acid fumes will be perfected, probably by an improvement in the manufacture of asbestos cloth.

Dr. M. W. Isles, of the Globe Smelting Works at Denver, has made the off-hand statement that his company suffers an annual loss of between 60,000 and 70,000 dollars through his inability to pass the roaster fumes through the bag-house. From the above statement it would appear that a very profitable field for investigation and experiment is here presented, and that a substantial reward awaits success in this direction.

By referring to the drawings (plate 17), which are of three-eighths of an inch scale, the details of construction of this furnace will be seen, the following is a brief description, embodying the main dimensions:

The roasting hearth proper has a length of 59 feet 8 inches from flue to flue, and is 13 feet 4 inches wide at the narrowest point, and 17 feet wide over all. It has eight stirring doors upon each side, 7 feet 4 inches from centre to centre.

The fuse box is 10 feet 3 inches in length over all, and 13 feet wide over all; both measurements are exclusive of buckstays. It is connected to the roasting hearth by means of a vertical flue, 5 feet 6 inches long, 16 inches wide, and 2 feet 2 inches deep from floor of roaster to floor of fuse box. It is 9 feet 8 inches long from the inner side of fire bridge to the inner side of vertical flue, the bridge is 2 feet 2 inches wide at the top, and rises 12 inches from the grate bars, and 8 inches from the fusion floor. It is built of fire bricks laid over strong cast iron bars, which are calculated to relieve the outer walls of the strain.

The fire-box is 10 feet 10 inches wide and 4 feet 10 inches deep over all, and has a grate area of 3,264 square inches, which is flat.

Both the fuse-box and fire-box are provided with a door on each side, which is situated at the centre of the side walls. The doorways are 22 inches wide, and are closed by rectangular wrought-iron frames lined with fire clay.

The top of roof of the furnace and the roasting hearth are 6 feet 5 inches and 3 feet respectively from the ground line, the latter measurement being that of the section of the hearth nearest to the fuse-box. Each succeeding section of the hearth occupies a plane 3 inches higher than the next lower one, thus bringing the charge 9 inches closer to the roof, at the flue end, which is horizontal. The cooling gases are in that way brought into closer contact with the charge before they escape into the dust chambers.

The fuse-box floor is built upon two brick arches, which form the roofs of two air-passages; these are connected with the ash-pit of the fire-box, the draught through which causes a current of cool air to circulate through them; this serves to prevent the overheating of the fuse-floor. In some works this floor is made by placing a mixture of ground quartz and slag over the brick and adobe face, and raising the heat until it fuses slightly; it is then paddled into shape, and allowed to cool. In other works this practice is not followed, the working bottom being formed by one layer of fire-brick laid upon their edges; the bricks are so disposed that a concavity or sump is formed.

The

The entire structure, with the exception of the lining of the fire-box, fuse-box, and the first section of the roasting-hearth, which is of fire-brick, is built of red brick, firmly bound together by buckstays and tie-rods. See the drawing (plate 17).

The cost of building such a furnace in Leadville would be 3,350 dollars, and the cost of same in Denver would be 3,000 dollars, approximately.

The materials required are—

	lb.
Cast iron	12,200
Wrought iron	3,940
Sheet iron.....	400
Old railway iron.....	10,000
Red bricks	86,300
Fire-bricks	15,000

Before touching upon the magnificent mechanical roasters of type (3b), such as the "Improved Brown O'Harra," "Brown Horseshoe," and the "Pearce Turret," furnaces, it will be well to give a short description of the process of roasting as conducted in Colorado. The writer has watched this operation in five of the largest works in the State, and has not been able to detect any essential difference in the methods adopted at any of them, and if one should strike a time when the charges being treated in the different works approximate closely in composition and in sulphur contents, the process would be practically uniform.

It will then be sufficient to describe this operation as conducted at one of the works, the name of which I am not at liberty to give, in order to illustrate the general practice.

The charge consists of from 2,000 to 3,000 lb., according to the nature of the ore. This is dumped by means of a hopper into the roaster at the flue of coolest end; it is then spread evenly over one-fourth of the hearth area, and there is allowed to remain, being stirred occasionally, until the charge nearest the fuse-box is roasted and pushed forward into the slagging-hearth; the contents of the other three sections of the roasting-hearth are then pushed forward one at a time; this requires two men, one on each side of the furnace. The tools used consist of two flat iron paddles, the blades of which measure $5\frac{1}{2}$ in. x $8\frac{1}{2}$ in. x $\frac{1}{2}$ in., and the handles are from 10 to 12 feet long, and of 1 inch round iron. The paddling has to be done carefully to avoid the raising of too much dust. The flue end is now vacant, and is immediately charged as before.

It is usual where the fuse-box bottom is composed of silicious matter to cover it with silicious ore before the calcines are drawn on to it; this is done in order to neutralize the corrosive action of the basic slags, which are formed when fusion takes place. It would perhaps be better for the fuse-box if this portion of it, which comes in contact with the fused mass, were lined with some basic material, such as magnesia bricks. As soon as the fuse-box is charged, as described above, the heat is raised and fusion begins; it is then necessary to stir the charge by means of rabbles, until the whole is intimately mixed. This rabbling is repeated at intervals of twenty minutes at the beginning, and later on it is again stirred for ten minutes, and again for five minutes just before the charge is drawn. The above will sometimes be modified by the behaviour of the charge itself. The fused mass is finally drawn into slag-pots, and, after solidifying, is turned out to cool, and then broken up and sent to the blast-furnaces.*

The chemical reactions involved in this operation are too well known to need description here. The reader wishing information upon this subject is referred to the works of Percy and others.

Considerations involved in determining what class of ores it is advisable to roast.

Although there exists amongst smelters such a unanimity of opinion about the method of roasting an ore, when once that course is decided upon, the opinions differ very greatly as to what grade of ore shall be roasted.

Since the roasting of ores effects the elimination of most of the sulphur and arsenic contained therein, and by so doing very materially reduces the amount of iron necessary to flux the charge, and at the same time reduces the amount of matter and speisse formed, and therefore increases the daily capacity of the furnace, it will be seen that the first consideration is one of economy, and involves the following points:—

1st. The character of the ore—is it pyrite, or is it galena? In the case of pyrite running over 15 per cent. sulphur, it is considered best to roast, although in cases where copper is present to a considerable extent the usual way of deciding the point is to calculate all the copper present to cuprous sulphide (Cu_2S), and roast down to within 1 or 2 per cent. of the amount needed. It is, however, on account of the non-volatility of iron pyrite, considered safe and always advisable to roast when the value of the ore leaves sufficient margin for that purpose. Another point which must be considered in this regard is what percentage of the charge will the matte be which will result from the presence of a given amount of sulphur. It is usual for convenience in calculation to assume that the matte consists of sulphides of copper and iron only; this is not strictly true, since sulphides of zinc, barium, calcium, &c., are frequently found upon analysis of the above. Sulphide of zinc is the most likely to be present in quantity, and since the atomic weight of zinc to that of iron is as 65:56, no serious error can result from so regarding it. Calculate

* When the lagging-hearth is separated from the roasting-hearth the only difference in the operation described above consists in drawing the calcines directly into barrows or cars and conveying them to the slagger, or they are drawn upon a cooling-floor, generally of brick or slag, and after cooling are taken to the slagger. In either case the fusion is conducted exactly as given above.

Calculate the whole of copper to ($\text{Cu}_2 \text{S}$) and the balance of the sulphur to (Fe. S.); if the amount of matte thus formed is in excess of 12 per cent. of the charge, it is better to roast the sulphides entering the mixture, or to dilute the sulphur by the addition of oxidised ores until the matte percentage is brought down. This is advisable, because with a greater percentage of matte the separation of the slag therefrom becomes more difficult, and larger amounts of silver are carried into it.

When lead ores are considered, the question of treatment is much more serious, as owing to the volatility of that metal the loss of both silver and lead is very much greater, and this loss increases with the percentage of lead. According to Newhouse,* ores containing 12 to 18 per cent. of lead suffer a loss in simple roasting of from 2 to 5 per cent. of that metal and no silver, but upon slagging the charge the loss in lead amounts to from 15 to 18 per cent. and in silver to 2 per cent. From this it will be seen that it is not safe to slag high-grade lead ores; some practitioners place the safety limit at from 8 to 10 per cent. From what has been said above it will be evident that the danger of loss during roasting by volatilisation will not depend upon the amount of lead only, as it is generally understood that the greatest loss of silver in roasting and smelting is not owing to the volatility of that metal itself, but is chiefly a mechanical loss incidental to the vapourising of lead and some of its compounds; that being so, it is clear that the loss in roasting and slagging ores of constant grade, as regards lead, will vary with the amount of silver contained in them—the higher the silver the greater the loss; and as the assay value of ore rises, a point will be reached at which the considerations previously discussed will be overshadowed by this one, viz.,—Are the benefits derived from roasting an ore equal to the direct loss in silver and lead entailed thereby.

The limit at which the economy of roasting lead ores ceases is one of the points upon which metallurgists differ. The limit has been variously stated at from 50 to 100 oz. of silver to the ton.

Now comes the consideration of the presence of zincblende in the ores. When much zinc is present it creates trouble in the blast-furnace. If it is fed to the furnace in the form of sulphide, it is in part decomposed by oxides and silicates of iron. The blende becoming oxide, enters the slag, and has, according to some authorities, the same function as lime. The remainder of the blende remains undecomposed, and enters the matte. The presence of a large amount of zinc sulphide sensibly affects the specific gravity of this latter, and interferes with the separation; whilst zinc silicate, owing to its high fusion point, lessens the fusibility of the slags, and therefore has the same bad effect. The presence of much zincblende in lead ore will sometimes demand its roasting, in spite of its grade in silver; this will, however, depend upon the proportion of lead in the ore. The higher the percentage of lead the more blende is permissible† in smelting raw ores, as a general rule, the practice being to smelt raw such galena ores in which the lead is in excess over the zinc; but to roast ores in which the zinc is equal to or in excess over the lead. There are, of course, cases in which this rule cannot be followed with advantage; for instance, when small amounts of ore of extraordinary richness are to be treated, it is generally better to scorify them in a small reverberatory furnace with lead, which results in a somewhat rich bullion and a small amount of very dirty slag, which can be safely treated in the blast-furnace.

General description of the Brown-Allen Improved O'Harra Roasting Furnace.

This furnace may justly be considered the first successful mechanical roaster introduced, and may lay claim to the distinction of having reduced the cost of roasting ores of all descriptions by at least 50 per cent. The furnace has some faults of construction, which will, perhaps, lead to its replacement by the mechanical roasters of the circular type.

The Brown-O'Harra furnace has been, and still is, in successful operation at the following works:—Boston and Colorado Smelting Co., Argo; Globe Smelting Co., Denver; the Pueblo Smelting and Refining Co., Pueblo; and at the Anaconda Smelting Works in Montana.

The following description of the furnace is given by the inventor. The advantages claimed for it have been fairly substantiated in practice, while several disadvantages have also been demonstrated. Some mention of these latter will be made later.

The Brown-Allen O'Harra is a double-hearth reverberatory furnace, stirred mechanically, being an improved form of what has long been known as the O'Harra furnace.

The original O'Harra furnace was a double-hearth reverberatory, stirred mechanically. The stirring was done by means of an endless chain, which passed through both hearths of the furnace and around wheels at either end. Attached to this chain were two triangular frames, upon whose angling sides were placed blades which acted as plows for stirring the ore.

The chain passed directly through the centre of each hearth, and to prevent its wearing, a groove about 8 inches wide and 8 inches deep was formed in the floor of each hearth its entire length. It was supposed that this groove would make room for the sag of the chain and prevent wear, but in practice the groove filled with hot pulp, through which the chain dragged, wearing it out very rapidly.

The stirrer blades or plows rested directly upon the brick bottom of the hearth, which caused them to wear out very quickly, and also destroyed the hearth itself.

This construction placed such great strain upon the chain, which was weakened by the intense heat and great wear, that it broke frequently, causing delays and expense to such an extent that the O'Harra furnace was considered a failure. To

* *Engineering and Mining Journal*, 28th February, 1891.

† *Hoffman's Metallurgy of Lead*, page 155.

To overcome these objections various improvements were made which have resulted in the furnace now built and known as the Brown-Allen Improved O'Harra Roasting Furnace.

In referring to illustrative cuts, the following descriptions will be readily understood.

By referring to cross-sections on plate No. 14, it will be seen that the roasting hearths are divided into three compartments, the centre one of which is the main roasting hearth, and the two side compartments for the tracks and moving mechanism. Wheeled carriers are placed upon these tracks and connected to two chains, which are operated in a similar manner to that employed in the original O'Harra.

From these wheeled carriers an arm is extended laterally through the slit or opening in the partition or diaphragm which cuts off the side compartment from the main roasting hearth, to the centre of the hearth as shown on plate No. 13 and on the cross-section sheet, plate No. 14.

To these arms are attached the stirrer blades or ploughs, which stir the charge constantly, and gradually work it through the entire length of the furnace.

By this construction the wheel carriers and all the moving mechanism is cut off from the intense heat and dust of the furnace, and so effectively protected that it has no perceptible wear, beyond that of ordinary machinery.

The stirrer blades are composed of sheet metal, and, when worn by the attrition of the ore through which they are drawn, can be quickly replaced.

The charge is fed into the furnace through the feed hopper A, plate 13, figs. 48 and 49, and gradually worked the entire length of the upper hearth, where it drops through an opening to the lower hearth.

The stirrers pass out through the revolving doors, and, passing around the carrying-wheel, again enter the furnace, where they take up the ore and gradually work it the entire length of the lower hearth, where it is discharged in the hopper B, inside of the inside wall of the furnace, or carried out to hopper C, and discharged into cars.

The hopper B, plate 13, fig. 49, is designed for accumulating the calcined material when used for hot charges—that is, when required for charging into a matting furnace in red hot state, and is now being done in the Anaconda works in Montana.

When not required to be used in hot charges, the calcines are discharged into hopper C, plate 13, fig. 49, comparatively cool.

Where ore or other materials require fusing after being calcined, the construction* shown on plate No. 20 is adopted. In this case the ore is discharged into the hoppers H H, and drawn into the fuse-box, where they are fused.

The manner of taking the heat from the fuse-box into the roasting hearth will be understood by referring to plate 20. By means of the passages and flues shown the heat is divided so as to enter the roasting hearth at four points, and in this manner is so diffused that all danger of overheating the charge is obviated.

In case the heat should be found too great, a portion of it can be passed directly to the dust chamber and stack by means of the safety-damper, as shown, or in the case of a stoppage of the machinery for any cause, the entire heat of the fuse-box can be taken directly to the stack.

The advantages of the Brown-Allen Improved O'Harra Furnace may be summed up as follows:—

- 1st. The absolute control of heat by means of the construction shown. This is very important in the roasting of mattes and for ore carrying a high percentage of iron and silica. By means of the fire-boxes, shown on plate No. 13, the heat is diffused evenly over the entire length of both hearths, which prevents the danger of partial fusing at any point.
- 2nd. In the frequency and completeness of the stirring. The entire charge is worked over the floor of the roasting hearth in a very thin layer, and is thoroughly stirred about twice each minute, and consequently every particle is exposed to the heat and oxygen, which ensures a rapid burning off of the sulphur at the lowest possible temperature.
- 3rd. In the economical distribution of air on the roasting charge, by means of revolving doors, the ends of the roasting hearths are kept practically closed, which prevents an undue influx of cold air on those points. The greater portion of air required for roasting is admitted into the small side compartments through the draft doors placed along the walls.

From here it finds its way into the main roasting chamber through the slit in the partition or diaphragm, which diffuses it in a thin sheet directly on the burning ores, and being cooler than the heated gases in the upper part of the chamber, it spreads all over the face of the burning charge before it becomes rarified enough to rise. This virtually has the effect of a gentle blast of air, and gives a much greater available supply of free oxygen than can be obtained in any other furnace known.

This excessive supply of oxygen, coupled with the frequency of the stirring and the absolute control of the heat, is invaluable in roasting mattes and ores high in zinc.

The action of the stirrers is constantly disintegrating and all the calcined products are discharged as "fines" without "balling" or "caking" at all.

We find by a careful comparison of the work of these furnaces on different ores that the following is an average of work being done. This takes in nearly the whole range of ores as treated at the works in this country, and embraces copper and iron sulphide carrying 38 to 45 per cent. sulphur, 8 to 15 per cent. zinc, 5 to 8 per cent. of lead and mattes carrying 16 to 22 per cent. silver and 15 to 40 per cent. copper.

Where

* This construction has been discontinued altogether. The fusion hearths are built separate from the roasting hearth. (See description of hand-stirred roaster.)

Where the ore is reasonably fine, 20 tons per day will roast to 2.5 per cent. silver; 25 to 28 tons, 3.5 to 4.5 per cent. silver; 30 to 35 tons, 5 to 6 per cent. silver; 35 to 40 tons, 6 to 7 per cent. silver.

The cost of roasting as above, including labour, fuel and repairs, will be from .75 to 1.00 dollar per ton, based upon average wages and prices of fuel in the mining sections of the west.

In roasting mattes the amount varies according to the richness and fusibility of the charge, but approximates very closely in results to the roasting of sulphide ores.

Plate 21 shows the arrangement where designed for chloridising silver ores, one of which is now in operation at the Cortez Mine (Limited), in Nevada.

The duty of a chloridising furnace represents a much higher tonnage, as the pulp is all crushed fine and sulphurs run much lower. The Cortez furnace has but two-thirds the area on the hearths of our standard roasting furnaces, but averages 30 tons per day to a very high per cent. of chlorinisation, making less than one-tenth the loss in flue dust as compared with the usual styles of furnaces for this purpose.

The extension of the floor shown forms a mechanical cooler and saves the room and dust incident to the usual practice. Cost of chloridising, 50 to 75 cents per ton for fuel, labour and repairs.

The chief disadvantages of this furnace are briefly the frequent stoppages for repairs, caused chiefly by the difficulty of keeping the furnace in alignment, owing to the sagging of the central horizontal wall which supports the upper hearth, this wall becomes excessively hot, through being strongly fired from both top and bottom. This exposes the vertical walls to a very heavy strain.

2ndly.—The enormous amount of brickwork and stays necessary to stand the above strain.

3rdly.—The great loss of fuel and time entailed in heating up this mass of brickwork, and in cooling same before repairs could be effected, before and after each stoppage.

The Brown Horseshoe Furnace,

As shown in plates 9, 10, 11, and 12, figures 30 to 47 inclusive, has been designed to remove the objections urged against the double-hearth "Brown O'Harra Roaster." And the labour and ingenuity which have been expended upon it, have resulted in the production of a machine which seems to possess the ideal qualities of a roasting furnace, to an eminent degree, inasmuch as that it is of simple design, is inexpensive to construct, easy to control, is almost entirely automatic, is cheap in operation, has a large hearth area, has reduced the cost of repairs, through ordinary wear and tear, to a minimum, and does perfect roasting.

The following description and drawings of this furnace should make its construction and operation clear:—

The furnace, as its name implies, is of a circular or horseshoe form, about four-fifths of its entire area comprising a roasting-hearth, and one-fifth an open cooling-floor for cooling off the calcines and the stirrers. By referring to the cross-section, it will be seen that the roasting-hearth comprises the central portion of the furnace between the main outside walls. By means of vertically disposed partitions (one-half being built on the floor and the other half forming part of the arch), with their adjacent ends a short distance apart, the tracks and working mechanism are entirely cut off from the roasting-hearth. This protects the moving mechanism and the tracks from the direct action of the heat, fumes, and dust of the furnace, and it has overcome all the objections hitherto urged against mechanically stirred roasting furnaces.

In construction, aside from the vertically disposed partitions, the furnace is exactly the same as an ordinary hand-stirred reverberatory, and does not require any more expense or skill to make a good furnace than is required in the construction of any hand-stirred furnace.

One objection to double-hearth furnaces has been the difficulty in keeping up the centre-wall between the upper and lower hearths, owing to the heat to which it is subject by being exposed from both sides, and to make a furnace that would keep in a sufficient alignment for ordinary purposes, it requires quite an outlay for brickwork, and a heavy expense for necessary buck-stays and binding-rods. The extreme simplicity in the construction of the horseshoe furnace in these particulars, will commend itself to practical men at once. There being but one arch to keep up, and that arch being exposed to the heat only one side, it will not become excessively hot, and also it will have elasticity enough to rise and fall with the varying heat of the furnace without putting such severe strains on the outer walls.

In the practical operation of this furnace there are no new features developed, as far as the metallurgical process is concerned, the whole practice being to expose the ore regularly and uniformly to a proper heat and a proper amount of oxygen, and, when this is done, it is apparent that the oxidation of the ore must necessarily follow. A brief description, however, of the mechanical movements will be necessary.

The ore is charged into the automatic feeder, which is a device so arranged as to feed any given amount with the passage of each stirrer. By means of a fluted-wheel the ore is forced out on to an apron which, when loaded, drops down, depositing the ore on the hearth, but, in the act of dropping, all the feed mechanism is thrown out of gear and the balance weight thrown so far forward that the apron remains down, and, of course, all feeding stops until the passing of a stirrer, which strikes a projecting lever and throws the machine again into balance, when the operation is repeated. By this simple means, the amount of ore can be regulated to a very few pounds per hour by simply adjusting the balance weight. The two ends of the roasting-hearth are closed by means of swing doors which allow the passage of the stirrers. From the feeder the ore is gradually
ploughed

ploughed along by the passing of the stirrer points until it enters the roasting-hearth, and is worked gradually forward until it has travelled the entire circle and is deposited at the discharge end of the hearth, not far from where it entered.

To prevent the overheating of the stirrers, that is, to allow them time to cool after passing each time through the furnace, the following plan is adopted:—

By referring to plate 10, fig. 35, it will be seen that there are two stirring carriages in the open space between the adjacent ends of the roasting hearths. These carriages are at rest, and, of course, being exposed to the air, are being rapidly cooled. It will also be seen that there are two stirrer carriages in the main body of the roasting hearth, at nearly opposite points. These carriages are travelling around, and when the forward carriage comes in contact with the two carriages which are at rest, they are pushed forward, and the one in the lead is attached to the drive cable, by means of an automatic grip, and travels on, while the one which has just come out of the furnace is released by means of an automatic stop, and becomes stationary. It requires about two minutes for each stirrer to make the circuit of the roasting hearth, and therefore each stirrer stands two minutes in open air. This allows the working points, which are the only ones that become heated, to cool off, and as they enter the cold ore; as they pass into the furnace they are so thoroughly cooled that they never attain a heat sufficient to cause any chemical action to take place between the sulphur thrown off and the iron. In this manner no wasting away occurs, and it is only by attrition of the ore that they are worn out.

The driving of the stirrers is accomplished by means of a cable, arranged exactly on the plan of a cable railroad going around a curve. This cable runs continuously, and one-third of it is all the time in the open air. There is also a little admitted at each guide-sheave or wheel, entirely around the furnace, so that there is a constant inflow of cold air, which assists in keeping the tracks and driving cable cool. The guiding wheels are so arranged that three-fourths of their entire surface is always in the open air, so they never become heated to a point that would make it unsafe to handle them without gloves. The slotted wall, or partition, is such a thorough protection that on furnaces which have been run a month a naked hand can be laid on the travelling cable, on the track rail, or on the inner wall, without danger of burning. It is not meant by this that the parts named do not become hot to the touch, but it is meant that they do not become sufficiently hot to effect them in any sense whatever as far as their durability is concerned.

The means employed for driving the cable are simply the well-known means for what is called road or cable drives, and consists of a grip-wheel with a tightener and guide-sheaves, so as to keep the rope always at the proper tension.

This driving cable passes around the furnace on the guide-wheels, which show on the inner wall. There is a 4-foot sheave-wheel, which runs close down to the hearth so that the bottom part of it comes on the same plane with the cable. The cable, in coming around passes under this wheel, which has two grooves, and passing up, goes over a clutch-wheel located on the top of the frame, and down under the tightener pulley and back over another pulley on the same shaft with the clutch-pulley, and coming down, passes under the lower sheave-wheel, in the second groove, and so on around the furnace. The object of the tightener pulley is to keep an even tension on the rope. The clutch-pulley, which is fitted up with a series of grips, move the rope forward as the wheel revolves and the other wheels act simply as idlers to keep the rope in position.

The stirrer carriages are formed like a triangle with a wheel under the three points. Near the forward end a gripping device is attached; this gripping device consists of a stationary jaw, which is bolted fast to the main frame of the carriage, and a movable jaw which is operated by means of a lever. When the clutch is thrown out of position, the movable portion drops down, and the lever stands vertically. The track is so constructed that at the proper point the forward end of the carriage is carried close to the rope or cable which is pressed tightly into the clutch. A fixed stop is placed, so that as the carriage moves forward the vertical lever comes in contact with it, and as the lever is forced down the jaw is raised until it grips the rope tight enough to pull the carriage. It is held in position by means of a ratchet and pawl. When the carriage has travelled the entire circuit of the furnace, a fixed stop which is secured to the track engages a lever which throws the clutch out of gear and the carriage stops. Before the clutch is thrown out of gear, however, the carriage which has been standing in the open space described above, is moved forward until the clutch is secured on the moving cable.

The fire-boxes are constructed entirely independent of the furnace walls, and the heat is conveyed into the main roasting hearth by means of a cross arch leading from the fire-box to an opening in the roof or arch of the main roasting hearth. The fire-boxes are adapted to the nature of the fuel to be used, in some cases inclined grates, in some step grates, and in other cases they are adapted for burning wood, these points being determined by the material to be used. The side walls and arch of the fire-boxes are constructed hollow, forming passages for the inlet of pure air which enters the main roasting hearth in a highly heated condition, which adds materially to the efficiency of the furnace.

It requires about $2\frac{1}{2}$ -horse power to drive the mechanism for stirring the furnace, the most of which power is absorbed in driving the different wheels, &c., the power of one man being sufficient to pull a single stirrer through a full charge of ore.

These furnaces can be made of any desired diameter and capacity.

The

The position of the stack, as regards the furnace, is not at all important, and any existing stack can be utilised by running a proper dust flue from the furnace to such stack. In the plates the stack is shown as within the interior walls of the furnace, which construction is economical where a new stack is to be built, but does not give sufficient length of dust chamber.

This furnace is adapted for roasting any material that can be roasted by hand, and will handle material, without danger of forming accretions on the hearth, that is considered very difficult to handle by hand-stirring.

The 55-foot (diameter) size requires about 100,000 red bricks to build the furnace proper and 35,000 bricks for a suitable stack, making a total of 135,000 red bricks. It requires of fire-brick and tiling an equivalent of 13,500. The price of the complete machinery and ironwork, excluding buckstays, is 3,500 dollars f.o.b. Chicago, weighing about 30,000 lb. The buckstays will cost about 150.00 dollars on the average, and are made of old railroad rails, which can usually be purchased as cheap where used as they could in Chicago.

A furnace of this size will have a capacity of from 30 to 35 tons per day, depending upon the nature of the material being treated.

The average cost of roasting the average pyritous ores of the west is from 0.75 dollars to 1.00 dollar per ton. Ores carrying a large percentage of zinc will cost a little more, but 1.00 dollar can be set down as a safe average. The roasters require but one man to a shift to run them. By this is meant that one man on a shift will attend to the furnace, keeping up the fires and looking after the machinery. The number of men to get in the ore and fuel and to remove the calcines will depend on the situation. Ordinarily one man will do all this. The ore hopper is calculated to hold a sufficient charge to run all night, and enough ore is to be put in during the day to last that time. At most an average of two men to a shift will do all the work. However, it is no more work to bring the ore and fuel to this furnace ton for ton than to a hand-stirred furnace, and while a day's labour on a hand-stirred furnace represents an average of about 2 tons, exclusive of the bringing in of ore and fuel and the removing of the calcines, with the mechanically stirred roaster a day's labour represents 12 to 15 tons.

Ordinary pyritous ores, if crushed so as to pass a four-mesh screen, can be roasted to below $2\frac{1}{2}$ per cent. of sulphur. Samples have been taken from the finer portions of the calcines where 28 to 30 tons per day were being roasted, that when below .5 of 1 per cent., and the average of the calcines was below 5 per cent. In this case the ore being treated carried 40 to 45 per cent. S., and contained a large amount of coarse pieces that were half-inch cubes.

Ores carrying 30 to 40 per cent. Pb. are roasted without difficulty, and so far there have not been any accretions of matte on the hearth. The inventor claims that 50 to 60 per cent. lead ores can be roasted without danger or trouble. Should there be a stoppage of the stirring mechanism for any cause, and the attendant should neglect to open the draught doors, there might be accretions of matte formed next the fire inlets. To provide for such a contingency I should recommend the placing of a man-hole in the furnace roof, just in front of each fire-box, which would be covered by a flat tile, so that a bar could be run in through this man-hole to raise the cakes and the stirrers would pull them out.

The constant stirring of the furnace has a tendency to disintegrate the ore, and unless the stirrers are actually stopped I do not believe accretions will ever be formed on the hearth.

The furnaces should have a connection with a system of dust chambers. The chambers and flues should be the same with these furnaces as are used with any other construction, but much less is lost by mechanical dust, and far less volatilisation. Owing to the frequent and uniform stirring, a much lower heat is required than has usually been thought necessary to break up the compounds, and much less loss of the more volatile metals is experienced.

The Pearce "Turret" Roasting Furnace.

Is another important addition to the roasting plant of the west. It very strongly resembles "Brown Horseshoe Furnace" in its general design; there are some minor differences in the details of the driving gear; and the furnace as constructed up to the present time is smaller—36 feet in diameter against 55 feet in the Brown Furnace. The most essential difference, however, consists in the forcing of heated air through the hollow stirrer arms upon the surface of the roasting charge, whereby (theoretically) a more rapid and more nearly perfect oxidation is obtained; it is, however, claimed that this constant stream of air under pressure playing upon the charge results in the raising of the finer portions of it, into the current of heated gases escaping to the flues, and in that way causes an undue amount of flue dust to be formed.

It is to be regretted that time will not allow of the preparation of drawings and a fuller description of this furnace, as it is an admirable one. However, it is so similar to the "Brown" furnace, and the claims made for it are very much the same, and are substantiated in the same satisfactory manner in practice, that a minute description of them both would entail a good deal of useless repetition.

There appears to be some dispute between the originators of these furnaces, owing probably to the striking similarity of detail which exists between them, as to the priority of right. With this, however, we have no concern.

It is unnecessary, owing to their being so well known, to do more than mention the other roasting furnaces, used to some extent in the west, such as the "Bruckner Cylinder," the "White Howell Revolving Cylinder," the upright roasting furnace of "Stetefeldt" (used chiefly for chloridising). These furnaces are not new, nor have they been particularly successful.

CHAPTER III.—THE BLAST FURNACES.

Owing to the amount of silica in the ores of the west, blast-furnace smelting is the almost universal practice in Colorado. In the whole of the great smelting centres of Leadville, Pueblo, Denver, and Durango, but one exception to this rule exists, viz., the Boston and Colorado Smelting Works at Argo, near Denver, where the practice is entirely reverberatory. They do not, however, treat lead ores for the reason given above.

The furnaces used vary but little in general construction. They are almost exclusively of the oblong form, either with rectangular corners or with the latter more or less rounded. The oval or round smelting furnace has almost disappeared, and is seen only in the works of small companies in remote parts of the State.

The furnaces vary in size considerably, ranging from 36 in. x 50 in. to 36 in. x 140 in. The tendency has been to increase the length of the furnace, but to keep the width within somewhat narrow limits, which is the most satisfactory proceeding, since, with a tuyere section of great width, the blast is unable to penetrate to the centre of the charge. Crucibles have been tried up to 50 inches wide, but have been abandoned for the reason mentioned. The general type of blast furnace, with its various modifications, is shown in plates 1, 2, 15, 16, 16a, and 20.

The height of the stacks has also been the subject of much experimentation, the result of which has been a very large increase in the distance between the tuyere centres and the feed-floor, which latter has gradually crept up from 12 feet to 22 feet above that point.

The writer is informed that a trial is now being given to a furnace whose feed-opening is 27 feet above the foundation line, and which is water-jacketed the whole way up. For a good many years metallurgists have been deterred from trying this experiment by the fear that the large increase in the power of the blast, which would be necessary to overcome the resistance of so deep a column of charge, would result in the reduction of iron to the metallic form, which would destroy the health of the furnace by forming iron sows, in addition to which it was feared that the force of the blast would carry quite a large percentage of the charge into the dust chambers. Dr. Iles, of the Globe Works, who is, perhaps, the most indefatigable experimenter in the Colorado corps of metallurgists, was, the writer thinks, the first to put these points to the test. He ran the brickwork of his stack up to about 7 feet above the feed-floor, which is 22 feet above the tuyeres, replacing the flush feed-opening and cast-iron cover plate with vertically disposed sheet-iron doors, which cover feed-openings springing from the floor. The down-take pipe, instead of tapping the stack at the side or end, as is the usual practice, rises from the top of the brickwork above the feed-doors, and, making an abrupt bend, continues down to the dust chambers. The furnace is kept filled with charge almost up to the feed-floor level, and the blast has been increased from 16 oz. to 32 oz., which is supplied to this furnace by an independent engine and blower. The result of the above alterations will be seen in the record of the furnace, given by Dr. Iles, which is as under:—

The capacity of the furnace was increased from 80 tons to 125 tons of net ore in twenty-four hours, the highest day's run being 135 tons. The furnace ran continuously for nine months without barring down, excepting, of course, such barring as would be done without stopping the furnace. This unusually long run is attributed to the manner in which the gases are conducted from the furnace. When the down-take taps the shaft at the side it has the effect of disturbing the even distribution of the blast, since it tends to draw the gases in a slanting direction towards itself. This causes wall accretions to form at points immediately opposite and under the flue orifice. These keep on growing towards each other until but a narrow chimney is left for the passage of the gases. The duty of the furnace is thereby reduced, and barring down has to be resorted to. Dr. Iles claims that when the down-take is disposed as mentioned in the description of his furnace, no such irregular air currents are induced, but that the draught rises evenly and naturally upwards until drawn off by the flues. In this way the formation of wall accretions is much less liable to occur. The result of the experiment seems to bear this statement out, and is eminently satisfactory. The loss from flue-dust has not proved so great as was anticipated. It would seem that the length of the ore-column has increased the filtering action of the charge, and that a considerable amount of the fines in the furnace is caught thereby.

The thickness of the brickwork at the bottom of the shaft of the recent furnaces has increased with the general dimensions, but in a more than corresponding ratio, the general tendency has been towards greater solidity.

A furnace of the following dimensions (at the Globe Works), 30 in. x 126 in. crucible, and with feed-floor 18 ft. 2 in. above centre of tuyeres, requires the following material for its construction:—

Cast-iron	27,450 lb.
Wrought-iron	3,280 „
Beams (steel)	4,300 „
Red bricks	17,500
Fire-bricks	9,600

The cost of erecting the above furnace in Denver was about 1,500 dollars, about 375 dollars of which was for labour.

The furnace shown in plate 15, figs. 53, 54, and 55, may be taken as a type of the lead furnaces in use in this State. The telescope stack is not so frequently seen, the top of the furnaces being generally arranged as shown in the matting furnace (which is designed for outside separation), and shown on plates 16 and 16a. Both of these furnaces are manufactured by the Colorado Iron Works, Denver, Colo., U.S.A. The latter

latter furnace is used in connection with a forehearth, as shown on plate 8, various figs. (figs. 20 to 29 inclusive), illustrate one of the most satisfactory of these hearths, which has been in constant use for some years at the works of the Arkansas Valley Smelting Company, at Leadville, and leaves but little to be desired. The other forehearth shown on the same plate has been described under "Pyritic Smelting."

There have been no new metallurgical features developed in the smelting practice of the west, but the scientific principles underlying the operation appear to be much more generally understood than was the case a few years ago. This improved state of things has been largely contributed to by the increase in the number of technical schools. These latter are now very numerous in this country, and are of excellent quality. The advent of the scientifically-trained metallurgist has had the effect of driving the rule-of-thumb man out of the field; he has been obliged to play a subordinate part in works where he was once supreme.

Slags, and the method of calculating them.

In the calculation of slags, the method adopted is that known as the "oxygen ratio," which means that the different slags are designated as singulo-silicate, bi-silicate, tri-silicate, &c., according to the ratio which exists between the oxygen combined with the basic constituents, and that in combination with the acidic constituents—for instance, the slag which is of greatest importance in lead-smelting is the singulo-silicate of lime and iron.

No. 1— $(\text{FeO}\text{CaO}) \text{SiO}_2$, the general formula being where R represents a diad base.

2 $(\text{RO}) \text{SiO}_2$, or $2\text{R}_2\text{O}_3$ plus 3SiO_2 , in which the basic oxygen is to the oxygen of silica as 1:1.

The calculated percentage composition of which is:

FeO equals	38.29	per cent.
CaO "	29.78	"
SiO ₂ "	31.91	"

99.98 per cent.

Manganese acts in the same manner as iron, and the latter may be replaced by it in the slags.

Baryta, alumina, magnesia, and zinc oxide are regarded as acting in some measure like lime, which may be replaced to some extent by those bodies; it is, however, not safe where barium and zinc are fed as sulphate and sulphide respectively. To calculate the whole of them as slag-forming constituents, since BaSO_4 is in the presence of carbon reduced to BaS , a portion only of which (generally speaking) reacts with metallic oxides, &c., and becomes BaO , which is then available as a base in slag formation. The undecomposed BaS is generally found dissolved in the slag, a very small amount also remaining with the matte.

In the case of zinc blende, it is generally thought sufficiently close for practical purposes to calculate one-half as ZnO to the slag, and to regard the remainder as going partially into the matte, and partially into the dust chambers. In regard to such bases as magnesia and alumina, the rule is to calculate them as silicates, although in the case of the latter it is supposed that it sometimes acts as base and sometimes as acid (as in aluminates), but just at what point this change of behaviour takes place there is, up to the present time, no satisfactory method of determining. These replacements hold good in any silicate, no matter what its designation may be, so that in extreme cases the formula of a singulo-silicate slag may have to be written thus:

No. 2— $(\text{Mn Fe}) \text{O} (\text{Ca Mg Ba Zn}) \text{O Si O}_2$, in which the lime and ferrous oxide may be, in part, replaced by any or all of those elements bracketed with them.

The bi-silicate slag of (Fe O and Ca O) has the following formula and composition.

No. 3— $\text{Fe O Ca O plus } (\text{Si O}_2)_2$ or $2 (\text{RO})$ plus $2 (\text{Si O}_2)$, or $(\text{RO}) (\text{Si O}_2)$ or $(\text{Fe Mn}) \text{O} (\text{Ca Mg Ba Zn}) \text{O } 2 (\text{Si O}_2)$ in which the oxygen ratio is as 1:2.

Composition—

Si O ₂ equals	48.38
Fe O "	29.03
Ca O "	22.58

99.99

A true bi-silicate is never run in silver-lead smelting, its fusion point being too high; the slags range from the singulo-silicate through mixtures of singulo and bi silicate in varying proportions to a slag having the composition—

$4 \text{R O} . 3 \text{Si O}_2$ or

$(2 \text{R O plus Si O}_2) \text{ plus } 2 (\text{R O plus Si O}_2)$ or

$(\text{Fe Mn}) \text{O} (\text{Ca Mg Ba Zn}) \text{O Si O}_2 \text{ plus } 2 (\text{Fe Mn}) \text{O} (\text{Ca Mg Ba Zn}) \text{O}$
 $(\text{Si O}_2)_2$

which is equal to a mixture of one part of singulo to two parts of bi-silicate, and has an oxygen ratio of 1:1.5.

The ideal slag in smelting oxidised lead ores is the singulo-silicate of iron and calcium; the lime may replace the iron until its oxygen equals that of the ferrous oxide, but beyond that point it is considered disadvantageous to go. A slag of the above description has most of the essential points of a good smelting combination. It is readily fusible, very fluid when melted, has a low specific gravity (about 3.4 to 3.6), and

is sufficiently solvent to prevent the formation of serious hearth accretions; it is run with ease and satisfaction in districts where lime and iron fluxes are not too expensive, but the growing competition amongst smelters and the preponderance of low-grade acid ores, have resulted in the crowding of silica into the charges, since every additional unit of silica that can be run without effecting the working of the furnace means an increase in the smelter's profits.

In cases where much raw galena is being smelted the singulo-silicate slag is, owing to its low fusion point, not suitable. It melts readily at a temperature which is below that needed to decompose the galena, which results in too little lead being reduced, and too much going into the matte. In order to obviate this it is necessary to raise the fusion point of the slag. It is usual in such cases to run a mixture which approximates in composition to the sesqui-silicate slag given in No. 4.

Below is given a few slags that have been run with continued success at some of the principal works, and may be regarded as typical:—

	SiO	(Fe Mn)O	(Ca Ba Mg)O	Total.
Pueblo Smelting and Ref. Co. ...	32.0	30.0	22	84
Omaha and Grant Co. ...	30.0	36.0	20	86
Globe Smelting and Ref. Co. ...	32.0	33.0	23	88
Philadelphia Smelting Co. ...	35.0	28.0	26	89
Colorado Smelting Co. ...	30.0	40.0	20	90

The following are the slag analyses for ten consecutive days at one of the smelting works with which the writer was connected:—

Lead Furnaces.

	SiO	(Fe Mn)O	(Ca Ba Mg)O	Pb	Ag. oz.
1	31.72	30.50	24.00	0.8	0.7
2	32.10	29.7	23.20	0.1	0.8
3	30.9	30.20	22.10	0.6	0.4
4	30.7	31.30	23.0	1.1	0.1
5	34.2	28.90	22.0	1.2	0.1
6	30.8	31.50	23.0	0.8	0.7
7	31.2	32.00	22.6	0.9	0.8
8	32.1	31.70	23.10	1.0	0.9
9	33.4	29.60	24.20	1.2	1.0
10	31.6	30.40	22.80	0.8	0.7

Matting Furnaces.

	SiO	(Fe Mn)O	(Ca Ba Mg)O
1	32.1	39.8	20.20
2	30.9	38.9	22.10
3	31.4	38.6	21.90
4	32.1	39.1	21.60
5	33.00	38.4	20.70
6	32.20	39.20	21.90
7	32.70	40.10	21.30
8	32.60	39.40	21.70
9	33.10	38.60	22.00
10	32.10	39.40	21.80

The large furnaces, with a 20-foot column of charge, gave slags as follows:—

Day	SiO	(Fe Mn)O	(Ca Ba Mg)O	Pb	Ag. Oz
1	38.32	27.80	18.50	0.9	1.0
2	39.10	28.00	19.10	1.0	1.0
3	39.60	27.30	20.20	1.1	1.2
4	40.20	26.40	19.70	1.2	1.2
5	40.70	26.20	20.00	1.1	1.0
6	40.10	26.90	20.40	1.0	1.0
7	41.20	25.30	20.10	1.4	1.2
*8	42.40	24.80	19.30	1.5	1.3
9	39.20	25.90	20.50	0.9	0.6
10	38.40	26.00	21.30	0.7	0.5

It will be observed that the silicas in the above table are very high. They are evidence of the struggle that is being made to run more acid charges than any of the type slags call for.

It will also be seen that the lead contents of the slag increases almost uniformly with the silica, and that the amount of silver is affected in the same manner. At no time during the period in which the above slags were made could the condition of the furnaces be considered healthy or normal, and that an extraordinary effort was being made was manifested by the almost strained alertness of the furnace gang, which was composed of the most experienced men on the staff, and by the frequency with which the various tap holes had to be opened up with the sledge and drill.

The attempt to run a 40 per cent. silica was certainly a praiseworthy one, and will, the writer thinks, prove quite successful when the proper amount of blast has been made available. In this case the run was made with the ordinary pressure of 16 oz., which is manifestly too low for such a tall column of highly silicious charge.

The

* This called for an alteration in the composition of the charge. In these large furnaces a change of feed did not manifest itself in the slag until from ten to twelve hours had elapsed.

The slags that were most popular a few years ago may be illustrated by the following, which is by Eilers. $3(2\text{FeO}\cdot\text{SiO}_2) \times (2\text{CaO}\cdot\text{SiO}_2)$ which is a mixture of three parts of singulo-silicate of iron, with one part of singulo-silicate of calcium. The calculated composition of which is—

Si O ₂	30.61
Fe O (group)	55.10
Ca O ,,	14.29
						100.00

That slag would, of course, work very satisfactorily, and upon high grade ores and a plentiful supply of cheap iron-flux would leave very little to be desired. Such a slag is, however, seldom seen to day, the nearest approach to it is the 30, 40, and 20-type, which is still run in some parts of the States.

Reference to the analysis of slags given in the preceding pages, will point to the fact that while the silica has been on the increase the iron has been decreasing, and the lime being cheaper than iron has been made to replace that metal until the limiting practical ratio in which the two bodies may exist in silver-lead slags has been approached.

In the face of all these signs it cannot be doubted that the most successful metallurgist of the immediate future will be he who can make his furnace treat profitably, a charge containing the greatest percentage of silica, and of such refractory bases as zinc, alumina, baryta, and magnesia.

Fuels used in Colorado.

The fuel used in blast-furnace smelting consists principally of coke and charcoal, coke alone being used by some smelters, and a mixture of the two by others. Chemically charcoal is the better of the two for the purpose, but physically coke is its superior, as owing to the greater strength of its cell walls it is more coherent than charcoal, and, therefore, better able to resist the crushing strain to which it is subjected in the furnace, and by thus retaining its form prevents the charge from packing, and thus causing uneven blowing.

The principal coke centres of Colorado are El Moro, Crested Butte, and Grand River, while a great deal of the coke supply used to be derived from Connelsville, Pennsylvania, the coke from which region is probably the best in the United States. The high cost of transportation has, however, operated in favour of the local product, which, though not quite so good, is (minus the freight upon the foreign article) cheaper.

The following table of analysis will show the comparative qualities of the American coke with that of Cardiff, Wales:—

	Cardiff, Wales.	Connelsville, Pennsylvania.	Crested Butte, Colorado.	Grand River, Colorado.	El Moro, Colorado.
Fixed Carbon	95.00	87.46	92.03	93.75	87.47
Volatile matter	0.011	1.35	1.85
Ash	4.26	11.32	6.62 ap	5.49	10.68ap
Moisture	0.01	0.49
Phosphorus ..	0.02	0.029	0.10
Sulphur	0.68	0.69	0.76	0.85

From the above table it will be seen that some of the local coking coals are of good quality, the cost of coke varies at the ovens from 3.25 dollars to 3.50 dollars per ton according to the grade. The general method of coking the coal is very similar to that in use in the Connelsville region—the ovens are chiefly of the beehive form, built of bricks, and vary in size from 10 to 12 feet in diameter, and from 5 to 7 feet in height, with an opening in the crown through which the coal is fed. The method of working is simple, and consists mainly in dumping the coal through the crown opening on to the floor of the oven. It is distributed evenly, and the thickness of the layer is dependent upon the time in which the coking is to be accomplished. For a 48-hour burning the stratum of coal is about 2 feet in thickness, for a 3-day burning it is increased to from 2½ to 3 feet. The discharge door is a rectangular opening, situated at the floor-level of the oven, this is partially bricked up and luted before the charge is thrown in as the burning proceeds, this orifice together with others that are provided to allow an ingress of air, are more and more completely luted up with clay, and the roof openings are finally closed up.

The firing of the coal is generally brought about by the residual heat of the oven left by the last charge. When the coking is complete the crown opening is removed and the coke quenched by the injection of water; when sufficiently cool the coke is withdrawn through the discharge opening, and the oven is immediately recharged.

The charge of an ordinary oven amounts to about 110 bushels, or about 8,360 lb. of coal, which yields on the average 132 bushels, or 5,280 lb. of coke. The percentage yield is equal to about 63.64, which requires about 1.58 tons of coal to 1 ton of coke.

The effect of increasing the time of burning is generally to render the coke harder; if at the same time its porosity or oxidibility is not impaired, this firmer coke should be more serviceable for blast furnaces, but this point has not yet been decided. Sometimes the burning is completed in twenty-eight hours, but the average time is forty-eight to fifty hours.

The coal deposits are very well distributed throughout the State and are very extensive, the aggregate area being estimated at upwards of 50,000 square miles. Curiously enough, the carboniferous periods in Colorado do not, with but one exception, *i.e.*, at Telluride, produce any coal, the chief deposits being in the much more recent Upper Cretaceous.

The

The groups which are designated the "Laramie Cretaceous Group," the "Fox Hill Cretaceous Group," and the "Colorado Cretaceous Group." The carboniferous period proper is, in Colorado, separated from the Upper Cretaceous by about 5,000 feet of strata.

The coal ranges in quality from a superior kind of lignite, through all the various conditions of bituminous, semi-bituminous, &c., up to very good anthracite.

The southern part of the State has the largest output; the northern division is perhaps second in that regard.

Good coking coal is found in the following counties:—Park county, at "Como;" Las Animas county, at "Cucharas" and "El Moro;" Fremont county, at "Oak Creek," and at "Coal Creek." The coal is semi-bituminous, which when mixed with El Moro bituminous coal cokes very satisfactorily.

These coals are composed as follows:—

Northern Division.

Golden lignites.

No.	Water.	Fixed carbon.	Volatiles.	Ash.	Total.
1	13.24	45.61	37.25	3.90	100.00
2	13.57	47.54	34.85	4.04	100.00
3	13.19	46.72	35.95	4.14	100.00

Ralston Creek.

No.	Water.	Fixed carbon.	Volatile matter.	Ash.	Total.
1	13.72	44.47	35.95	5.86	100.00

Langford, Boulder county.

No.	Water.	Fixed carbon.	Volatile matter.	Ash.	Total.
1	11.82	58.96	26.08	3.14	100

Fremont County—Semi-bituminous coal.

No.	Water.	Fixed carbon.	Volatile matter.	Ash.	Sulphur.
1	4.50	56.80	34.20	4.50	0.35
2	5.49	51.00	39.33	4.17	0.36

Las Animas County, El Moro—Bituminous coal.

No.	Water.	Fixed carbon.	Volatile matter.	Ash.	Total.
1	0.36	65.66	29.76	4.22	100.00
2	1.46	60.18	34.58	3.78	100.00
3	1.44	54.95	35.69	7.92	100.00

Crested Butte—Bituminous Coal.

No.	Water.	Fixed carbon.	Volatile matter.	Ash.	Total.
1	3.60	61.17	30.97	4.47	100.00

3	1.20	72.51	25.10	3.19	100.00

Crested Butte—Anthracite.

The following is the mean of a large number of analyses, made at different times and by different Chemists, the writer among the number:—

No.	Water.	Fixed carbon.	Volatile matter.	Ash.	Total.
1	1.25	90.19	5.18	3.38	100.00

The wages paid to coal-miners varies from 85 cts. to 1.40 per ton of coal raised.

Average value per ton of the entire production of the State varies, year in and year out, from 2.15 dollars to 2.35 dollars at the mines. The retail price in Denver varies from about 3.00 dollars to 8.50 dollars per ton, the latter figure being for the best grade anthracite; the lignites, similar in quality to those of the "Golden," "Ralston," and "Marshall" beds, are worth on the average 4.00 dollars per ton, although at the present time, owing to a rate war which is raging between the various coal companies, these can be purchased for 2.50 dollars per ton delivered.

CHAPTER IV.—THE PYRITIC SMELTING PROCESS.

The "Pyritic" or "Austin" process is specially designed for the treatment of low-grade, argentiferous, and auriferous iron and copper pyrites, associated with zinc-blende, &c.

Foundation of the process.—The above is essentially a fire concentration process, and is founded upon the fact that when "sulphides" of the metals, *i.e.*, iron pyrites, chalcopyrite, zinc-blende, &c., are smelted in a furnace, the air supply, or blast to which, is heated to a given temperature; in practice this is generally about 600 degrees Fahr.; they are at first, it is supposed, reduced to a lower state of oxidation (FeS_2 to FeS) in the case of iron pyrites. The ferrous sulphide formed above is in turn decomposed; in part, either by reaction with the oxides present in the charge, or by the direct oxidising action of the hot-blast, into FeO and SO_2 , the formation of the latter compound is accompanied by the evolution of much heat, which is turned to account in the furnace. Of this we will have occasion to speak more fully later on. A portion of the iron is in this way rendered available for slag formation, together with such oxides as ZnO , BaO , Al_2O_3 , MgO , &c., resulting from the decomposition of the corresponding sulphides, sulphates, silicates, carbonates, &c., of those bodies. It will be evident that the amount of iron (FeO) formed above will depend directly upon the amount of sulphur oxidised or burnt off in the furnace, and as this will vary considerably with the conditions of temperature, atmosphere, the amount of carbonaceous matter on the charge, &c., the amount of ferrous oxide which will go to form slag, and, therefore, the amount of ferrous sulphide that will remain as matte cannot be pre-determined.

Difficulty of calculating the slag.—From the above it will be seen that the composition of the resultant slag, and the weight of the resultant matte, cannot be accurately calculated.

The effect of uncontrollable variations in the percentage of silica in the slags.—And since the amount of silica from any given mixture going into the slag will remain constant, whilst the amount of iron varies, up or down, the percentage of silica will vary in like proportion; experience has shown that this variation may, at times, be quite considerable, so much so that in ordinary cold-blast or silver-lead smelting the danger of frequently freezing the furnace up, with its attendant inconvenience and expense, would be great. The effect, however, of these variations in the composition of the slag in "pyritic" smelting is not so serious, as, owing to the great size of the furnace, (140 in. x 33 in. crucible), and the much higher temperature at which it is run, a much more refractory charge can be treated than in the lead furnace; this is one of the chief points of advantage claimed. The next most important point of advantage which this process possesses lies in the fact that, notwithstanding the much higher temperature at which this furnace is operated, there is a very decided saving in fuel [*see* comparison further on]. This saving is directly attributable to the utilisation of the heat produced in the oxidation of the sulphur in the charge, the ignition of the sulphur does not appear to be confined to the region immediately above the fusion zone, but seems to take place throughout the entire mixture in the stack, and soon reaches the furnace top, which it is impossible to keep cool. The contrast between this and the lead furnace is, in this respect, very striking, the top of a properly-handled stack of the latter type showing no evidence of the combustion which is taking place a few feet below; the top of the former, however, presents quite a fine spectacle with its gorgeous mixture of parti-coloured sulphur flames.

The unsuitability of this process for the treatment of lead ores.—It is this hot top which renders it impossible to profitably smelt in the pyritic furnace, ores containing any considerable amount of lead, as the loss by volatilisation of lead and silver would be very

very great. It has been claimed by some metallurgists engaged in pyritic smelting that in running a straight or dry charge, the loss in fume and flue-dust was too small to render its collection profitable. There are, on the other hand, however, many experienced smelting men who hold contrary views. The justice of these contrary views is in a measure proved by the fact that extensive flues and dust chambers are being constructed at one, at least, of the pyritic smelting works at Leadville.

Separation of matte from slag.—The portion of the ferrous sulphide which is undecomposed, as mentioned above, remains, together with any copper present, as matte, into which, theoretically, is concentrated all the gold and silver that was contained in the charge. How close an approximation to this theoretical concentration will be obtained depends largely upon the skill with which the furnace is handled. The first thing to be aimed at, after a successful fusion has been obtained, is the complete separation of the matte from the slag; this is best done at the highest temperature, and, consequently, when the matte and slag are at their greatest degree of fluidity. The composition of the matte must be such that its specific gravity will be superior to that of the slag. The pyritic process, in its original form, aimed primarily at the formation of an iron matte, and it was claimed that an almost perfect separation could be obtained; this claim has, however, not been borne out in practice. At works where the original formulæ were adhered to, very dirty slags were, in most cases, the result, some of these, of which I have records, running from 8 to 10 oz. of silver per ton; the reason of this being, that the specific gravity of iron matte approximates very closely to that of the rich iron slags made in this process; and, consequently, the matte particles had difficulty in separating themselves from the somewhat pasty slags, resulting from the refractory nature of the charge.

The advantage of small amounts of copper on the charge.—It soon became evident that some means of obviating this difficulty must be found. Previous experience in ordinary matte smelting suggested the advisability of employing a small amount of copper on the mixture. This was tried, and it has since been found that the use of a small amount of that metal (in the form of ore) adds so greatly to the efficiency of the process as to be practically indispensable in localities where the cost of obtaining copper ores does not exceed the saving in silver resulting from their use. The cleansing effect of copper in a matting process appears to be due, not only to the superior specific gravity of its sulphide to that of the corresponding iron salt, and its greater chemical affinity for the precious metals, but also to its greater fluidity, copper matte being much more fluid than iron matte at a given temperature.

Cost of fuel per ton of charge.—The use of the contained sulphur as fuel, as mentioned above, reduces the proportion of coke upon the charge very considerably. It has been claimed by the patentee that the furnace can be successfully run with but 2 per cent. of fuel, but in practice that figure is nearly always exceeded. At the Bi-Metallic Smelting Works, at Leadville, they claim a consumption of from 3 to 4 per cent. of coke, the latter figure being the maximum. The liquid fuel (residuum) used in heating the blast is estimated to be equal to an additional 3 per cent. of coke on the charge. The total amount of coke used is thus shown to be from 6 to 7 per cent., generally 6 per cent. in summer and 7 per cent. in winter. The capacity of one of these furnaces (140 in. x 33 in.) is nominally from 140 to 150 tons* in twenty-four hours. Assuming, for safety sake, the smaller capacity, the day's run will consume from 8.4 tons to 9.8 tons of coke, which costs at Leadville from 8 to 9 dollars per ton. There are times, of course, when through strikes, railroad blocks, &c., the prices of coke rises beyond the figures given above, but the former of those two figures is the one which generally obtains, and, therefore, can be safely taken as the basis of the following figures. The cost of the fuel used in smelting 140 tons of charge will, therefore, range from 67 dollars 2 cents in summer to 78 dollars 4 cents. in winter, or from 48 to 56 cents per ton. If this is compared with the fuel consumption in silver-lead smelting, the economy of the process in that regard will be apparent. In order to make the comparison a just one, the figures given by the silver-lead smelting practice in the same locality (Leadville, 10,120 above sea-level) are taken. The amount of fuel consumed ranges from 18 per cent. in summer to from 20 to 22 per cent. in winter, so that the cost of smelting the same number of tons of the much less refractory mixtures treated in the lead furnace (25.2 to 30.8 tons of coke) would be 201 dollars 6 cents in summer and 246 dollars 4 cents in the cold season, or from 1 dollar 44 cents to 1 dollar 74 cents per ton, to which would have to be added, if the same mixture were treated, the cost of roasting.

The figures upon fuel percentages given above will no doubt appear high to those metallurgists whose smelting experience has been confined to sea-level, or to but slight elevations above that point. It must, however, be borne in mind that the amount of fuel required to smelt a given number of tons of the same mixture increases with the altitude at which the operation is conducted.

And as the difference created by two extremes of elevation is considerable, that fact should not be lost sight of in comparing the rival advantages offered by different localities for the erection of a smelting plant, especially where the fuel has to be brought from afar, as in this case, the cost of smelting will not only be increased by the additional amount of fuel consumed, but also by the freight rates upon the greater quantity of coke carried.

Cost

* Of charge.

Cost of Labour.

Having considered the cost of fuel in this process, we will take up the cost of labour in running a ton of charge through the furnace. The following is the average rate of wages at Leadville:—

Downstairs—

Foreman	\$5 to \$6 per day of twelve hours.
Furnacemen	\$4 " "
Pot-pullers	\$3 " "

Feed Floor—

Feeders	\$4 " "
Weighers	\$3.5 " "
Wheelers	\$3 " "

*Labour allotted to each Furnace.**Downstairs—*

One furnaceman	\$4 per twelve-hour shift.
Two pot-pullers	\$6 " "
One man to attend to jackets*	\$3 " "

Feed Floor—

One feeder	\$4 " "
One weigher	\$3.5 " "
Two wheelers	\$6 " "

Total \$26.5 " "

Or \$53 per twenty-four hours' run.

Proportion of day foreman's pay (say) 1/3	\$2
" night foreman's pay, 1/3 (\$5)	\$1.66
" superintendent's salary	Variable
Approximate total	\$56.66

* In large works one man is made to look after a number of furnaces.

To which, of course, must be added the proper proportion of insurance, depreciation, blowing, lighting, &c. About 40 cents will, therefore, be the cost per ton of charge through the furnace.

Nature of the Charges treated.—The mixtures treated in the pyritic furnace are made up mainly of raw pyrite, chalcopyrite, sphalerite, and arseno-pyrite, together with silver and gold bearing silica, and, where obtainable, value-bearing limestone, baryta, alumina, and magnesia may be present without seriously affecting the successful operation of furnace to much greater extent than in ordinary smelting.

NOTE.—A charge that has been run with good results at the Bi-metallic Smelting Works at Leadville is composed as follows:—The composition of the different ores, here appended, is not the result of ultimate analysis, but is taken from the figures given by the technical methods in use in the smelting laboratory, which are only approximate, such bodies as baryta, alumina, magnesia, and arsenic, if present, appear to have been totally disregarded. The approximation is, however, sufficiently close for the purpose of illustration, or even for slag calculation. These minerals, if not present in large amounts, are regarded as belonging to the lime group of bases, as they comport themselves in the furnace very much as does that body, and may, as has been stated above, be present to some extent without causing trouble.

Silicious ore, 300 lb.—

Si O ₂	70.00 per cent.
FeS ₂	10.00 " "
H ₂ O	6.50 " "
Undetermined	14.50 " "
	<hr/> 100.00 "

8oz. of silver and a trace of gold.

Raw, 1 st. ; matte, 100 lb.—

Cu	8.00 per cent.
Fe	56.25 " "
S	34.12 " "
	<hr/> 98.37 "

70 to 100 oz. of silver and 0.46 oz. of gold.

Limestone, 400 lb.—

CaCO ₃	99.00 per cent.
SiO ₂	1.00 " "
	<hr/> 100.00 "

Which is equal to—

CaO	55.44 per cent.
SiO ₂	1.00 " "
CO ₂	43.56 " "
	<hr/> 100.00 "

Pyritic ore, 800 lb.—

S	43.70 per cent.
SiO ₂	12.00 " "
Fe	35.00 " "
Zn	7.00 " "
H ₂ O	2.00 " "
	<hr/> 99.70 "

35 oz. of silver.

Pyritic

Pyritic ore, No. 2, 200 lb.—	
S	43.10 per cent.
Fe	35.00 "
SiO ₂	5.21 "
Zn	4.10 "
Cu	4.00 "
H ₂ O	8.00 "

99.41 "

36 oz. of silver.

Dirty slag, 400 lb.—	
SiO ₂	31.25 per cent.
FeO	40.72 "
CaO	21.80 "

93.77 "

And from 4 to 5 oz. of silver.

NOTE.—This slag was obtained from the dump of the old La Plata Smelting Works, which the bi-metallic people were re-running.

Calculation upon the above data gives the composition of the charge as follows:—

S	24.38 per cent.
Fe	27.33 "
SiO ₂	22.55 "
CaO	15.08 "
Zn	3.20 "
Cu	0.80 "
H ₂ O	3.80 "

97.14 "

The smelting of the foregoing charge results in the production of a matte having, approximately, the following composition:—

Cu	8.01 per cent.
Fe	57.24 "
S	34.42 "

99.67 "

And in the production of a slag, as under:—

SiO ₂	32.88 per cent.
FeO	40.43 "
CaO	22.00 "
ZnO	3.45 "
Undetermined	1.24 "

100.00 "

Which assays 2.40 oz. of silver.

Another slag, which is made at the "Kokomo" works, is of the following composition:—

SiO ₂	36.25 per cent.
FeO	39.81 "
CaO	12.33 "
ZnO	10.12 "
Undetermined	1.49 "

100.00 "

The slags run in this process, may, as a general thing, be said to range between the following limits of composition:—

SiO ₂	from 30.00 to 40.00 per cent.
FeO	" 35.00 " 45.00 "
CaO	" 10.00 " 25.00 "
ZnO	" 5.00 " 14.00 "

The matte formed above is resmelted without roasting, either by itself or with sulphide ores added. It is not usual, in this second smelting, to use any fuel other than that used in heating the blast.

The concentration effected in this operation equals from seven to eight into one, and results in the production of a matte running from 45 to 50 per cent. copper, and in some cases as high as 60 per cent. copper. The silver contents vary from 70 to upwards of 300 oz., and the gold from 1 to 4 oz.

This is the shipping product, as so far none of the works operating this process have erected plant for the further treatment of their mattes, and is either sold outright or is sent to the refinery to be treated. As an example of the treatment terms that can be obtained upon these mattes, the following may suffice:—

The refineries make a 14 dollars per ton treatment charge upon mattes running up to 200 oz. of silver, with an additional 2 dollars per ton for each increase in grade of 100 oz. Ag.

They pay for 95 per cent. of the silver at the market valuation, and for all the gold at 20 dollars per oz. The copper is paid for at the rate of 1 dollar per unit. The lead must not exceed 10 per cent., or a rebate will be made. In fact some refiners charge for each unit of lead contained in the matte. This rebate will, however, never be made in the case of pyritic products, since they do not contain any of that metal.

The

The method of conducting the "pyritic" smelting operation differs very little from that of ordinary silver-lead smelting. The charging is done in precisely the same manner, the fuel fluxes and ore being fed in the usual sequence.

The blowing in of a furnace differs only in the absence of lead in the crucible, and is done entirely upon a charge of old slag.

The bulk of the matte is allowed to settle in the crucible, from which it is tapped, through the matte tap on either end of the furnace, at intervals dependent upon the speed with which the furnace is running.

The slag, together with some matte, is allowed to flow in a continuous stream through the water-jacketed side spout shown on plates 1 and 2 into the forehearth shown on plate 8, figs. 17, 18, and 19, in which the greater part of the matte escaping from the furnace with the slag is separated, and is drawn from the lower tap shown in fig. 17, and shown enlarged in fig. 19. The almost completely cleansed slag flows continuously from the spout situated near the top of forehearth (fig. 17) into a final settling pot, which is simply a large slag pot, with three stout legs and a detachable carriage, by means of which it is placed in position, and removed therefrom when sufficient matte has been caught therein. From this final settling pot the slag overflows in a thin stream into the granulator, whence by means of the water it is conveyed to the dump in a finely granulated condition. The contents of the final settling pots are re-run. The matte is cast into thin sheets, about 1 inch thick, by being poured into flat cast-iron plates with raised rims. The plates may be of any convenient size; in this form the matte is very readily broken up into suitable pieces for re-treatment or for shipping.

The forehearth mentioned above is the result of a good deal of trial and failure. It is found to be more effective and much less costly than the somewhat complicated fire-brick lined water-jacketed hearths that have preceded it. It is used entirely at the Kokomo works. It is kept open as long as possible by means of coke or charcoal placed upon the top of the slag, but when it does freeze up, a duplicate hearth is run up to the tap upon the opposite side of the furnace, which is opened, and the first one closed; the frozen hearth is then wheeled to the end of the short length of railway, upon which it stands, where the pins are knocked out and the side plates removed; the mass of slag and matte is lifted away, the plates are put together again, and the hearth is once more ready for use.

The hearth weighs complete about 3,300 lb., and costs on the cars at Denver 125 dollars; freight to San Francisco at 1.40 dollars per 100 lb., 46.20; 171.20 dollars at San Francisco.

The granulator used in connection with the above is a very simple and remarkably effective piece of apparatus, and consists of a piece of 6-inch wrought-iron pipe of any desirable length, one end of which is closed with a screwed iron cap, through the centre of which passes a 2-inch water pipe, which continues up to within an inch or two of the opening in the upper side of the 6-inch pipe. (See fig. 67 B.B.) The other end of this pipe connects with a wooden flume of any convenient size, lined with sheet-iron to withstand the attrition of the sharp granules of slag. Sufficient fall must be given to this pipe and flume to enable the stream of water to keep them clear. The water nozzle C, fig. 67, is best made tapering as shown, or flattened, in order to increase the velocity of the jet. To operate the granulator, water is turned on by means of the valve K, fig. 67, and the overflowing slag from the settling pot is allowed to fall directly into the water jet, issuing at C, where it is instantly granulated and conveyed by the water through the flume to the dump. A neater method of getting rid of slag than this cannot be conceived; the whole operation goes on continuously without noise, without steam, or disturbance of any kind. It is needless to say that a considerable saving in pot-pullers' wages is effected by this device.

In populous neighbourhoods a market for this slag is being created, it is used in place of sand and pebbles in concrete, for which it is particularly well adapted. In addition to which a resident of Denver claims to have invented a simple reverberatory treatment, by which this substance is converted into hydraulic cement.

Mr. Bretherton, of the American Smelter, at Leadville, has tried the experiment of granulating matte in the manner mentioned above, in order to remove the necessity of pulverising before roasting. The idea promised well, but I am informed that the matte in being so suddenly cooled, takes the form of shot, the outer surfaces of which resemble chilled metal, and are too hard to be accessible to the roasting action of the furnace. The experiment has, therefore, not been quite successful.

Specification for Hot Blast Water Jacketed Smelting Furnace, 33 in. by 140 in., as used in the "Austin" or "pyritic" process, for the treatment of low-grade argentiferous and auriferous iron and copper pyrites, zinc-blende, &c.

Columns.—Four cast-iron columns, 8 inches diameter at the bottom, and tapering to 7 inches diameter at the top, 1 inch metal; a flange cast solid on bottom end of column, 16 in. by 16 in., and one bracketed flange at top end, 16½ in. by 16½ in., all 1½-inch metal. The columns are faced off on both ends, making them of uniform length. The necessary lugs are cast on the columns; all holes drilled to receive deck-beams and brace-brackets for carrying bustle-pipes.

Deck-beams.—One set of deck or mantel beams, as follows:—Two girders of two 12 in. 32 ✕ beams, 16 ft. 7 in. out to out; two girders of two 12 in. 32 ✕ beams, 7 ft. 8 in. out to out. The girders fitted with cast-iron separators, and bolts about every 30-inch centres, and 16 inches across over all. All necessary holes drilled for lugs, bracket-irons, and skew-back castings, the necessary lugs and brackets forged and attached for receiving irons to carry the bustle-pipes. The girders are fitted together with heavy splice-plates bolted with eight bolts at each joint.

Skew-backs.

Skew-backs.—Four skew-back castings bolted to girders on the corners to receive the thrust of the brick arches. They are made of 1-inch metal, with brace brackets cast on the inside.

Buck-stays.—Twelve cast-iron corner buck-stays, 4 in. by 4 in., 1-inch metal, 6 feet long, and four 5 ft. 1 in. long, with the necessary lugs for receiving the tie-rods.

Tie-rods.—Twenty-two buck-stay tie-rods, $\frac{7}{8}$ -inch diameter, 17 feet long, nuts at each end. Twenty-two buck-stay tie-rods, $\frac{7}{8}$ -inch diameter, 8 ft. 1 in. long, nuts at each end.

Lintel girders.—Two girders for top of charging-doors, each of two 4-in. $7\frac{1}{2}$ ✱ beams bolted together with five sets of separators, and bolts 10 inches across flanges; length over all, 14 feet 2 inches.

Charging doors and frames.—Four cast-iron door-jambs for 13-inch wall, $\frac{7}{8}$ -inch metal, 4 ft. 10 in. long. The guides are cast solid on jamb, returning on the outside of wall; two $\frac{5}{8}$ -inch grooves made smooth to receive the sliding doors. Two centre columns, 10 in. by 6 in., $\frac{3}{4}$ -inch metal, 5 feet long, faced off to make uniform lengths, columns are flanged inside on both ends; two guide-plates (one for each column), are provided and bolted to the 6-inch side of the columns, grooves made smooth to receive sliding door. Eight $\frac{7}{8}$ -in. by 14-in. anchor-bolts, with 6-in. by 6-in. anchor-plate for anchoring the jambs into place. Four feed-doors of 12 ✱ iron, 5 ft. 6 in. by 6 ft. 5 $\frac{1}{2}$ in., fitted with draw-lugs and stiffening angles. Each door is attached by lugs on the doors, which is brought together and fastened at centre with a ring to attach the wire rope to, necessary wire rope, and with eight iron sheave blocks with eye, and four iron buckets to load up and form balance weights.

Charging floor.—Eight cast-iron charging floor-plates, 3 ft. 2 $\frac{1}{2}$ in. by 6 ft. by 1 $\frac{1}{4}$ in. Four cast-iron charging floor-plates, 1 ft. 10 in. by 4 ft. 2 in. by 1 $\frac{1}{4}$ in., with all necessary holes drilled therein.

Jack-screws.—Eight complete jack-screws for holding up and adjusting the furnace bottom. Said screws are 10 inches square at base, and 22 inches long over all. The screw proper is 2 $\frac{1}{2}$ -inch diameter, square-cut thread; are all thoroughly fitted.

Furnace bottom.—One cast-iron furnace bottom, made 62 inches over all in the widest part, and 13 ft. 1 in. over all extreme length, 2 $\frac{1}{2}$ inches thick, with strengthening ribs 3 in. by 2 $\frac{1}{2}$ in., and a 1-in. by 2-in. flange around it to form shoulder for jackets. This bottom is made in two pieces, planed joint, drilled holes, and bolted together with 1 $\frac{1}{2}$ -in. bolts, 16 inches centre to centre. Seat pockets are provided to receive the jack-screws. All necessary lugs are provided, holes drilled to receive the screws for adjusting the spouts.

Jackets.—One set complete, comprised of fourteen side jackets, four end jackets, two water blocks, four side and two front sump jackets. Two of the fourteen jackets are made of steel; balance of all the jackets are made of cast-iron, made in dry sand. All jackets have planed joints, all necessary hand holes and all holes tapped for the required piping. The side jackets have two tuyere holes in each, bored out to receive tuyeres; the end jackets have but one each, which are bored out in like manner. Each jacket has dovetail lugs cast on it to receive the loose lugs, and 112 cast-iron lugs, with necessary bolts for securing jackets in place.

Spouts.—Two cast-iron water jacketed spouts, fitted ready for adjusting screws; two square thread-adjusting screws, fitted with forged jack-screw head one side, and a loose nut, tapped and secured to furnace bottom plate. This device, with all necessary straps, &c., is for adjusting the above spouts at will, as required.

Bustle pipes.—Bustle-pipes are made of cast-iron $\frac{3}{4}$ inch thick, 12 $\frac{1}{4}$ inches outside diameter. They are made in sections; flanged ends, faced, drilled, and bolted with all necessary bolts. There are two pieces 6 ft. 8 in., two pieces 8 ft. 6 in., and one piece 6 ft. 11 in. long, with four elbows, one tee 5 ft. 7 in. long, with branch to receive main, 16 $\frac{3}{4}$ in. in diameter. The above bustle pipe has sixteen branch elbows; said branches are faced to true joints. The drop pipes are sixteen in number, with top end elbow shape faced off. Between the elbows on bustle pipe and drop pipe is placed a finished adjusting flange. These are secured together, and to the bustle pipe with $\frac{7}{8}$ -inch bolts, each fitted air-tight. The lower end of drop plates are cast with an outlet on each side. Each outlet is fitted with a tee for tuyere pipes, and between each tee and the drop pipes there will be tight-closing air valves; said valves are made of steel, finished to work against a finished iron seat. The valves are worked by fulcrum levers and link, and are held in any position by lock nuts, and are all thoroughly fitted in place. The above-mentioned tees are made tapering and bored out to receive the tuyeres.

Tuyeres.—Thirty-two forged steel tuyeres, turned to fit into the tees mentioned above; the small ends of tuyeres finished to fit the bored tuyere openings in the jackets. The large end fitted up with a double-handled reducer, containing the peep-hole. The said peep-hole is covered with mica, and held in place by a brass peep-hole cap, screwed into place. All the necessary wrought-iron clamps, bolts, and cap-screws, supplied to fit all into position.

Brackets to carry Bustle Pipes.—Eight brackets for carrying bustle pipe, made of tee and bar iron, fitted up with necessary bolts and with bolts for securing them to the columns and deck beams respectively.

Water Pipes.—A complete set of water pipes, as follows, to wit:—The main pipes are of cast-iron, provided with branch pipe openings, drilled and tapped to receive their respective pipe. All sections with flanged ends, fitted together with gaskets and bolts;

bolts ; all flanges faced to joints. The sections are all 3-inch inside diameter, and there are two sections 8 ft. 8 in., two 8 ft. 1 in., one 8 ft. 6 in., and one 2 ft. 6 in. long, three ells, and one flange cap. The branch pipes for supply are comprised of 1-inch fittings, excepting the hose, which is $1\frac{1}{4}$ -inch.

Sundry fittings as follows:—

Sixty-eight nipples.			
Four pieces of pipe	6 inches long.		
Two	"	$6\frac{1}{2}$	"
Ten	"	7	"
Two	"	$7\frac{3}{4}$	"
Two	"	3	"

Two unions.			
Two pieces of $1\frac{1}{4}$ -inch hose	20 inches long.		
Two sections of trough made of 16 \times galvanised iron 6 inches wide, $3\frac{1}{2}$ -inch radius, with necessary discharge nipples. All the wrought-iron brackets and bolts required to carry supply and discharge pipes are supplied.			

The specification given above is that of the furnaces in operation at the works of the Summit Mining and Smelting Co., at Kokomo, Colorado.

The area of the iron-shod feed floor is 176 square feet. The buckstays run straight up to 20 feet above the feed-floor, which is 15 feet above the foundation ; and there are seventeen courses of brick above the top of buckstays.

Foundation.—The foundation is made of stone or brick laid in cement, with flag-stone blocks embedded flush at top to receive columns and jack screws. The thickness of the foundation will, of course, depend upon the ground in which it is laid. If the furnaces are being erected at existing works, the foundation may be very economically made of a sort of slag "breccia" made by cementing together coarsely-broken fragments of slag by means of fluid slag.

The furnaces used in pyritic smelting are of two kinds ; the first one is that specified above, in which no dust chambers are used. The furnace top is finished off with a sheet steel or iron stack about 30 feet long, through which the products of combustion and decomposition are discharged directly into the atmosphere. This is not a good practice, for not only are the fumes very disagreeable to inhale but they are actually injurious to both plant and animal life ; and in addition to that there is the economic objection to be urged, that the strong current of heated gas escaping from the furnace draws with it solid particles which carry more or less value, and their ejection into the air results in some loss.

It appears to the writer that a very good proposition is presented here, in connection with this furnace. If, in one of the districts of New South Wales in which large bodies of argentiferous pyrite and highly zinciferous galena occur, in which the zinc carries silver as well as the lead, a plant of this nature was erected to work the pyrite directly, and connected with a crude system of sulphuric acid chambers, an acid of sufficient strength to leach the zinc from the roasted galena could be very cheaply produced. The silver in this solution could be inexpensively recovered by cementation, and the zinc could be recovered as sulphate, or as metal by electrolysis.

By referring to the analysis of the charges treated by this furnace (page), it will be seen that a single stack in twenty-four hours discharges 27.90 tons of sulphur into the air, which is equal to 69.75 tons of sulphuric anhydride SO_3 , or 85.44 tons of absolute sulphuric acid H_2SO_4 . The whole of this sulphur is already paid for in the treatment charges made upon smelting the pyrite ; and moreover, some of the sulphur leaves the furnace in the form of the higher oxide SO_3 , which simply needs to be dissolved in water. To convert the whole of the SO_2 to H_2SO_4 would require a lead chamber, steam, and either potassium or sodium nitrate. The acid produced would necessarily

necessarily be crude, and would most likely contain metallic sulphates derived from particles of ore which would, in the absence of special means for their collection, be carried into the acid chamber. It would, however, be quite good enough for the purpose, and might, in addition, find a ready sale at a low figure in other localities.

Bricks required to construct the furnace.—21,000 common red bricks and 5,000 fire bricks.

Weights and prices of complete ironwork.

Price of complete ironwork as specified above, on the cars at Denver ...	3,700·00 dollars.
Weight is 59,000 lb.	
Freight to San Francisco at dol. 1·40 per 100 lb.	826·00 ,,
Price at San Francisco.....	4,526·00 ,,
Manufactured by the Colorado Iron Company, Denver, Colorado, U.S.A.	

In the second case the design of the furnace is somewhat modified, the feed-floor is 18 feet above the top of the foundation, and a downtake is provided to make connection with the dust chambers. The feed-hole on furnace top is simply an aperture in the floor, closed by a counterpoised cover plate of cast-iron. The following additional specifications will cover all the points of difference:—

Bottom plate.—One heavy cast-iron bottom plate 12 ft. 9 in. long, and 3 ft. and 10 in. wide inside the flanges, $2\frac{1}{2}$ inches thick, heavily ribbed, and with a flange around the top-side to form a shoulder for the water-jackets, and eight lugs on underside to form seats for the top of jacket-screws.

Water-jackets.—

12 side-jackets 20 inches wide by $55\frac{1}{2}$ inches high.
2 " 20 " " 45 " "
4 side sump-jackets.
2 front " "
4 end-jackets $22\frac{1}{2}$ inches wide by $55\frac{1}{2}$ inches high.

All joints in the jackets are planed on a machine. Each side-jacket is supplied with two bored tuyere holes, and one hand-hole fitted. Each end-jacket is supplied with one bored tuyere hole, and one hand-hole fitted. The front sump-jackets are fitted with an adjustable spout adjusted with a temper-screw, said screw passing through a stationary lugged-nut attached to the bottom plate. All jackets are fitted with necessary tapped-holes for water connections, and with lugs on same dovetailed to receive bolt-lugs. Each set of jackets has 120 bolt-lugs, dovetailed to fit the lugs on jackets, and sixty bolt-rods with brass nuts. These are used for securing the jackets in place, making it exceedingly easy to remove any one or more, and replace when necessary. The jackets are made of select pig-iron. The cores are made in iron core-boxes, making the metal thickness uniform and of exceeding durability, if attention is paid to the cleaning. Every section is tested by hydrostatic pressure.

Water-pipes.—One set of cast-iron pipes fitted together with flanged face-joints, fitted with gaskets and bolts with all necessary drilling and tapped connections for the branches, and with a tapped flange to receive the main water-pipe. All necessary ludlow-valves with nipples, ells, pipe, and fittings, to make connections with jackets for supplying the cold water including the wrought-iron hangers for same. All necessary galvanised-iron troughs with connections and hangers for receiving the discharged hot water from the jackets. One piece of rubber hose with hose-pipe attached to main furnace water-pipe for wetting down around the furnace.

Columns.—Four cast-iron columns 8 ft. 5 in. long (to top of brackets) flanged bottom to said columns faced off in a lathe to make all a uniform length. The column is 8 inches diameter, 1 inch metal. These columns are used to receive the mantel plates which carry the brick-work above.

Mantel-plates.—Each mantel-plate is made of heavy channel-steel, curved to a proper radius to carry the brick-work above. The ends are fitted to the top of the columns, and eight heavy rods fitted to reach from column to column around the furnace, two to each section. These hold the thrust of the mantel-plates.

Water-jacketed mantel girders.—A set of auxiliary water-jacket girders made of steel-plate riveted to form. Fill the space from the top of the furnace-jackets to a point above the top of the arched mantels and inside of the latter. (See figs. 56 and 57, plates 16 and 16a.) These mantel girders carry the fire-brick lining of the stack, and at the same time protect the curved mantels carrying the main brick-work from the heat.

Petticoat-pipe, branch pipes, and tuyeres.—All fitted complete with metal joints, universal in action. Thirty-two tuyeres arranged in pairs with universal joints and independent shut-off valves for each, whereby the blast may be shut off from any one or any number of tuyeres, at pleasure, and any tuyere nozzle may be withdrawn for the purpose of introducing bars for removing obstructions inside the furnace. One flanged-blast valve fitted to pipes 24 inches.

Corner Buckstays.—Four corner buckstays, 8 feet long, of heavy cast-iron, provided with lugs to receive the rods.

Tie-rods.—Eight tie-rods, 17 ft. 6 in. long, 1 in. iron, with nuts both ends; eight tie-rods, 8 ft. 7 in. long, 1 in. iron, with nuts both ends. These are to secure the buckstays to place.

Floor-plates.—One set of feed floor-plates, $1\frac{1}{4}$ inches thick, equal to 193 square feet. The joints are made lap, and fitted with countersunk head-bolts. The inner edges are reinforced with wrought-iron, 4 in. by 1 in., riveted to place flush on top.

Cover-

Cover-plate.—One heavily-ribbed cast-iron cover-plate, to use over feed opening, fitted with eye-bolts, chain, and link for wire-rope attachment. One set of sheave-blocks, with bucket-weights, and wire-rope for raising the said feed-plate.

Down-take Irons.—One set of irons for brick-flue. Said flue connects furnace with dust-chamber, to wit—four 4-in. by 4-in. steel angles, about 16 feet long, with the bolts and nuts complete, and necessary lugs.

Hoods and Stacks.—Two sheet-steel hoods, with stacks, are furnished to carry off the fumes from furnace discharge-spouts, one each end or side.

Brick required.—Nine thousand common, for furnace; 5,000 fire-brick. Brick for dust-flue (down-take flue) not included.

The foregoing specifications are for one complete stack, ready for main blast-pipe and main water-pipes. The distance from top of foundations to feed-floor 18 feet.

Specifications for Hot-blast Stove.—Capacity to suit the above-specified Furnace.

Foundation.—The foundation is prepared in the same manner as for the smelting-furnace.

Doors and Frames.—Fourteen 14-in. by 18-in. iron doors and frames, with fifty-six anchors for same. The doors are hinged. Two fire-fronts, each with double fire-doors, lined, and with double ash-doors; doors hinged, and necessary anchors for same.

Steel Beams and Pipe-hangers.—Eight steel I-beams, 13 lb. per foot, 13 feet long. Ninety-six hangers, of flat wrought-iron, to loop over bearers and fasten to U-pipes, with iron bolts through lugs on the pipes, and each hanger fitted with two wedge-keys.

U-pipes.—Forty-eight cast-iron U-pipes, made of select pig-iron, and cast on ends in dry sand moulds. Each U-pipe has two flanges cast on same; said flanges faced off in a lathe; holes drilled and fitted with bolts and gaskets for fitting one to another, and with the main pipes.

Main Blast-pipe.—Four sections of cast-iron main blast-pipes, of square-box pattern, 1,233 inches area; all the necessary flanges cast on same, faced, drilled, and fitted with bolts and gaskets to secure the U-pipes to same, and to connect the sections together. One cast-iron Ell fitted ready to receive the cold blast, and to conduct it to the U-pipes, and the necessary box blast-pipe, with ells, flanges, gaskets, and bolts to connect the blast-stove with the smelting-furnace, said distance not to exceed 27 feet centre to centre.

Stacks.—Two cast-iron stack bases.—Two stacks, 18 inches diameter by 30 feet long, made of No. 16 steel, each fitted with stiffening bands and guy band, 300 feet of guy wire-rope.

Buckstays and Tie-rods.

Four old rail buckstays,	10 feet long.
“	12 feet 6 inches long.
“	6 feet 9 inches long.
Two	6 feet 3 inches long.
“	17 feet long, bent to suit contour of furnace.
“	16 feet 6 inches long.
“	5 feet 6 inches long.
Six loop rods,	17 feet 10 inches long.
Two	20 feet 10 inches long.
“	4 feet 6 inches long.
Eight loop anchors.	

Grates.—One set of grate bars to fill fire-box, 3 ft. 1½ in. x 14 ft. 5 in., with four rests for same.

Tiles and Asbestos.—Fifty-nine sections of special tile to form a ceiling over the U pipes, and 336 square feet of magnesia covering, and one barrel of plaster and 500 feet of copper wire for covering the hot-air pipes.

Bricks required.—Bricks required for one hot-blast stove to suit the above specified irons:—32,000 common bricks (red), 11,000 fire bricks, 6 tons of fire clay (ground).

Weight and price of complete ironwork and tiles of stove as specified.

On the cars in Denver.....	3,400 dollars
Weight, 85,000 lb.	
Freight to San Francisco, at \$1.40 per 100 lb.	1,190 „
Price in San Francisco	4,590 „

The general construction and design of the hot-blast stove will be understood by referring to plates 5, 6, and 7, figs. 10 to 16 inclusive. Fig. 10 represents a longitudinal section through fire-box and system of U pipes, showing general arrangement of the latter, which are forty-eight in number and 6 inches in diameter, internal measurement, and are connected to main air-pipe and blowers in eight series of six each, by means of the square cast-iron box-pipe shown at A and A', A being the induction and A' the eduction pipe. This latter is connected to the bustle or petticoat pipe of the blast furnace by means of a cast-iron service pipe, 16¾ inches in diameter, and ¾-inch metal. This is completely lagged with magnesia fabric secured in place by copper wire, and carefully luted with a plaster of the same material.

The U pipes are suspended from I beam girders by means of wrought iron links, made adjustable by taper wedges. [See fig. 12, plate 6, and fig. 10, plate 5.]

The

The roof of the stove is made up of flat fire-clay tiles, made to embrace the U pipes just below the bend, and carefully luted with fire-clay at the joints, and the whole rendered fire-proof.

The combined capacity of the U pipes is very much greater than that of the induction and eduction pipes, so that the speed of the air current is very much reduced upon entering the stove, and at the same time the surface exposed to the heat is greatly increased.

The air enters the stove at the ordinary temperature of the blower room, and leaves it at between 600 and 700 degrees Fahr.

Fig. 11 shows the plan of the same combination, giving position of grate, fire, and inspection doors, the fire-brick wall which promotes the distribution of the heat amongst the heating tubes, and the escape flues leading to the double stack, and also showing completely the fire-brick lining of the stove.

Figs. 14, 15, and 16, plate 7, represent the stove in side elevation, stack-end elevation, and furnace-end elevation respectively, and are self-explanatory.

This stove has given satisfaction so far, wherever tried; it is, however, only capable of supplying one blast-furnace. Where a number of furnaces are operated it would be necessary to build additional stoves, or else to very largely increase the capacity of the general one. The erection of a stove for each blast-furnace would entail a very heavy expenditure, besides taking up a great deal of room, thereby increasing the area of the works, and, consequently, the cost of transporting ores and products about them.

Perhaps, with a stove built upon the principle of the "Siemens" regenerative furnace, the hot blast supply for a battery of smelting stacks could be more satisfactorily and inexpensively obtained.

The stove, as used, is either fired with solid fuel (coal, &c.), or with liquid fuel (residuum). The latter is the more convenient of the two, and is no more expensive than the former. Residuum results from the distillation of the more volatile constituents in the manufacture of coal-oil. It is a greenish-black semi-fluid mass, and costs at Leadville about 1 dollar 25 cent. per barrel. Where used, it is kept in zinc-lined tanks. Its fluidity is increased by means of a steam-coil, connected with the exhaust from the engine.

It is conducted to the stove or boiler room through a compound pipe, which consists of an outer iron steam pipe, surrounding an inner oil pipe. The outer pipe is constantly supplied with live steam. It is a good practice to pass the last few feet of this pipe through the fire-box. In this way the steam becomes superheated, and the oil is supplied to the atomiser in a highly heated condition, which promotes the complete combustion of the resultant spray. From this point the heat is handled by means of fire-bridges, fire-walls, &c., exactly as when coal or other solid fuel is used.

Residuum is used very extensively in Leadville and district under steam-boilers. It has been found a very satisfactory fuel. The facility with which it is handled, and its cleanliness, being amongst its chief recommendations. Perhaps the only objection that can be urged against it is the noise made by the atomisers. It is found to be easier on the boiler-plates than either coal or coke, as owing to the strongly reducing nature of its flame, very little scale through oxidation is formed. It makes little, if any, ash; and being completely combustible, does not foul the flues and fire-tubes with deposited carbon.

CHAPTER V.—THE BARTLETT PROCESS.

This process is in operation at the works of the American Zinc-Lead Company, at Canyon City, Colorado.

The aim of the process is the solution of the great problem which presents itself in the profitable treatment of complex zinc ores running low in gold and silver values. A great deal of attention has lately been given to this question, and a vast number of schemes have been advanced. These have, for the most part, been leaching propositions. The leaching operation proper being preceded by an oxidising or sulphatising roasting. The zinc sulphate (together with any other soluble sulphates that may be formed during the roasting) is leached with acidulated wash-water—the acid used sometimes being sulphuric, and sometimes sulphurous, &c. Few if any of these schemes, owing to their costliness, and to the limited market for the zinc salts produced by them, can be regarded as successes up to the present time, nor can it be said that any of them promise much in the near future.

In addition to the many leaching methods proposed there have been some few electrical methods propounded. None of these have, however, had any extensive trial, and may be regarded as still in the experimental stage.

The Canyon City process is a modification of the "Joplin Missouri" ore-hearth method for the production of paint pigments from lead ores.

Mr. Bartlett, in a paper upon the subject, written for the *Colorado School of Mines Scientific Quarterly*, says, "The basis of the patents used at the works is the fundamental principle that unroasted zinc ores can be mixed with coal, and the zinc and lead expelled by heat and air, without loss of silver, provided there is kept in the charge an excess of sulphur. This addition of sulphur is made preferably in the form of iron and copper sulphides."

Mr. Bartlett leaves his readers in doubt as to the exact meaning of the term excess of sulphur, as applied in this case; and, with a certain amount of inconsistency, goes on to say, in a latter paragraph of the same paper, that the pigment, as put upon the market, contains from 4 to 5 oz. of silver per ton.

Perhaps

Perhaps it will be well to give here a description of the process, as given in the originator's own words. The following is from Mr. Bartlett's paper quoted above. The writer will append some additional data which have been gleaned from independent sources.

Mr. Bartlett says: "The process is brief, consists in blowing up on a perforated grate, with a heavy air blast, the raw ores mixed with about 75 per cent. of their weight of any fine coal. This eliminates a large portion of zinc, lead, and sulphur. The process is stopped before the sulphur contents are too much reduced, thus retaining the silver. A cinder or scoria is formed which retains nearly all the gold, silver, and copper.

"This scoria is then smelted into a matte, in a peculiar blast furnace, mixing with the cinder other ores, principally copper. In this case, as in the other, sulphur is present in excess, and the process is, strictly speaking, a pyritic smelting, since the sulphur largely replaces the fuel. The slag formed in these furnaces is kept very silicious, and rarely contains more than $\frac{1}{4}$ oz. of silver. While the zinc contents are from 2.5 to 7 per cent., the silica contents range from 35 to 42. Any less percentage of silica would retain the zinc and cause more loss of silver. The charge is run low and hot, and a complete volatilisation of the zinc and lead is intended.

"The zinc contents in the charge, including fluxes added, usually run from 12 to 20 per cent. Lime is used to a limited extent. Any more than 5 per cent. of lime, however, causes a sticky, pasty slag, hence iron is used mostly for slagging off silica. The loss by volatilisation is greater in the blast furnace than in the first or blowing-up process, and is greatest when the matte produced is the least in quantity.

"The fume produced in both the blowing-up process and in the blast-furnace process is a mixture of ZnS , $ZnSO_3$, $ZnSO_4$, PbS , $PbSO_4$, $PbSO_3$, containing some carbon, and many of the rarer elements, as well as Sb and Hg . This fume is submitted to a roasting and grinding process, whereby the more volatile elements are driven off, carbon burned out, and the sulphites reduced. The completed product is a dense white homogeneous compound, consisting mainly of zinc oxide and oxysulphate of lead. This product finds a ready sale as a substitute for white lead and zinc white. It makes a fine opaque body for painters' use, which is equal to the best white lead, and the sale of these goods is constantly being increased.

"The Canyon City works are the only ones in the world treating silver-bearing zinc ores. The different processes used are covered by fourteen patents. The chief drawback is the limit in production. The trade at most cannot absorb more than 50 tons daily of the pigment, and as 200 tons of ordinary zinc ores will produce this amount, it follows that Colorado will always have a sufficiency of ores for the purpose. Modifications of this process can be used, however, in treating any class of zinc-bearing ores. By allowing the zinc fumes to escape, and only saving the silver, gold, and copper, the process becomes applicable to any ore, the only requisite being a fairly cheap supply of coal. So far as the writer knows, it is the only reliable process in use to-day which will profitably extract silver from zinc ores.

"Modifications of the process can be worked out to apply to any ore which does not contain any material value in lead, as any lead in the ore is bound to be lost when pigment is not being made. But as any quantity of ores exist which contain valuable quantities of silver and gold, with little lead, the lead question can be ignored.

"Take many of the ores of Gilpin County, for instance, especially the concentrates, which often run up as high as 35 or even 40 per cent. zinc, with 1 to 2 oz. gold, 40 to 100 oz. silver, and from 2 to 8 per cent. lead. Such ores can be treated by a modified process at much less loss and expense than is now incurred at the lead smelters.

"It may be added that the process as carried out at Canyon is made up out of old, well-known methods, by combining and improving with the addition of but few really new processes. One great advantage is that fine ores can be used. The cementation which takes place in the blowing-up process makes a cinder of the finest kind of ores, which will hold together in any blast furnace.

"Summing up, the process as used in Canyon is as follows:—

"I.—*Blowing-up Mixture*.—Zinc ore crushed to pea and dust size, plus 75 per cent. of fine coal. Average contents: Zn., 30 per cent.; Pb., 8 per cent.; FeS. and silica to balance; Ag., 10 to 20 oz.; Au., 1–10 oz.; Cu., 1 to 2 per cent. Treatment, by blowing four hours. Results: Fume (a) and cinder (b).

"II.—*Treatment of Cinder*.—Cinder (b), containing ZnS., 12 to 15 per cent.; Pb., 1 per cent.; Ag., 10 to 20 oz.; Cu., 1 to 2 per cent.; balance, FeO., FeO., SiO₂, FeS., &c. This is mixed with 5 per cent. lime and copper ore added, which may contain Ag., Pb., Zn., Fe., S., and SiO₂. If too silicious, iron fluxing ore is added. This is smelted in the blast furnace with a small per cent. of coke. Results: Fume (a), slag (c), matte (d).

"III.—*Treatment of the fume*.—The fume, which is collected in woollen filter-bags, is submitted to the roasting and grinding process, and is sold for pigment. The impurities driven off contain a mixture of As., Sb., Hg., Fe., SO₂, Fl., Cd., and many rarer elements. The pigment contains 4 to 5 oz. of silver per ton.

"IV.—Slag (c) is thrown away. This contains .75 oz. Ag., 2 to 7 per cent. Zn.; no lead or gold.

"V.—Matte (d) is either refined on spot or sold for refining; contains 75 to 200 oz. Ag., $\frac{1}{2}$ to $\frac{1}{4}$ oz. gold, 30 to 40 per cent. Cu., 2 to 4 per cent. Zn. While the process looks simple and easy, it requires experience in working. Especially is this true if pigment of a pure white is to be made, as the slightest colour in the goods would injure their sale. The matting furnaces also require quite a different treatment from that

that in use in copper and lead smelting. The great excess of zinc and sulphur, together with silica in excess, makes a different charge to run and one which, if attempted in the ordinary blast furnace in the usual way, would almost instantly freeze the furnace.

"Success in working this scheme, as in many others, depends largely on experience and practice."

The process, if not successful at Canyon City, cannot be successful anywhere; the situation of the works is, perhaps, the best possible; they are supplied by the local coal mines with an unlimited amount of slack at 50 cents per ton,—indeed, the writer is informed that a contract for a large amount of this slack has been made at 25 cents per ton. Then again, it is on the direct line from Leadville, which is the source of the most favourable kind of zinciferous tailings for the process. Mr. Bartlett claims to be able to treat profitably the immense bodies of tailings, such as the "Colonel Sellers," which are lying at Leadville, and which can be purchased on the ground for 75 cents per ton, and landed at the works at Canyon City for 4 dollars per ton. The average composition of these tailings is as follows:—

SiO ₂	=	10·00 to 12·00	per cent.
Fe.	=	20·00 ,, 24·00	,,
Zn.	=	19·00 ,, 24·00	,,
Pb.	=	4·00 ,, 8·00	,,
Ag.	=	10·00 ,, 15·00	oz. per ton.

Although it is claimed that the process is entirely covered by patents, there is a remarkable amount of reticence displayed by those connected with the concern in regard to what is being done at the works; in fact it is impossible to secure the privilege of an independent examination of the works, and, therefore, precise information in regard to the process is very difficult to obtain. The following additional data have, however, been gleaned.

The mixture of coal slack and ore is treated in furnaces not unlike assay muffles in form, the capacity of which is about 1 ton per diem each; the works contain forty-six of these furnaces, in a current of heated air, introduced through tuyeres; the resultant zinc-lead fume is conducted over a regenerative fire to long flues, where it is cooled and finally collected in woollen bags [see description of the Bartlett Bag House]. This "raw pigment" is refined by being passed through moderately heated (dull red) iron tubes—these are inclined at a small angle with the horizontal—uniform transit through which, and uniform exposure of the charge to the evolved gases (SO₂?)—it is claimed that this gas has a bleaching effect upon the pigment—during transit, is secured by means of revolving screws. During this treatment carbonaceous matter is burnt off, and the sulphides reduced. During the operation a carefully regulated current of air is made to circulate through the tubes, the product (white pigment) is delivered from the lower end of the tubes into the boxes, bins, hoppers, or any other suitable receptacle, and after packing is ready for shipment.

A sample of the product obtained from a point in the flues 400 feet from the furnace assayed 1 oz. of silver per ton. This cannot, however, be regarded as proof that no more than this amount of silver per ton of pigment is volatilised, since the flue-dust is well known to be richest at the beginning of the chambers.

The slag assays made at the company's office gave a trace of copper and 1 oz. of silver per ton; the record of lead and zinc contents of these slags was not accessible, but samples taken and assayed privately gave:—

No.	Zn.	Cu.	Pb.	An	Ag.
1	7·20	1·10	None.	oz. None.	oz. 1·4
2	5·75	1·30	"	"	1·5
3	6·45	0·96	"	"	0·94

The high-grade mattes are shipped to New York refineries, and bought upon the following bases:—5·5 cents per lb. for the copper, 95 per cent. of the contained silver and gold is paid for at the market valuation; there is no treatment charge made. The freight to New York is 14 dollars per ton.

The low-grade mattes are shipped to Argo, near Denver, where a treatment charge of 20 dollars per ton is made, and the metallic contents of the matte paid for as follows:—Copper, 5 cents per lb.; 95 per cent. of the silver and gold is paid for at the market valuation. The freight to Argo is about 3 dollars per ton.

The books of the company show that in 1892, 2,397,929 lb. of pigment were shipped, the greater part of it going to the company's warehouse in Chicago, where the product is graded, packed in barrels, and finds its way into the market. 250,000 lb. of pigment were sold directly from the works—the larger part of it went to San Francisco, the remainder was sold to paint works in Colorado. The books, however, do not show that the whole of the pigment was sold, no record of the receipt of payment for it being accessible.

A short description of the "Bartlett Bag Process," for the recovery of flue-dust and fume, as used at the Canyon City Works, and a modification of which is in successful operation at the Globe Works at Denver, may be of value, since it will help to elucidate the method of recovering, not only the paint pigment produced at Canyon city, but also the method of applying it to the condensation of silver-bearing fume produced in argentiferous lead-smelting.

The

The fumes are drawn from the furnace by any rotary suction device, such as the Sturtevant exhaust fan, the orthodox size of which is 6 feet in diameter, and makes from 290 to 300 revolutions per minute. They are conducted through a dust chamber (of brick) about 40 feet long, 18 feet high, and 26 to 27 feet wide; they are then passed out at the top of the chamber through a horizontal pipe (of sheet-iron) 5 feet in diameter, which is supported upon iron columns 20 feet in height, to the fan, and from it through another sheet-iron pipe 4 feet in diameter, supported upon 12-foot iron standards, to the bag-house, which is a brick building 96 feet long, 50 feet wide, and 45 feet high, and is divided into two sections by a partition passing through its length; the building is also divided into two storeys by a floor 12 feet from the ground. The materials used in constructing the house are ordinary red bricks and iron piping. The lower floor contains the sheet-iron hoppers, into which the dust collected in the filter-bags is discharged. These are disposed in four rows of nine each; they have the form of inverted four-sided pyramids, with their apices truncated, and the apertures thus formed are fitted with sliding doors or dampers; they are supported by iron pipes enclosed in burnt-clay drain-pipes. The upper ends of the hoppers are covered with thin sheet-iron, which is pierced by sixteen 18-inch holes fitted with thimbles, which are $12\frac{1}{2}$ inches long. The bags are made of unwashed wool, are about 58 inches in circumference, and 33 feet long when new; their upper ends are firmly closed with strong cords, which also serve to suspend them from the beams provided for that purpose near the roof. The lower ends of the bags fit over the sheet-iron thimbles, and thus the dust hoppers and the bags are brought into connection. There are 576 (?) bags in the building. There are foot-platforms or gangways built upon light iron scaffolding between every two lines of bags.

The main flue pipe is 4 feet in diameter, and varies in length from 350 to 400 feet. This is in order to allow the gases time to cool in transit from the brick-dust chamber to the bags. At the bag-house end the main is tapped by four branches, which connect with the end hopper of each of the four rows, the hoppers are connected together in series of nine, as mentioned before.

When the gases reach this point they are cool, and are forced by the fan into the hoppers, and thence upward into the bags which intercept the dust, with which the draught is laden, and also filter the fume, which falls down into the hoppers. These are emptied at intervals of two or three days.

At silver-lead works the greater part of the flue-dust proper is caught by the dust chambers, but not so the fume. This generally escapes into the atmosphere. It is this fume, together with a small amount of dust, which the flues fail to arrest, that the bag-house system is designed to catch.

The writer understands from Dr. Iles that the saving effected by the introduction of this system at the Globe Works is quite considerable. When applying the bag-house to the collection of silver-lead smelter fume the series of flues described above may be replaced by the ordinary flue chambers, providing that the latter are of sufficient length to allow the gases to cool before entering the bags. In this case the gases from the roasters must not be mixed with those from the blast furnaces, since the acid nature of the former would destroy the fabric of which the bags are composed.

CHAPTER VI.—ORES OF COLORADO AND THEIR OCCURRENCES.

The ores of the metals in Colorado are confined almost entirely to the rocks of the mountainous region. The richest deposits are, indeed, found in the very hearts of the various mountain systems, as, for instance, the Leadville deposits and those of Aspen, Central, Idaho Springs, Silverton, Telluride, Ouray, &c., &c. As the mountains are forsaken for the plains, mining, other than placer, becomes scarcer and scarcer; even the foothills are productive of coal only.

Although the metals are confined to a few geographical localities, they are by no means so restricted in their geological occurrence, as deposits of these ores are found in nearly every geological age. The veins of Boulder, Central, and Georgetown occur in the Archean age, but are sometimes found at the contact between porphyry and gneiss. The great deposits of Leadville and the lesser ones of Alma occur in the Silurian and Carboniferous ages. The veins of the former occur at the junction of quartz porphyry and dolomitic limestone generally.

Those of Gunnison and Crested Butte occur in the Cretaceous age, which is also characterised by the occurrence of iron ores.

The rich veins of the San Juan region are in the rocks of the Tertiary, and in the Triassic eruptive rocks.

The Quaternary age has its representative in the gold of the placer regions, but this has probably been derived from the detritus resulting from the degradation of some of the older rocks.

Although the metals are very well distributed among the different formations, those of the older periods, *i.e.*, the Archean, Silurian, and Carboniferous, are by far the greatest producers.

The minerals with which the precious metals are associated are, in Colorado, varied and complex.

In Leadville the ore deposits are almost invariably found in limestone. It would appear that the limestone had derived its mineralisation from the eruptive quartz porphyry with which it is in juxtaposition, since the latter is nearly always mineral-bearing, while, on the other hand, the former rock is always barren, excepting in the vicinity of its contact with the porphyry.

The

The oxidised ores are chiefly carbonates and sulphates, of which the principal bases are iron, manganese and lead, and silicates, such as crysocola and calamine. The carbonates are of two classes, the hard or massive, and soft or sandy carbonates. The silver in these ores is chiefly in the form of cesargyrite, embolite, and occasionally pyromorphite and wulfenite. Latterly minetite has been found in considerable quantities.

The great superstratum of oxidised ores in Leadville, as has been the case in nearly all the mining camps, has been nearly used up, and the sulphides now comprise the greater part of the ores that offer themselves to the miner. These sulphides are for the most part galena, pyrite, and chalcopyrite, with more or less blendeinter mixed. They seem to contain silver disseminated through their mass in various forms, associated with the following:—Argentite, polybasite, tetrahedrite, stephanite, &c.

In the San Juan region, the veins occur chiefly in the eruptive rocks of the Tertiary and Triassic periods, and are fissure veins penetrating eruptive sheets of igneous rocks, and consist of hard gray quartz, which sometimes resembles jasper in its general colouring, structure, and hardness. The veins contain mineral in various forms, as galena, tetrahedrite, polybasite (tellurides, petzite, and hessite), pyrite, argentite, proselite, pyrargyrite, stephanite, cuprite, azurite, malachite, crysocola, bismuthinite, &c., &c. The principal productive mineral is, however, argentiferous galena.

Pitkin County.

The Aspen deposits occur in the same geological horizon as those of Leadville, *i.e.*, the lower carboniferous limestone, but, unlike those of the latter place, they do not occur in contact with the eruptive porphyries, but are found principally in the contact between two kinds of limestone, *viz.*, the pure blue carbonate of lime and the brown double carbonate of lime and magnesia (dolomite). The productive ore is limestone, pierced by small gashes or fissures, filled with silver-bearing galena, polybasite, and stephanite. Barite is very common in this camp, and so also is magnesia, from the dolomitic limestones.

A few analyses of the characteristic ores of the principal mining districts are given below.

It has already been said that the oxidised ores of Leadville have disappeared as the depths of the workings increased, and sulphide ores are now the rule. In addition to this, the percentage of zinc has increased, and the silver contents decreased, so that the profitable smelting of the ores of to-day is a much more difficult proposition than was presented ten years ago, at which time the ores were simply mined and smelted directly. Such a thing as a roasting furnace was scarcely known in the camp. A very good idea of the altered conditions of mining and smelting of to-day and of ten years ago may be obtained by comparing the two following analyses, the first of which is taken from Guyard's monograph, "Argentiferous Lead Smelting," written ten years ago, and represents an average sample of 1,000 tons of ore, collected from every producing mine at that time.

The second is taken from "Hoffman's Metallurgy of Lead," p. 37.

H ₂ O	5.58	per cent.
CO ₂	5.58	"
PbO	25.77	"
Ag	0.31	"
SiO ₂	22.59	"
S	0.90	"
FeO	0.89	"
Fe ₂ O ₃	24.86	"

Al ₂ O ₃	3.99	"
CaO	2.36	"
MgO	3.04	"
As	0.01	"
Sb	0.02	"
(KNa) 2	0.98	"
Cl	0.09	"
Au	Trace.	"
Cu	"	"
Zn	"	"
Total	101.00	

	Minnie Mine.		Moyer Shaft.		Colonel Seller's Mine	
	Galena.	Mixture.	Galena.	Mixture.	Lead Ore.	Zinc Ore
Pb	72.65	50.86	44.0	15.0	27.40	10.70
Zn	5.66	12.86	13.0	24.0	25.00	24.50
Fe	1.60	9.30	11.0	16.0	6.00	16.60
S	15.66	24.50	30.0	40.0	35.00	40.00
Ag., oz.	41.50	11.50	14.0	11.0	26.90	54.30
Au	Trace.	Trace.	Trace.	Trace.
Insol	4.12	1.88	3.00	3.40
H ₂ O	2.00	2.10

It cannot be said that the above represents an average of the ores of Leadville to-day, but it will serve to show how greatly the character of the ores have changed. Further evidence of this is given by the presence of the costly roasting-plants, which are attached to each and every smelter in the camp, excepting, of course, the "pyritic" smelters.

The

The following analyses of Aspen ores have been made by the writer for the purpose of showing their principal constituents :—

No. 1.		No. 2.	
SiO ₂	15·2	SiO ₂	16·20
Fe.	6·0	Fe.	1·20
BaSO ₄	5·70	BaSO ₄	25·30
CaO.	26·90	CaO.	14·00
Ag.	18·00 oz.	Ag.	32·50 oz.
H ₂ O	3·00	HO	3·30
		Pb.	4·40
No. 3.		No. 4.	
SiO ₂	20·00	SiO ₂	14·80
Fe.	7·10	Fe.	2·00
BaSO ₄	39·70	BaSO ₄	30·00
CaO.	11·50	CaO.	6·20
Ag.	40·00 oz.	Ag.	70·30 oz.
H ₂ O	4·20	Pb.	17·10
		HO.	3·00

Ores of San Juan region may be represented by the following :—

No. 1.		No. 2.	
SiO ₂	42·20	SiO ₂	38·17
Fe ₂ O ₃	16·92	Fe ₂ O ₃	18·76
Al ₂ O ₃	5·71	Al ₂ O ₃	3·94
Pb.	19·10	Pb.	23·24
CaO.	2·00	CaO.	1·74
ZnO.	1·52	ZnO.	3·40
SO ₃	4·46	SO ₃	5·00
CO ₂	2·41	CO ₂	·96
H ₂ O	5·31	H ₂ O	5·60
Ag.	115·4 oz.	Ag.	94·00 oz.
Au.	24·00	Au.	0·30

To give an idea of the comparative cost of smelting in Colorado and in New South Wales, the writer thinks that since there are no data to hand upon which to calculate the cost of smelting New South Wales ores of given composition in Colorado, the purpose will be served by giving the method of calculating the smelting charges upon samples of ore which are submitted for bids in the latter place. This method can readily be applied to any ore of known composition in New South Wales, and thus the miner can, for purposes of comparison, find out just how much his ore would cost to smelt in this country.

The general principle of the method is as follows :—

The smelter makes what is termed a minimum charge for smelting, which is based upon the average cost of running a ton of ore through the furnace. This is 3·00 dollars at some works and 4·00 dollars at others.

An ore in which the sum of the metallic iron and manganese is equal to the silica, and which contains 13 per cent. of lead is called a neutral ore, but for ores in which the silica is in excess of (Fe. and Mn.) a debit of 15 cents per unit is made, and a credit of 15 cents per unit of iron in excess of SiO; 50 cents per unit for Zn. in excess of 10 per cent. This latter, however is subject to contract.

Let us arrange the items in columns.

Dr.	\$4·00 minimum smelting charge.	Cr.	Nothing for Pb. up to 10.
	·50 unit of Zn. over 10.		95 of total value.
	·15 unit of SiO. over (Fe. Mn.)		25 cents per unit of Pb. between 10 and 20.
	·10 unit of Pb. under 13.		30 cents per unit of Pb. between 20 and 40.
	2·00 for roasting.		35 cents per unit of Pb. between 40 and 50.
	1·00 per 50 oz. Ag. over 100 oz.		

Let us take for an example the case of an ore of the following description :—

No.	Au.	Ag.	Pb.	SiO ₂ .	Fe.	
1.	20 oz.	80 oz.	35 per cent.	45 per cent.	6 per cent.	
Dr.						
	39 units SiO. at 15 cents					\$3·85
	Minimum smelting charge					4·00
			Smelting charge			\$7·85
Cr						
	20 oz. Au. at \$20·00					\$4·00
	80 oz. Ag. at \$0·78					62·40
	36 units of Pb. at 30 cents					10·50
						73·06
						\$76·90
					Deduct 5 per cent. for loss ...	3·84
						73·06
					Smelting charge	7·85
						\$65·21
					Net value of ore	\$65·21
