No. 49.—WRECKS and other CASUALTIES to SHIPPING within the Jurisdiction of New South Wales.

Date.	Vessel.	Tonnage.	Master.	Owner.	No. of Crew & Passengers	No. of Lives lost.	Description and Value of Property lost.	Particulars of Casualty.
1886. 13 Jan...	Mary Bannatine, schooner	115	Alfred Feast.....	R. S. Johnson .....	7	Nil...	Cargo of coals; value of vessel and cargo, £1,275; insured £1,000.	This vessel was taken aback by a sudden squall, when crossing the Clarence Bar, in the attempt to enter river, and she went ashore and became a total wreck.
15 „ ...	Lizzie Davis, schooner.....	85	R. A. Kearney...	J. W. Dixon.....	6	Nil...	In ballast; value, £1,400 .....	The Lizzie Davis drifted ashore near Tacking Point in a calm, the anchors not having been let go in time and she became a total wreck.
9 Feb...	Murray, steamer .....	199	David Anthorn...	John See .....	55	Nil...	General cargo; value of vessel and cargo £4,500; insured, £4,000.	This vessel was totally wrecked by striking on the rocks about 2 miles to the southward of the Old Manning Bar.
27 „ ...	Glossarial, steamer .....	85	Daniel Callaghan	R. Pyers .....	7	Nil...	Cargo of coals; value of vessel and cargo, £1,200.	Sprung a leak and foundered about 5 miles east south-east from Manning Head.
13 Mar...	Ann, ketch .....	28	Christopher Han- son.	Mary Woodward.....	3	Nil...	In ballast; value of vessel, £500; insured, £250.	The Ann was beached at Port Stephens during an easterly gale to save life; she became a total wreck.
30 „ ...	Emperor, brig .....	284	Thomas Kehoe...	Thomas Kehoe.....	9	Nil...	Cargo of coals; value of vessel and cargo, £1,750; insured, £1,400.	This vessel missed stays when working out of Port Stephens; there being no room to wear, she went on shore and became a total wreck.
4 April	Champion, ketch .....	36	F. Taylor .....	Messrs. Hutchins and Taylor.	4	Nil...	Cargo of timber; value of vessel and cargo, £1,000.	In the attempt to shift to a more secure berth inside the bar at Cape Hawke, when bad weather came on, this vessel's chain parted; she drifted on the edge of a small sand spit, and became a total wreck.
23 May...	Fifeshire, steamer .....	28	G. W. Webster...	J. Amos .....	23	Nil...	Cargo of produce; value of vessel and cargo, £3,000; insured £2,000.	This vessel went ashore during a dense fog on Morris' Beach, Terrigal, and became a total wreck.
30 „ ...	Ly-ee-Moon, steamer .....	745	A. Webber .....	A.S.N. Co. ....	86	71	General cargo; value of vessel and cargo, £25,000.	The Ly-ee-Moon struck on Green Cape and became a total wreck.
6 June..	Falcon, schooner .....	195	J. Wilson .....	B. Byrnes.....	8	1	In ballast; value of vessel and cargo, £2,500; insured, £1,500.	This vessel when working out of Sydney missed stays and drifted on to the North Head, and became a total wreck.
6 „ ...	Malua, steamer.....	20	J. Johnson .....	J. Johnson .....	5	Nil...	In ballast, value, not known .....	Went ashore to the south of Port Hacking during a fog, and became a total wreck.
16 July...	Prince of Wales, steamer...	41	A. M'Kay .....	J. Waterhouse .....	4	2	In ballast; value of vessel, £2,750.	In attempting to get the tow line from the ship Peterborough, the wheel chains of the Prince of Wales became jammed; this caused her to get athwart hawse the ship, which sank her.
25 „ ...	Jane, brig .....	160	W. Costen.....	P. Hogan .....	13	Nil...	Cargo of logs; value of vessel and cargo, £850.	This vessel went ashore from her anchors in Tallow Bay, near Cape Byron, during an easterly gale, and became a total wreck.
5 Aug...	Annie Powell, schooner ...	123	H. Harman .....	G. Troy.....	6	Nil...	Cargo of blue metal; value of vessel and cargo, £1,700; insured, £1,000.	During the passage from Kiama to Sydney, this vessel sprung a leak and foundered about 5 miles off Five Islands, near Wollongong.
8 „ ...	Condong, schooner .....	72	W. Coster .....	Messrs. Corrigan and Reidy.	6	2	Cargo of coals; value of vessel and cargo, £2,000; insured, £1,000	This vessel was caught in a sudden squall, she capsized and foundered about 9 miles east by north from Port Stephens.
18 „ ...	Mary Pashley, schooner...	71	M. Andrews .....	M. Andrews .....	6	Nil...	General cargo; value of vessel and cargo, £1,635; insured, £1,200.	While on the passage from Sydney to Nambucca the Mary Pashley came into collision with the steam-tug Game Cock, and sank off Red Head, near Newcastle.
25 Sept...	Sovereign of the Seas, ketch.	31	John Caffrey ...	Henderson & Spragg ...	3	Nil...	Cargo of sundries; value, not known	A portion of the wreck of this vessel was found on the beach near Port Macquarie, supposed to have been beached, and maliciously destroyed by the runaways in the Thames murder case.
6 Nov...	Kalara, steamer .....	90	R. D. Henry.....	D. L. Brown .....	14	Nil...	Vessel and cargo of timber valued at £5,150; insured, £3,750.	The Kalara sprung a leak and foundered about 1 mile north-easterly from Point Danger.
16 „ ...	Jessie Kelly .....	145	J. Conway.....	B. Burns .....	6	Nil...	Vessel and cargo of coals valued £1,920; insured, £1,200.	This vessel was lost by missing stays when working out of Port Stephens; she drifted on the rocks and became a total wreck.
6 Dec...	Corangamite, steamer .....	1562	Le Nevu .....	Messrs. Huddart Parker	141	Nil...	General cargo; value of vessel and cargo, £35,000; insured, £25,000.	The vessel went ashore in Wreck Bay during a fog, and became a total wreck.
8 „ ...	Keilawarra, steamer.....	784	N. G. Buttrey ...	Messrs. Howard Smith..	66	31	Vessel and general cargo valued £25,000.	Sunk by coming into collision with the steamship Helen Nicoll off North Solitary Islands.
8 „ ...	Helen Nicoll, steamer .....	384	R. A. Fraser.....	John See .....	58	4	General cargo .....	Loss of life occasioned when she came into collision with Keilawarra
18 „ ...	Brunswick, steamer.....	118	James Benson ...	John See .....	11	Nil...	Cargo of coals; value of vessel and cargo, £4,600.	When attempting to enter the Manning River the Brunswick struck on the bar and became a total wreck.

NOTE.—Where more than one kind of work is carried on under one establishment, it has frequently been found impossible to separately distinguish the number of hands, power, and value of plant of each work; in such cases the whole have been credited to the principal industry.

JOINERY.—Only establishments using steam were included in returns prior to 1886. METAL WORKERS.—Horse-shoers have been omitted in the return for 1886. Government Railway Shops have been set down as one establishment, and included in South Sydney. FURNITURE.—Only works using steam were returned prior to 1886. PRINTING.—All establishments are included in 1886. SADDLERS.—Manufacturing establishments only returned for 1886. WATERWORKS.—Sydney Waterworks not included. For totals see Table No. 7.

				£2,289,497	13	8						

Total amount of deposits in the Savings Bank of New South Wales, £2,081,498 8s. 7d.

The rate of interest payable upon depositors' accounts closed during the year is £5 per cent. per annum; and on deposits in the bank up to 31st December the rate of interest is fixed by the trustees when the yearly accounts are made up.

The rate of interest paid on 31st December, 1886, for the year ended was £6 per cent. per annum.

When deposits made by any one individual exceed the sum of £100 no interest is allowed on such excess.

NOTE.—Interest is allowed on the full amount deposited by Penny Savings Banks, Charitable Institutions, and Friendly or other Societies.

<sup>a</sup> This includes the amount of the postage contributions of the United Kingdom and the Australian Colonies to the cost of Ocean Mail Subsidy. <sup>b</sup> Of this amount the sum of £13,995 18s. 1d. was received on account of postage due to the Colony by the United Kingdom for the years 1875 and 1876. <sup>c</sup> This number embraces all letters posted in the Colony for delivery within the Colony, and includes those letters hitherto classified as Town Letters. <sup>d</sup> The total collections for this year amounted to £24,000 more; this sum was transferred to Stamp Duties as approximate value for Postage Stamps used for Duty Stamps purposes during the year. <sup>e</sup> This does not include outstanding liabilities, but is the total amount expended during the year, irrespective of date of claims. <sup>f</sup> During the year 1885 the practice of weighing instead of counting the correspondence posted was introduced, as the limited time at the disposal of the sorting staff prevented the counting from being very carefully done, and it was thought that by weighing and allowing a certain number of letters, &c., to the lb., greater accuracy would be insured. The returns for 1885 may therefore be considered more reliable than those for previous years.

## MONEY ORDERS.

No. 57.—MONEY ORDERS issued and paid at each Office in the Colony during the year 1886.

## SYDNEY UNIVERSITY.

No. 9.—RETURN of the NUMBER of STUDENTS and RESULTS of PUBLIC EXAMINATIONS, 1876-86.

Year.	Number of Students qualified for Matriculation.	Number of Students attending Lectures.	Public Examinations.			
			Number of Seniors who came up.	Number of Juniors who came up.	Number of Seniors who passed.	Number of Juniors who passed.
1876 ... ..	34	58	53	356	40	212
1877 ... ..	23	61	63	303	38	135
1878 ... ..	24	62	58	364	41	243
1879 ... ..	58	83	76	333	64	247
1880 ... ..	64	76	66	381	54	209
1881 ... ..	80	81	48	392	36	231
1882 ... ..	101	97	57	398	43	240
1883 ... ..	85	128	57	473	36	299
1884 ... ..	142	203	65	563	48	379
1885 ... ..	115	203	84	645	73	440
1886 ... ..	122	340*	107	858	83	548

\* Of this number, 137 non-matriculated students attended courses of evening lectures.

NOTE.—The Public Examinations are similar to the *Middle Class* Examinations of Oxford and Cambridge. They are held annually, in November, and are intended to test the qualifications of boys and girls attending schools or being instructed privately. They are divided into Senior and Junior, and certificates of competency in the *several* subjects of examination are given to the successful candidates. These examinations are *distinct* from the examination for the Civil Service.

Greatest fall and date unknown.

No detail.

For December only.

Commenced observations in February.  
No observations for August, with exception of rainfall.

No returns—January, March, and April.

No observations for last six months, with exception of rainfall.  
Evaporation from a bucket, if this is reduced 35 per cent. it equals that from a tank.

Greatest fall and date unknown.

Commenced observations in September.

Commenced in July.

Greatest fall and date unknown  
do do.  
do do.

No detail.

do.

METEOROLOGY—continued.  
 No. 4—(continued).—ABSTRACT of METEOROLOGICAL OBSERVATIONS taken at various Stations in the year 1886—continued.

Stations.	Least distance from East Coast in Miles	Height above sea in feet.	Mean of Observations taken at 9 a.m.							For 24 hours previous to 9 a.m.					Remarks.			
			Barometer	Temperature in Shade.	Humidity, 0 to 100.	Wind.		Clouds 0 to 10	Temperature in Shade.		Rain.			Evaporation, inches.				
						Direction	Force. 0 to 6.		Means.	Extremes.	Total Fall, inches.	No of Days	Greatest Fall, inches			Date.

## No. 16.—CLASSIFIED RETURN of the LETTERS OF REGISTRATION for INVENTIONS granted in New South Wales during the year 1886.

Class of Invention.	Number of cases referable to each class.	Class of Invention.	Number of cases referable to each class.
1. Drains and sewers, including the manufacture of drain-tiles and drain-pipes	1	16. Preparation of India-rubber, gutta-percha, vulcanite, ebonite, celluloid, &c...	1
2. Sewing and embroidering	2	17. Production and applications of gas	7
3. Manure	5	18. Metals and alloys—	1
4. Preservation of animal and vegetable substances (without the use of cold); also, preparation of same for market...	2	(1) Alloys	...
5. Marine propulsion	...	(2) Antimony	...
6. Manufacture of iron and steel	...	(3) Bismuth	...
7. Aids to locomotion	...	(4) Copper, &c.	...
8. Steam culture	...	(5) Gold—Alluvium, &c.	...
9. Watches, clocks, and other time-keepers	...	(6) Gold	5
10. Firearms and other weapons, ammunition and accoutrements	2	(7) Gold, silver	2
11. Paper: Manufacture of paper, pasteboard, papier mâché, &c.	1	(8) Gold, silver, other metals, precious stones	3
12. Cutting, folding, and ornamenting paper, including envelopes, cards, paper-hangings, &c....	1	(9) Quartz, &c.	...
13. Typographic, lithographic, and plate printing (excluding electro-telegraphic and photographic printing); also advertising	4	(10) Minerals and other substances (including precious stones)	...
14. Bleaching, dyeing, and printing calico and other fabrics and yarns	...	(11) Ores, minerals, metals, &c.	12
15. Electricity and Magnetism—	...	(12) Nickel	...
(1) Galvanic and thermo-electric piles and batteries	...	(13) Quartz, &c.	1
(2) Magneto and dynamo-electric generators	...	(14) Silver, &c....	1
(3) Miscellaneous apparatus for generating	...	(15) Sulphurets, amalgam, &c.	...
(4) Electric and magnetic motors; transmission of energy to a distance; electric distribution systems and apparatus	1	(16) Tin, &c.	...
(5) Circuits, conductors, cables, and insulators; insulating and coating conductors	3	(17) Platinum, iridium, &c.	1
(6) Electric current governors and regulators; starting and stopping devices for dynamos; safety appliances	...	(18) Lead	...
(7) Armatures, commutators, contact-makers and breakers, switches, cut-outs, relays, coils, magnets, and solenoids	...	19. Photography, photo-lithography, and photo-mechanical printing	3
(8) Measuring and testing electric currents	1	20. Weaving	...
(9) Telegraphic and signalling systems and apparatus, call-bells, studs, keys, &c.	...	21. Ship-building, repairing, sheathing, launching, &c.	...
(10) Telephonic systems and apparatus; application of the telephone to medicine and to scientific research; microphones, &c.	3	22. Bricks and tiles, artificial stone and concrete	6
(11) Electric lighting systems and installations; arrangement of leads and lamps	...	23. Plating or coating metals with metals	...
(12) Electric lamps and candles, carbons, filaments, regulators, &c.	1	24. Pottery	2
(13) Various applications of electric lighting	...	25. Medicine, surgery, and dentistry	3
(14) Electrolysis, electro-deposition, electro-metallurgy, and the applications of electricity to the arts and manufactures	3	26. Music and musical instruments	1
(15) Electric and magnetic fire-alarms, methanometers, water-gauges, sorting apparatus, &c.; the applications of electricity and magnetism to medicine, meteorology, and navigation	...	27. Oils, fats, lubricants, candles, and soap	2
(16) Secondary batteries and accumulators for storing electric energy	1	28. Spinning, including the preparation of fibrous materials and the doubling of yarns and threads	1
		29. Lace-making, knitting, netting, braiding, and plaiting; including the manufacture of fringe and chenille...	...
		30. Preparation and combustion of fuel	6
		31. Raising, lowering, and weighing	7
		32. Hydraulics	3
		33. Railways and tramways	12
		34. Saddlery, harness, stable-fittings, &c.	1
		35. Roads and ways	5
		36. Bridges, viaducts, and aqueducts	...
		37. Writing instruments and materials	3
		38. Railway signals and communicating apparatus	1
		39. Furniture and upholstery	3
		40. Acids, alkalies, oxides, and salts	4
		41. Aeronautics	...
		42. Preparation and use of tobacco	2
		43. Books, portfolios, card-cases, &c.	...
		44. Lamps, candlesticks, chandeliers, and other illuminating apparatus; excluding inventions for lighting by gas or electricity	7
		45. Needles and pins	...
		46. Carriages and other vehicles for railways and tramways	12
		47. Umbrellas, parasols, and walking-sticks; awnings and sunshades	1

NEW SOUTH WALES.

## ROYAL COMMISSION—CONSERVATION OF WATER.

## FINAL REPORT OF THE COMMISSIONERS.

To His Excellency the Right Honorable CHARLES ROBERT, BARON CARRINGTON, Knight Grand Cross of the Most Distinguished Order of Saint Michael and Saint George, Governor and Commander-in-Chief of the Colony of New South Wales and its Dependencies, &c., &c., &c.

MAY IT PLEASE YOUR EXCELLENCY,—

We, your Commissioners, appointed on the 10th day of May, 1884, “to make a diligent and full inquiry into the best method of conserving the rainfall, and of searching for and developing the underground reservoirs supposed to exist in the interior of this Colony, and also into the practicability, by a general system of water conservation and distribution, of averting the disastrous consequences of the periodical droughts to which the Colony is from time to time subject,” have the honor to submit this our Final Report:—

In our First Report we dealt fully with the general subject remitted to us for inquiry; and in the second with the utilization of the flood-waters of the river Murray, and with the works for water conservation and irrigation carried out in Victoria. In the former we indicated that it was our intention to make a careful examination of the northern tributaries of the Darling, and to endeavour to ascertain the extent to which it might be practicable to conserve the flood-waters at the heads of the coastal river basins, with a view to the irrigation of the lower lands.

Scope of First and Second Reports of Commission.

We then directed attention to the necessity of having the country explored by competent engineers and surveyors, with a view to devise the most appropriate schemes for conserving and distributing water in the different river basins of the Colony; and again, in March, 1886, we requested the Honorable the Colonial Secretary to cause a sum of £12,000 to be placed upon the Estimates to be laid before Parliament, which we calculated would be sufficient to defray the cost of eight survey parties for a period of twelve months, to be employed in surveying the principal western and coastal river basins. This exploration we regard as essentially necessary before any practical work can be accomplished; and we think it would be a great public advantage if it could be completed by such time as Parliament has passed some legislative enactment on the lines of that sketched out in our First Report. We understand that the late Parliament did make the appropriation asked for; but we are not aware that any steps have been taken to organize the field parties required to do the work.

Suggested surveys of western and coastal river basins.

Examination of head-waters of Murray in connection with Victoria.

Having in view the fact that the Colonies of Victoria and New South Wales contemplated an agreement for the utilization of the flood-waters of the river Murray, in regard to which the present state of circumstances represents a loss to this Colony which, on the basis of the value for irrigation of water in other countries, may be computed at over £200,000 per annum, we desired to have made a thorough examination of the head-waters of the Murray, and to appoint our engineer, in conjunction with an engineer to be appointed by Victoria, to that duty. Our communications on this subject, however, do not appear to have been considered.

Conference between Commissioners of Victoria and N. S. Wales on the Murray waters.

Our Second Report bore special reference to the two Conferences which had been held between this Commission and the Water Supply Commission of Victoria, on the subject of the utilization of the waters of the River Murray. The outcome of these Conferences was a number of proposals which the two Commissions mutually agreed to recommend to the Governments of New South Wales and Victoria as the basis of a treaty between them, setting forth the conditions under which each Colony should be permitted to divert supplies from the river.

Objections on part of South Australia.

It would seem that, subsequently, the Government of South Australia expressed much surprise that a treaty affecting the River Murray had been considered by an Intercolonial Conference upon which that Colony had no representation. That South Australia was not invited to take part in the Conference arose from no want of courtesy, nor from any desire on the part of Victoria, or of New South Wales, to exclude her from their deliberations. These had exclusive reference to that portion of the Murray which formed the common boundary of the two Colonies, and to the tributaries from each. Provision was made for maintaining the normal flow of the river, and for the diversion of such surplus water only as might be available after that condition had been met.

Suggestions as to Conference between Commissioners of South Australia, Victoria, and N. S. Wales.

While, therefore, the object of the Conference was to provide for as complete a utilization of the Murray waters as possible, it was not sought to infringe on any rights which South Australia might be deemed equitably to possess. It was natural, however, that South Australia should be apprehensive that her rights of navigation and to the normal flow of the river might be jeopardised by the action of a Conference upon which she had no representation; and she has suggested the holding of a final Conference between this Commission, the Water Supply Commission of Victoria, and a Commission which she has appointed for that purpose.

It was anticipated that the Conference would have taken place before now, but as the President of the Victorian Commission, the Hon. Alfred Deakin, M.P., found it necessary to leave Victoria to attend the Imperial Conference now being held in London, the date of assembling was deferred until his return. He is expected to arrive in Melbourne in June or July next. Soon after that date it may be practicable for representatives of the three Colonies to confer together upon the subject, with a view to submit to the Government of each the conditions upon which the flood-waters of the Murray and its tributaries may be best conserved and equitably appropriated.

Diversion from Murray by Victoria and South Australia.

It appears to us that the question is one which demands immediate consideration; for although a large part of the Murray is within the geographical boundaries of New South Wales, Victoria has already entered upon schemes for intercepting the flow of her principal tributaries to the Murray, and has assumed the right to grant to the Messrs. Chaffey Bros. power to divert from the main stream an indefinite supply to carry on irrigation operations over a large tract of land in Victoria. South Australia is also dealing with the matter exclusively from the point of view of her own interests; and in our own Colony large landed proprietors are exercising the power of appropriating the water of several of the principal rivers without permission or regulation by constituted authority.

Examination of country between Murray and Murrumbidgee.

The large extent of valuable country lying between the Murray and the Murrumbidgee seemed to us to possess many special advantages for purposes of irrigation, and we therefore determined to ascertain, as far as the means at our disposal would enable us to do it, to what extent it might be practicable to use the waters of those rivers for irrigation, as well as for stock and domestic purposes. In pursuance of instructions issued by us in May last to our Engineer, Mr. H. G.

M'Kinney,

M'Kinney, that officer has made a detailed inspection of the Murray and Murrumbidgee Rivers, gauging them in a number of places, as detailed in his report, which is appended, and also examining various lakes and other natural depressions. The main objects of the engineering investigations were to determine—1st, whether works for water conservation and supply on a large scale in the southern part of Riverina are practicable; 2nd, to ascertain what quantity of water could be made available for such works; and 3rd, to indicate the nature of these works, and state what surveys are required for them.

On several previous occasions Mr. M'Kinney furnished reports, in compliance with our instructions, regarding questions connected with the Murray-Murrumbidgee doab,\* and as our recent instructions included the entire doab within their scope, these reports should be considered as preliminary to and connected with that now appended. The first of these reports related to the Yanko Creek, and gave the results of levels and investigations carried out by him from the point on the Murrumbidgee which he proposed as a new outlet down to Cuddell, as well as furnishing opinions regarding the works required for the improvement of the creek, together with an estimate of their cost. With the data so supplied, the subject of the Yanko Creek was dealt with by us and made over to the Harbours and Rivers Department. The first of our recommendations regarding the construction of a new outlet from the Murrumbidgee to the Yanko Creek has been carried out by that Department, and the result has been that a much better supply of water has passed down the Yanko and Colombo Creeks for some months past than would otherwise have been afforded. We also recommended that in a number of cases the necks of bends on the former creek should be cut through, and this also is now in progress. Although in this case only the utilization of flood-water is contemplated, the importance of the improvement of the Yanko Creek is much greater than the cost of the work would indicate. There can be no doubt that the length of this creek, following its bends, is considerably over 200 miles, and that of the Colombo Creek little, if anything, short of 100 miles. Residents in the neighbourhood consider it doubtful whether a supply would have flowed more than 30 miles in the Yanko Creek if the improvements had not been carried out. A stream actually flowed through the whole length of the Colombo Creek for some time, and the water in the Yanko was expected to reach the Billabong during last December. Only those acquainted with such districts as that in which the Yanko and Colombo Creeks are situated can appreciate the value of such an important increase to the water-frontage.

In addition to his report on the Yanko Creek, the Engineer furnished a report on the river Murray as a source for canals, another on the Murrumbidgee River as a source for canals, and a third on the Tantangara Basin, which is situated on the Upper Murrumbidgee. These appeared in the Appendix to our First Report, and they require to be referred to now, as they contained statements of a very important character which our Engineer considers his fuller investigations have completely borne out. In the report on the River Murray as a source for canals, dated 8th April, 1885, Mr. M'Kinney, after an inspection of plans of the Murray, and of the river itself from Dora Dora to Tocumwal, gave the opinion that the best site for the head-works of a canal for the diversion of a supply of water from the Murray through the district between that river and the Billabong Creek is at the end of the Jindera Range of hills, and about 8 miles west from Albury. Further examination of the proposed site and its neighbourhood has confirmed the opinion first formed by the Engineer.

For the purpose of supplying water for irrigation, and in a less degree for stock, in the district between the Murray River and the Billabong Creek, the project brought forward by the Engineer, as the result of his investigations, is to have a weir constructed across the Murray at Jindera to divert a supply of water into a canal which would follow the general direction of the Murray to near Howlong, and then turn off towards Coreen. Beyond that place the main canal would follow a line slightly to the north of west, and passing along nearly in the centre of the strip of land between the Billabong and Tuppal Creeks, would tail into the former at some point near Moulamein. At a short distance beyond Coreen one branch would proceed in a north-westerly direction towards Jerilderie, and another in a south-westerly direction

\* A doab is the tract of country lying between two rivers.

Tuppal Canal. direction towards Tuppal. This system of canals might fairly be termed "permanent," as the Murray at Albury has never been known to fail entirely.

Proposed weir  
at Tocumwal.

For the purpose of affording a supply when the river is high to the country between the Murray and the Edward, the Engineer proposes that a weir should be constructed across the former river at Tocumwal, and he suggests that the Victorian Government might be willing to share the cost of this work. He has ascertained from the projects prepared by the Government of Victoria that a pumping station is proposed to be erected by that Colony on the Murray, about 8 miles up stream from Tocumwal. From the information which he has collected, the Engineer thinks it not unlikely that a supply of water can be diverted in a south-westerly as well as in a north-westerly direction from Tocumwal; and if that opinion proves correct, there is little doubt that the Victorian Government will be willing to co-operate with this Colony in the construction of a weir.

It will be seen that the works proposed for the water supply of the districts lying between the Murray River on the south and the Billabong Creek and Edward River on the north embrace the following:—(1) A system of high-level canals with head-works at Jindera, near Albury; and (2) a system of canals, partly artificial and partly natural, with head-works at Tocumwal.

Area irrigable  
by Murray  
Canal.

It is anticipated that these canals will be availed of for domestic purposes and for stock, but their chief use will be for irrigation. Judging from the river records of the last eight years, the Engineer estimates that the area which can be irrigated annually from the canal taken off near Albury is 420,000 acres, of which 290,000 acres will be thoroughly irrigated, and 130,000 acres would receive one flooding only. From the supply to be drawn off near Tocumwal he estimates that an area of 150,000 acres will be irrigated, thus making the gross area irrigated by the Murray waters 570,000 acres. Although this is a small extent of land compared with the whole irrigable area, still the immense importance of even a proportion of 1 acre of irrigation annually to about every 10 acres unirrigated, will be at once understood and appreciated by anyone who has seen the results of irrigation on the Murray, the Murrumbidgee, or the Darling. Reference to our First Report will show that even in the countries where irrigation is practised on an extensive scale the area under irrigation in any one year is but a small fraction—in America the two hundred and fiftieth part—of that requiring irrigation.

Necessity for  
immediate  
surveys.

We are strongly of opinion that the reasons advanced in favour of the Engineer's proposals warrant the initiation of the surveys necessary for the preparation of the details of both projects. Not only so, but we consider that delay in the commencement of the surveys means serious loss to the Colony. The value of the waters of the Murray which run uselessly to the ocean amounts to several hundreds of thousands of pounds annually, and these projects, for which we recommend that surveys should be made without delay, are the first of a definite nature which have been advanced to deal with the subject.

Utilization of  
Murrumbidgee  
waters.

With regard to the utilization of the waters of the Murrumbidgee, the proposals of the Engineer are of an equally bold and comprehensive description. In this case, as in that of the Murray, his recent investigations have confirmed the opinion given in his report of 8th April, 1885, regarding the best site for the head-works of a permanent canal. The site recommended on the Murrumbidgee is at the foot of the Malibo Range, about 6 miles from Wagga. One advantage of the highest importance is claimed for this site, namely, that the nature of the country near it is such that the same weir will enable a supply to be obtained for a canal on each side of the river. These canals would follow courses approximately parallel to the Murrumbidgee, but at a considerable distance from it, and would extend to the One Tree Plain on the north side, and to the Old Man Plain on the south. The northern canal would, in an average year, irrigate 180,000 acres, and the southern canal system, including Lake Urana, 340,000 acres. In addition to the branch canals for the distribution of the water, the Engineer proposes to have a large supply branch capable of carrying 2,000 cubic feet per second, the chief purpose of which will be to maintain a supply of water in Lake Urana, and thereby turn to useful account the immense storage capacity of that natural basin. This part of the project depends on proof being obtained that Lake Urana can be converted

Proposed weir  
near Wagga.

Area irrigable  
from Mur-  
rumbidgee.

Lake Urana.

into

into a suitable storage reservoir at a moderate cost; but this is a point about which there appears to be little doubt.

The system of canals having their head-works at the Malibo Range would carry a supply at all seasons; but for the distribution of flood-water only the Engineer proposes a series of weirs, one of which would be near Pevensy, and about 12 miles north-west from Hay; another is proposed at a point on the Murrumbidgee almost due east from Paika Lake; a third would be required at or near Balranald; a fourth below the outlet to Lake Waldaira, and in addition one would be required near Maude, and two between Paika and the junction of the Murrumbidgee with the Lachlan. The propriety of constructing a weir at the new outlet of the Yanko Creek is left an open question till time has elapsed to test the action of the improvements which are now in progress.

Proposed weirs on the Murrumbidgee.

As in the case of the Murray, so in that of the Murrumbidgee, we are of opinion that the surveys for the system of canals and weirs proposed by our Engineer should be commenced without delay. Whilst the surveys are in progress legislation on the lines recommended in our First Report should be enacted. In the comprehensive Bill which was recently passed in Victoria the leading principles which we recommended have been adopted, and form, in fact, the groundwork of the Bill. The soundness of the principles laid down in our First Report regarding legislation may therefore be assumed; and as our neighbours on the other side of the Murray have profited by the general principles we have laid down, so we may perhaps find much to adopt in the details of their Bill.

Necessity for immediate surveys.

With reference to the necessity for these works, the Engineer, in his report on "Irrigation in Riverina," has furnished a statement showing approximately the number of stock in the districts which will be benefited by the proposed canals—that is, the tract of country extending from the railway line connecting Wagga and Albury on the east to the junction of the Murray and Murrumbidgee on the west, and from the Murray on the south to the Mirool Creek on the north. The whole of this land is occupied by pastoralists, and as the land, with comparatively trifling exceptions, consists of rich, deep, alluvial soil, the numbers of stock given are a mere fraction of those which could be supported if the resources of the land were developed by irrigation. But the necessity for the proposed works is still more forcibly illustrated by the following table, which shows the loss in stock resulting from one bad season alone—namely, 1884—in the stock districts mentioned:—

Loss of stock through drought.

Stock District.	Number of Sheep.				Number of Cattle.				Number of Horses.			
	1st January, 1884.	1st January, 1885.	Increase.	Decrease.	1st January, 1884.	1st January, 1885.	Increase.	Decrease.	1st January, 1884.	1st January, 1885.	Increase.	Decrease.
Albury .....	381,984	410,396	28,412	.....	6,220	12,877	6,657	...	2,389	5,828	3,439	...
Balranald ...	1,501,745	1,094,078	.....	407,667	8,552	5,106	...	3,446	2,740	2,535	...	205
Corowa .....	415,292	329,314	.....	85,978	2,960	3,385	425	...	2,255	3,361	1,106	...
Deniliquin ..	983,465	787,480	.....	195,985	4,427	5,367	940	...	3,183	4,249	1,066	...
Hay .....	1,593,585	1,058,696	.....	539,889	5,368	3,495	...	1,873	2,443	2,608	165	...
Narrandera...	1,083,283	928,312	.....	154,971	6,258	6,613	355	...	1,788	2,461	673	...
Urana .....	750,132	601,038	.....	149,094	3,959	1,827	...	2,132	2,012	1,703	...	309
Wagga .....	1,495,009	1,108,408	.....	386,601	2,763	13,367	10,604	...	9,442	6,793	...	2,649
Totals ...	8,209,495	6,317,722	23,412	1,920,185	40,507	52,037	18,981	7,451	26,252	29,538	6,449	3,163

This statement shows that the actual diminution in the number of sheep in the districts specified was 1,891,773, whereas, taking the natural increase at only 12 per cent., there should have been an increase of 985,139, so that the total loss in sheep for the year was 2,876,912. It is necessary to explain here that the figures given are for the whole area of the stock districts mentioned, while in the Engineer's report the numbers refer only to so much of the districts as will be benefited by the canals he proposes. As some of the districts enumerated—in particular, Albury and Wagga—are, to an important extent, refuges in times of drought for the stock of other less-favoured places, the table may fairly be taken as a whole to show the absolute loss in sheep in the tract of country represented in the list. In explanation of these losses, the Chief Inspector of Stock, referring to the statistics of the whole Colony, says that the decrease was "caused by the severe drought, through loss of lambs, deaths from starvation, and from forced sales, and removals to other Colonies."

In

Value of  
stock lost  
through  
drought.

In addition to the loss in the number of sheep, the wool on those remaining was naturally deteriorated in an important degree. It would be impossible to estimate the amount of loss sustained through this deterioration in the quality of the wool, and it would also be impossible to estimate the value of the sheep removed to other Colonies, and disposed of by forced sale; but if we take these two items as balancing, we have the actual net direct loss represented by the value of 2,876,912 sheep. Assuming the value of these as 6s. 8d. per head, we find the amount to be £958,971, or, in round numbers, £960,000. In other words, the *direct* loss in stock alone in Southern Riverina due to drought was *in one year* about one-fourth of the estimated cost of all the works required for the utilization of the waters of the Murray and Murrumbidgee. It has to be remembered, too, that the direct loss thus ascertained is only an important portion of the total loss. Now, the construction of the works proposed will not only render such losses impossible, but will enormously increase the carrying capability of the land, as it has been proved that even the most primitive form of irrigation, namely, the flooding of the native grasses, will make such land as that in Riverina capable of carrying five sheep to an acre, whereas at present the average is over two acres to a sheep.

System of  
surveys.

With regard to the system of carrying out the surveys we have recommended, we are of opinion that the most expeditious, economical, and satisfactory arrangement would be one similar to that adopted in the case of the original projects for water conservation in Victoria—that is to say, that the surveys and levels should be carried out by contract under the control and supervision of one or two competent engineers experienced in the construction of canals, and who would apply such checks as they might deem necessary to the work supplied to them by the engineers and surveyors employed by contract. On the superintending engineer or engineers would devolve the duty of preparing in detail from the plans and measurements supplied to them the detailed estimates and plans of the proposed works, and the estimates of returns from them. This is substantially the method which was adopted in Victoria when the preparation of projects for water conservation was placed in the hands of Messrs. Gordon and Black. It will be seen from our Second Report that the projects prepared by these gentlemen formed the groundwork of all the schemes which have been carried out, as well as of others which are likely to be undertaken.

Necessity for  
maintaining  
records of  
river gauges.

There is another point referred to in Mr. M'Kinney's report which calls for special remark, namely, the necessity for maintaining the records of the various river gauges, and also of continuing the system of observation of discharges which he has initiated under our instructions. These records and observations are especially necessary in the case of the Murray and the Murrumbidgee, but it is also highly desirable that the same procedure should be continued on all the western rivers of the Colony. Not only so, but we are of opinion that a similar system should be adopted on our coastal rivers.

Stations of  
river gauges.

When the Commission entered on its duties, it was found that, with the exception of the gauge records maintained by Mr. Russell, the Government Astronomer, the information obtainable regarding our rivers was meagre and fragmentary. Even in the case of the observations supplied to the Government Astronomer, much remained to be done to connect the results with known levels, and to gauge the discharges corresponding to recorded heights of the river. What we have done may, we consider, be fairly regarded as a sound basis on which the system we have initiated may be continued and extended. Besides availing ourselves of the records obtained by the Government Astronomer, copies of which that gentleman kindly supplied to us regularly, we deemed it advisable to make special arrangements for obtaining river records from Albury, Tocumwal, Moama, Euston, Wentworth, Hay, Balranald, Dubbo, and Warren, and returns of the gauge readings at these places are regularly forwarded to us.

Absence of  
proper legis-  
lation.

The utilization of the waters of our rivers must soon become the most important question before the Colony. Already the absence of proper legislation regarding water-rights has been known to exercise a retarding influence on pastoral and agricultural enterprise. As matters at present stand, the enterprising grazier or farmer who erects machinery or constructs works for purposes of irrigation does so at considerable risk, as his right to use water for irrigation may be disputed either

by

by private individuals or by the Government. Preferring the uncertainty of the seasons to such risk, the great majority allow the water to pass by and go to waste. Very different is the state of affairs in Victoria, and even in South Australia. The former Colony is proceeding so rapidly with works for water conservation that in all probability within a few years from the present time no quantity of water will reach the Murray, except in high floods, from any of its Victorian tributaries west of Albury, excepting the Ovens. To pave the way for the works which have been and are being carried out in Victoria a system of discharge observations of a very complete description is followed, and till we have complete information of a similar nature in this Colony we cannot satisfactorily undertake any important work.

In our First Report we alluded to a survey which we had entrusted to Mr. Cornelius Haylock, L.S., for the purpose of determining whether it would be possible to divert a portion of the Snowy River water into the Murrumbidgee.

Diversion of Snowy River into the Murrumbidgee.

To Mr. P. F. Adams, the late Surveyor-General, is due the suggestion that such a scheme might be possible. In his evidence before the Commissioners (see Appendix to First Report), he expressed his opinion that the respective levels were favourable to the project, but the country to be traversed by the canal might prove to be of too mountainous and rocky a character to justify the large expenditure which would be necessary for tunnels, excavations, &c. Mr. Adams suggested that the canal should leave the Snowy River at a point about 5 miles above the junction of the Eucumbene, and be led across the lowest gap on the watershed dividing the Snowy from the Murrumbidgee, and thence into Slack's Creek, a tributary of the Murrumbidgee.

Levels of country.

Mr. Haylock began his survey at a point about 10 miles on the road from Cooma to Jindabyne, and carried it for a distance of 31 miles. The severe drought which prevailed at that time compelled him to abandon the survey abruptly. No future opportunity presented itself for Mr. Haylock to prosecute his survey, and as the question of the proposed diversion still remained undecided, Mr. J. B. Donkin, one of our number, was deputed in January last to ascertain by means of barometric observations, the difference of level between the proposed offtake on the Snowy River and the gap in the Dividing Range.

Mr. Haylock's survey.

From Commissioner Donkin's Report (*See Appendix*) it appears that the most suitable point of offtake would be below the junction of the Gungarlin and Snowy Rivers, at about 180 feet above the Gap, and that the supply which could be availed of, including a contribution from the Crackenback and Eucumbene Rivers, would be about 16 million gallons per hour in the driest seasons. Such an increase to the volume of the Murrumbidgee, coming at the most opportune time of the year, when the river is at its lowest, would not only serve to keep a constant stream in the river, but would also afford a supply which it might be found practicable to divert into Lake George.

Report by Commissioner Donkin.

The value of Lake George as a natural reservoir cannot be over-estimated if complete surveys bear out the cursory examinations of Commissioners Donkin and Gipps; and should it be possible to effect the proposed diversion of Snowy water into the lake it is not improbable that, by commanding the divide between the Murrumbidgee and the Lachlan, a considerable supply could be devoted to irrigation, and to the use of miners on the Temora, Young, Wombat, and Grenfell Gold-fields. As the mining industries of these fields are at present in a languishing condition, and must continue to be so while the water supply is precarious, we consider that a series of surveys should be undertaken for the purpose of ascertaining whether the several schemes are possible of accomplishment.

Diversion to Lake George.

The investigations carried out by Mr. Donkin have so far placed beyond the region of doubt the question as to whether the levels of the intervening country would permit of a diversion from the Snowy into the Murrumbidgee, but there still remains the task of demonstrating absolutely by a detailed survey and levelling whether, in view of the physical difficulties to be overcome, the necessary works can be constructed at a cost which would afford a reasonable presumption that they would be remunerative.

Necessity for detailed survey.

In order to encourage the further development of the dead river-beds of Kiandra, already proved to be highly auriferous, and for purposes of water conservation, it is advisable that the survey of the Murrumbidgee River should commence

Development of gold-bearing drifts at Kiandra.

at

at the head of the Tumut River, one of its largest tributaries, at a point under the Big Bogong Mountains, where, according to the opinion of Commissioner Gipps, C.E., extensive flats and swamps offer a favourable opportunity for conserving a large body of water, which he considers could be led on to the highest gravel-drift spurs of the Kiandra Gold-field by a canal and pipe line under 40 miles in length. After serving this purpose, he contends that the supply, together with a large stream from the head-waters of the Snowy River, could be discharged into a capacious reservoir at Providence Flat, and conducted thence by canal over the divide of the Murrumbidgee River into the Bolaira Plains, where a dam 60 feet high would impound an immense reservoir. He proposes that this supply should be allowed to flow down the rocky bed of the Murrumbidgee River for about 40 miles, till it reaches the offtake of his proposed canal scheme near the junction of Slack's Creek. This canal would provide for the irrigation of a large portion of the Manero Plains, and for the delivery into Lake George of the flood-waters of the different rivers and creeks intersecting its course. From this immense natural reservoir he suggests that it would be possible to supply different towns and gold-fields, and to irrigate a large area of agricultural land on both sides of the divide of the Murrumbidgee and Lachlan Rivers.

Providence  
Flat.

Diversion into  
Lake George.

Country be-  
tween Bogan,  
Darling, and  
Lachlan  
Rivers.

The area of country lying between the Bogan, Darling, and Lachlan Rivers and the Willandra Billabong—represented as an almost total blank on most maps of the Colony—having attracted the attention of the President, he deputed Mr. Victor Czarlinski, M.E., C.E., to examine and report on the district, with a view to ascertain whether it would be possible to divert a portion of the waters of the Bogan and Macquarie across that part of the Colony, over the lowest point on the range.

This portion of the Colony may be considered as practically destitute of water for use in irrigation. The rainfall, though not insignificant as regards the annual mean, is not ample and frequent enough to permit of the adoption of irrigation on an extensive scale. The falls of rain are so scanty, and come at such irregular periods, that the creeks are really intermittent.

Under these circumstances the settlers have been obliged to have recourse to tanks and dams for the conservation of sufficient water for stock. These means of storage seem to supply this want fully, but so far they are quite inadequate for the purposes of irrigation. Settlers in the Cobar District suffer more from want of grass than from want of water; and it seems probable that this privation must continue till such time as an efficient supply of water for irrigation is placed at their command. Mr. Czarlinski is of opinion that this object may be achieved by means of a canal to divert water from the Upper Macquarie basin.

Canal from  
Upper Mac-  
quarie basin.

He also concurs in the opinion expressed originally by the Engineer of the Commission, Mr. H. G. McKinney, M.E., M.I.C.E., that it would be practicable to divert supplies from the Macquarie along the right bank of the Bogan from Narromine. The natural features of the country are such that the works would be comparatively inexpensive.

Gingham  
Gap.

Mr. Czarlinski reports that it is possible to bring the waters of the Upper Macquarie through the Gingham Gap on to the ridge between the Bogan River and the Bulbodney Creek.

The district examined by Mr. Czarlinski appears to him to be wholly outside the influence of the Darling; and even should it be possible to divert water south-west from Brewarrina, the canal could not follow a higher level than the bank of the river, and no supply could be sent into the arid country between the Darling and the Lachlan. Nor is there any possibility of bringing water across from the Darling at Wilcannia to the Willandra Billabong, as the place where the latter runs out is found to be higher than the bank of the Darling.

Willandra  
Billabong.

cretaceous  
formation.

Mr. Czarlinski entertains no doubt as to the existence of water-bearing strata under the cretaceous formation east of the Darling, and he is confident that considerable supplies may be obtained near the river at a depth of about 700 feet. He advances the theory that the supply in this cretaceous strata is derived from a tract of country extending along the north-western limit of the Darling watershed in Queensland, and flows southward till its progress is arrested by the old Devonian range which crosses the Darling near Wilcannia. To the objection which might

be

be raised that in course of time this cretaceous basin, vast though it be, would overflow, it is urged that the rainfall over the Queensland portion of the basin is not copious or frequent enough to admit of such a contingency; besides, a large quantity of the water which soaks into the strata is returned again to the surface by capillary attraction, and by vegetable absorption at the principal point of infiltration.

During his tour of inspection Mr. Czarlinski became impressed with the necessity for destroying the noxious scrub and useless timber, which not only absorb moisture, but prevent a considerable quantity of water from reaching the tanks and dams. Noxious scrub.

In March, 1886, we employed Mr. J. B. Hotson, C.E., to make an examination of the river Darling from Mungindi to Lake Poopelloe, with a view to ascertain what depressions near the river could be used as storage reservoirs. We directed Mr. Hotson that he should, after having satisfied himself by a preliminary inspection that any depression had, or could at a moderate expense be made to have, a capacity of at least a thousand million gallons, with an average depth of at least 15 feet, make such survey and sections as would fix the position of the depression on the map, and indicate approximately its capacity. He was directed to connect such depression with the river by a surveyed and levelled line, and to obtain information which would enable an estimate to be prepared of the cost of utilising the depression. Mr. Hotson's survey of depressions along Darling River.

This part of the country, as will be seen by reference to the evidence which we took at Walgett, the minutes of which are appended to our First Report, had been visited by one of the severest and most protracted droughts which had ever desolated any portion of the Colony. But soon after Mr. Hotson began his work heavy falls of rain occurred, and the country became almost impassable. The Barwon was in flood, and it was with extreme difficulty that any work whatever could be done. Under these circumstances long delays ensued, and but a very small portion of work could be accomplished. Mr. Hotson had only reached Walgett when it became apparent that the survey must be abandoned for a time at least, as the flood now spread for miles on each side of the river. Survey stopped by floods.

Mr. Hotson's examination was not, however, wholly barren of results. At the township of Gundabloui, on the Mooni River, he marked a site where a dam, if carried to a height of 8 feet above summer level, would impound a large body of water, which would probably extend a distance of about 20 miles. The water, in addition to being used for irrigation on the banks of the Mooni, could, by means of pumping to a small height, be employed to fertilise the adjoining waterless country in the south-west. Dam site at Gundabloui.

To the south of Gundabloui, at a point about half-a-mile above the junction of the Mooni with the Barwon, it would appear that a dam might be erected with advantage. No specific site was, however, determined on by survey.

On the Ballone River or Creek, an ana-branch of the Boomi, Mr. Hotson selected two sites for overshot dams—one on the northern arm of the creek, and one on the southern; but at a subsequent period of his inspection he was led to the conclusion that such works would be rendered unnecessary by the erection of a dam at the Werribilla waterhole, a natural reservoir in the channel of the Barwon, about a mile above the junction of the Gwydir. The water, which is about 40 feet deep at summer level, is held back by a bar of rock which crosses the main channel, and abuts on the banks. The position appears to be eminently favoured by nature for the construction of an overshot dam. By means of such a work the several Ballone and Banarway Channels could be maintained permanently full, the dry country to the north and west of Collarindabri would be brought within reach of irrigation, and the surplus water of the Barwon could be diverted westerly to join the natural drainage system trending towards the big Warrambool. The flooded state of the river prevented Mr. Hotson from taking cross-sections of the stream and running a line of levels; but he is of opinion that the dam would require to be about 25 feet high and 130 feet long. No apprehension need exist as to the effect of such a work on the navigation of the stream, there being no steamer traffic on the upper portions of the Barwon. Dam sites on Ballone River.

Dam site  
below  
Moomin and  
Gwydir  
Rivers.

Below the junction of the Moomin and the Gwydir there exists a site for an overshot dam, which would probably back the water a distance of 15 miles up both streams; and several sites may be found where an overshot dam would be of local advantage.

Dam sites on  
Grawan  
Creek.

On the Grawan Creek, which falls into the Barwon a few miles below Collarindabri, Mr. Hotson surveyed two sites for dams; and on the Meaki, the main branch of the Grawan, he noted a site, but was unable to determine its true position. In connection with these works a dam would be necessary at the lower end of the Thalaba Creek, near the Pian Creek, and one some distance up the Thalaba. The country between the Grawan and the Thalaba could be commanded for irrigation by pumping to a height of about 10 feet above the level to which these works would raise the water.

Dam site on  
Pagan Creek.

In the lower portion of the Pagan Creek an overshot dam of about 20 feet in height would maintain water in the creek to a considerable distance.

Mr. Hotson, on his return journey to Sydney *via* Narrabri, obtained information as to sites on Pian Creek where timber overshot dams might be constructed with benefit to the district. These structures, which need not be of a great height, would throw the water back for miles between well-defined banks.

Results of  
Mr. Hotson's  
survey.

It is to be regretted that Mr. Hotson's survey had to be so abruptly stopped, because of the continually inundated condition of the country along the banks of the Barwon. But though the principal object of the survey has not been achieved, yet what has been accomplished possesses a decided value. A number of sites have been indicated where the construction of dams will impound large bodies of water that may be diverted over tracts of country at present absolutely waterless. The soil is fertile, and abundant building materials exist for the construction of dams. Nothing but action on the part of the State is wanting to make these natural conditions contribute to the general prosperity of the Colony.

Inspection of  
Darling River  
by Commis-  
sioners Donkin  
and Gipps.

At a later period of the year the flooded state of the Darling presented a favourable opportunity for a personal visit, and for obtaining information respecting the river. We accordingly deputed two of our number, Commissioners Donkin and Gipps, to make an inspection of the river from Bourke to Wentworth. Proceeding by steamer, with the exception of a journey by coach from Wilcannia to Menindie, they examined a number of witnesses, and, where opportunity offered, inspected some of the lakes in the vicinity of the river. These depressions are filled by the overflow of the Darling. When the river falls most of them flow back into the stream, and, as in the case of Lake Menindie, contribute so materially to the volume of the river as to prolong by two or three months the period for which navigation is possible. Others of these lakes retain the water for a time until it finally disappears by percolation and evaporation, leaving in most instances a luxuriant growth of herbage behind.

Menindie  
Lake.

Menindie Lake and Cawndilla Lake (which are, in fact, one lake) cover an area of over 60,000 acres, with a depth in places of 16 feet, and according to the opinion of Mr. W. J. Hanna, C.E., the local Road Superintendent, this body of water could be retained at a cost of about £700. (*Vide* Evidence.) At the time of the Commissioners' visit, Lake Woytchugga, near Wilcannia, covered an extent of about 4,000 acres, with a depth of 10 feet in places; and Mr. J. W. Brougham, of Outer Netallie Station, was confident that the expenditure of £100 would be sufficient to retain the water. A simple dam which he threw across this lake at a cost of £10 held back a considerable body of water for two years. (*Vide* Evidence.)

Diversion into  
lakes by  
means of dam  
on Terya-  
weynya Creek.

On the east side of the Darling the flood-waters of the river have been diverted as far as Lake Bullabulka, filling a system of about twenty-two lakes, which comprise an area of about 52,000 acres. This very satisfactory result has been achieved through the enterprise of a number of pastoral lessees in the district who combined to defray the cost of a dam on Teryaweynya Creek. (*Vide* Appendix to Report on Darling River.)

The examination by the Commissioners was too cursory to justify any absolute expression of opinion concerning these lakes; but there can be no doubt that it would be

be possible at a small cost, in the manner recommended in the Commissioners' Report on the Darling, to make use of them as large natural reservoirs.

During the late drought the losses in stock from want of grass and want of water have been startling. It would be impossible to give even an approximate statement of the mortality, but some idea of it may be formed from the fact that on three stations in the Darling District the loss in two years was over a quarter of a million of sheep, irrespective of the deficiency in lambs. On Billilla Station the actual loss in two years was 156,000 sheep, and in one of the years there was no lambing. Feed of course rose to famine prices—hay and chaff being sold at £50 a ton, and flour (which was given to the horses for want of fodder) at £40 a ton.

Losses in stock  
in Darling  
district.

Individual effort so far seems to have been powerless to cope with these disastrous droughts, and it would appear that irrigation and water conservation must be resorted to as a means of counteracting their effects. At present the Darling country seems to have attained its limit of expansion; and unless the benefits of irrigation can be placed within the reach of the pastoralist his enterprise must remain restricted, and he must continue to see his flocks perish in the frequently recurring times of drought.

Necessity for  
irrigation.

Wherever irrigation has been tried on the Darling it has been successful. At Winbar 7 acres yielded 30 tons of lucerne hay per annum, at a cost of about £3 a ton, during a drought when chaff delivered at the station cost £23 a ton. The Manager estimated that the experiment had resulted in a saving of £1,000 in one year. (*Vide Evidence.*) At Tapio eighteen sheep to the acre were maintained in splendid condition on a patch of 22 irrigated acres, while on the rest of the run 13 acres barely sufficed to keep a sheep alive. In view of this fact the statement of Mr. N. Sadleir, of Albemarle Station, that by means of irrigation the carrying capacity of country is increased a hundred-fold need not be regarded as a mere figure of speech. On an area 3 miles square, irrigated by the flow of flood-waters over low-lying land, he kept 8,000 sheep in the middle of summer, and had a good lambing; and he avers that the very same land, not irrigated, did not carry 1,200 sheep. In fact no opinion adverse to irrigation was expressed by settlers on the river. The only difficulties which seemed to present themselves were in regard to the maintaining of a permanent supply in the river to make irrigation possible during the time when it is most needed—a prolonged drought, and the want of practical knowledge to employ the methods of irrigation.

Successful  
results of  
irrigation.

The solution of this difficulty lies in the construction of weirs at various points in the Darling. Throughout the whole course of the river traversed by the Commissioners there exist bars of rock at frequent intervals. These would afford excellent sites for weirs; and the construction of such works is rendered still more practicable by the presence of abundance of building material at many points on the river.

Rocky bars in  
Darling River  
regarded as  
weir sites.

In this connection the question must arise as to the possible influence which an artificial obstruction in the stream might exercise on the banks. It may yet be premature to hazard a decided opinion on the matter, but if we may judge from existing natural conditions there is no reason to apprehend that a weir across the Darling would cause the banks to erode. At Brewarrina and at Curranyalpa the presence of a bar of rock of considerable magnitude has not induced the river to cut a fresh channel. At the time of the Commissioners' visit to the former place during the drought of 1885 it came under their notice that the natural bar, which is known as "The Fisheries," backed up the water in the Barwon a distance of about 30 miles, there being a considerable depth immediately behind the bar.

Erosion of  
banks.

Though navigation must occupy a secondary position with regard to irrigation, yet, should weirs be constructed on the Darling, it may be possible to preserve both navigation and irrigation. The maintenance of a constant stream, and the extension of the railway to a point lower down the river than Bourke, would undoubtedly direct to Sydney a considerable amount of trade which is now diverted to adjoining colonies. At present the settlers on that part of the Darling which may be regarded as inaccessible to the railway at Bourke experience great inconvenience and uncertainty in receiving supplies and sending away produce. The river is their highway, but when it ceases to be a river they are subjected to loss and delay

Navigation of  
Darling.

delay through having to fall back on the tedious and costly land carriage by teams. Instances have occurred where wool has been detained for twelve months awaiting dispatch to market; and on one occasion a steamer occupied over three years in the journey from Morgan (S.A.) to Bourke.

Detention of wool on river.

Uniform method of adjusting river gauges necessary.

Commissioners Donkin and Gipps observed that no uniform method of adjusting the river-gauges is adopted on the Darling. In some places the height of the river is read as from the bed; in others it is taken as from "summer level," a term which receives a variety of interpretations. To obviate the confusion which arises from these irregular methods, and to ensure trustworthy records along the whole course of the river, it seems advisable that some common zero should be adopted from which to read the heights of floods. It appears to us that zero should be regarded as that level of the water when the river just ceases to flow over the rocky bars.

Examination of coastal rivers.

In pursuance of our decision to examine the coastal rivers and the northern portion of the Darling Basin, we held meetings and took evidence at Camden, Penrith, Richmond, and Windsor, in the drainage area of the Hawkesbury, and subsequently deputed three of our number, as well as our Engineer, to proceed to the Macleay, Clarence, and other rivers of the northern coast, and also to the tableland of New England. The programme arranged was carried out in full, excepting that part of it relating to the Macleay, and this was left over with the intention of taking it up afterwards in conjunction with other coastal basins further south. There has not, however, been time to carry out this intention, which is a matter to be regretted, as there is reason to believe that the valley of the Macleay will be found to afford a favourable field for irrigation.

Valley of the Hawkesbury.

The evidence obtained by us regarding the beneficial effects of irrigation in the valley of the Hawkesbury was conclusive on this point. As the average rainfall at Windsor, obtained from returns extending over a period of twenty-three years, is nearly 33 inches, and that at Richmond, found from the records of the last five years, 26 inches, it might be inferred that the want of irrigation would not be felt. It must, however, be borne in mind that a good average annual rainfall is not by itself sufficient proof that irrigation is not necessary. The true position of a district in this respect is not known till it is ascertained, first, what are the products of that district, and, second, whether the rainfall is sufficient for those products in the seasons when most required. In the case of the Hawkesbury District, we found that fruit, maize, fodder-producing crops, and vegetables are extensively grown; but that the rainfall, so far from being seasonable, is greatest in winter and least in spring. Hence it is not surprising that the evidence obtained was strongly in favour of irrigation. In a number of instances evidence of this description was based on actual experience. The well-known scientist, Mr. John Tebbutt, F.R.A.S., of Windsor, who is the proprietor of a valuable agricultural estate, described the result of irrigation on his land as "magnificent." Mr. John Gow, of Mulgrave, who expended £250 on plant for the irrigation of 10 acres of vines and fruit trees, expressed himself as well satisfied with the experiment, as his crops were doubled by the first season's operations. The water in this case was raised 55 feet, so that altogether it was an instance of irrigation carried out under most unfavourable circumstances, yet with satisfactory and remunerative results.

Results of irrigation.

The technical questions involved in the utilization of the waters of the Nepean and Hawkesbury Rivers, on a large scale, were dealt with briefly by our Engineer in two reports, which are herewith appended, as is also a copy of the plan referred to in one of them, showing the extent of land subject to floods near Richmond and Windsor. Combining the information which these reports and the plan afford with the evidence which we obtained, we are in a position to state (1) that there is a widespread demand for irrigation in the valley of the Nepean and Hawkesbury, and (2) that, so far as technical information is available, it tends to show that there are great facilities for satisfying this demand.

Enterprise prevented by existing riparian laws.

Our inquiries on the Nepean and Hawkesbury corroborated the conclusions at which we had arrived from our investigations elsewhere, that the present unsatisfactory state of the law on the subject of water-rights acts as a bar to agricultural progress. The enterprising men who have already commenced irrigation, and who are

are thoroughly convinced of its value, know that their operations are carried on at more or less risk of interruption. It is not surprising that there are others who appreciate the importance of irrigation, but who are deterred from resorting to it by the risks involved.

It has frequently been stated, and with much apparent reason, that the first step towards dealing effectively with the question of water conservation on the Darling is to provide for the storage of surplus water on the upper parts of the basin of that river, so as to be in a position to, in some measure, equalize the flow. The investigation of this question was one of the leading objects in view in connection with the visit of the Commission to what, in our First Report, was termed the "effective" portion of the basin of the Darling. Under this designation are included the upper parts of the drainage area of the Gwydir and the entire drainage areas of the Macintyre and Dumaresq Rivers.

In examining the nature and requirements of this district, a point which claims prominent attention, and which cropped up repeatedly in the evidence taken by us, is the decrease in the rainfall in a westerly direction from the summit of the Dividing Range. Another matter which has an important bearing on the supply of water is the presence of a large extent of heavily timbered and gently undulating tableland, and also of plains of considerable area in this upper portion of the Darling Basin. The combined effect of these two important features is sufficient to explain why even the Upper Darling is far from being such a river as might be expected to flow from such an extensive catchment area. A light rainfall, a gently undulating or comparatively level country, deep soil, and heavy timber, are conditions which tend to prevent the formation of streams and to reduce the discharge of rivers; and these are the conditions which exist on a large proportion of the drainage area of the Upper Darling.

Another point which is made clear by these considerations is, that while in places like Glen Innes, which is near the top of the Dividing Range, or like Inverell, which is in a valley on its western slope, the rainfall may, in ordinary seasons, be sufficient, it is necessary to travel but a short distance from Inverell, in a westerly or north-westerly direction, to find land suitably situated for irrigation, and on which the rainfall is so deficient and irregular as to point inevitably to the conclusion that, without irrigation, agriculture and horticulture will be subject to great risk. Thus, while the rainfall at Walcha, Glen Innes, and Tenterfield is respectively 25.25, 31.96, and 29.71 inches, that at Goolhi, Moree, and Tullooona is, respectively, 18.31, 17.90, and 18.52 inches, the respective distances between the corresponding places in their order being 100 miles, 110 miles, and 100 miles. The diminution of the number of rainy days as the distance from the Dividing Range increases is still more marked. Under these circumstances, as might be expected, the evidence obtained by the Commission at Glen Innes, Inverell, and Tenterfield, while tending to show that the want of water conservation at those places is seldom felt, the case is quite different beyond a distance of 40 or 50 miles west from them. Regarding the district beyond this limit, the evidence conclusively showed that the necessity for irrigation has already begun to be felt.

On the subject of the storage of flood-water in the basin of the Upper Darling, the result of the inquiries of the Commission was not as satisfactory as had been hoped. The only really extensive natural reservoirs brought to notice in the evidence taken by the Commissioners were that known as "The Mother-of-Ducks Lagoon," and the Llangothlan Lagoon, situated on Ben Lomond, and about 25 miles from Glen Innes. The former, which is the much more important mountain lake, covers an area of about 3,360 acres, and, though shallow, would afford such storage capacity as would make it well worth utilizing if its situation were more favourable; but located as it is, almost at the top of the Dividing Range, and with no possibility of diverting any very large supply of water into it, there is very little hope of making the lagoon play an important part in any large project for water conservation. It is not unlikely, however, that, as stated by one of the witnesses, it may be turned to account for purposes of town supply.

Though the general conclusions arrived at from the partial inspection of the effective portion of the drainage area of the Darling, as well as from the evidence taken,

taken, were, on the whole, less encouraging than might have been anticipated, yet, according to Commissioners Gipps and Townsend, the prospect of augmenting the low supply in the Darling by storing water on a large scale in times of flood, and allowing it to escape by degrees afterwards, is not altogether doubtful. The former Commissioner, guided by a hasty examination, and the latter by an intimate knowledge of the country embraced in the heads of the Gwydir, Macintyre, Severn, Dumaresque, Peel, and Namoi Rivers—recommend the examination of extensive reservoir sites above the junction of the Bluff and Mole Rivers—on the Bluff River, below the junction of Deepwater and Mole Rivers; on Deepwater River, at Bolivia Station; on Beardy River, at about 352 miles on the Northern Railway line, and at the head of Limestone Creek. They are of opinion that the water supply from such reservoirs could be availed of for irrigating a very extensive area of rich agricultural land, and for developing a large mining district known to abound in extensive gravel drifts containing gold, tin, and diamonds, which would yield very profitable returns if provided with a liberal supply of water.

Drainage area  
of Clarence  
River.

The drainage area of the Clarence is in marked contrast to that of the Upper Darling, and a comparison of the two brings out clearly the main points of difference between the eastern and western slopes of the Dividing Range. It has already been pointed out that, in the case of the Upper Darling, the leading features of a large portion of that district tend strongly to reduce the flow of surface water, and to keep down the discharge of the river to a minimum. In a great measure the case of the basin of the Clarence is precisely the reverse of this. The eastern face of the Dividing Range, on which the Clarence and its principal tributaries, except the Nymboi and the Orara, take their rise, is steep and in many places precipitous, and the mountains, amongst which are the sources of these two tributaries, are of a similar description. With a few exceptions, the rivers and creeks which combine to form the Clarence flow in narrow ravines, and might, as a general rule, be classed as mountain torrents. The average rainfall is high, and exceptionally heavy falls of rain frequently occur within very short periods of time. These circumstances combined have the effect of making the discharge of the Clarence River great at all times in proportion to its catchment area, and of occasionally causing extraordinary floods, which attain the most formidable dimensions, but last for only short periods. The information available regarding the flood discharges of our rivers is very meagre, but what there is tends to show that a high flood in the Clarence represents a greater discharge than is ever carried at any one time to the South Australian border by all our western rivers combined. Mr. E. J. Statham, Assistant Engineer in the Roads Department, stated in his evidence that the flood discharge of the Nymboi, below its junction with the Little River at Buccarumbi, was found by him to be about 270,000 cubic feet per second. In Appendix A 7 to the First Report of the Commission is a table which was compiled by the late Mr. P. H. Gell from observations made by him, and from this it will be seen that the combined discharge of the Murray, Murrumbidgee, and Lachlan, during the period extending from August, 1871, till August, 1874, never exceeded 67,500 cubic feet per second. The northern arm of the Clarence—that is, the Clarence River proper—is considerably larger than the Nymboi, and, in addition to the latter, the Orara and Mitchell Rivers have to be taken into account. Hence, it is a fair inference from Mr. Statham's evidence that, with a high flood in the Nymboi and the Orara, and a moderate flood in the Clarence and in its other tributaries, the discharge at Grafton is at least 500,000 cubic feet per second. On the other hand, there can be no doubt that the discharge of the Darling at Wentworth is less than that of the Murray; so that, according to the evidence received, the volume of water passing Grafton in a high flood is from four to five times greater than the flood discharge, below Wentworth, from the whole western basin.

Great floods.

Discharge of  
Clarence com-  
pared with  
discharge of  
western rivers.

Flood dis-  
charge at  
Grafton.

Causes of  
great flood  
discharge.

It is a matter of considerable difficulty to obtain anything better than rough approximations in the case of the flood discharges of such rivers as the Nymboi; but, making ample allowance for probable errors, it seems perfectly safe to conclude, from Mr. Statham's figures, that the flood discharge of the Clarence is much greater than that of our whole western system of rivers combined. This conclusion, startling though it appears at first sight, is very easily explained. The exceptionally great discharging capabilities of the drainage area of the Clarence have already been described, and we have only to contrast them with the unfavourable circumstances under

under which the western rivers carry their gradually diminishing supplies to Wentworth. It has to be borne in mind, too, that the duration of a flood in the Nymboi is reckoned by hours, in the Clarence at Grafton by days, and in the Murray at Wentworth by months. In short, Mr. Statham's figures, remarkable though they are, can be in a large measure accounted for by the circumstances of the case. The catchment area of the Nymboi at Buccarumbi, where it was gauged by Mr. Statham, is little, if anything, under 2,000 square miles. If a fall of 5 inches of rain were to take place within twenty-four hours, at a time when the ground was already moist, the proportion which would flow off would, in all probability, amount to over three-fifths of this. Three inches of rainfall over 2,000 square miles would be sufficient to cause a flow of 161,000 cubic feet per second for twenty-four hours; but the maximum discharge would be much greater than this, as the surface water in such a flood would reach Buccarumbi from almost every part of the catchment area within twenty-four hours. The discharge obtained by Mr. Statham is considerably over that mentioned, but it is only natural that, at the period of maximum confluence of the streams which constitute the Nymboi, the discharge would be in excess of the mean outflow produced by the rainfall.

In our Engineer's report of 23rd October last, which is appended, he has pointed out the difficulties which the high floods of the Clarence place in the way of any projects for irrigation. The same causes would operate in some degree in adding to the expense of works for the utilization of the water for motive power or for hydraulic sluicing. Still, we believe there is a profitable field for the employment of a portion of the Clarence waters for both these purposes.

The area of the basin of the Richmond River is about 2,660 square miles, and of this the proportion of plain country is so small that the whole area may be classed as "effective." As compared with the western rivers of the Colony, the Richmond is of far greater importance than would be anticipated by judging from the extent of its catchment area. From the mouth of the river to Lismore, which is at the head of the navigation on the North Arm, the distance is about 70 miles. Lismore is at the junction of two large creeks—Leicester Creek and Wilson's Creek—the former about 140 feet wide, and the latter about 125 feet wide, at the ordinary surface level. From Lismore to Coraki the general width of the North Arm is from 200 to 300 feet, while the width of the river below the confluence of the North Arm with the main stream at Coraki is from 300 feet to a quarter of a mile. The North Arm has been known to be affected by the tidal waters as far as Wyralla, which is about 15 miles below Lismore. The main Richmond River is navigable for steamers of small draught to within about  $2\frac{1}{2}$  miles of Casino, while the Bungawalban Creek, or South Arm of the Richmond, is navigable for vessels drawing 5 or 6 feet of water to a distance of from 20 to 30 miles from the main river. It will thus be seen that the Richmond River is a great natural highway, by means of which all parts of the rich delta land through which it flows possess navigable communication with the ocean. But the circumstances which combine to provide great facilities for navigation militate against the use of any large proportion of the river water for purposes of irrigation.

The rainfall of the Richmond River District, though high, is frequently unseasonable, and on this account serious losses have occasionally been sustained. The mean rainfall at Casino is nearly 39 inches, yet the Clerk of Petty Sessions at that place estimated that in 1885 the loss of cattle through scarcity of grass and water in the Richmond River District was between 15,000 and 16,000. In one case at least, pumping from the river for watering stock and for irrigation purposes has been resorted to with advantage. At Ballina we found an instance of irrigation, chiefly of fruit-trees and vegetables, carried on with water raised from a well by a windmill. It is evident from these facts that notwithstanding the high average rainfall the question of water conservation in the Richmond River District should be kept in view, so that when Crown lands are disposed of, whether by sale or lease, the bearings which such land might have on any possible project for the storage or distribution of water should be carefully considered.

The causes set forth in the Engineer's report of 23rd October last, which will render irrigation on a large scale difficult, if not impracticable, in the valley of the Clarence, apply, though with less force, to the basin of the Richmond. In the

case

case of the former river the influence of the tides extends throughout the delta land and to some distance among the hills bordering on it; but in that of the Richmond the influence of the tidal water ceases to be felt at a considerable distance within the limits of the delta. Other points in favour of irrigation on a large scale in the Richmond River District, as compared with that of the Clarence, are,—(2) that the alluvial land is less broken into islands; (3) that the river is narrower, and the construction of weirs easier; and (4) that the extent of the alluvial land is greater. The causes which operate against any large irrigation project are,—(1) the high average rainfall, which tempts the majority of the landholders to endure present risks; (2) the uneven nature of the ground; (3) the presence of marshes, and the consequent necessity for drainage in conjunction with irrigation; and (4) the high cost of compensation.

**Site for a weir.** Should a project for utilizing the water of the North Arm of the Richmond be found practicable, it is probable that the best site for a weir will be found about half a mile up-stream from the Wyralla Saw-mills. The width of the river at that place is about 200 feet, the bank on the right side is from 12 to 15 feet high above the ordinary level of the water, and on the left side there is a hill into which that end of the head-works would abut. We do not, however, anticipate that the necessity for irrigation on an extensive scale will be felt and appreciated till this part of the country is more completely opened up. As an essentially agricultural district, a much larger population than the present is required for its development. Until a greater proportion of the land has been cleared and broken up, and a larger population has been settled upon it, the question of water conservation for purposes of irrigation may be expected to remain in abeyance. It seems surprising, however, that nothing has been done towards utilizing the waters of the Richmond, and particularly of the main river near Casino, for motive power. Above Casino, and for some distance below that place, the Richmond has the character of a hill torrent. The supply of water is abundant, the rate of fall is evidently very rapid, and the facilities for utilizing the river for motive power are correspondingly great. The chief reason assigned for taking no step towards utilizing the river for this purpose is said to be the risk of damage from floods; but, even taking into account the exceptional height of the floods, we are confident that means can be found to obviate the risk.

**Drainage areas of Brunswick and Tweed Rivers.**

**Sugar-cane crop.**

The extreme north-east of the Colony is occupied by the drainage areas of the Brunswick and the Tweed, the extent of the former being, roughly, about 100 square miles, and that of the latter 400 square miles. Throughout both areas the rainfall is very high—that at Antony, near the mouth of the Tweed, being about 59 inches. Although navigation will probably continue to be regarded as the most important question in connection with these rivers, and drainage will demand a certain amount of attention, still, as sugar-cane is, and probably will remain, the chief product of the district, and as it is a crop which benefits largely by irrigation, the question of water conservation for this purpose should not be lost sight of. For domestic purposes, and for stock, the demand for a better water-supply has already arisen. The Tweed, which is navigable to a distance of 30 miles from its mouth, is affected by the tides to such extent that its waters, when the river is low, are salt to a distance of 25 miles from the ocean. As the supply in wells is not good, the question of providing water for all purposes in the valley of the Tweed, from Murwillumbah downward, is one which, in a rapidly rising district like that of the Tweed, should not be long deferred. Settlement on the Brunswick is still in its infancy, and the Tweed District is developed to only a very limited extent; but the fertility of this part of the Colony must ensure rapid settlement and give the district a degree of importance altogether out of proportion to its area.

**Coastal Rivers.**

Our investigation having reference to the coastal rivers was necessarily dependent upon the means at our disposal for the purpose. The amounts placed to our credit were wholly inadequate to do what was requisite, and the long intervals which occurred between the payment of them, during which the rent of offices and the salaries of the office staff had to be continued, has had the result of making this portion of our work dilatory, expensive, and ineffective. It was not until the period allotted for the existence of the Commission had nearly expired that arrangements could be made for the visit of a delegate from the Commission to the rivers on the northern coast. Our application for an extension of time was granted eight weeks after

after it was made, and too late to enable us to make that careful examination of the Macleay, Hastings, Manning, and Hunter Rivers which their importance demanded. While we regret that the information which we have been able to obtain in reference to the possibility of storing flood-waters at the heads of the coastal rivers, and their diversion for the purposes of irrigation in dry seasons, and the mitigation of floods in wet years, is not commensurate with the importance of the subject, we trust that the inquiries which we have made will be of value in directing the attention of those who may hereafter be entrusted with the instrumental examination of the country to points of vantage; and we are not without hope that the more regular and abundant rainfall of the districts lying between the ocean and the Main Dividing Range, the natural fertility of large areas of the soil, the greater density of population settled in this portion of the Colony, and its proximity to large markets, will, consequent upon legislation, enable the inhabitants to combine their energy and capital in the creation of schemes of water supply, speedily lead to the establishment of large and prosperous farming communities, the rewards of whose industry, being no longer dependent upon the vicissitudes of the seasons, will cease to be precarious.

Since, in our First Report (page 104), we expressed the opinion that the Government should establish farms in localities having command of water for irrigation, we have become more deeply impressed with the propriety of such a course as a means of making known to the agricultural community the benefits of irrigation, and of giving practical instruction in the art of wet cultivation. The great advantages of irrigation are readily admitted as a matter of theory, but agriculturists as a body are generally slow to adopt new methods. A State irrigation farm, carried on by means of youths such as those who are now drafted from the "Vernon," or even as a reformatory for juvenile offenders, would, we anticipate, be self-supporting, and would do more to substitute for the present haphazard and unprofitable methods of agriculture a system of scientific farming adapted to the Colony than could be expected as the result of any amount of merely theoretical teaching.

There are numerous localities where such farms might be established, and we think it would be desirable that they should be so placed as regards the varying soils and climates of the Colony, as would give scope for the growth of the widest range of vegetable products peculiar to the temperate and sub-tropical zones.

#### SUMMARY AND CONCLUSIONS.

The system which we followed in dealing with the important questions which we were appointed to consider has already been briefly alluded to, but it is necessary to give a complete outline of it before stating the conclusions at which we have arrived, and the recommendations which we desire to make.

On entering on our duties we found that there was great divergence of opinion on the subject of water conservation and supply, that the information available regarding our rivers was meagre and fragmentary, and that on some important points public opinion was in danger of being misled by statements and theories which there was ample evidence to refute. Under these circumstances we saw that the first step to take was to ascertain the opinions held both by the leading experts and by the pastoralists, farmers, and others whose practical experience qualified them to give useful evidence on the subject of water conservation. Whilst pursuing our investigations on this principle we instructed our Engineer to prepare from all available sources a compilation of the levels which had been taken along the courses of our rivers and throughout the interior of the Colony generally; also to deal with the question of river gauge records, to make discharge observations, and to collect details regarding the extent, nature and physical conditions of the principal drainage areas of the Colony.

In the preparation of our First Report it was our aim to furnish a concise summary of the information obtained in evidence, and of that collected as described, regarding the rivers, lakes, and drainage areas—in other words, to supply in a compact form a description of those physical features which have an important influence

influence on the question of water conservation and supply in the interior of the Colony, together with an abstract of the evidence obtained, and our conclusions regarding the preliminary action required. As we deemed the evidence conclusive as to the necessity for water conservation throughout the country west of the Dividing Range, we mentioned in our First Report some of the surveys which should be made, and we gave a draft of a bill such as, in our opinion, is required to deal with the question of riparian rights.

Having thus described the western drainage areas so far as regards their bearings on the subject of water conservation, and having summarized the available information bearing on the same subject, and stated some of the steps most urgently required, we were in a position to concentrate our attention on the consideration of intercolonial rights in the River Murray. This is a question which was brought prominently forward, owing chiefly to sweeping suggestions which were made to the Government of Victoria for utilizing the waters of the Murray in that Colony. In order to arrive at an understanding on this subject, we had two conferences with the Water Conservation Commission of Victoria—the first being held in Melbourne, and the second in Sydney. At the latter a series of resolutions was adopted as containing the basis of an equitable agreement for the division of the Murray waters. An account of the proceedings of the Conferences, and a description of works for water conservation and supply which we visited when in Victoria, constitute our Second Report.

Intercolonial rights in River Murray.

Coastal rivers

Having disposed of the question of the Murray waters, so far as our powers extended, it remained for us to carry out an inspection of the coastal rivers, to investigate more fully the conditions of the River Darling, and to obtain information of a definite nature as to the best means of utilizing some portion of the water available in the interior of the Colony. Owing in a large measure to causes which have already been referred to, this programme has been only partially carried out. In the case of the surveys which were commenced under our instructions on the Upper Darling, the season proved so unfavourable for such work that the survey had to be abandoned. But notwithstanding these drawbacks we have received much valuable information on the subject of our inquiry, whilst our Engineer's report on irrigation in Riverina, which will be found in the Appendix, contains, in our opinion, by far the most important proposals of a definite nature which have yet been made in this Colony regarding water conservation on an extensive scale.

Survey of Upper Darling.

Irrigation in Riverina.

The general conclusions at which we have arrived as a result of our investigations are:—

Vital necessity for water conservation.

(1.) That on water conservation mainly depend the prosperity and the development of the whole extent of the Central and Western Divisions of this Colony, and that, though less required in the Eastern Division, it will add in many places there also in an important degree to the productiveness, and therefore to the value, of the land.

Water for stock.

(2.) That as the landholders, as a general rule, are quite equal to the task of providing sufficient water for the stock which the land can carry under present conditions, Government works for supplying water to stock are required only on a limited scale, and generally only on travelling stock routes.

Irrigation.

(3.) That the great object of water conservation in this Colony, and particularly in the country west of the Dividing Range, is for irrigation.

Chief purposes of irrigation.

(4.) That the purposes for which irrigation is chiefly required are (a) to provide fodder and grain for horses, cattle, and stud sheep; (b) to afford supplies to be kept in reserve for saving stock of all kinds in bad seasons; (c) to produce fruit, vegetables, and miscellaneous crops; and (d) to increase generally the productive powers of the land.

Prospect of irrigation being profitable.

(5.) That any well-considered and properly-executed project for irrigation in the country west of the Dividing Range would afford a good direct return on the capital invested, and would be a distinct benefit to the Colony at large.

Necessity for legislation.

(6.) That legislation on the subject of water rights is a matter of pressing necessity, both to protect the rights of the State, and to foster and encourage local and private enterprise.

Our

Our recommendations, which are based on the foregoing conclusions and on the experience we have gained regarding the necessities of the country, may be classed under two heads; namely, 1st, those of a general nature, and relating chiefly to the subject of water conservation as a whole; and 2nd, those relating to particular projects or to local action. Under the first head we beg to recommend,—

- (1.) That the maintenance of river gauge records as extended by us should be made still more complete, and the records kept continuously and in a careful and systematic manner. River gauge records.
- (2.) That the gauging of the rivers initiated by us should be continued in a systematic manner, so that the discharge of all rivers likely to be tapped for water supply purposes may be known for all readings of the gauges. This information is particularly necessary in the cases of the Murrumbidgee, the Darling, and the Murray. Gauging of rivers.
- (3.) That the subject of legislation on the lines suggested in our First Report should receive early consideration. Legislation.

Regarding particular works and projects we beg to recommend,—

- (1.) That as projects for the construction of irrigation canals from the Murray and the Murrumbidgee have been submitted to us in a definite form by our Engineer, and as the information supplied with these projects has been carefully worked out, and is of a most favourable nature, the necessary funds for the required surveys should be sanctioned as estimated, and the surveys started forthwith. Necessity for immediate surveys for canals from Murray and Murrumbidgee.
- (2.) That a sum of £5,000 should be sanctioned for a more complete examination of the Lachlan, Macquarie, and Darling Rivers; and of Lake George, Lake Bathurst, and Lake Cudjellico. Other surveys.
- (3.) That, as great bodies of water from time to time flow down the Paroo, Bulloo, and Warrego, and run to waste in polygonum swamps, and down fissures in the ground, a survey should be undertaken to ascertain whether it would be possible, by the conservation or diversion of these waters, to turn them to greater national advantage. Paroo, Bulloo, and Warrego.

With reference to the foregoing recommendations and conclusions, we desire to add that in our opinion water conservation is fast becoming the greatest question with which the Government and people of this Colony have to deal. Though, in a season such as this, its paramount importance may be lost sight of by many those who have had practical experience of the droughts of past years will readily admit that the losses which have severely affected an important proportion of the landholders might have been in a large degree mitigated if works such as those for which surveys are now recommended had been in existence. We trust that the question will be dealt with by the Government in a broad and comprehensive manner; that the charge of water conservation will be made a distinct office, and placed in competent and experienced hands; and that, in short, the whole subject will be treated with the consideration which its importance demands. Paramount importance of water conservation.

It is our painful duty to announce the death of one of our number, Mr. Richard Lennon Murray, who from the outset of our inquiry devoted himself with untiring zeal to the work. In spite of an enfeebled constitution he maintained an unceasing and active interest in the investigations of the Commission until shortly before his death, a few months ago. In expressing our regret that, in the preparation of our Final Report, we have been deprived of the benefit of his information and matured judgment, we desire to place on record our high sense of the important assistance which Mr. Murray rendered during the progress of the inquiry. Death of Commissioner R. L. Murray.

Mr. G. W. Townsend, one of our number, having been exclusively employed upon the Colo Valley railway survey for the last two years, has been unable to give the attention to the affairs of the Commission that he was anxious to have done. Commissioner G. W. Townsend.

At the outset of our inquiry three years ago, we found it necessary to engage the services of certain gentlemen to assist us in the engineering and surveying, clerical and draughting work of the Commission. We selected Mr. H. G. M'Kinney, M.E., M.I.C.E., as our engineer, Mr. J. S. Ramsay as assistant secretary, and Mr. W. C. Higinbotham as draughtsman. About eighteen months ago we also appointed Mr.

F. H. Maynard as assistant draughtsman. These officers having performed the duties of their respective positions entirely to our satisfaction, and having become conversant with the direction which our inquiry took, and the conclusions at which we have arrived, we recommend that, in the public interests, their services be retained by the Government to assist in continuing to carry out work which we have initiated, and which may be undertaken on the strength of our proposals.

As it is unnecessary to make any recommendation regarding our secretary, Mr. Charles Robinson, since he already occupies an important and responsible position in the public service, the Commissioners desire to express their thanks to him, and to mark their appreciation of the valuable services rendered by him, by recording in this place their unanimous feeling of satisfaction at the zealous attention, the large experience, and the tact displayed in the management of his portion of the work of the Commission.

Publications  
collected by  
the Commis-  
sion.

We attach hereto a list of the publications relating to the subject of our inquiry which we have obtained from various parts of the world, and which we are now prepared to hand over to the Government.

Maps and  
plans.

The maps, plans, and diagrams which have accompanied our reports have been prepared under the direction of Mr. Cyril Higinbotham. Our President, being aware of many inaccuracies and defects of the Colony maps hitherto published, instructed that gentleman to compile a map of New South Wales on a scale of 2 miles to the inch. No map on that scale has yet been published; and while this map will show all the information obtainable up to the present date, it will have the immense advantage over all others in that it will be almost absolutely accurate. This map is necessarily incomplete, but we strongly recommend that steps may be taken to finish the work remaining to be done. We desire to acknowledge the ready help which we have received from the officers of the several Government Departments when we have had occasion to apply to them for information. To the Surveyor-General, Mr. P. F. Adams, we are indebted more particularly for courteously placing at the disposal of the Commission the services of Mr. James Tayler (chief lithographer) and his staff, by whom the plans and maps accompanying our Reports have been reproduced.

Collection of  
county and  
parish maps.

In connection with our inquiry, we found it necessary to obtain the county and parish maps of the Colony. These maps, which form the most complete collection in existence, we are now prepared to hand over to the Government.

Maps pub-  
lished by the  
Commission.

Among the appendices will be found a sketch map of the Colony, which shows by a red tint the maps already published by the Commission, viz.:—The north-eastern portion of the Western Division, the Lake District near Menindie, and the Murray and Murrumbidgee drainage area. These maps will form useful guides in the preparation of the proposed Colony map, part of which is in course of compilation (shown by blue hatching), and for which our draftsman has laid down the basis, and reduced over 225 plans of feature surveys to the scale of the map, 2 miles to 1 inch. When complete, this map will show cities, towns, villages, settlements, railways constructed and proposed, mountains, hills, rivers, creeks, and other water-courses, dry channels, lakes, lagoons, swamps, springs, Government wells, tanks and dams, lessees' improvements (including fences, dams, tanks, wells), main roads, tracks, travelling stock routes, trucking stations, boundaries of counties, runs (leasehold and resumed areas), and the marked trees along surveyed lines.

Appendices.

We attach appendices, as follows:—

Minutes of General Evidence.

Letter from Mr. A. Dewhurst, District Surveyor, Tamworth.

Reports on Water Conservation and Irrigation in Europe and America, received through the courtesy of the Colonial Office.

Notes and Memoranda regarding the Nepean and Warragamba Rivers, by the Engineer.

Memorandum of the Levels of the Hawkesbury River, by the Engineer, with plan showing Windsor and Richmond during the flood of 1870.

Reports (4) on Survey of Upper Darling (Barwon) River, by Mr. J. B. Hotson, C.E. Memorandum

- Memorandum on the Clarence River and its Catchment Area, by the Engineer.
- Report on the district between the Lachlan, Bogan, and Darling Rivers, by Mr. V. Czarlinski, M.E., C.E.
- Report on the Darling River, by Commissioners Donkin and Gipps, with Minutes of Evidence taken.
- Further Report on the Darling River, by Commissioner Gipps, C.E.
- Minutes of Evidence taken by Commissioners Murray, M'Mordie, and Gipps, on Northern Coastal Rivers, &c.
- Report by Commissioner Targett on the Northern Coastal Rivers.
- Report on Irrigation and Water Conservation in Riverina, by the Engineer.
- Report on the proposal to divert the Snowy River into the Murrumbidgee River, and into Lake George, by Commissioner Donkin.
- Catalogue of Works on Water Conservation and Irrigation, collected by the Commission.
- Sketch Map, illustrating maps published by the Commission.
- Map of Colony, for reference.

We have the honor to be,

Your Excellency's most obedient servants,

WILLIAM JOHN LYNE, *President.*

RUSS. BARTON, *Vice-President.*

Sydney, 9 May, 1887.

#### DISSENT ON CERTAIN POINTS FROM THE COMMISSIONERS' REPORT.

I REGRET to be compelled to differ from the rest of the Commissioners relative to the treatment proposed for the irrigation of the districts included in the lower portion of the Murray and Murrumbidgee valleys, or what are termed by our Engineer as the south-western districts of the Colony. The reasons for my objections may be stated as follows:—

1. Because I consider that the examination and survey of these rivers should comprise the whole area of their basins, instead of the limited portion recommended by the Commissioners.
2. Because I consider that the storage and distribution of the Murray and Murrumbidgee Rivers should commence at a much higher point on their streams than the above recommendation contemplates.
3. Because I consider the permanent canals proposed, with the exception of the Lower Murray Canal, are impracticable under present conditions, and, for many reasons, are inadvisable.
4. Because I consider that by erecting a series of movable weirs across these rivers, and by pumping with the horse-power available from the fall of water over the crest of such weirs, a large volume of water could be thrown into surface or inundation canals, which would irrigate different sections of the country far more economically than would be possible by the proposed permanent canals.

It is evident that no correct estimate of the water-supply to be derived from any river basin can be properly gauged unless its rainfall records are accompanied by a faithful representation of its topographical features. For in some parts the rain falls into swampy flats, where it quickly evaporates and soaks into the soil; whilst in other parts, where steep ridges prevail, it serves at once to swell mountain torrents, and to produce floods. In order, therefore, to derive the highest value from rainfall it is absolutely necessary to initiate such a system of examination and survey as will ensure the fullest advantage being taken of the physical features of the country, so that each section of a watershed may be made to contribute its largest capacity of water-supply. Especial attention should, however, be directed to the storage of water in the high-lands of a river basin, because when it is known in what position and quantity water can be stored at such an elevation it is easy to determine how it can be distributed to the best advantage. In fact there should be one continuous chain of evidence from the top to the bottom of every valley as to its water-supply, and as to the best means of conserving and distributing such supply, otherwise its value can never be justly appreciated.

By simply surveying detached portions of a river basin, in order to provide only for their requirements, great and lasting injury may be done to the basin as a whole. Such a course might seriously interfere with, and perhaps altogether prevent, the due development of its powers for water-supply, thus prohibiting the promotion of different industries which could have been maintained by a more efficient and systematic treatment of the basin. In this country, unfortunately so liable to continuous droughts, we cannot afford to lose any opportunity in connection with increasing the water-supply, when and where most available; therefore it is the more necessary that there should be an exact examination and survey of the Murray and Murrumbidgee valleys before the country is committed to the expensive irrigation canals proposed.

With regard to the storage and distribution of the Murray and Murrumbidgee waters, it seems to me that the Commissioners in their support of the above canals have been too much influenced by the figures of the Engineer, who, in his proposals for such capacious permanent canals, without any provision for storage of water above their point of offtake, appears to have been guided entirely by his experience on the Baree Doab Canal in India. But in that country the constant streams of some of the largest rivers in the world contribute a fraction of their supply to feed the canals, whereas in this country the longest rivers are often reduced to mere brooks. Their flow is so irregular that no dependence can be placed on them for a constant supply of even the smallest volume, whilst just at the time their streams are lowest the country suffers most from drought. Hence the positive necessity for some provision for storage reservoirs before constructing canals.

In

In my Report on the Upper Murray, included in the Appendix of the First Report of the Commission, I have drawn attention to several sites for impounding lakes, of so great capacity that not only would they serve largely to diminish the evil consequences of high floods, but they would conserve sufficient water to maintain a constant navigable stream from Welaregang to Albury—over 150 miles—and it would then be available for irrigation canals below. Besides these sites, I am convinced, after an examination and partial instrumental survey of the country at the head of the Tooma River (one of the chief tributaries of the Upper Murray), that the large swamps and flats at the foot of some of the highest peaks offer excellent opportunities for the conservation of immense sheets of water, which could be conducted by an economical canal along the divide of the Murray and Murrumbidgee Rivers so as to command the Marracle, Tumberumba, Ouranie, and Jingellic Gold-fields, after which it would provide for the irrigation of a large tract of the rich agricultural lands in the Billabong Valley from Germanton downward.

Our Engineer, Mr. McKinney, M.I.C.E., after a hurried ride through the district on beaten tracks, has instructed the Commission that such a canal would be a commercial failure, in comparison with his proposed low-level canals, on account of the difficulties attending its construction, and its consequent great expense. He also ridicules the accepted idea that American canals are constructed under similar difficulties, although he has never visited that country, and has consequently had no experience in the construction of such canals. Actual observation and experience, both in America and this country, compel me to differ entirely from his opinion relative to the cost of such a canal; and in support of my contention I append a list of American canals, some of which have been constructed through the roughest portions of the Sierra Nevada Mountains.

Name of Canal.	Length in Miles.	Discharge in cubic feet per second.	Discharge in 24 hours in gallons.	Total Cost.	Cost per Mile.
North Blomfield .....	157	800	432,000,000	£ 141,768 0 0	£ 903 0 0
Milton .....	80	750	405,000,000	78,315 0 0	978 0 0
Eureka Lake .....	163	625	337,500,000	144,668 0 0	887 0 0
South Yuba .....	123	{ 1,750	{ 945,000,000	112,337 0 0	913 0 0
San Juan .....	32	{ 750	{ 405,000,000		
La Grange.....	20	325	175,000,000	58,618 0 0	1,832 0 0
		750	405,000,000	90,000 0 0	4,500 0 0

The greater portion of the La Grange Canal is cut in granite, and in places it is supported by solid stone walls from 50 to 70 feet high. Thus it is evident to any unprejudiced mind that canals can be constructed in a mountainous country at a much lower estimate than those inexperienced in their construction can possibly imagine; and this is chiefly due to the great fall or steep declivity that can be given them, owing to their elevation, which largely reduces their sectional area. By actual survey of over 30 miles of the rough precipitous ridges near the head of the Tooma and Tumut Rivers, and by the construction of a large mining ditch, 6 miles in length, I have proved that canals could be constructed as economically in our mountain ranges as in the Sierra Nevadas, as an equal fall is available. The number of settlers and miners that would be served by the high-level canal proposed by me would be over 1,000, exclusive of towns; and this, owing to the inducement offered by a large permanent water-supply for hydraulic sluicing, would rapidly increase, whilst the settlers served by the proposed low-level canals from the Murray would not exceed 500. Therefore, by assuming (after a hasty inspection, and without a more careful examination) that there is no possibility of irrigating or improving the water-supply of the Upper Murray District, a very great injury may be inflicted on its principal industries, and its settlement thereby retarded.

My reasons for objecting to the proposed permanent canals are as follows:—  
 1. Insufficiency of water-supply. 2. Great cost of construction. 3. Cost of maintenance. 4. Small returns, and consequent heavy loss to the State, which would increase annually. 5. Possibility of changing the course of both rivers connected with them during a heavy flood.

In

In the first place it must be assumed that a constant stream will have to be allowed to flow down the Murray and Murrumbidgee Rivers for the supply of settlers on both banks, and to satisfy claims on account of riparian rights. For this purpose I would allocate 1,500 cubic feet a second, which would represent a flow in the river Murray of 1 foot above summer level at Albury, and a flow of 3 feet in the Murrumbidgee above summer level at Wagga Wagga. On this hypothesis, and by taking as a basis of calculation the Government Astronomer's records of the mean height above summer level of the western rivers, it appears that the supply available for the proposed Murray River Canal below Albury in 1885 would have been almost nil for January, February, March, April, May, and December; for July, 800 cubic feet per second; for June, August, and November, about 2,000 cubic feet per second; and for September and October, over 2,000 cubic feet per second. For six months, therefore, during the driest period, there would have been only a small uncertain and intermittent supply for the canal, barely sufficient to account for leakage and evaporation, whilst its service for the rest of the year would have been greatly neutralised on account of the abundant rainfall in June, August, and September. According to the records of the Murrumbidgee flow for 1884, the supply available for the proposed permanent canals would have been almost nil for January, February, March, April, May, June, August, and December; for July, 300 cubic feet per second; for September, 2,300 cubic feet per second; for October, 800 cubic feet per second; and for November, 1,000 cubic feet per second. Consequently, there would only have been a scanty intermittent supply for eight months in that year, whilst the copious rainfall in June and October would have largely neutralised the benefits of the canal's supply in July and September. From this it is apparent that neither the Murray nor Murrumbidgee canals can be termed permanent, nor can they be made so without very extensive storage provision above their points of offtake.

The cost of the proposed Murray Canal just below Albury is estimated at £1,412,250, but this provides for no lining, for no interest during construction, and for only £25,000 for land resumption. In comparison with the cost of similar works in Europe this estimate is decidedly low. The average cost of French canals, only 5 feet deep, is £11,600 a mile. The Cavour Canal in Italy cost £80,470 a mile. The Caluso Canal, Italy, with a supply of only 366.26 cubic feet a second, and the steep declivity of 17 feet per mile, cost £1,700 a mile. But supposing this Murray Canal could be constructed for £1,412,250, it is still questionable whether it would prove a profitable work. The interest on the cost, at  $4\frac{1}{2}$  per cent., would amount to £63,549 a year, and the working expenses are estimated at about £13,951 per annum, whilst the gross revenue is estimated at £177,500 per annum. This estimate evidently assumes that the whole irrigable area commanded by the canal will be irrigated immediately after its completion, which is hardly probable, considering that there are not more than 500 settlers dwelling on it, and their homesteads are scattered, whilst a few large landholders own most of the rest of it. Even if the district were densely populated, on comparing the prospective returns of such a work with those actually obtained in India, where labour costs only £3 a year for an ordinary workman, it will be seen by the following table that very different results might be anticipated than those suggested in the estimate of our Engineer.

Name of Canal.	Year.	Outlay to end of year.	Interest at $4\frac{1}{2}$ per cent.	Working expenses.	Receipts from water-rates.	Irrigable area in acres.	Irrigated area in acres.
		£	£	£	£		
Baree Doab .....	1877-78	1,537,990	67,955	50,240	93,876	.....	266,995
Agra .....	1877-78	808,479	32,215	8,319	3,709	.....	163,634
Orissa ... ..	1876-77	1,728,400	76,300	18,050	4,049	100,000	100,000
Midnapore .....	1876-77	683,500	29,790	9,570	6,150	80,000	54,000
Sone .....	1876-77	1,908,504	73,660	18,620	5,090	500,000	300,000
North Behar .....	1884-85	1,100,000	45,000	10,000	7,500	100,000	50,000

It is evident, therefore, that even under exceptionally favourable circumstances, when there is a very extensive area under cultivation supporting a dense population, and when labour is very cheap, both for cultivation, for the construction of the canal, and its maintenance, even then large irrigation canals are rarely profitable.

In

In the above table it will be seen that the lowest working expenses are noted opposite the Agra Canal, which has a capacity of 2,000 cubic feet a second, being equal to that proposed for the Murray Canal. If, with labour at £3 a man per annum, it cost £8,300 to maintain and serve the distribution of the supply of the canal, it must surely be assumed that similar services in this country would cost more than double that sum.

At the same time I fear many generations would pass away before the returns of the Murray and Murrumbidgee Canals would realise sufficient to cover even the interest on their cost of construction.

According to the valuable report on the state of the Public Lands by Messrs. Morris and Rankin, in 1883, it appears that there were only 244 settlers in the Deniliquin District, including the counties of Townsend, Cadell, and Wakool, and embracing 4 million acres at the lower end of the Edward and Billabong Rivers, whilst  $2\frac{1}{2}$  million acres were aggregated in large estates. The Counties of Denison and Hume were little better, the selectors having chiefly sold out to pastoralists; consequently less than 500 *bonâ fide* settlers would be benefited by the proposed Murray Canals. Nor does the prospect of profitable canals improve with the Murrumbidgee Canals, for most of the country traversed by them is in the hands of pastoralists, whilst in the instance of Waradgery County, having an area of 1,836,160 acres, the land is almost entirely included in twelve pastoral holdings. There is no doubt that these canals would greatly increase the value of alienated land in the districts they would traverse, but unless the Government resumed it, the State would reap no advantage from such enhancement.

Bearing in mind that the slope of the Murray Canal from the point of off-take at Bungowanna is 1 foot in 5,000 feet, whilst that of the river itself averages only 9 inches a mile from that point downward, it appears possible that, unless the head works are very substantial, and of sufficient height to resist the entrance of any flood, the river—in such a flood as 1867, which was 27 feet above summer level, and 10 feet above the right bank below the site of weir—might force its way into the canal, and pouring down it with overwhelming force, might form an entirely new channel for itself. Such a disaster has actually happened in the Mississippi River from the cutting of a channel of less than one-quarter the area of the proposed canal. The same danger threatens the Murrumbidgee Canal, which has a fall of  $1\frac{1}{2}$  feet towards the Urana Lake, in comparison with a fall of only 10 inches a mile in the river bed. Thus there would be a possibility of these two rivers reuniting their streams near Jerilderie, and following the course of the Billabong River.

In consideration of the many and serious defects I have alluded to, it is evident that the proposed canals, under present conditions, would be injudicious and impracticable.

As an instance of the stimulus to manufacturing as well as agricultural industries that might be anticipated from the erection of movable weirs in favourable positions across the Murray and Murrumbidgee Rivers, I would briefly refer to the experience of a similar structure across the Kansas River at Lawrence. The river bed at the point of its location is 600 feet wide, and is composed partially of rock, sand, fine gravel, and strata of blue clay. The length of the weir is 700 feet; its height is 8 feet. It provides a supply to two canals 60 feet wide on one bank and 50 feet on the other. The available horse-power from these canals is estimated at 2,500, which it is anticipated might be increased to 4,000 horse-power by adding 2 feet to the height of the weir. The canals are each  $\frac{1}{2}$  mile long, and their frontages are divided into water-power allotments from 150 to 450 feet in length. The water-power not only provides motive-power for several large mills, but also raises several million gallons of water a day, 150 feet high, for the supply of the town.

The value of this power on the Murray and Murrumbidgee Rivers at each point of location of weirs, estimating only on the small average flow of 500 cubic feet a second, with a fall of 10 feet, would be equal to 567 theoretical and 400 effective horse-power with turbines. No less than 13,200 cubic feet of water could be raised 16 feet high a minute by 400 horse-power, which is far more than that proposed by the largest pumping scheme on the Victorian side of the Murray. This height of 16 feet would be sufficient for the discharge of the water supply into surface or inundation canals, which would cost infinitely less in construction and maintenance than the proposed permanent canals, whilst the supply could be distributed with much greater facility.

The

The cost of the movable weirs, if constructed on the Poiree Needle system, would not exceed £40 a foot,—so that it may be estimated that they could be thrown across the above rivers at a cost of £20,000 each including headworks for canal. This estimate is based on the average width of the rivers not exceeding 400 feet.

The rent of the available horse-power at each station, at £10 per horse-power per annum, would probably return over £1,000 a year, supposing Water Boards to rent it for the supply of surface canals constructed under their authority. Supposing Government constructed the canals from each station, the supply of 13,200 cubic feet a minute would be sufficient to irrigate 60,000 acres in winter and 25,000 acres in summer. With a charge of 5s. per acre a revenue of £21,250 would be realized, which would allow of 5 per cent. on an outlay of £200,000 for the construction of the canal and weir works, and £11,250 per annum for maintenance expenses.

The advantage of such a system is at once apparent. It could be expanded gradually to meet the requirements of the country; it would stimulate all classes of industry, because the same water-supply would be available for a large number of weirs on each river flowing from one pond to another, and on its course distributing the great benefit of 400 horse-power at each weir location, and it would cost far less than permanent canals. With all due deference, therefore, to the opinions of my colleagues, and with much regret at being called on to differ from them, I would submit that the system of impounding the Murray and Murrumbidgee Rivers by movable weirs would, on account of the above reasons, be of far greater advantage to the country than the proposed permanent canals.

FRED. B. GIPPS, C.E.

---

#### REMARKS BY COMMISSIONERS ON MR. GIPPS'S DISSENT.

Mr. Gipps's protest may be divided into two parts: first, an expression of opinion by that gentleman on points regarding which he dissents from our Final Report; and second, a series of statements, some of which are at variance with facts, and others very misleading. If Mr. Gipps had confined himself to the former, that is, to a statement of points in which he could not agree with the other members of the Commission, no exception would have been taken to the position assumed, but the course adopted is very different. The paragraphs numbered 2, 3, and 4, on page 22, the first paragraph on page 23, the last paragraph on page 23, and the second and fifth paragraphs on page 25, are mere expressions of opinion which Mr. Gipps is entitled to make. But the first numbered paragraph on page 22, which states his dissent from the Report on the ground that complete surveys are required, as well as the lengthy remarks on the same subject throughout his protest, cannot be considered a dissent, as we have not placed any limit on the completeness and comprehensiveness of the proposed surveys. On the contrary, we have laid stress on the necessity for an extended series of discharge observations, and for complete and accurate surveys. In both the present and past reports of our Engineer on the subject of canals from the Murray and Murrumbidgee the same point is insisted on, and he has stated that the more complete the surveys are made the less will be the first cost and the charges for maintenance. Mr. Gipps's remarks as to the necessity for surveys are, therefore, an endorsement of the Report, and not in any sense a dissent.

Mr. Gipps's remarks regarding our Engineer, Mr. M'Kinney, create the impression that the experience of the latter was limited to the Baree Doab Canal, and did not include any works through hilly or mountainous districts. As a matter of fact, both of these points suggested are entirely incorrect. The statement of Mr. M'Kinney's experience given in his report, which is now appended, and which is altogether at variance with Mr. Gipps's remarks, is in accordance with original testimonials submitted to the Commission at the time of his first appointment. Mr. Gipps's inaccuracy on this subject is remarkable, as he was a member of the Commission when Mr. M'Kinney was appointed.

Regarding the list of large American canals mentioned by Mr. Gipps, we have been unable in the short time at our disposal to verify the statistics given, but it appears strange to us that if these canals bear any analogy to possible canals in these Colonies, neither Mr. Deakin nor Mr. Derry, who were sent specially from  
Victoria

Victoria to report on such works, seems to have heard about them. This omission of Mr. Deakin and Mr. Derry is doubly surprising when we consider that these gentlemen described in detail works of comparatively trifling importance, while the South Yuba canals, which Mr. Gipps describes as carrying 2,500 cubic feet per second, are not referred to.

We entirely fail to see the consistency of Mr. Gipps's remarks regarding the Engineer's estimates. Mr. Gipps first gives a list of statistics regarding American canals, to show that these estimates are too high, and afterwards instances of European canals, to show that they are too low.

During the tour of the Engineer he regularly forwarded a diary, showing in detail the journeys, surveys, and inspections made by him. These journals show that Mr. Gipps's description of that tour as "a hurried ride over beaten tracks" is inaccurate and unfair. Mr. Gipps should be the last to make a charge of this kind, as he repeatedly urged that the Engineer was taking too much time in his investigations.

The table of statistics of Indian canals which Mr. Gipps supplies is altogether misleading. The Baree Doab Canal was commenced before the Mutiny, and when this event took place the work had to be stopped. Half-excavated channels and great quantities of building material were left as they then stood, and the work was abandoned for years, so that exceptional losses were incurred. Both the Agra and the Sone Canals were incomplete, and the irrigation but partially developed at the time the statistics were compiled. The Orissa, Midnapore, and North Behar Canals were made chiefly in response to agitation in England regarding the necessity for preventing the possibility of famines, and are probably the worst specimens of Indian canals which could have been selected. In proof of this statement it is sufficient for us to add the following extract from the last official report on the Canals of the North-west Provinces:—

"The net profits and the percentage on the total capital outlay derived in 1885-86 from all the canals in the North-western Provinces is compared with the results of the previous ten years in the following statement:—

Year.	Capital at end of each Year.	Net Profits.	Percentage on Capital.
	Rupees.	Rupees.	
1875-76 .....	39,856,800	2,426,186	6.08
1876-77 .....	42,012,822	2,576,406	6.13
1877-78 .....	43,466,488	3,155,858	7.26
1878-79 .....	44,621,616	3,828,437	8.57
1879-80 .....	46,035,380	2,806,249	6.09
1880-81 .....	64,561,716	3,538,941	5.48
1881-82 .....	66,206,214	4,082,750	6.17
1882-83 .....	67,633,960	4,301,052	6.36
1883-84 .....	69,092,987	5,069,145	7.33
1884-85 .....	70,283,698	3,128,769	4.45
1885-86 .....	75,149,595	3,544,623	4.72

"Notwithstanding a second year of abnormally heavy rainfall and disastrous floods, and the increase of the capital account by 48½ lakhs [one lakh at par = £10,000], due to the completion of the Betwa Canal, and commencement of work on the Nadrai Aqueduct, it will be seen that the net result is a clear profit of Rs. 3,544,623, or 4.72 per cent., on the total outlay of 751½ lakhs invested in the canals of the North-western Provinces."

## SYNOPSIS OF THE EVIDENCE.

	PAGE.
<b>J. BOOTH.</b>	
Darling River: existence of rocky bars—facilities for erection of weirs—reservoir—locking of the river—Poopelloe and Wangalara Lakes—evaporation—wells—carrying of produce—navigation—removal of rocky bars—Sandy Creek—sand-drift in Darling—inlet for storage of water ... ..	1-3
<b>J. K. CHISHOLM.</b>	
Productiveness of soil about Camden decreased by rust—floods—rainfall—effect of alluvial deposits by floods—dealing with flood-waters—Bent's Basin and other storage places—irrigation—payment of a water-rate—legislation—town supply—state and pollution of Nepean River—decrease of the supply in the Nepean through the waterworks—the Bargo River—windmills—extent of virgin land broken for cultivation—suitable crops for irrigation—model farm ... ..	4-7
<b>F. FERGUSSON.</b>	
State of agriculture—causes for occurrence of rust—irrigation—suitable crops for irrigation—silos—floods—town supply—supply in Nepean River—model farm—increased value of land through irrigation—well—Bent's Basin—character of country—farming on improved principles—population of Camden ... ..	7-9
<b>J. F. DOWNES.</b>	
Failure of crops—causes of the want of prosperity in Camden district—irrigation: its effects on value of land—willingness of people to pay water-rate—works to be carried out by Local Trusts—floods—damage done and benefits derived from floods—place for storage of water at Menangle—available land for irrigation—model farm—Bent's Basin—way of discharge for flood-waters—cultivation of American wheat—compensation for diverted water—local water-supply ... ..	9, 10
<b>W. H. PALING.</b>	
Silos: their construction, size, cost, and results therefrom—irrigation—storage dam—water-rate—supervision of works—legislation ... ..	11-13
<b>J. LAKEMAN.</b>	
Height of floods of the Nepean, and means for averting damage caused by them—storage—irrigation—want of water for stock—legislation ... ..	13
<b>J. B. MARTIN.</b>	
Nepean floods—Sir W. Macarthur's letters to the <i>S. M. Herald</i> —damage done by and benefits derived from floods—works to avert damage by floods—sites for storage of water—conditions required for successful irrigation—town supply for Camden—suffering by diversion of water to the Prospect reservoir—width of the river at Bent's Basin—quality of water in creeks affected by mineral salts ... ..	14, 15
<b>A. COLLESS.</b>	
The Nepean—width, and obstructions in the river—state of river—removal of the bar—valuable land suffering from want of a permanent supply—town supply, and payment of interest on its cost—benefits from creation of a movable weir—value of property—price of water—ridge between Nepean and South Creek—Peppercorn's and Woore's schemes ... ..	15-17
<b>D. J. WORBOYS.</b>	
Increased value of land on the Hawkesbury—floods and droughts—water-rate—rent paid by farmers—supply of Penrith—deposits of silt—average value of land—water impounded through formation of a bar—change of the river course—principal crops grown in the district, and average yield—factories or mills ... ..	17, 18
<b>R. C. RILEY.</b>	
Fall of the Mulgoa—settlement towards the Warragamba—nature of country—distribution of water by gravitation—supply above Regentville—effect of water distribution on value of property and increase of produce—position for storage reservoirs in Mulgoa Valley ... ..	18, 19
<b>J. PRICE.</b>	
Hawkesbury floods—extent of flood in 1867—stream in Rickaby Creek—value, property, rents, and size of farms—artificial constant supply, and its value—payment of water-rate—irrigation and orchards—supply for Penrith—number of householders buying water—supply from Glenbrook Creek—unfit quality of Nepean River water—crops grown, and yield—value of vineyards—effect of floods on crops ... ..	19-21
<b>S. JACKSON.</b>	
Supply in the Warragamba—gorge below junction of the Nepean—Mulgoa Creek—levels taken by Lieutenant Woore—throwing water back into Mulgoa Creek by a tunnel and weir—effect of droughts on value of property—site for reservoir—removal of boulders from the Nepean—depth of the river—site for a dam and erection of a distributing canal ... ..	21, 22
<b>J. CLEEVE.</b>	
Sufferings from want of water—raising of water by windmills for domestic purposes—causes accounting for people not having recourse to irrigation—introduction of proper system of farming to increase productiveness of land—area of land suitable for irrigation—water-rate per acre—manufactories—fruit-growing—establishment of model farm to induce people to irrigate—expenditure of money for distribution of rates warranted by enhanced value of land ... ..	22, 23
<b>V. J. S. BLOMFIELD.</b>	
Site for storage of water in Wheeny Creek—increase of supply from Colo River—Clarke's Flat as storage reservoir—damming of the Grose River—irrigation of a vineyard and orchard—result—payment of water-rate—source of supply for stock and for domestic purposes—schemes of town supplies for Richmond and Windsor—levels in connection with Clarke's Flat—character of Hawkesbury River-bed and banks—South Creek—diversion from Colo—extent of floods—flood-levels—wells—relative importance of Grose and Hawkesbury Rivers—crops—sunken weir to interrupt soakage—irrigation of flats and high lands—extent of agricultural land—character of ridges—basaltic outcrops ... ..	23-25

	PAGE.
G. M. PITT.	
Effects and duration of floods—irrigation—water-rate—sites for storage reservoirs on the Grose and the Wheeny—contour survey of 1867 flood—underground currents—sunken weirs—bad water from springs corroding galvanized iron—wells—water-holding capacity of soil—geological formation of soil—crops—value of arable land—extent of Grose and Wheeny water-sheds—causes of 1867 high flood—windmills—drift and silt in Grose River—compensation for land taken up for reservoirs . . . . .	25-28
T. H. F. GRIFFIN.	
Farmers' state of prosperity, and effects of floods and droughts—rainfall—wells—mineral character of the water—irrigation—water-rate and supervision of works by Trusts—site for a reservoir at the Vale of Avoca . . . . .	28, 29
W. LAMROCK.	
Height of silt deposited by 1867 flood—causes of the flood—benefits expected from irrigation—water-rate—supervision and carrying out of irrigation works—yield of crops—supply of water from the Wheeny and Grose Rivers—distribution of rain—irrigation of orange-trees—dairying—value of orange-crops... . . . . .	29, 30
A. DIGHT.	
Losses caused by floods—crops of lucerne—small farms—former droughts—change in course of river—character of soil.	30-32
REV. DR. CAMERON.	
Effects of floods—quantity of corn per acre—wells—water-supply of Richmond and Windsor—Little Wheeny Creek—Grose River . . . . .	32-33
B. RICHARDS.	
Flood of 1831—effects of floods—drought of 1828-31—average crop—irrigation—natural reservoirs—silting up of river by floods—flood of 1867—irrigation tax . . . . .	33-34
J. B. JOHNSTON.	
Enriching of land by floods—irrigation—dam site at Pitt Town Common—droughts of 1840-41 . . . . .	34-35
J. TEBBUTT, F.R.A.S.	
Record of floods since 1856—record of rainfall since 1862—good and bad effects of floods—alteration in bed of river—injury to trade through silting up of river—former droughts—rainfall—clearing of timber—splendid effects of irrigation—well—rainfall in gallons—value of land—payment of water-rate—lucerne—pollution of creek—navigation in former years—frosts—causes of flood of 1870—water-supply of Windsor—storage site at Killarney . . . . .	35-38
H. J. WEST.	
Eastern Creek—water for motive-power—reservoir site—Local Government Bill—well—application for Government bore—soil . . . . .	38-40
J. GOW.	
Good and bad effects of floods—corn crop—irrigation by steam-pump—good results—Grose River—water-rate—water raised 55 feet for irrigation—cost—system of watering—well—water in South Creek . . . . .	40, 41
W. T. POOLE (first examination).	
Irrigation in Lombardy—system of watering—sluices—crops—soil—dam on the Meuse at Namur—combined needle and automatic dams—applicable to rivers of this Colony . . . . .	41-44
W. T. POOLE (second examination).	
Works on the Meuse—method of working needle weirs—timber used in weirs—velocity of the Meuse—silt—series of weirs on the Meuse—river-beds used as storage reservoirs—automatic weirs adaptable to the Darling River—navigation—height of needle weirs—cost of needle weirs compared with cost of masonry dams—weirs and locks near Tewkesbury, Severn River . . . . .	44-47

ROYAL COMMISSION ON CONSERVATION OF WATER, &c.

MINUTES OF EVIDENCE.

THURSDAY, 7 JANUARY, 1886.

At Sydney.

Present:—

MR. BARTON, M.P.,  
MR. DONKIN, J.P.,  
MR. FRANKLIN, C.E.,

MR. GIPPS, C.E.,  
MR. LYNE, M.P.,  
MR. M'MORDIE, B.E., M.I.C.E.,

MR. G. W. TOWNSEND.

W. J. LYNE, ESQ., M.P., PRESIDENT, IN THE CHAIR.

Mr. John Booth called in and examined:—

9909. *President.*] Please state your name? John Booth.
9910. Where do you reside now? At Cultowa.
9911. That is near the Darling? It is on the Darling, and frontage. Mr. J. Booth.
9912. Has it frontage to the Darling? Yes, nearly 14 miles. 7 Jan., 1886.
9913. What is the state of the Darling now? When I came down a few weeks ago it was almost dry, there being but a few waterholes in it. State of Darling.
9914. Are there any rocky bars along your frontage? There are none just immediately on our frontage, but there is one above and one below us. The one 17 miles below our place is a very large rocky bar, about 150 feet wide I should think. Bars.
9915. What is the kind of rock? It is a sort of limestone with rotten granite bars through it, as far as you can judge.
9916. From your knowledge of the Darling and of the soil, do you think it would be possible to erect weirs at any inconsiderable cost on bars of that kind? I should think you could do so at a comparatively small cost. The foundations are all made—you could not have better foundations than the rock—it is solid and well defined right across on each side of the banks. Weirs.
9917. Do they rise with the banks? They run straight across, and rise a little with the banks. There are bars of rocks that run right through that portion of the country.
9918. If a weir were made to the top of the bank it would back the water for many miles? I should say so.
9919. Lake Poopelloe is partly on your run? Wangalara is the name of the lake on our run, and Poopelloe is the name of the big lake adjoining it on Murtie Run. Poopelloe and Wangalara Lakes.
9920. Is that a permanent lake? It is not exactly permanent. The Suttors had Cultowa for about twenty-three years, and they say that during that time it was dry for long only about twice. We have had the run only five years, and there has been no water in it all that time. The lake is not properly shown on the map. There are really two lakes separated by a small ridge, one of which is on Murtie.
9921. The lake is filled by the Darling water? Yes.
9922. Is there a defined channel? Yes. Channel.
9923. Would there be any difficulty in deepening the channel and bringing the water into the lake? You would not gain anything by that; you would do away with the difficulty of filling the lake, but if you cut the channel lower, you lessen the depth of the lake.
9924. *Mr. Franklin.*] The water would flow back? Yes.
9925. *President.*] Is there a rocky bar below the outlet from the Darling to the lake? Yes, but not near it; it is some distance from it, but near enough to influence the water filling the lake. Bar at outlet.
9926. What depth is the lake? I have never seen the lake full, but the marks on the trees indicate that it must hold from 14 to 17 feet. Depth.
9927. Is it good holding ground? Very good. Ground.
9928. I suppose the water keeps fairly fresh? It is quite fresh, though there was just a little in the lake when we bought the run there was about 3 feet of water in the lake, and that was quite fresh, although it was about four years previous to that since the lake had been filled. Freshness of water.
9929. Do you know if the Darling is lower now than it has been for many years? Not from my own knowledge, but old Darlingites say it has never been so low before. State of Darling.
9930. Having been there only four or five years, you cannot give us reliable information as to the extent of evaporation? Not from calculation; I could give a sort of a guess. Evaporation.
9931. What would that guess be based upon? From observations made on the water in the tanks.
9932. What is your idea of the evaporation? About this time of the year, that is during this month and the next, I find our tanks go down from 1 to 2 inches a day.
9933. You find they go down much more in windy weather than in calm weather? Much more quickly; the wind scoops the water out and dries it up.
9934. What is the area of the lake? It is about 9 miles long, by nearly 6 miles\* wide. Area of Lake.
9935. Is the country surrounding it of such a nature that it could be raised by embankment in any direction? Yes; the question is could you fill it to any extent.

9936.

\* NOTE (on revision):—I should have said "5 miles."—J.B.

- Mr. J. Booth. 9936. You could not fill it above the level of the flood? No; the flood rises over the surface about 6 feet above the present lake, that would make it 6 feet above 17 feet; you could raise it to that height by a large gate.
- 7 Jan., 1886.
- Gate. 9937. Would it be expensive? We were thinking of doing it ourselves one time; we reckoned the gate would cost from £1,000 to £1,500.
- Crown Lands. 9938. Is the country around the lake sold, or is it Crown Lands? Crown Lands, nearly every inch of it.
- Shafts. 9939. Have you sunk for water on your run? All around it; I have put down shafts at the ends and sides every few miles.
- Supply. 9940. With what success? With a success of salt water in every one of them excepting one; in this one I got a splendid supply of fresh water, enough to water 20,000 sheep, and the rest of the wells were as salt as the sea.
- Depth. 9941. At what depth was the fresh water? They were all at the same depth—about 50 feet.  
9942. Did you ever go deeper, that is through the salt water? No.  
9943. You never tried to tap the under strata? No.  
9944. Did you get salt water above the fresh? We struck the fresh water at the same depth as the salt.  
9945. Have you any idea of the cause of the difference? I have no idea.
- Fresh and salt water. 9946. Have you any idea of the cause of the salt water? Not the slightest. If you put one shaft down you get fresh water, and a few hundred yards away you put down another and you get salt, it must be a different run of water—there must be a bar between the two; you get fresh water quite near the salt water, in the same drift and at the same depth.
- Creeks. 9947. *Mr. Franklin.*] Are there any defined creeks on the upper part of the Darling above the lake, running towards the lake? No.
- Reservoir. 9948. Do you think it would be possible, by raising a head of water on the Darling above the lake and carrying it through the country, that that might be made a permanent reservoir? I think so.  
9949. Could you give any idea of the height of the weir that would raise the water within a mile of that place? If you take the bar of rocks about 50 miles above our place, known as the Curanyalpra rocks, and put a weir there, you could raise the water to the top of the banks of the lake; by doing that you could store about 30 or 40 feet of water.
- Diversion. 9950. Supposing that could be made a permanent lake, do you know how the country lies to the south and west—is it possible to direct water to the south? I think so; I do not think you could do it to any great extent except towards the south.
- Levels. 9951. You are not aware of the levels? Except just from general observation; I have improved all the country myself, and having been running the levels for the different drains and tanks, I have a sort of an idea.  
9952. Do you know to what height the water should rise in the Darling at the entrance of the creek that runs into the lake? If the water rises 12 feet above ordinary summer level, it runs from the river towards the lake.
- B nks of river. 9953. What is about the height of the banks of the river at that part? About 30 or 40 feet.  
9954. Do you know if there are any difficulties between those two points, from the bar of rocks, along the course that might be adopted towards the lake; are there any heavy cuttings necessary, or is the country generally level? There are no difficulties at all; there is a slight rise going about 5 miles from the river, and after that point it is a dead level to the lake.
- Area of lake. 9955. You give 54 square miles\* as about the area of the lake? Yes.
- Depth. 9956. What would you take as the general average depth over that area? If you skirt off a batter of about 200 yards from the outside top surface of the lake, you would get about 14 or 15 feet of water inside that.  
9957. But take the lake as it is now with its sloping banks, what would be its greatest depth? I would have to go into figures to tell you that.  
9958. Would the mean depth be 3 feet? It would be more than that a long way; I think it would be roughly about 14 feet—it is an immense body of water.
- Produce carrying. 9959. *Mr. Donkin.*] How do you get your produce away from the station—by navigation or railway? By navigation when the river has been high enough, but this year we are availing ourselves of the railway to Bourke.
- Locking of Darling. 9960. Do you think the country would be warranted in going to any great expense in locking the Darling for navigation, or would it be more advisable to look forward to a railway? I should say if there were no railway you should lock the Darling, because all the foundations of the locks are formed.
- Navigation. 9961. *Mr. Franklin.*] Would not the water be more valuable to you for stock than to use it for navigation? There is no doubt it would be a great advantage to all the runs along there if the river were locked.  
9962. *Mr. M' Mordie.*] Locking and making weirs are different things; locks are for the passage of steamers? Yes, but I suppose they answer the same purpose in damming the river.  
9963. Of course a weir could be combined with a lock, but a weir would dam the water without a lock? Yes.  
9964. *President.*] Do you not think that if you had a 50 or 30-mile stretch of navigable water it would be quite sufficient for all practical purposes? But then you could not do that without spoiling the navigation of the river.  
9965. But suppose that between Wilcannia and Bourke, about 170 miles by land, you had three weirs—one below Wilcannia, one above Bourke, and one in the centre—do you not think that would be quite sufficient navigation to tap both railways, the railway to Bourke and a railway to Wilcannia? Well, yes, it would tap the railways, but that would not do away with the difficulty of high carriage in that district, because the railway rates are very high.  
9966. It would not open navigation to the Murray, but it would answer all other purposes? Yes, at a certain rate.  
9967. It would tend to give you facilities to catch the railway at other places? Oh yes.
- Evaporation. 9968. *Mr. Townsend.*] You mentioned that about 2 inches of evaporation occurred in some hot days in the summer months: did that include what was used for stock, or was it in excess? That is the rate without stock drinking. I know this from a measure which I kept in the centre of the tank.  
9969. What is the least amount you have ever lost? It has been so small during the cool parts of the year that you could hardly notice it. 9970.

\* NOTE (on revision):—It should be 45.—J.B.

9970. What is the steepness of the slopes of the tanks? They are all 3 to 1, and from 18 to 20 feet deep. Mr. J. Booth.
9971. Have you seen anything lately in the newspapers about a proposal by the Harbours and Rivers Department to remove the rocky bars in the Darling? I have. 7 Jan., 1886.
9972. Do you think it a wise one? Certainly I do not. Removal of bars.
9973. *President.*] Why? Simply because there are the natural bars, and you gain nothing by removing them; they must be used some day for locks, and I would not injure them.
9974. Do you think that if the rocky bars were moved or lowered it would tend to lower the water in seasons like the present? It would simply do this: if you remove the bars now in front of the big water-holes, you would lessen the water-holes by that much and do no good.
9975. *Mr. Townsend.*] You were speaking of wells: do you know a well sunk on the 70-mile track? I know a little about it; it is only a drift well. Wells.
9976. Do you know the creek called Sandy Creek, that heads from the ranges? Very well. Sandy Creek.
9977. Do you think that runs down to the Darling? It comes near the Darling; it runs out on one of our neighbour's back blocks.
9978. Do you think it finds its way into Lake Poopelloe? I do not.
9979. Could water be taken from Lake Poopelloe towards Teryaweyna Lake? Yes, at a very small cost. Lakes.
9980. *Mr. Donkin.*] Have you ever seen any sand in the Darling? No. Sand.
9981. Could you get a cartload of sand? I do not think you could as drift; there is little or no sand between our place and Bourke.
9982. *Mr. Gipps.*] What is the greatest depth of the lake you have ever known? I have never seen the lake full—I can only judge by the marks on the trees—I have only seen about 3 feet of water in the lake, but we have only had the place five years. Depth and area of lake.
9983. What area did that 3 feet cover? It covered about the area I have already stated.
9984. How long did that last? It lasted about six months.
9985. Did much stock water at it? We had about 9,000 cattle on it.
9986. What is the character of the watershed around the lake? A sort of light sand and firm clay. Watershed.
9987. You do not see any rocky outcrops? Not a bit of rock. There is one other thing I should like to point out about the lake. There is an inlet in the country about 3 miles from the border and the lake, where I believe you could store enough water to supply the whole district; it lies about 20 feet below the lake, and a channel of about  $2\frac{1}{2}$  or 3 miles would fill it; it is about 2 miles square. Inlet for storage.
9988. Does the water never get into it? There is rain-water in it now, about 14 feet deep.
9989. *Mr. Franklin.*] It has no inlet from the lake? No.
9990. It is good holding ground? Splendid.
9991. What would be the extent of the work required to be done? The Suttor Bros. had a survey made from point to point to see what it would cost. The deepest part of the cutting would be about 15 feet deep. There would be about a mile at that depth, and the rest would be from 5 to 6 feet.
9992. *President.*] What would be the average depth over that 3 miles of water? It is a flat sort of a place; it would average about 40 feet solid water, and about 3 miles in circumference.
9993. *Mr. Gipps.*] What is the character of the bed of the lake; what is the soil—is it loamy? It is a sort of stiff clay. Soil.
9994. It would not take up much water? Yes, it takes up an immense lot of water when dry. The river runs in for two or three weeks before it makes any impression.
9995. *Mr. Franklin.*] Do you find when the lakes are getting low that the water has a tendency to become salt? This lake has no such tendency; it is not as sweet as when full, but it is good drinking water. Quality of water.
9996. *Mr. M'Mordie.*] What is the greatest loss of water you have known in that lake during the summer? I have never known any great loss in it. It was nearly dry when we bought the place. The 3 feet of water in it lasted about six months for watering stock. Loss of water.
9997. What could you allow for evaporation during that time? There were cattle on the lake. You can scarcely tell the evaporation; the cattle were all over it. Evaporation.
9998. It would be considerably less than the 3 feet during the six months? It dried up within six months.
9999. It dried up with evaporation and the watering of stock? Yes.
10000. The evaporation during the six months must have been less than 3 feet? Yes.
10001. *Mr. Franklin.*] Have you any sheet of water you do not disturb by the stock, and on which you could take observations of the evaporation? I think we have, but not for any length of time.
10002. *Mr. M'Mordie.*] Evaporation at the rate of 1 inch a day would dry up the 3 feet in a month? Evaporation alone?
10003. Yes? Well, that is the rate in a tank, and the water is confined to a depth; but the lake is an immense body of water about 9 miles long, spread over an area of about 54\* miles and about 3 feet deep—that makes a great difference.
10004. The evaporation would be greater in a shallower depth? Yes.
10005. Still the lake did not evaporate 3 feet in six months? I should think it was about six months.
10006. *Mr. Gipps.*] Was there any rainfall during the six months in the lake? A little—not much—but it was during the coolest six months of the year.
10007. *Mr. Franklin.*] You do not raise river water for growing crops? No.

\* NOTE (on revision):—It should be 45.—J.B.

SATURDAY, 3 APRIL, 1886.

At Camden.

Present:—

MR. BARTON, M.P.,  
MR. DONKIN, J.P.,MR. GIPPS, C.E.,  
MR. GILLIAT,

MR. MURRAY.

RUSSELL BARTON, Esq., M.P., VICE-PRESIDENT, IN THE CHAIR.

Mr. J. K. Chisholm called in and examined:—

- Mr. J. K. Chisholm. 10008. *Vice-President.*] How long have you been resident in this district? I was born in it, and have been for nearly thirty years an actual resident.
- 3 April, 1886. 10009. During that time your experience has extended to the nature of the country, its productiveness, its floods, and all that kind of thing? Yes.
- Productiveness. 10010. In the early days was this particular district producing better crops, and better adapted for agriculture than now? It produced much larger wheat-crops. In fact, wheat was the great crop of the district. It has now given place to other crops.
10011. Is there any particular reason for it? Wheat is now grown, but it is grown more for fodder, that is for hay, than for grain.
- Rust. 10012. Why? About twenty-three years ago the rust attacked the whole of the wheat-crops. And since then it has scarcely been possible to grow wheat.
10013. Is that about twenty-three years ago? I think it was in 1862 or 1863.
10014. To what do you attribute it? That is a question upon which doctors differ very much. I have no doubt myself that it is the result of some atmospheric condition which we do not quite understand. It is a fungoid disease. I believe it is very analogous to mildew, which attacks the crops very much in England.
10015. Do you think it is more likely to arise from changes in the condition of the temperature than from the fact of certain qualities in the soil being exhausted? I think it must be owing to atmospheric conditions, because luxuriant crops in new lands often suffer most.
10016. And that is the consequence of the district not being able to produce as much as it formerly did. Has it increased or decreased in prosperity? It has remained comparatively stationary. It certainly has not progressed as it should have done. I believe we have less population than we had some fifteen or twenty years ago, but that is owing to a variety of causes.
10017. You do not attribute it entirely to the fact of your not being able to produce grain? No.
- Want of water. 10018. But I suppose that under the present conditions if there were sufficient water the district would produce crops equally remunerative? Yes, I should say so. The want of water here has had this effect, that people rely more upon stock than they formerly did upon farming.
- Rust. 10019. Did you find any great difference in the rust of wheat on the higher and the lower lands, that is to say, on the lands subject to floods and the lands which are above flood-mark? I think there was not much difference to be observed. Rust seems to attack the crops almost everywhere.
- Floods. 10020. I should like to obtain your experience with reference to the floods of the district? I have no accurate knowledge of the floods previous to 1860. My knowledge of previous floods I have derived from Mr. Russell's work on the climate of New South Wales, and from other sources.
10021. How frequently have these floods occurred since 1860? I think that up to 1860 no really high flood was recorded here; a great part of Camden, as perhaps you are aware, was really built, as subsequent events proved, within the flood-mark, and in March, 1860, the highest flood occurred within the knowledge of Sir William Macarthur, one of the oldest residents, and in April of the same year, within six weeks, a still higher flood occurred.
- Rainfall. 10022. Did that flood do a great deal of damage? Yes, a large amount of damage to all the land within its reach. Hearing I was to be examined by the Commissioners, I made out last night a copy from my rain-gauge of the amount of rainfall for the last twenty years, made at my residence, within 6 miles of this place. (*Appendix A.*) I suppose that would be applicable to the whole district; from that you will see that the average is about 33·31 inches; on one particular occasion we had a phenomenal rainfall of 2·19 inches in twenty minutes.
10023. What quantity of rain has fallen at the times of those excessively high floods? The rainfall in 1860 was the heaviest I recollect, but neither Sir William Macarthur nor myself kept a rain-gauge at that time.
10024. But, since then? Since then, the record I have given you will pretty well tell you the heaviest rainfalls within the twenty-four hours.
10025. Then, according to that, from 4 to 5 inches of rain falling in twenty-four hours is sure to give a flood? Yes; if it fell within twenty-four hours, it would most decidedly; but it would depend upon the dry condition of the land previously—that is to say, how long the drought had lasted.
- Alluvial deposits from floods. 10026. What proportion do you think the benefit derived by the district from an extended flood would bear to the damage done—what I mean is this, that in a flood there is a considerable amount of deposit, an enormous amount of alluvial matter is placed on the low lands? I think that is incorrect; the only deposit we get is land which has been swept off the agricultural lands higher up towards the source of the river, and the fertilizing properties of that deposit would depend upon how long that land had been cultivated; my opinion is, that the deposit generally is a very slight one.
10027. From which the district generally receives little benefit? Of course, alluvial lands are benefited, but not to any appreciable extent; grass-lands are occasionally benefited to some considerable extent, but it is on the principle of robbing Peter to pay Paul; flood-waters passing over agricultural lands which have been recently ploughed strip them of the loose earth (if there is any current), which is partially deposited on the lands below, which become submerged by the back-water; but this is obviously at the expense of owners higher up the stream.
- Dealing with flood-waters. 10028. Has there ever been suggested to your mind any particular direction in which action might be taken to prevent these floods, or to assist the carrying off of great bodies of storm-water? Sir William Macarthur's idea was, that if some cutting were made at an angle of the river, enabling the flood-waters to pass off more rapidly.

rapidly, floods would not rise so high above ; but there is very little fall in the river ; so, if the water could be made to run three miles an hour instead of two, it would hold one-third more water ; it could be done, to some extent, by the way I suggest ; and further down too, at a place called Shancomore, I think something could be done.

Mr. J. K.  
Chisholm.

3 April, 1886.

10029. What is the average height of the very high floods that have done so much damage? The flood of 1867 rose 30 feet over the floor of the Camden bridge.

10030. What would it be above the present summer-level of the river? I do not know the height from the bed of the river to the floor, but I should think it would be about 50 feet.

10031. And you think the floods have been 20 feet over that? Yes.

10032. That would be 70 feet altogether? Yes; I do not say that from any measurement I have made.

10033. Do you think it is only the last few feet of this high-water which has done any damage, or, taking 70 feet as the maximum of the high floods, how high would the water have to rise before it did any great damage to the district? Of course, where the water passes over newly turned soil, it would not take a very high flood to do a great deal of damage; but the chief damage sustained by the crops is really from logs passing down the stream.

10034. What I want to know is, supposing we take 70 feet as the maximum of floods, would a 50-foot or 60-foot flood do any considerable amount of damage—how high would a flood have to go, taking that as a proportion, before any great damage would be sustained through the whole district? I should say the higher the flood rises the greater would be the damage done in proportion; what we call minor floods, or freshets, really do no damage whatever.

10035. To what height do they rise without doing any damage? From 10 to 12 feet over the floor of the bridge; a flood of that height would not do much damage.

10036. Then it would mean that, taking 70 feet as the maximum, a 60-foot flood would do very little damage? Comparatively little.

10037. Do you know anything about a gorge, some 10 miles from here, I understand, called Bent's Basin? Yes; that is the part of the river I was alluding to when I mentioned Shancomore; that is where the obstruction exists.

10038. Do you know on the river or its tributaries in this district any place where large quantities of flood-waters might be stored at a reasonable cost by damming the river or its tributaries—that is, by impounding water in any way? I have never examined the district with a view to ascertain that, but I have no doubt that there are a number of such places.

10039. Do you think that there are large quantities of land, of large acreage, which would be considerably benefited by irrigation, if it were possible? Yes, I do.

10040. Do you think the nature of the soil is adapted to irrigation? I do.

10041. And that it could be made to produce much larger crops than it does at present? I think decidedly so.

10042. Do you think, in case that any work of that kind were undertaken by the Government, people would be prepared to bear the expense in the shape of interest on the capital invested? I think that if they saw any benefit was to be derived from it they would.

10043. Have they had any experience in the district to guide them as to the expediency or otherwise of irrigation? Only upon a small scale. The recent droughts are directing their attention very much to the necessity for some irrigation scheme for agricultural lands. Of course, I understand, you refer to agricultural lands.

10044. I am alluding to either agricultural or pastoral lands—that is to say, if pastoral lands will be made to pay better than the agricultural; but that is a question which does not seem to have been decided anywhere? I do not think the time has yet arrived here for the irrigation of pastoral lands, unless to a very limited extent. For the production of fodder-crops it would prove invaluable. I think that in England pastoral lands are mostly irrigated by sewage highly diluted.

10045. It is your opinion, then, that people would be prepared to pay from 4 to 4½ per cent. upon outlay? I have every reason to think so. In such seasons as we are now having it is simply a question of crop or no crop. If they could see the crop would pay, they would pay any reasonable amount.

10046. Do you think that in this district legislation is necessary to enable private individuals to avail themselves of the surplus waters or the waters which are at present available? Yes; I should think the question of riparian rights might be involved in any private attempt. I think it is very desirable there should be legislation.

10047. What direction do you think legislation should take—do you think that in any legislation the Government, or a Trust under the Government, should have entire control of all the water-rights, that is to say, over all the systems of the Colony? That is a question I am not quite prepared to answer. I may say that I have read the report of your Commission and, as far as I can understand it, some of the suggestions there contained quite meet with my approval.

10048. You think that the suggestions contained in the report of the Water Commission would be likely to meet the case for the benefit of the general public? I think so.

10049. You say that there has been some irrigation on a small scale in the district, but you are hardly prepared to give us an opinion as to what increase of crop would be upon that land? No; we have really had no practical test of it yet.

10050. Could you give us any idea of the acreage of the district which might be brought under irrigation if water were available? I should say nearly the whole of the alluvial lands upon the river.

10051. Have you any idea of how many acres or square miles that would be? No; it varies so much. In some cases the land goes a long way back, and in other cases the alluvial lands are very confined.

10052. Has there been any interest in the question as to the best supply of water to the town? The people are very anxious to have a better supply. The present supply is distributed from water-carts from the river.

10053. I suppose the river is subject to pollution from the town and district? No; I think that none of the sewage of the town finds its way into the river. The pollution at the present time is chiefly from stock. The river has been so low that the stock, in drinking the water and standing about in the bed of the river, have polluted it.

10054. Has the river ceased running during this year? It has never actually ceased, but it has simply trickled. Up to last Saturday it was running, and that was about all; but some heavy rain fell at the source, and brought down a little flood of about 4 or 5 feet.

- Mr. J. K. Chisholm. 10055. From what source is it proposed to bring the supply of water for the town? I saw a gentleman here who is, I suppose, acting under the directions of the Government making surveys, as I understand, with a view to bring water from the canal near Kenny's Hill.
- 3 April, 1886. 10056. And you think that would be the best supply which you could get? I think that in some ways it might be the best. It would fall then by gravitation, whereas if the water were taken direct from the river it must be pumped, and there would always be a difficulty in placing an engine out of the way of a flood. Some means would have to be taken for its protection.
- Supply in Nepean. 10057. Do you think that taking water off from the Nepean for the waterworks has materially decreased the quantity of water running down the river? Most decidedly. Nearly the whole of the available supply was diverted to the canal, which I believe for some time did not exceed 3,000,000 gallons a day.
- Bargo River. 10058. And is there no tributary of any importance between here and the source from which a supply could be drawn? I think the Bargo River is left free. I do not think that is included in the Sydney supply.
- Supply. 10059. Is that an important tributary? In an ordinary season it would give quite an ample supply for all purposes here. It has hardly ever been known to cease running. I may say that Mr. Russell, in his work upon New South Wales, spoke of the river as being quite dry in 1839. Although I was rather young at that particular time, I recollect that my father lived where I now live, and nearly all the drinkable water in that part of the country dried up. My father had to send a cart to Camden three times a week to get a cask of water for drinking purposes.
10060. Was that to the river? Yes.
10061. And it was not dry at that time? It had holes in it, but it had ceased to run, from all accounts.
10062. *Mr. Gipps.*] What is the distance between the Sydney supply canal and Camden? In a direct line, from 3 to 4 miles.
10063. What is the difference in height? That I cannot quite say. I saw Mr. Stack when he was making surveys, and he told me that the water would rise to the church hill.
10064. Do you know the locality of the proposed compensating dam on the Bargo River? No.
10065. I believe that a site was proposed by Mr. Clark for a compensating reservoir? I am not aware of that.
- Dam. 10066. You do not know of any site which could be made available? The Bargo River is confined between precipitous banks. I should think there would be no difficulty in constructing a very large dam there.
13067. Has the river there much fall? That I can hardly say. Where the old road used to cross, there was a considerable fall; the water flowed rather rapidly.
10068. You would want a very high dam to throw the water back over a great distance? No, I think not.
10069. And the water thrown back would be impounded between very steep walls? From my knowledge of the place I think so.
10070. What width should you say it would be? It is narrow where the road crosses, but I could not say exactly.
10071. Would it be 200 or 300 feet? Not quite so much as 300; I think it might be about 200 feet.
10072. And what would be the distance from that point to Camden? I only know it by the road. We used to travel, I should think, about 18 miles from Camden.
10073. Are there no basins higher up? I do not know. I have very little knowledge of that particular district.
- Irrigation. 10074. Have you yourself attempted irrigation? No, I have made dams; the district is admirably adapted for making dams. We have a very retentive soil, and couch-grass grows well to bind the banks.
- Dam. 10075. What is the height of the largest dam? I should think not above 15 feet.
10076. Is it just an embankment thrown up? Yes.
10077. There is no puddle-wall in it? It was puddled in making, but nothing further; it is just an ordinary earthen bank.
10078. And does it hold water well? Oh, very well.
10079. Are there any wells in the neighbourhood? I hardly know of one; if you go down any distance, you would come in contact with brackish strata, and you would get almost unusable water.
- Sand. 10080. You do not go through any sand at all? I am speaking of my own side. There is a great difference between the other side and this.
10081. On the flats just below here would you not get into any sand? I think you would.
- Water. 10082. And you would get good water? I think so.
- Depth. 10083. At what depth? Alluvial soil varies; in some places it might be 15 or 20 feet deep, and then you come to gravel, and then sand.
10084. You do not know of anyone who has a well? I do not know of anyone. They have nearly all cemented tanks.
- Windmill. 10085. Do you know anyone with a windmill, or do you know anything of the use of windmills? There are a few. I think in most places they are being discarded for steam-engines.
10086. They are not found to act? Being dependent on the wind, they are irregular in their action.
10087. You do not know of any yourself? Yes; Mrs. Onslow has had one for some time.
10088. What is the diameter of the sails? I could not say; it is not a very large one.
10089. Do you know anything of the locality near Bringelly Creek, at Saddleback? No.
- Bent's Basin or Shanmore. 10090. *Mr. Gilliat.*] You referred just now to Shanmore or Bent's Basin; can you give us any information as to the width of the gorge there; is it much contracted from the width of the river above? The basin is deep; it is some 300 or 400 feet in length, by from 80 to 100 in breadth, as far as I can recollect. I have been there occasionally, but I cannot say what the actual width of the gorge is.
10091. It is decidedly narrower than the river above? Yes.
- Cultivation. 10092. *Mr. Murray.*] Do you know of any ground being broken for cultivation in recent years in this district? Most of the land under cultivation has been so for a great many years.
10093. What I wanted to know is, whether, where the virgin soil is broken, the wheat has been subject to rust in the present season? From my knowledge, I should say very little new soil has been broken during the last few years.
- Rust. 10094. You do not know actually whether the rust is the result of the soil being deprived of some of the properties necessary to the production of wheat, or whether the rust is produced from atmospheric changes? I know that up to 1862 no rust attacked the wheat-crops; we had the most luxuriant crops. It is hardly likely

likely that the constituents of the soil would have been exhausted so suddenly. The rust in that year was universal, and was not confined to this district, nor to the Colony. I think there were visitations of the same thing in Tasmania, and even at the Cape in the same year, showing that the cause was a very wide-spread one.

Mr. J. K.  
Chisholm.  
3 April, 1886.

10095. In the event of the Government adopting a system of irrigation for the district, what class of crops would be likely to be grown? This district used to be rather noted for its maize crops. I think that agricultural lands which have been so long tilled would, even with a system of irrigation, require manuring to get really good crops.

10096. Then you think the crops would be maize and hay, that is, oats and wheat grown for hay? Under an effective system of irrigation, I have no doubt many other crops might be grown, such as lucerne, rye-grass, turnips, mangolds, &c., by which a great impetus would be given to dairying, and all kinds of farming.

10097. *Vice-President.*] Have you had any experience in the difference of the value of land with and without irrigation? I have not.

10098. Have you any idea of the increased value of land under irrigation? No.

10099. Do you think it would be advisable for the Government to undertake any irrigation works on a model-farm, as an educational medium? I do decidedly, because I think people would be much more likely to approve of irrigation, if they saw a practical working of the system.

Mr. Francis Fergusson called in and examined:—

10100. *Vice-President.*] How long have you been resident in this district? Thirty-eight years. Although I have been here a very long time, my experience and knowledge are confined to purely local matters.

Mr.  
F. Fergusson.  
3 April, 1886.

10101. During your residence here you have, of course, had experience of the agriculture of the district? I have.

10102. And what is the state of agriculture here now as compared with what it was (say) twenty-five or thirty years ago; the place is not nearly so prosperous, in consequence of—what? The failure of the wheat crops. At the period you mentioned wheat was fetching a high price; but I do not know, considering the low price of wheat at the present time, whether it could be grown here profitably, even supposing that other conditions permitted of its growth.

State of  
agriculture.

10103. Have not the crops failed in consequence of the rust? Yes.

Rust.  
Causes.

10104. To what do you attribute that? Entirely to the absence of phosphate of lime in the soil. I am led to that conclusion from a knowledge that the wheat-plant takes up lime very largely. I know also that in Argyle, where the soil is on the limestone formation, rust is entirely unknown. I heard the last witness state that in one year it was almost universal; that might be owing to the minute spores being carried by the wind. I do not think, however, that they would injure the plant, because they would not be able to live upon it. That is my opinion.

10105. Do you think the present want of prosperity in the district is simply attributable to the failure of the wheat-crops? No, I do not think that. I think it is owing to a series of bad seasons—we have had five consecutive bad seasons—and the bulk of the tenant farmers are not very well off. Every bad season now, of course, helps to make them worse.

10106. What crop has been substituted for the wheat-crop which has failed? Mostly hay. Of course, a great deal of the land has been turned into pasture for the production of milk, to supply the Sydney market.

Crops.

10107. Do you think the district could be improved by largely applying the principle of irrigation? I am certain that it would be improved, but I have no idea of how you could distribute the water upon the hilly land in such a way that it could be made of use for the purpose of cultivation. I can understand how water could be distributed on the hill-side, but I cannot understand how they would cultivate between the drains.

Irrigation.

10108. Do you think that the soil here is adapted for irrigation? I do.

10109. Have you had experience leading you to suppose that it would produce very much larger crops with than without irrigation? On a small scale I have, but it is scarcely worthy of consideration. The piece of land I put under irrigation this year has yielded enormous crops, while similar land not watered produced nothing.

10110. And what crop do you suppose could be grown here with advantage under a system of irrigation? Lucerne, hay, and maize. As to the pasture land, I may say that I think that would be greatly benefited, if you were to cultivate under some system of irrigation such grasses as Italian grass and the prairie grass for dairy purposes.

Crops.

10111. Do you think it would pay to have large orchards in this district; is the soil adapted to them? It is particularly adapted to grape-vines.

Orchards.

10112. Would it pay to grow the vines under a system of irrigation? I scarcely think so. It would be very seldom that the grape-vines, if the ground were properly prepared, would require irrigation, unless you had an exceptionally dry season; it is a very deep-rooting plant. The plant would doubtless be benefited by irrigation in a season like this; but this is an exceptional season.

Vines.

10113. With reference to other orchard-trees, do you think it would pay to irrigate? I think it would pay well.

10114. Do you know what has been done in other countries with regard to this matter? I do not. But speaking of applying it to fruit-trees, I may mention that I had peach-trees growing upon land which was not irrigated, and the fruit was the size of walnuts; but some other trees of the same kind, growing upon land which was irrigated, produced fruit the size of cricket-balls. That is the effect which irrigation has upon the peach-tree.

Peach-trees.

Effect of  
irrigation.

10115. I suppose both descriptions of trees were healthy? Yes.

10116. Have you had any experience in silos in the making of ensilage? None. I have no personal knowledge; but I see a gentleman present who has had a large experience, and he will be able to give you some valuable information. I may state, however, that I thoroughly believe in it; I think it is a splendid thing for the storing of feed for cattle.

Silos.

10117. You said just now that you hardly knew how irrigation was to be carried out on the hills—do you think that the flats are more suited to irrigation? I did think so until I was told differently by a practical man. This practical irrigationist told me that it was easier to water upon a hill-side.

Irrigation on  
hills.

- Mr. F. Fergusson. 10118. Do you think that the hilly country here is sufficiently rich to produce good crops under irrigation? The bulk of the hills are worn out, and you would require to put into them proper food for the plants. The flat lands, on the other hand, where there has been a back-water at any time, require no manure. I have known such land to be cultivated for thirty years, and to produce the most luxuriant crops without any manure. Of course, there is a great deal of difference between a back-water and the flowing water. The flowing water takes away the fertilising particles, whereas the back-water deposits them.
- 3 April, 1886.
- Floods. 10119. During the last thirty-five years you have seen some of those large floods? I have.  
10120. What is your idea of the maximum height of these floods? I should say from 70 to 75 feet from the bed of the river, but I may say that previous to the passing of Sir John Robertson's Land Act, we did not have such severe floods as we have now.  
10121. Do you really think that that had the effect of increasing the floods? I know that in the Mitta-gong Range, and in the Wingecarribee country at one time, a week's rain would produce a very small flood, but now twenty-four hours' rain produces a considerable flood.  
10122. To what do you attribute that? Well, I think the clearing of the land has a great deal to do with it. Every tree which you take away is a natural dam; now that all those are removed the water comes down more quickly—now there are no trees to take up the water. Each tree might take up a very small quantity, but in the aggregate the quantity would be enormous.  
10123. And do you not think that the consolidation of the ground by stock has had something to do with it? Yes.
- Fresh. 10124. Take 75 feet as the maximum, how much below that point could a flood rise without doing material damage to the district? A rise of 55 or 60 feet from the bed of the river is only a fresh; it would do no injury unless it went over a crop at a certain stage. If it went over a crop of wheat in flower, of course, the crop would be spoiled. If it went over a crop of maize at a certain stage, it would spoil it; but if there were no crops growing, it would benefit the place instead of injuring it.
- Benefits to land. 10125. When a flood has not been high enough to do any damage you think, then, that it has benefited the land? Yes, if it is back-water; if the water rushes over the land, it does it a positive injury, but if not, it leaves a fertilising sediment. I have already said that flowing water takes away the fertilising particles lying on the top, and if the land should happen to have been recently ploughed, the chances are that a great deal of earth would be taken away. In such cases as this, of course, a flood would do a considerable injury, because when you take away the top soil you take away the cream of it.  
10126. If any means could be adopted by which these very high floods could be prevented, would it be of great benefit to the district? Yes, in case of the very high ones.
- Town supply. 10127. Have you formed any opinion as to the best way of conveying water to the town for the use of the inhabitants? I think the most economical way would be to have a pumping apparatus and reservoir, at the highest point of the town; you would then be able to let the water flow to each house by gravitation.  
10128. Would that be easier than the gravitation supply from the canal at Kenny's Hill? Very much. The price of the pipes would form a very large item in the expense of such a scheme as that.  
10129. Do you think that the river here is sufficiently pure for the purpose? Generally speaking. It may be a little bad just now; but there has been a drain upon it, which perhaps may not occur again for years. I presume that, when the Prospect Reservoir is full, they would not take away any of our water at a time like this.
- Supply in river. 10130. Has the taking up of the water for the temporary supply decreased the water in the river? Very materially; so much so that until the last few days in many places the river had practically ceased to run. Down below here it was very little more than a chain of water-holes.  
10131. Was any injury done to the people in consequence? I have not heard of any.
- Model farm. 10132. Do you think it would be a good thing for the Government under certain conditions to establish a small farm under irrigation in an agricultural district like this, for the sake of educating the people? I do; if you demonstrate to the people the practicability of the thing, that will be sufficient. They want to see the scheme working first, and then they would be willing to pay interest on the outlay. The more enterprising people would certainly do so.  
10133. Do you think the majority would do so? Yes; but it must first be demonstrated that the thing is practicable.
- Value of land. 10134. Say that you have a farm or orchard of 100 acres of good alluvial land, what would be the difference in the value of that land under irrigation and its present value? I can only form an opinion; but I should say, roughly speaking, that land which would be worth a pound per acre without irrigation would, if irrigation were applied to it, be worth about four times that amount.  
10135. Do you know that in other parts of the world—in California, for instance—that land, which ten years ago could not be sold for a dollar an acre, is now worth £30 an acre after irrigation? I have heard of the increased value of the land.  
10136. And that has been done under the same climatic conditions as those which you find here? Yes, excepting, as I understand, that they construct receiving places for irrigation at a less cost than we could do here.
- River bed. 10137. *Mr. Gipps.*] What is the character of the bed of the river here? Mostly sand.  
10138. And does it extend for any distance on each side of the river? Yes, a considerable distance.
- Well. 10139. Has that been proved? Yes; I have seen it proved by the sinking of a well. I have seen a well sunk 500 yards away from the river, and when you got to the bed of the river you came to the sand and to the water.  
10140. Did they try to pump it out? No, that was in the olden times; the water was drawn up by a windlass.
- Supply. 10141. Did you think that an unlimited supply of water could be obtained? Yes.  
10142. And good water? Yes.
- Country. 10143. What is the character of the country between the Bargo and Wollondilly? I should say it was a very rough country with bad soil, rocks, and sandstone—a rough, wild country.
- River banks. 10144. Would the banks of both rivers be rocky and precipitous? Yes; but I only speak from looking at them casually. I have no personal knowledge.  
10145. Have you been upon the Wollondilly? No, but I have been upon the Bargo.  
10146. Do you know of any site there for a dam? No, I do not.  
10147. *Mr. Gilliat.*] Can you give any idea of the area of land liable to flood? No, I cannot. I can only speak with reference to the immediate neighbourhood. 10148.

10148. Can you give us any idea of the area available for irrigation—that is, the alluvial flats—the richest part of the land of which you were speaking just now? No, I cannot.
10149. Have you any idea how much it would be in square miles or acres? I could not form an idea.
10150. You spoke of the supply of the township with water; you think that this should be done by pumping from the river to an elevation in the neighbourhood—that scheme would contemplate the construction of a weir in the river? Not necessarily. The water might be taken from the holes.
10151. You do not think a weir would be necessary? No; it might be necessary in a season like this, when you were taking all the water away to Sydney; but I hope it will not always be so.
10152. Can you give us any information with reference to Bent's Basin? Yes; I know that there is a great contraction in the river there, and that is the place, I think, which causes us to have such high floods.
10153. You attribute the floods then to the checking of the water in the gorge? Yes.
10154. *Mr. Murray.*] Is the depth of the soil on the flats very great? Very great.
10155. The country about here is mostly of an undulating character? Yes, very undulating.
10156. What is the present state of cultivation? The ground is very good; but if it were to be brought again under cultivation, it would require manure as well as irrigation.
10157. Is the soil light on these ridges? Yes.
10158. What sort of subsoil have you? Clay in the majority of instances.
10159. And you think that all these ridges could be improved by irrigation? Undoubtedly.
10160. *Vice-President.*] I understand that several gentlemen who have lately come to the district have gone to great expense in attempting to irrigate their land and to farm on improved principles? Yes.
10161. Do you think that that in itself would be sufficient without the Government undertaking anything of the sort—do you think that the properties of these gentlemen would act as a sort of educational farm? I do not think they would have the same good effect that the Government institution would have.
10162. I believe that these gentlemen have improved the mode of farming here considerably? Yes.
10163. They have not only altered the system of farming; I believe they have attempted irrigation, and are endeavouring to effect an improvement in stock? Yes.
10164. *Mr. Gipps.*] As to the water-supply question of the town, what do you estimate to be the cost of the pipes? I estimate that the town could be supplied copiously at a cost of considerably less than £1,000. That is, taking the engine, pumps, pipes, and everything into consideration. A Tangye pump, with boiler and 3-inch pipe, would supply everyone in Camden most copiously.
10165. Would that supply be sufficient for the motive power of manufactories and that sort of thing? No, I do not think so.
10166. I think you could lay a foot wrought-iron pipe connecting the canal with Camden, that would be 4 miles at about £3,000. Do you not think it would be far more advantageous to bring a large quantity of water, which you could apply for irrigation or manufacturing purposes, than to simply obtain sufficient water for domestic purposes? You see you would require an enormous reservoir.
10167. But you must remember that in the scheme which you suggest pumping would be a constant expense? Yes.
10168. But in the other case, you would have laid the pipes and would have done with it? Yes, but you would want an enormous reservoir.
10169. Would you not have a great advantage in being able to use the water under pressure for motive power? Yes, if the pressure were sufficiently great.
10170. What is the population of Camden? That is a statistic which I cannot give you. The population varies very much. I know that, speaking of the district generally, we have 1,500 people less than we had twenty-five years ago.
10171. And is the population gradually diminishing? Until recently it has been diminishing; all the young and more enterprising of the people have gone away to the newer districts. There is no outlet for young men here; they have gone away in order to get more room.
10172. Lately, the population has been steady? Yes.

Mr. Jeremiah Frederick Downes called in and examined:—

10173. *Vice-President.*] Have you been long resident here? Twenty-six years. I succeeded Mr. George M'Leay in 1859.
10174. Have you been connected with the Agricultural Society here? Yes, to some extent.
10175. And have you paid particular attention to agriculture since you have been in the district? Yes, I have a good number of tenants all living by agriculture.
10176. I believe, for a great number of years the wheat crop here has almost entirely failed? You may say for nearly twenty years, that is since rust first attacked it. A great deal of wheat is grown now, but it is cut for hay.
10177. To what do you attribute the failure of the wheat crops? To rust.
10178. What is the cause of the rust? I think it is atmospheric; that is my own idea. I have tried all kinds of lands—virgin soil and other soils, and the result has been just the same.
10179. You have found no improvement in the matter of rust in virgin soil as against the old soil? No; there was a description of wheat brought from America a few years ago in which there was a large amount of silica, which resisted the rust for two years; in fact, my son had a very good crop of wheat, free from rust, but last year the rust affected it. He succeeded for two years, but in the third year the grain gave in.
10180. Do you think the present crops grown are less profitable than the wheat-crop would be? No. At the present price of wheat it would decidedly be better to make it into hay.
10181. Then you do not attribute the present want of prosperity in the district to the failure in the wheat-crop? No.
10182. To what do you attribute the want of prosperity in the district—we have been told that there are not as many persons here as there were fifteen or twenty years ago; if that is the case, there must be a reason for it? I think the dry seasons during the last five, six, or seven years have had a great deal to do with it. You may say that this is the seventh year of drought.
10183. Have you any experience of irrigation in the district? No, I have not.
10184. Have you formed any opinion of the value of irrigation in a district like this? No, I have not. I have

- Mr. J. F. Downes. have noticed that after floods on grass-land, in my own district, the production of grass after the flood has subsided has been enormous.
- 3 April, 1886. 10185. And you think that the effects of irrigation would be the same? I should say so, to a great extent.
- Value of land. 10186. Judging from your experience, to what extent do you think the value of the land would be enhanced by systematic irrigation? It would certainly be trebled or quadrupled in value. I think you would be able to grow on one acre as much as you could otherwise grow upon four or five.
- Water-rate. 10187. And is it your opinion that if any work of that sort were undertaken by the Government, under trustees or otherwise, the people would be prepared to pay interest on the outlay? Yes, I think so.
- Local Trusts. 10188. You think they would pay a tax to recover the interest on the money? Yes, I quite think so.
- Floods. 10189. Supposing any irrigation were undertaken, what would be the best means of carrying it out? I think local trusts would perhaps be best.
- Height. 10190. You have had during the time you have been here experience of floods? Yes.
10191. What do you imagine is the highest point attained by a flood over the summer level? As far as I can remember, about 70 feet. It would be higher, I dare say, in Camden, because the water is thrown back from Mr. Fergusson's land and the Macquarie Grove estate; there is an embankment on the other side which throws the water back; at Camden, it is over the tops of the fences before it breaks over the banks with us at Brownlow Hill, which is 5 miles below Camden.
- Damage. 10192. Have you found that these high floods do a great deal of damage? The chief damage is done to the fencing; but since we have adopted wire, we have found it a great saving.
- Benefits. 10193. Is there no corresponding benefit derived by the district from these floods? Yes, from the back-water; the chief flood-water is back-water; it leaves a sediment behind which enriches the land.
- Highest flood. 10194. What height does the flood have to rise, allowing 70 feet to be the maximum, before it would damage the district? I have found that the lower floods do the most damage. A flood rising to 50 feet above the level of the bed of the river has been much more destructive than a very high flood when the water passes over everything. My own place is 50 feet above the plain, and the water in 1873, the highest flood I remember, was 14 feet up towards my house. That was a very high flood in the river. Mount Hunter Creek was higher than I have ever seen it. The water came down to me a banker; it backed up, and went over the plains above, where I had never seen it. The greatest damage I remember a flood doing was in 1860, I had nine stacks of wheat and hay, and the whole of it was taken away. I had the whole plain under crop that year, and I think I must have lost 2,000 bushels of wheat. There have been much higher floods than that since, but it was high enough to float the stacks, and it took them over the tops of the fences. I have seen floods 20 feet higher than that since.
- Storage. 10195. Do you know of any place in the district where we could conserve large quantities of flood-water so as to make it available for irrigation? I do not, except about Menangle. I think there is a place there, a few miles from Menangle, which might be used. The river lately has been very low until this last week.
10196. Has it been lower this season than you have ever known it before? Yes; since the water has been taken, I have seen it so low that you could put the whole of the water through a 12-inch pipe.
10197. And the place you mention is the only place you think water could be conserved at? I am not acquainted with the upper part of the river, I have been as far as the Nepean Towers.
- Available land for irrigation. 10198. Do you think that, if a large work were carried on, a considerable quantity of land could be made available for irrigation? Yes, I think so.
10199. What would be the extent of it? Some thousands of acres. I am speaking now more of the alluvial flats adjoining the river.
10200. Do you not think that the ground back from the river would pay for irrigation? It would, but it is not equally good, although some of the very best ground is on the high lands.
10201. Would there be a proportionate increase of crops upon the high land? I think there would, upon a great deal of the land; it would depend a great deal upon the land; the water upon the poor ground would be of very little account.
- Model farm. 10202. Do you think it would be a wise thing for the benefit of the district and the country generally for the Government to initiate some scheme, such as a model farm, in order to show the advantage of irrigation to the district? I think it would; the cost would not be very great, and I think that the farm could be made to pay for itself.
10203. You think that it would be advantageous as an educating medium in the district? Yes, I think it would be a very great benefit. There is nothing like ocular demonstration in these matters.
- Agricultural Board. 10204. What do you think would be the best principle of supervision over any work of the sort? I think that something like an Agricultural Board or a local Trust would work well.
- Bent's Basin. 10205. Do you know anything of a place some ten miles below here which throws a large quantity of water back over the district—an enormous steep gorge? I know Bent's Basin, but I question very much whether, though that were opened up, it would relieve the water here very much. I do not think it would. As I said before, the water is thrown back from Fergusson's land and the Macquarie Grove estate long before it comes down to me. I do not think that, as far as Camden is concerned, the work suggested would benefit us in the slightest degree.
- Discharge of floods. 10206. What would be the best direction in which to move, with the view to relieve Camden and the immediate district from these high floods? There is a place where the water passes through some large granite boulders. Some of them are immense; if they could be blown up and lowered out of the run of the water, I think it might do great good. Not long since, I was down looking at the point where the water passes through a mountain. The bed there is full of timber and boulders; if they were cleared, it would make a vast difference.
10207. We heard that there was a large bend in the river below here, which retarded the outflow of the water, and that if a channel were constructed across there, to carry off the water at a very rapid rate, it would relieve this part of the district—do you know anything of that? I do not quite understand where that would be; a part of my own land is very high on one side, and the other is an outlet on to the plains; if you opened this gap, as it is called, I think you would jeopardise the people below.
10208. You think that the relief should be found above? Yes.
10209. Is it your experience that these floods have increased in number or in height of late years? We have had nothing to speak of since 1873. We have had only a very few floods.
10210. But previous to 1873? They were numerous; in 1860 and 1861 they were very numerous.
10211. And very high? Yes, now the clearing of the land has increased the flow of the water very much.
- 10212.

10212. Have you found that of late years a small amount of rainfall has produced a very high flood? Yes. Mr.
10213. And it is in consequence of the great drought that you have had less floods of late years? Yes. J. F. Downes.
10214. Referring back to the irrigation question, do you think that a system devised by the Government, by offering bounties either directly or through the local societies, for the irrigation of the land and showing the results, would be desirable or practicable—do you think it would be as beneficial as though the Government were to do the work themselves? If you get a few men like Mr. Paling in the district, I think there would be no difficulty in the way. 3 April, 1886.
10215. As a matter of fact, some gentlemen in the district, Mr. Paling amongst them, laid out considerable amounts of money in attempts at irrigation? Yes, no doubt. There is no doubt, I think, that they will pay, but the first cost is more than most people could afford. Irrigation.
10216. *Mr. Gilliat.*] You referred in your evidence to your son having been very successful for several years in the growth of an American wheat extremely rich in silica, but you say that the grain subsequently deteriorated? Yes; last year it gave in: the rust attacked it. American wheat.
10217. Have you paid any attention to the question as to whether that deterioration might not have been the result of the absence of some constituent from the soil, say the silica itself? That is very likely.
10218. You do not, then, attribute the failure of the wheat-crop to the wearing out of the land in any other way; still, you think that the failure of some constituent in the soil might have been the cause of the rust? It might have been.
10219. Do you think the people of the district would be willing to contribute towards the interest on a system of irrigation if it were adopted? Yes, I think so, provided it be not too heavy and the works were likely to give them good results. I should like to say at this point, with reference to the water-supply of Camden, that I should like to know what the people below are going to do if that scheme is adopted. They come to the river for water; it was on the point of ceasing to run the other day, when this fresh came down. In the course of a few days, I think, it would have ceased to run altogether. Water-rate.
10220. *Vice-President.*] But is not the river, like most others, full of large waterholes which would always be full? There would be holes, but the water was becoming very bad. Waterholes.
10221. *Mr. Gipps.*] You think the people would be justified in making a claim upon the Government for compensation for the water which they had diverted from the higher point? Yes. Compensation.
10222. And that they should supply you with water as compensation? Yes; I have thought so all the way through.
10223. Is the population sufficient down the river in any locality to warrant the Government in undertaking a water-supply for them? Yes. Population.
10224. Are there any towns below this? There is no town below Camden until you come to Penrith. Towns.
10225. As to the water supply at various places down the river, do you think that some overshot dams should be constructed to conserve water for the use of the inhabitants without any very great expense—do you think the river is so formed as to permit of it? Oh, yes; but even if we could depend upon such a supply of water as we have had during the last few days, I think it would be better that, instead of the water coming down the channel to Sydney continually, we should be allowed to take it once a fortnight or once a month for (say) twenty-four or forty-eight hours. I think that would be sufficient to give us a supply, but since the water has been cut off altogether, we have been nearly at a stand-still. Local supply.
10226. Do you think, if such a supply as you have named were left occasionally, that it would be sufficient for the use of the inhabitants? Yes.

Mr. William Henry Paling called in and examined:—

10227. *Vice-President.*] I think the matter about which we wish to examine you chiefly, Mr. Paling, concerns the silos. I believe you have had recent experience in the storage of ensilage; I believe you have gone to considerable expense in constructing silos, and have had some experience in the results. Will you kindly tell us what they have been? The silos we have constructed have been made upon a very substantial basis, cemented and bricked; and we have put different sorts of food—grass, and maize, and mixed food—into them. A great many people thought that they would be a tremendous failure; we were almost afraid to open them, but to our great astonishment we found that the food was very good, and that the cattle ate it greedily. Mr. W. H. Paling.
10228. What have you found in your experience to be the best size for the silo? I cannot say that we have had any experience beyond that which we have gained from the silos which we have made. 3 April, 1886.
10229. And what size are they? About 12 feet by 12, divided into four compartments. Silos.
10230. What is the depth? 13 feet. This year we have had them filled with green maize.
10231. Could you give us any idea of the cost? I could give you the cost to a penny, but I have not the figures with me. I think, however, that the shed, silos, and everything cost about £270. Cost.
10232. You say that you have found them admirably adapted to green produce; is it necessary that the produce should be in any particular state when it is put into the silos? We find that it must be put in green. Putting in produce.
10233. And does it matter whether it is wet or dry when it is put in? No.
10234. If you were cutting down your hay in wet weather, you would still put it into the silos direct? Yes.
10235. And without any ill effect? Yes.
10236. Is it a fact that you can keep that material for any length of time you please? We have found that we can keep it for eight months. In fact, the longer we keep it the better it gets. On the whole, we are very much pleased with the silos; in fact, I am so pleased that I wish to enlarge them. Results.
10237. Are they adapted for the food of both cattle and horses? Yes.
10238. Have you any experience in irrigation at all? None whatever.
10239. Have you formed an opinion as to the practicability of irrigation? Yes, I formed some ideas in the course of my travels. I found that, in Italy, where they irrigate they get as much as ten times the lucerne they get otherwise. In one year the crop is increased tenfold. All that I have seen of irrigation leads me to believe that it cannot fail in increasing the crop if it is properly carried out. Irrigation.
10240. Have you formed any opinion as to the best form of irrigation for this particular district? In order to ensure plenty of water we have erected a very large dam. The basin contains about fifty million gallons. From that basin we intend to convey it to different parts of the farm, and to pump it where it is necessary to raise it.

10241.

- Mr. W. H. Paling. 10241. What is your opinion of the increased value of the land by a proper system of irrigation? I should say that it would be worth from four to ten times the value.
- 3 April, 1886. Storage. 10242. Do you know of any place in this district which would be adapted for the conservation of very large bodies of water? Yes; Camden is particularly adapted for that purpose. It is hilly, and we have merely to dam the water up to keep it.
10243. Have you had any experience of floods since you have been here? No.
10244. We have it in evidence that the Nepean has almost stopped running during the last few weeks. Did you experience any inconvenience from the shortness of supply during that time? No; we are not yet ready to irrigate. We have plenty of dams on our own place—plenty of water.
10245. You do not find the water materially deteriorated in consequence of the short supply? No; it has not affected us. I may say that, in order to go systematically to work, I had my farm surveyed, and the levels have been taken.
- Dam. 10246. What is the height of the dam? 31 feet.
10247. Over what area will that impound water? It will cover 11 or 12 acres.
10248. What is the average width? About 2 chains. I did not do it very accurately, because it was not necessary. I roughly estimated that the dam would hold about fifty million gallons. There are several large hollows coming into the creek where a large quantity of water will be stored.
- Level. 10249. What is the difference between the level of the river and the by-wash? 34 feet.
10250. What is the height of the dam above the water-mark in the basin? About 4 feet.
10251. What is the height of the top of the dam above the river-level now? 35 feet.
10252. Then, in an ordinary flood the dam would be 10 or 15 feet under water? It would be quite that. If there were a flood, we should expect to see the water coming over the dam.
10253. How do you propose to protect the dam from a flood? Various plans have been suggested to me, but I have not yet determined which to adopt.
- Catchment area. 10254. Do you know the catchment area for the dam? I suppose there would be about 500 or 600 acres. We are so situated that we get all the water from our neighbours' land.
- Supply. 10255. In ordinary seasons you would expect to have the dam kept supplied by the rainfall? Yes. We shall also pump from the river. We intend to use a Tangye pump, to put the water over the adjoining lands for the purpose of agriculture. In the case of no rain coming, we shall pump from the river. We have a 14-horse-power engine for that purpose, and a 10-inch pump.
10256. Has anyone else in the district attempted irrigation on a scale like this? No. In making the dam, we found that all the good soil of the farm had been washed down to the bank of the river, and when the dam was in course of construction, I had the fine earth distributed over the land again.
- Cost of irrigation. 10257. To what cost do you intend to go in your irrigation works? We have expended something like £2,000 for irrigation, and we shall expend perhaps another £2,000.
10258. That will be £4,000 for these experimental works? Yes.
- Area. 10259. How many acres do you hope to irrigate? Five hundred.
10260. The first cost then would be something like £8 an acre? About that.
- Water-rate. 10261. Do you think that, if the Government were to undertake any large works of this kind, the people of the district would feel inclined to pay interest for the outlay on irrigation? I think they would borrow money on their watch to do it. I am sure they would, if they had any sense.
10262. You do not think there would be any doubt about their being willing to pay the interest? Not the slightest.
- Supervision. 10263. Under what supervision do you think it would be well to place works of this sort in the district—do you think it would be best to place them under a local trust, or to have an engineer? I think you want a competent agricultural engineer. I do not think you would find the people here with the requisite knowledge; you would have to teach them first. I do not know that any local man would have the requisite knowledge; I do not think they have even read books on the subject. I am trying to get a man over from Victoria to assist me in my irrigation works.
- Legislation. 10264. Do you think that any legislation is required at present in order to regulate and protect riparian interests throughout the country? I think that in some cases it would be well to give the people a right to construct dams across the rivers.
- Irrigation. 10265. *Mr. Gipps.*] You say that you propose to conserve fifty million gallons of water in this reservoir, and with this fifty million gallons you propose to irrigate 500 acres? Yes, we intend to do that; if we find that that quantity is not sufficient, we must adopt other means to increase the supply.
- Water per acre. 10266. Do you know what quantity of water per acre that would allow; how many waterings would you give in the course of a year? In dry seasons I should say there would be a watering once a month, perhaps twice a month, if we could afford it.
10267. Therefore you would want at least twelve waterings a year? Yes.
10268. And how many inches would you allow for each watering? Not less than 3 or 4. If you irrigate at all you must irrigate very well.
10269. That means, then, with only one watering a month, 48 inches a year? Yes.
10270. Are you aware that your fifty million gallons would only provide for less than about one-sixth of that quantity; you would not be able to irrigate more than 100 acres; two waterings a year of 2 inches each would take up your fifty million gallons? But of course we propose to refill the dam.
- Force of pumps. 10271. How much does your pump throw up? I am told that it will throw up over 10,000 gallons a minute, but I cannot say accurately.
10272. Then you propose to continue filling the reservoir—you will not be dependent upon the storage? Certainly not; that is why I built the pump near the river. We have secured a 10-inch pump. I believe the water contained in the dam, with the means we have of refilling it, will be sufficient for the 500 acres.
- Watering in Italy. 10273. Do you know how many waterings in Italy they give in the course of a year? I could not say exactly.
10274. Are you aware that it is 2 inches each watering, and that there are from four to six waterings a year? I dare say, unless you water liberally it is of no use at all?
- Silos. 10275. *Mr. Murray.*] Have you weighed the stuff which you have put into your silos? No.
10276. Nor when you have taken it out? No.
10277. So you do not know how many tons you have put in? Our silos will contain about 35 tons each. We calculated that by reckoning the dray-loads we put in. About 120 dray-loads were put into four silos.
- 10278.

10278. You are keeping no accounts, then, as to the real value, allowing for the cost of labour and interest on the outlay? No; I do not think the ensilage loses weight when taken out: yesterday, when the members of the Commission were present, as I daresay you observed, it was quite as moist as when it was put in.

Mr.  
W. H. Paling.  
3 April, 1886.

Mr. John Lakeman called in and examined.—

10279. *Vice-President.*] How long have you been a resident of the district? I have lived here since my birth.

Mr.  
J. Lakeman.

10280. Then, of course, you have had considerable experience of the floods? Yes.

10281. There seems to be a diversity of opinion as to the heights to which these floods actually rise; we should like to ascertain, as nearly as possible, what height a good flood would reach over the present summer level of the river? I have heard it said as much as 70 feet. I do not know whether any actual measurement has been taken; but you must have noticed the building immediately above the tram station, the water was in that building to a depth of something like 18 inches. It was of course in the building round the corner as well, and almost up to the corner opposite Toll's.

3 April, 1886.  
Floods.

10282. Is it your experience that these floods do a considerable amount of damage to the district? They have done.

Damage.

10283. We have had in evidence this morning, that the floods do little or no damage up to a height of about 55 or 58 feet, and that it is the last 10 feet which really do the great damage? There is a great deal of truth in that. The last few feet in a small rise do not do a great deal of harm; they may catch some crops.

10284. Has it suggested itself to you, that there might be some means adopted of relieving the district of these floods? Yes, I think that improvement might be made at the gorge, which has been mentioned in evidence, if you do not fall into the danger of flooding the lower lands too quickly.

10285. Do you think it would be possible to stop the rush of water on these higher flats, somewhere higher up the river? I think it is very likely.

10286. Have you noticed during your long residence here that the floods have increased in size of late years, in proportion to the height which they obtained before? Up to 1873, when we had our highest flood, there had been an increase in the height of the floods caused by heavy rainfalls, and the clearing of the land; but since 1873, the rainfall has been so light that we have had no floods worth speaking about.

Increase of  
floods.

10287. And I suppose the consolidation of the land by the treading of stock has contributed to an increase in the size of floods? I do not think that has a great deal to do with it. The measurement of the rainfall as regards inches has not much to do with it. There may be 6 or 7 inches of rainfall without any perceptible rise, and at another time you may get more rainfall in a much less time, causing a flood. I have had experience at my own place; I built a dam in a dry gully; I suppose it drained about 200 acres of very steep land; below the dam was a small gully, coming in off a cleared paddock. After it had been raining for twenty-four hours, I went down and found that very little water had run from the timbered country, but was running fast from the small paddock which had been cleared. I saw the mistake which I had committed in making the dam higher up, and I intend to divert the water from the cleared land on to the area drained by the dam.

10288. Are there any places in this immediate district where large quantities of water could be conserved at a reasonable cost by means of dams? I think the gorge is the most likely place; of course, provision would have to be made for an outlet. In times of flood it is naturally dammed. It has been suggested that a blind creek passing through Saddleback Hill should be used to carry off the flood-water in case of a high flood, and so relieve the country above it.

Storage.

10289. Have you had any experience in irrigation? None whatever.

10290. Do you think it would benefit the district if the Government should see their way to construct large works for the conservation of water, with a view to irrigate many thousands of acres? I think it is a question on which the people will want a lot of education. In the first instance, we have not yet a population which cares for steady plodding with small results.

Irrigation.

10291. You do not think people are yet educated up to that? I am afraid not.

10292. Do you think it would be advisable for the Government to undertake irrigation on a small farm, or something of that sort, as an educating medium for the people here? It might do good.

Model farms.

10293. Has there been any great outcry for the want of irrigation in this district; has the want been felt sufficiently to make people interested in the construction of works of that sort? No; of course, there is a great want of water for stock, but I do not think the people have given irrigation much attention beyond that.

Want of water

10294. Is there any water for stock in the present season? At Brownlow Hill, where I live, water is dearer now than it was ever known to have been.

10295. To what do you attribute that? We have had rains enough to bring on the crops on the cultivated land during the last five years, but we have had no rain for the last ten years to thoroughly soak the land. I know of some cases in the present season where people could not get a bucket of water to wash their faces with.

10296. Where is that? That is at the back of Mr. Downes's property at Brownlow Hill. You asked me a question just now with reference to legislation, I think that is the keynote of the matter. We want undoubtedly legislation on this subject; a great deal might then be done. Many people would help themselves if they were protected, but in the present state of affairs they hesitate to do so. A case like this often occurs: Take a creek on each side of which there is an owner, it may be advantageous to one of the owners that a dam should be constructed; it may cost a mere bagatelle; if the adjoining owner objects, of course, he cannot construct the dam. No harm would have happened to that man by conserving the water, and yet on the dog-in-the-manger principle he objects to the construction of the dam. I know of one case on a creek at which it is very narrow; the bank on one side is about 20 feet higher than that on the other, and the work of half-a-dozen men for two months would make a dam to throw the water back a mile. It so happens the land belongs to two individuals, and the party on one side would like to make a dam, but he does not know whether he could get permission for the use of the clay on the other side. And then there is the question of flooding to be considered.

Legislation.

10297. You think, then, it would be wise to have legislation to protect people's rights, and to encourage the conservation of water; you think that that would be a great benefit to the country? Yes; I have no doubt that

that

Mr. J. Lakeman. that a great deal would be done in the shape of irrigation, not only by damming the rivers, but by the selection higher up of places where there are large reservoirs, from which you would be able to obtain a pressure.  
3 April, 1886.

Mr. John Benson Martin called in and examined :—

Mr. J. B. Martin. 10298. *Vice-President.*] You have been a resident here for a great many years? In the town since 1852; in the district, I think, about four years more.

10299. During that time you have had experience of a great number of floods? Yes.

3 April, 1886. 10300. What do you think is about the average of the highest floods above summer level? That I am quite unable to say; I never studied the question. I never made any inquiry; but this morning I handed to Mr. Donkin some newspaper slips, among which were two letters to the *Sydney Morning Herald* by Sir William Macarthur; he was a very accurate observer, and you can rely upon the facts given by him in these letters. (*Appendix B.*)

Floods. 10301. The evidence which we have had to-day establishes the maximum height of these floods at about 70 feet? I cannot form an estimate; I never looked into that particular question; the information is easily obtainable. The surveyors were here the other day inquiring into the supply for the town; they took their levels from the highest point of flood-mark. A gentleman asked me to show him a suitable place both for obtaining a supply from the river and for a reservoir on the hill; and requested me to point out to him the highest known flood-level about the town; that is opposite the tram station; he took that as his datum point.

Damages. 10302. Has it been the rule that these floods have done a great deal of damage to the district? Not for many years. The singularity about them is that they have been disastrous only since 1860.

10303. Previous to that they were not so? Not at all so. To estimate how little we cared about them, I may tell you that my father purchased 640 acres in 1832, 8 miles in a direct line down the river, perhaps 12 miles following the course of the river. He lived at Parramatta at that time, and managed by a farm overseer. They commenced clearing on the river banks, and in his case, as in other cases on the river frontage, the house was built on the first bank of the river, so little apprehension was there of any damage. They used to take a yoke or a pair of bullocks, and they went down to the river to supply themselves by that means.

10304. In what year was that? That would be about 1845 or 1846.

10305. And at that time there was no apprehension at all from floods? No; we all lived upon the river banks. I think the floods taught the people the danger. Every one lived upon the banks; in fact, in those days, if any one had become the possessor of land at the bridge here, he would have built on the banks near to it; in fact, there was a police station-house on the other side of the bridge.

Increase of floods. 10306. To what do you attribute the great increase in floods after that? In a great measure to the clearing of the country; in some degree to the accidental direction of a storm.

Benefits from floods. 10307. Is there any compensating advantage in these floods? None whatever; so few benefit by the still water. The scour does far more damage than is compensated for by the still water. We had an instance here: the land above here, as far as Mr. Fergusson's farm, lies under the direct scour; I daresay there has been at least 6 or 7 feet of alluvial soil taken away from that land.

10308. In a series of floods? Yes; there is nothing but a bare clay-pan in the centre of the scour now. A blade of grass has never grown since.

10309. It has been said that only high floods have done any great damage to the district: suppose we take 70 feet as the maximum of high water at flood-time, how many feet under that would the water have to rise before it would do any damage? I have a map here and the plan of my house, from which you will see the extent of damage which I myself suffered. I had 30 acres of land fronting up the street bounding the tram station; I had it on a lease of ninety-nine years, and I built upon it a house costing about £600. I felt as sure as any person could reasonably hope to be that I should make a fortune out of the place, as it possessed some attractive building sites; the position was good, and the soil magnificent. You may now see, outside, the foundations of the house. I had occupied the place a few months, and had built several additions; I had just finished building a large dining-room, when, without any warning whatever, the flood rose to the eaves and nearly drowned the whole of us. Large masses of cumulus clouds came up from the south-east, and in the course of a couple of hours the rain fell in such incessant torrents as I had never before seen. If the water had reached only the level of the houses, probably no one in the town would have suffered. The question of damage of which you speak in the case of the lower floods would depend upon the season of the year. If a flood occurred during the ripening of the wheat, it would do an immense deal of damage; but, leaving out of the question the chance of its coming during the ripening of the crops, very little damage would happen, if it did not go beyond a certain level.

Relief works. 10310. What would that be—10 or 12 feet lower than its highest level? Yes, about that.

10311. Do you think there is any possibility of relieving the district of these floods? I have suggested that an angle of the river might be cut off. I could not say that that would be certain relief, because the floods depend upon a combination of causes. I can show you on the map here the point where the mischief is done; it is at a point of the river between Campbell's Ford and Bent's Basin; but that is not the only obstruction.

10312. We have been told there are a number of granite boulders at the bottom of the river? They must be sandstone; there is no granite in the district.

10313. It is said that if these were removed the water would be assisted to run off in time of flood? I defy you to remove them; if you blast them all to pieces, it would be impossible for you to get them away; they would still lie there in blocks. You would alter their shapes, but I do not see how you could remove the obstruction.

Storage. 10314. Have you in your experience of the district noticed any places on the river which would be good sites for dams for the conservation of large bodies of water? I cannot say that I have, because my general recollection just now is, that if one side is firm the other is not. The river acts as rivers usually do; where on one side you have a hard soil, the whole force of the water is thrown upon the opposite bank. The drift is carried that way generally; hence you have sand on one side. My opposite neighbour on the river had a farm on the high bank, which was not affected by floods; on my side, the bank was cut away by the scour of the stream.

10315.

10315. Have you had experience of the advantage of the irrigation of land in this district? I could not give any evidence favourable to any notion of irrigation; I am prejudiced against it, and being so, it is only fair I should tell you so. I have given the matter very little study, except with the view of finding what would be likely to condemn it, and for this reason the few attempts at irrigation in this district must end in failure. The attempts have been made only by rich men. If they intend to grow crops of corn for ensilage or grain, they will find it would cost them at the rate of about 10s. a bushel. My idea is that irrigation can only be carried out with advantage when the land is situated at the base of a mountain-stream which is fed by perpetual snows or springs; then, when you can get a certain supply by gravitation, it might pay. Mr.  
J. B. Martin.  
3 April, 1886.  
Irrigation.
10316. Have you thought out the question of water supply to Camden? Only as it has been suggested to me by the gentlemen who were looking for a site for the reservoir and comparing the two projects, that is to say, the supply from the river here and the supply from the canal at Kenny's Hill. Town supply.
10317. Which do you favour? I think that from Kenny's Hill would be better. You might take the water from some point nearer than that, perhaps; then we should get it by gravitation, and should never incur any risk with reference to the engine. I do not see how you could sufficiently protect an engine near to the river here.
10318. Do you think that the people on the river have suffered by the diversion of water for the Prospect scheme? Yes; I am so far impressed with the idea that we have suffered, that I was about to ask the people to unite in a petition to the Government, praying them to allow us to have even a week or two of the run of the water, to let us have a mere cleansing fresh. The river has never been like this; I never saw the river before when you were obliged to go under the bridge for water. Now they had not only to go under the bridge, but a fortnight ago they were obliged to go some hundreds of yards up the river. We were not absolutely deprived of water. Suffering through proposed scheme.
10319. In case of great drought, do you think it would answer the purpose if the water were allowed to run down and flush the river once or twice in the month? I was going to propose that a public meeting should be held; but a thunderstorm happened at the head of the river, and raised the water four feet in one night. We have suffered from two things; the old bed of the river being filled up by sand, its shape is altered—the corners are cut off; on the banks there is a stratum of ironstone, and as soon as the water-pressure is removed the springs begin to run, and thus little pent-up pools become perfectly red, full of flocculent matter which is stirred up until you cannot see anything. On the surface there is an iridescent film produced, I think, by oxide of iron. We suffer from the foulness of the water in that way until the river is cleansed by a fresh from above. The water will become hard from the cause I have named, or perfectly green from stagnation.
10320. *Mr. Gilliat.*] What is the width of the river at Bent's Basin or Shancomore Gorge? Where the river enters the gorge at Campbell's Ford I should say about 100 yards wide. Width of river.
10321. What is the width of the gorge at its narrowest point? Very little more than the river; I should think about 40 or 50 yards.
10322. Could you give the Commission any information as to the area in miles or acres of land which is subject to flood in this district? That is a matter of calculation; I cannot speak off-hand upon a matter of that kind. You spoke just now about the difference between the height of the floods now and in former years, but not with reference to the special causes of the floods being worse at one time than at another, either now or then. I believe that depends a great deal in the first place upon the fact that the ground has been cleared everywhere, and has been trampled hard; it therefore follows that all the water is brought down more rapidly to the river than ever it was. Every year that is becoming worse and worse. Besides that, there is not so much land under cultivation as formerly. When the lands on the hills were under cultivation, they acted on the water like a sponge; now that they have reverted to grass, the old furrows running up and down the hills become little watercourses themselves, deep gutters cutting into saline subsoils. In fact, I may say that the quality of the water has been affected, creeks which were formerly sweet are now so full of mineral salts that they would float an egg in dry weather. Flooded country.  
Quality of water.

WEDNESDAY, 7 APRIL, 1886.

At Penrith.

Present:—

MR. DONKIN, J.P.,  
MR. FRANKLIN, C.E.,  
MR. GIPPS, C.E.,

MR. GILLIAT,  
MR. MURRAY,  
MR. TOWNSEND.

F. A. FRANKLIN, Esq., C.E., IN THE CHAIR.

Mr. Alfred Colless called in and examined:—

10323. *Chairman.*] You are proprietor of the *Nepean Times*? Yes.
10324. Have you been a resident of Penrith for any length of time? I have been in the district close on thirty-five years; I am a native of the district, and I have not been out of it more than a fortnight at a time. Mr. A. Colless.  
7 April, 1886.
10325. How far south of Penrith are you acquainted with the Nepean? As far as the junction of the Nepean and Warragamba rivers, and along the whole line dividing the Nepean electorate. The Nepean.
10326. Do you know the actual distance from the railway-bridge at Penrith to the junction of the Warragamba? I have always understood it to be 12 miles.
10327. Do you know whether the average width of the river from the bridge upwards has been ascertained? I do not. Width.
10328. Are you aware whether at any time accurate soundings have been taken? Yes, when Mr. Clark was here making inquiries respecting the scheme for supplying water to Sydney. Soundings.
10329. Would you say that the water is standing at ordinary summer-level now? No; my idea is that at the present time the river is 18 inches or 2 feet lower than it ever was before within my recollection.
10330. Is there any point of natural obstruction below the bridge? Yes, about a quarter of a mile below.
10331. What is the nature of that obstruction? A natural dam; I may tell you that a large portion of the dam has been removed. Obstruction.

10332.

- Mr. A. Colless. 10332. What does the dam consist of? Boulders embedded in natural drift and silt.
10333. Does the bar seem to be sufficiently retentive to hold back the water? Yes.
- 7 April, 1886. 10334. In ordinary seasons it has been sufficient to retain the water at a permanent level? Yes; 18 inches above the present height.
10335. Since when did the lowering of this natural reservoir take place? Within the last two or three years.
10336. What is the cause of it? The removal of the boulders for road-metal.
10337. Have the boulders been removed by the Government? No.
10338. By whom? Private people—by persons owning adjoining land.
10339. I suppose that the bar is of considerable magnitude? Yes; it extends for some distance on either side. The removal of the boulders has been stopped.
10340. Can you give any idea as to the quantity which has been removed (say) per month? No; they have been removed from different places; the whole locality is composed of bluestone.
11341. At present the stream appears to be too low to be serviceable to the surrounding country—does it benefit the lower part of the river by allowing the water to go? No.
- Lowering of bar. 10342. You do not think that the further lowering of the bar would benefit people on the banks lower down? No.
10343. If the river were lowered still further, would it damage any interest established on the river where pumping is carried on? I am not aware that any pumping is carried on between here and Richmond, except by one or two windmills.
- Population. 10344. What is the population of the electorate of Penrith? I should imagine that it is between 7,000 and 8,000.
10345. Notwithstanding the immense volume of water in the river, you say that no means are adopted to supply these people and stock with water? Not by means of pumping or gravitation.
- Valuable land. 10346. The land eastward of the river is exceedingly valuable for agricultural purposes? Very.
10347. And it would be largely benefited if it had a good supply of water? Yes.
- Water-supply. 10348. Does the district suffer very much owing to the intermittent supply of water? Yes, very much; and on the western bank some very valuable farms are affected.
10349. How do the people on the area between South Creek and the Nepean, including Penrith, supply themselves with water in drouthy seasons? Principally by tanks and wells.
- Town supply. 10350. How are they supplied in the town itself? By tanks, and when these fail, water is drawn from the river in casks. There is a small tank in connection with the railway station where people obtain water at so much per cask.
10351. So that, in fact, that is a small private water-supply? Yes.
10352. But it is not adequate? No.
10353. Are you aware whether any suggestion has been made recently for raising water from the river for the general supply of the district? Yes; not for the Penrith ward of the municipality only.
10354. Has anything like the cost of the work been arrived at? An estimate was made by Government officers.
- Water-rate. 10355. Have the municipality or the people in any way pledged themselves to pay the interest on the cost of tanks which would give them a permanent supply of water? They have never gone so far as that; I should say that the basis of calculation would be the annual value of the ratable property. I believe that a calculation has been made at so much per room.
10356. So that if any means could be adopted for lifting water within a reasonable distance of Penrith, which by gravitation would supply the town and district for stock and other purposes, there would be little doubt about getting the interest on the cost? Very little with regard to the town; I cannot speak with regard to the district.
- Bar. 10357. *Mr. Gipps.*] Has the removal of the bar of the river below the bridge been discontinued? I believe it has been stopped by the Government.
10358. What is about the width of the bar down the river? Fully 500 feet.
10359. And then the river goes into another bend? Yes.
10360. Does that extend any distance further down? Yes.
10361. Is there a similar bar below that again? Yes; portions of that bar have also been removed, but I believe the removal of it has been stopped.
- Movable weir. 10362. Suppose a movable weir were thrown across the bar so as to allow of the use of the water for motive power, would the population avail themselves of that water for manufacturing purposes; would it be a benefit to the town? It would be a great benefit; I think that if something of the kind were done it would be availed of by people outside the district.
- Value of property. 10363. What is the value of property per acre on either side of the river? I imagine that property on this side, being agricultural land, would be worth £40 or £50 per acre. On the otherside it is more valuable; I have heard of as much as £100 per acre being paid.
- Price of water. 10364. What is the price per cask of water drawn from the railway-engine tanks? The drawer pays 4d. per cask to a private speculator, Mr. T. Smith, who has to pay 3s. per thousand to the Government. He then charges from 1s. up to 2s. 6d. per cask of about 80 or 90 gallons according to distance.
10365. Can you give any idea as to the aggregate amount paid for this supply? I have no means of ascertaining.
10366. Would it be £1,000 a year? Not so much.
10367. How many people avail themselves of this means of supply? It depends entirely on the weather. I know that a few days ago the lessee of the tank paid £12 for a month's supply, that is at the rate of 3s. per 1,000 gallons.
10368. *Chairman.*] You know all the country between this and the commencement of the precipitous banks of the Nepean? Yes.
10369. Do you know whether any suggestion was ever made for getting water out at any point of the river this side of the precipitous banks? No; I have not heard of any suggestion being made by engineers.
- Peppercorn's scheme. 10370. *Mr. Gipps.*] Have you heard of a scheme proposed by Mr. Peppercorn? Yes; but I do not know where he proposed to take the water out.
10371. You know that the Mulgoa Creek enters the Nepean near the property known as Regentville, and that on the southern boundary of Regentville, the banks of the river begin to rise precipitously? Yes.

10372. And that there is a low ridge of land to the eastward of the river intervening between that and the general level of the valley of the Nepean? Yes.
10373. Do you know the height of that range just before you enter the gorge—I mean the little saddle-back to the eastward of the river? No.
10374. The valley behind that is, I suppose, the general level? Yes.
10375. Is the fall pretty general all the way down towards Richmond and Windsor parallel with the banks of the river? Yes. Mr. A. Colless.  
7 April, 1886.
10376. Can you indicate roughly on that line between Penrith, and Richmond, or Windsor, the contour which is made by the flood-level line? I could hardly do so without being on the spot.
10377. Are there any intervening ridges between the Nepean and South Creek to prevent the waters of the two from joining at flood-time? There is a ridge between Penrith and South Creek, the ridge which you see at the back of the town. Ridges.
10378. Do you know of any place between Penrith and Castlereagh, or towards Windsor, where the water passes through the range and joins South Creek? No.
10379. Do you know any place below where the waters of the two join and make one line of flood? No.
10380. *Mr. Murray.*] How much do you think the land on this side of the river would be enhanced in value if it had a supply of water in dry seasons? I should say, 25 per cent. Enhanced value of land.
10381. Do you think that the people of the district would be willing to pay a reasonable rate of interest on the cost of works which would give them an adequate supply of water? I think they would. Water-rate.
10382. Have you any idea of the extent of the agricultural land which would be benefited by a comprehensive system? The whole of the land along the eastern bank of the river would be benefited.
10383. How many miles along the river, commencing from the population boundary of Penrith? The whole distance from Penrith down.
10384. Then all the land intervening between South Creek and the Nepean would be benefited? Yes.
10385. In addition to that you think the supply to the town would be availed of by the people, and that they would have no objection to pay their share of the interest on the cost of the works? Yes.
10386. Suppose the river were dammed at some point above Penrith, do you know of any outlet in the mountains through which the country behind might be watered? Only from the Mulgoa Creek.
10387. *Chairman.*] You are acquainted with the locality where the Nepean and Warragamba Rivers join; do you know the relative levels of the height of the Mulgoa and the present water-level of the river? No. Levels
10388. Does the country fall rapidly above the bank of the river towards the Mulgoa? Yes.
10389. In a distance of two miles, how much do you think it falls? I could not say.
10390. *Mr. Donkin.*] Did people in the district take much interest in Mr. Woore's Warragamba scheme? They did not. Woore's scheme.
10391. What is the quality of the water in the river? It is usually good; of late it has been a little muddy; I do not know what is the cause of this. Quality of water.
10392. Has there been any appreciable difference in the quantity of water coming down since the Sydney water-supply works have been in operation? No.
10393. Has not the water gone down gradually within the last two or three years? Yes, it is 18 inches or 2 feet lower than it used to be.
10394. Has not the rainfall been less? Very much less.

Mr. David John Worboys called in and examined:—

10395. *Chairman.*] You have been a resident of this district for some time? Nearly forty years. Mr. D. J. Worboys.  
7 April, 1886.
10396. During that time has the valley of the Hawkesbury gone on increasing in value? Most decidedly.
10397. Has the increase in the value been in a great measure due to improvements made on the land? I think it may be attributed to several causes; for example, increase of population, and the increase in competition in consequence. Increased value of land.
10398. But have not the farmers contributed towards the improvement and value of the land by improved methods of working it? I should not say they have to any great extent; the droughts during the last few years have materially affected the crops. A few years ago, the district was regularly visited by floods every second year or so. These materially improved the quality of the soil; but for some years past there have been no floods, consequently the land has become poorer. Floods.
10399. Then it is the absence of periodical supplies of moisture which throws the district back? Decidedly so.
10400. The advantages of a good supply of water having been fairly demonstrated to the farmers over a long period, can you tell us what they have done themselves to make up for the deficiency in the rainfall? Absolutely nothing that I know of. Water conservation.
10401. They have never attempted to devise any scheme by which they might serve themselves, by taking water out of this large natural reservoir between the Nepean Bridge and the Warragamba? Nothing has been done; there has been a great deal of talk about it.
10402. Are you aware that in Victoria, in closely settled districts like this, they raise water by inexpensive means, and distribute it over the land? Yes. Water-raising.
10403. And are people in this district acquainted with the fact? Many of them are.
10404. Do you think that they would be prepared to pay for a supply of water which would enable them to produce crops to the same extent as formerly—would they pay sufficient to return the interest on a moderate outlay? I think that some of them would; but you must remember that a large proportion of the farmers are tenants. They have farms from 30 to 40 acres in extent, and the tenancy in the majority of instances is from year to year. Unless they should get leases of their farms, I doubt whether these farmers would be willing to pay any large amount for a supply of water.
10405. What rent do they pay per acre? It varies according to the locality, from 15s. to 25s.; in some cases, more. Rent.
10406. In that case it would be advisable for the proprietors of large areas to make themselves responsible for the interest on the outlay, which would entitle them to charge more in letting the land? Decidedly so; that would be the safest way of doing the business.
10407. You have assessed the values of properties here for municipal purposes? Yes.
10408. Do you think that the land has deteriorated in value in consequence of the absence of water? I think so. Deterioration of land in value.

- Mr. D. J. Worboys. 10409. Suppose a constant supply of water could be provided, to what extent do you think the value of the land would be increased? Nearly 100 per cent. on many farms; there are isolated cases where the benefit would not be great. The land immediately on the banks gets more moisture than that farther back; but taking the districts throughout, I say the value of the land would be materially increased if a good supply of water were provided.
- 7 April, 1886. 10410. Would it be increased 80 per cent. throughout? I believe so.
- Supply of Penrith. 10411. In dealing with the large body of water between the railway-bridge and the junction of the two rivers, by pumping and conveying it along the valley of the Hawkesbury, do you think it would be advisable at the same time to consider the supply to Penrith for domestic purposes? I think so.
10412. Suppose that the people in Penrith had to pay 5s. per room per year for a supply of water, do you not think they would be paying much less than they are now paying for a very small supply? Decidedly so; it would be one-half less than I myself pay.
10413. How many houses are there in Penrith? 500.
10414. How many rooms are there per house? They average about six rooms.
10415. Taking the average at four, then, at 5s. per room, that would represent a return of £500 per annum—do you think the townspeople would willingly pay that? I think so.
- Flood-level of Nepean. 10416. *Mr. Gipps.*] What is the height of the highest flood-level of the Nepean above summer-level? I cannot give the exact figures; but I know that in the flood of 1867 the water rose to the bottom of the railway-bridge. A log was lodged on the coping of the piers.
10417. How many days did it take for the flood to rise to that level? About nine days.
10418. Was there continuous rain during the whole time? Nearly so.
10419. What time did it take for the flood to subside? The water did not go down to the usual level for some weeks; but it was well within the banks of the river in about twelve or thirteen days.
10420. Are floods more numerous than they used to be? They are not nearly so numerous.
10421. Are they as high as they used to be? We have had no flood to speak of since 1867; there have been freshes which have broken over the banks twice only since then.
- Silt. 10422. Is much silt deposited by the floods? A great deal.
- Value of land. 10423. What is the average value of land in the district generally? Farming land on an average is worth from £40 to £50 per acre, in some cases as high as £100 per acre; but in back land (say) 2 miles from the river, not more than from £15 to £20 per acre.
- Reach. 10424. How do you account for the impounding of the water in the reach above the bridge? A little lower down than the bridge the water is shallow. There used to be an old wooden bridge there many years ago, and this has been covered with silt; the bar has been formed in this manner—at any rate, that is my idea.
- Bar. 10425. Is the bar impermeable? I think so, especially the bottom one.
10426. Before that was filled up there was no reach at all, then? Yes, the reach was there; it was all deep water right down from the spur of the mountains to Penrith.
- Depth of water. 10427. What is the depth of the water over the bar below the bridge? Not above 4 or 5 inches; in summer-time never more than 12 inches, unless there is a rise in the river.
- Width. 10428. What is the width of it? There has been a slight rise during the last day or two. A fortnight ago it was only about 40 feet wide; I walked across it without wetting the tops of my boots.
- Undercurrent. 10429. Is there another branch or bed of the river just below the bridge? I believe there is an undercurrent.
10430. Where does that run into the river again? About 2 or 2½ miles lower down.
- Bar. 10431. Then there is another bar? Yes; in fact, from this to Richmond the river is partially filled up with boulders, sand, and dead timber, and thus bars have been formed at different places.
- Change of river-course. 10432. Has the river changed its course, to your knowledge? Yes; just below the bridge it used to run to the westward of the present course; it is only when there is a rise in the river that the water runs in the old course.
10433. Did the river run in two channels? Yes.
10434. Where did they meet? About 2 miles lower down.
- Crops. 10435. What are the principal crops grown here? Corn, pumpkins, and hay, and fruit, and vines. A very large amount of land is under vines, and a large revenue is obtained from grapes and wine.
- Yield. 10436. What is the average yield of corn? It has been so poor this year that the farmers have simply cut it down to feed the cattle on the stalks.
- Fruit. 10437. Is much fruit grown here? A good deal.
10438. Does the drought make any difference in the yield of the orchards? Decidedly so—poorer fruit and smaller quantity.
- Decrease of floods. 10439. *Mr. Murray.*] To what do you attribute the decrease in the floods during recent years? I cannot give any reason.
10440. As a rule, we have ascertained that floods have increased in most of the rivers during recent years? They have been on the decrease here.
10441. Do you think that the lowering of the river would be injurious to the district? Decidedly so.
- Value of ratable property. 10442. What is the value of ratable property in the municipality? Over £22,000, rental value.
10443. Suppose a scheme for a supply of water to the town were adopted, do you not think that many people would avail themselves of the water for garden purposes, and that thus more than the £500 which you estimated would be collected? I think so.
- Factories. 10444. Are there any factories or mills which would make use of the water? I think not.
10445. Would a good supply of water be likely to call into existence any factories? I believe it would.

Mr. Robert C. Riley called in and examined.

- Mr. R. C. Riley. 10446. *Chairman.*] You are a resident in the district? Yes.
- 7 April, 1886. 10447. Where do you reside? On the Mulgoa, between Regentville and the Fairlight estate, about 6 miles from here.
- Fall of Mulgoa. 10448. Is there much fall from the upper part of the Mulgoa into the Nepean? There is a range at the back of us which extends to the river; from the top of that range there is a tremendous drop down into the Mulgoa valley.
10449. What is the drop from the precipitous banks of the river into the Mulgoa? The country falls all the way; it is very abrupt in some places. 10450.

10450. What is the distance between the river and the creek at your place? The nearest point would be about a mile; in other places, from  $1\frac{1}{2}$  mile to 2 miles. Mr. R. C. Riley.
10451. Can you give any idea as to the difference between the height of the bed of the creek and the water in the river at the present time? No. 7 April, 1886.
10452. Is there much settlement beyond you towards the Warragamba? Very little. Settlement.
10453. What is the nature of the country? Rough grass-tree country, which is only used for stock. Country.
10454. Did it ever occur to you that water could be raised into a reservoir at Regentville, and be distributed by gravitation below the gorge? I believe it could be done there; there is a gully higher up. My father had levels\* taken from that with the idea of getting water from the river. Distribution of water.
10455. From that gully could you throw water upon the lower part of the Regentville property? Easily.
10456. Then if water were lifted into that gully, it could be conveyed on to the lower land? The gully falls right into the Mulgoa valley; the gully is about  $\frac{3}{4}$  of a mile above the Regentville boundary.
10457. There is an inexhaustible supply of water there, is there not? Yes, and it is very deep; I have tried in several places and found it to be from 15 to 16 feet right up to the banks. I have tried it in the middle, but could never reach the bottom with an ordinary fishing-line. Supply.
10458. Suppose the water contained in that large natural reservoir were distributed over the district, would it not materially increase the value of the land and the prosperity of the farmers? There is not the slightest doubt of it; it would make a tremendous difference both to pastoralists and agriculturists. Value of land.
10459. To what extent do you think it would increase the produce? I should say double. Produce.
10460. Do you not think that in considering a general scheme of water-supply for the district, a supply for the town of Penrith ought to be considered at the same time? I think it would be a decided advantage to combine the two. Town Supply.
10461. *Mr. Gipps.*] Does Mulgoa Valley rise rapidly from the river? I do not think it does; it is gradual. Mulgoa Valley.
10462. Has it not a much steeper fall than the river itself? It must have.
10463. Are there any positions for storage reservoirs in the creek itself, in large floods? As you get higher up, near Mulgoa village, there may be; that is 6 or 7 miles. There is a good bit of water there at flood-time. Storage.
10464. What would be the area of any one of the floods? I suppose you can get them from 2 to 3 miles back on either side of the creek. Area of flood.
10465. Do you know the height of that above the river? I could not say.
10466. Did you ever look down from the top of the range on to the river? Often.
10467. Does the river seem much lower than the creek? I should say it is a great deal lower.
10468. *Mr. Gilliat.*] Can you give any information as to the height of the flood-water at your place in the river? I have not taken particular notice. Height of floods.
10469. *Mr. Gipps.*] What is the height of floods in the Mulgoa Valley? I should say that the water was backed up for 2 or 3 miles in the creek from the river in the highest flood I have seen.
10470. Have you ever known a flood in the creek without there being a flood in the river? I do not remember it.
10471. *Mr. Donkin.*] Do you call this a dry season? It is the worst season we have had for many years. Dry seasons.
10472. Do you think that there are 40 feet in the gorge near Evans's? I believe there is.

Mr. John Price called in and examined:—

10473. *Chairman.*] How long have you been a resident in the district? Thirty years. Mr. J. Price.
10474. In what way have you been employed? As a working man. 7 April, 1886.
10475. Farming? Part of the time.
10476. You have seen all the floods which have occurred in the district during that period? Yes. Floods.
10477. Which was the greatest flood in your recollection? That in 1867.
10478. Do you know how far that flood-line extended along the eastern valley of the Hawkesbury; for instance at Penrith, how far did it extend on the line of railway towards the ridge near us? About a quarter of a mile from the river, east.
10479. From Penrith south, towards Regentville, do you know what form the flood-line took? I know that it extended as far back as Windmill Hill, as we call it. The water rose almost up to the railway-station in that flood.
10480. Then the Court-house is far above the flood-level? Yes.
10481. Is there a depression between Penrith and Castlereagh, out of which the water passes in flood-time on to the back country? There is, 6 or 7 miles down; it comes into Rickaby Creek. Depression.
10482. Then a defined level above flood-line would be found on the eastern side of Rickaby Creek? Yes.
10483. Then below that, where does the water break through into South Creek from Rickaby Creek? Rickaby Creek runs into the river close to Windsor. Rickaby Creek.
10484. Do you know of any flood-line from Rickaby Creek round towards Riverstone? No; I am not well acquainted with that part. I know that there is a tremendous stream in Rickaby Creek between here and Richmond.
11485. Is the high-land known as the Castlereagh Reserve isolated like an island at flood-time? The stream cuts off again between that high land and Penrith. Castlereagh Reserve.
10486. Since you have been here I suppose property has been gradually increasing in value? The rents have increased. Value of property.
10487. Has the general value of property increased? I think so.
10488. From your earliest recollections what was the nature of the holdings in the district? 50 acres was considered a good farm for agricultural purposes. Size of farms.
10489. Then the holdings have been small, and the farms have been rented? Yes; until lately they nearly all belonged to the M'Henrys and their representatives.
10490. What rent can farmers afford to pay for these farms of 40 or 50 acres considering all the conditions? They have to pay £1 an acre. I paid £50 a year for 60 acres. Rent.
10491. I suppose one of the conditions was, you had to keep the fences in repair? There was no condition of that sort, but for our own safety we kept the fences up.

10492.

\* NOTE (on revision) :—Mrs. J. J. Riley has the papers of these levels.

- Mr. J. Price. 10492. It is evident you must have produced the rent of your farm? I did, and £200 over it, in five years.  
 10493. Did you have good seasons? Far better seasons than we have now.  
 7 April, 1886. 10494. Would you consider that a fair return for the acreage? Ycs.  
 10495. Would that return have been continuous if you had a continued supply of water? Yes.  
 Artificial supply. 10496. As the rains are not to be depended on, do you think that the condition of things could be maintained by an artificial supply of water? If water were supplied at reasonable rates I am sure it would.  
 10497. I suppose you lost by bad seasons, and could make a profit no longer? My successors have not done so.  
 Value of constant supply. 10498. Then the value to you of a constant supply of water would have been almost equal to 15s. per acre? Yes.  
 10499. You think that a constant supply of water would increase the value of the land about ninety per cent.? I believe there is material in the ground to produce such a result. A farmer who has got four bushels of corn to the acre this year told me that he would have had a hundred if there had been a seasonable fall of rain.  
 Quality of land. 10500. This is one of the best agricultural districts in the colony? It is one of the best, but not equal to the Hunter River district.  
 10501. Can you tell why it is, considering that this flat is so valuable, and that it suffers from the want of water, that no effort has been made to urge on the Government the necessity of utilizing the water lying at your very doors? The owners of the property would not take any steps, and the tenants were not in a position to do so.  
 10502. Do you think the tenants would voluntarily pay more rent if they had the advantage of a permanent supply of water? No doubt of it.  
 Water-rate. 10503. Have you any reason to believe that the owners of the land would willingly pay the interest on the outlay for permanent supply if it were done at a moderate cost? I think so.  
 10504. You must have heard all sorts of opinions expressed on the subject? Yes; we are now trying to get water from Glenbrook for the town.  
 10505. Suppose we were to deal with a comprehensive scheme for supplying all the different towns on the Hawkesbury and the country on the flats, do you not think it would be advisable to include Penrith in the scheme? I should imagine so.  
 Irrigation. 10506. Do you know of any irrigation in the district by pumping from the river? No; in some places there are wells and windmills to raise the water for orchards.  
 Orchards. 10507. The natural condition of the orchards is very good, considering all the changes which have taken place? Yes.  
 Supply of Penrith. 10508. You say that there is immediate necessity for supplying Penrith with water; what is the cause of that necessity—is it that you have had continuous drought? Yes.  
 10509. How are you supplied with water now? From the tank at the railway-station.  
 10510. I suppose the people do not avail themselves of that supply until their tanks run out? There are hundreds of people who have no tanks; they have to buy water all the year round.  
 Householders. 10511. What is the number of householders in Penrith? I think there are over 600 houses.  
 Buying water. 10512. Do you think that two-thirds of the people would be under the necessity of buying water for half the year? Quite that number. Many have to buy it all the year round.  
 10513. Then there must be an enormous sum of money paid during the year for water? Yes.  
 Glenbrook Creek 10514. Far and above the proportionate rate for a permanent supply? Yes; I think the houses will average four rooms each. We have had a survey made of Glenbrook Creek with a view to get a supply from that source.  
 10515. Where is that creek? A mile or two above Mr. Dibbs's house, on the western side of the river.  
 10516. How do you propose to bring the water across the river? Either at Regentville or across the bridge. We have asked the Government to furnish us with an estimate of the cost of the work, but up to the present we have not received a report.  
 10517. Do you think that if water were raised from the river at Regentville, there would be sufficient fall to supply Penrith? The water in Glenbrook is better than that in the river. Glenbrook is an ever running stream; it is discharging sufficient water now to fill a 3-foot pipe—enough to supply Sydney, I should think. It is 500 feet higher than Penrith. We have had an offer from a private company to undertake certain works, but we have refused it pending the report from the Government. The objection to the river water is that there is too much magnesia in it, and I have known the water in the river to be unfit for use for a great length of time; it has been muddy for some months past.  
 Quality of river water. 10518. You think that if we could give a permanent supply of water along the whole valley of the Hawkesbury, it would be beneficial generally to the district? I do indeed. I wish I could persuade you to recommend that the water be put on Mr. Riley's mountain on the eastern side of the river, nearly opposite Glenbrook. It would supply Sydney.  
 10519. *Mr. Gipps.*] Where was your farm? On the bank of the river just below Regentville.  
 Crops. 10520. What crops did you cultivate? Maize and lucerne.  
 Yield. 10521. What number of bushels per acre did you get in a good year? I could not tell you; I used to feed pigs, and different things; I kept no record.  
 10522. How many cuttings of lucerne did you make in the year? Three.  
 10523. What height would the crop be when cut? The highest would be from 15 to 18 inches; some would be considerably lower than that.  
 10524. Did the lucerne run out? The seasons became very dry, and I thought it a good thing to get out of it.  
 10525. Are they growing lucerne there now? I think they use the land for grazing.  
 Vineyards. 10526. Do you know the value of vineyards here per acre? I have had no experience myself, but from report I believe that if they get one shilling a piece for a vine it is a paying business.  
 Yield. 10527. What would be the average crop for a vine? Perhaps about 4 lb. for a staked vine.  
 10528. *Mr. Donkin.*] Did your farm have a frontage to the river? Yes.  
 10529. That is permanent water? Yes.  
 Irrigation. 10530. When you had permanent water, did you ever think of using it for irrigation? No.  
 10531. Why do not the people make use of it for that purpose? Simply because the landlords do not seem inclined, and the tenants are not able.

10532. You say that the land at Maitland, on the Hunter, is richer than the land here—how do you know that? All that I go by is the fact that in the Maitland District I hear that they get six cuts of lucerne a year, whereas here four is the very outside. Mr. J. Price.  
7 April, 1886.
10533. How do you account for the difference? I suppose the land is richer, and there is more rain or moisture.
10534. *Mr. Murray.*] Has the cessation of floods caused a material fall in the value of land? When we had floods we had greater crops. I have known as many as four floods in the year. Effect of floods.

Mr. Samuel Jackson called in and examined:—

10535. *Chairman.*] You have been a resident in the district for some years? Upwards of 50.
10536. During those years you have been engaged in the capacity of surveyor? I have been a surveyor for about 40 years. Mr.  
S. Jackson.  
7 April, 1886.
10537. Do you know the locality of the junction of the Warragamba with the Nepean? Yes; at present the water is not more than knee-deep at the mouth of the Warragamba, then you get into deep water again. I have never seen the river dry there. The Warragamba.
10538. Do you know a spot immediately below the junction of the two rivers where there is a narrow gorge with precipitous banks? Yes; the water runs there a little at present. That is the only spot between that point and Penrith where the water is running. Gorge.
10539. Do you know the nature of the back country to the east of this particular point, about a quarter of a mile below the Warragamba towards Mulgoa Creek? It is a ridge; there is no opening until you are a considerable distance down. Ridge.
10540. Mulgoa Creek is situated at the bottom of a steep gorge, is it not? Mulgoa Creek takes its rise at Luddenham. It flows through a valley; it is a very gently falling creek. At present it is a series of water-holes. Rise of Mulgoa.
10541. Taking the point which I have indicated, what would be the comparative levels of the present water-level and the creek? Lieutenant Woore made levels there. Levels.
10542. Were levels taken over to the Mulgoa Creek? Certainly, the whole way to Sydney, and Mr. Woore's family have the papers still.
10543. How did Lieutenant Woore propose to get the water across the ridge? After carrying the water across the Nepean, there would be a short tunnel.
10544. How did the levels correspond? After coming out into the valley, he crosses Mulgoa Creek and goes off away down by Prospect; there is a gradual descent all the way. Lieutenant Woore's dam was to be 170 feet high, and he considered that that would be sufficient to throw the water down. He took levels, but he did not run a check level. I told him that the thing was altogether impracticable. He did the work as an amateur; the Government simply found him the men.
10545. Does the country between the river and the creek fall abruptly? Yes.
10546. Do you know whether the difference of the levels has been ascertained? It has.
10547. Suppose we went below the junction of the Warragamba and the Nepean, in order to throw water into any part of the Mulgoa Creek, would a tunnel have to be a mile or two miles in length, or of what distance? You would have to raise the water considerably higher than Lieutenant Woore proposed to raise it, because his weir was to be above the junction in the Warragamba itself. Tunnel.  
Height of weir.
10548. How far back does the water go up the Mulgoa Creek in flood-times? In 1867, when we had the largest flood which I have ever seen, the water came up to my fence, which is near the junction 4 miles from Penrith.
10549. What height was that above summer-level? About 50 feet or more.
10550. From that you say that there is a difference of 100 feet between the levels of the river and the creek, if the creek rose in the same ratio all the way back? I should think there is quite that; but of course you would have to take levels to make sure. Levels.
10551. The district has been suffering of late owing to drought? This is one of the driest times we have had for many years; the river is lower now than I have ever seen it. Droughts.
10552. These continued droughts deteriorate the value of property? Yes; I should like to point out an easy way in which the land could be watered. It is a well-known fact that the banks at the river are a little higher than the land beyond, which is all good farming land. If the water be once raised to the tops of the banks, this land can be watered with the greatest of ease, there being a gradual fall; this applies to the land all the way down to Windsor. In flood-time the water runs along Lennox-street, Richmond, towards the Common; the same thing occurs all the way up the river. Watering of land.
10553. How do you account for this? By the action of the floods when receding.
10554. Do you know the average depth of the long basin of the Nepean from the bridge to the junction of the two rivers? It has been sounded in several places—not long since by Dr. Cox, and some gentlemen who came up for the purpose of examining Erskine Creek, to ascertain if that would be a good site for a reservoir. Site for reservoir.
10555. Do you know what the average depth is? I do not; there is no very great depth in any part.
10556. Do you know that beyond the obstruction below the Nepean bridge—that is the natural weir—there is a gradual fall in the bed of the river all the way to the sea? Yes; the river has been lowered by the removal of boulders from that weir, but the Government have stopped it. Removal of boulders.
10557. What was the objection to the removal of the boulders? Simply that it was ruining the river—that it would ultimately let all the water off.
10558. Is it not a fact that the river is exceedingly deep in places from the bridge to the mouth of the gorge? At the present time there is a shallow spot immediately opposite the cloth factory; it is so shallow that at the time of the champion race we had to caution Hanlan to beware of it. You might strike it there by a deep-drawing boat. This spot was selected by the late Sir John Jamieson for the foundation of a pier. Depth of river.
10559. Suppose we were to determine on a general scheme for supplying the river-flats of the Hawkesbury, which do you think would be the best site at which to raise the water? The water in the Warragamba is exceedingly pure; but you would have the disadvantage there of having to cross the Nepean; below the junction, there are many places. Site for raising water.
10560. Before you can raise the water of the Warragamba into anything like a natural outflow, you would have to run up a dam 100 feet high? Yes. Dam.  
10561.

10561. Suppose we were to raise water at some points on the Regentville property, do you not think that we should get a level from which the water would gravitate throughout the Hawkesbury? Immediately opposite my door there is a nice plateau where a reservoir might be placed. Of course, it would necessitate machinery to pump the water up. The height of this is about 420 feet above the river; and when Mr. Fuller, surveyor, was here, he told me it would be quite sufficient to throw the water into Crown-street reservoir. This is one of the proposals for supplying Sydney, which was condemned as being too expensive. For the purpose of supplying the valley, this would be one of the best places you could select, because once you raised the water to that point, you could supply the whole neighbourhood.
- Canal. 10562. Suppose we were to raise the water at that point, what direction would a canal have to take, going by Castlereagh, so as to work out into Riverstone? It is quite practicable to do that. The old Castlereagh township is on high land; you cannot pass between that and the river. You can go from Regentville to Penrith, following the ridge. From Penrith you skirt the lagoon, and then proceed below the high land of the Castlereagh. You would have to pass nearly parallel to the river to get down to Richmond. In my opinion a much readier method would be to raise small weirs along the river, at such places as Jackson's falls and Howell's mill-dam.
10563. The canal which we want must be above flood-level; how does the land lie above flood-level? The Richmond road runs on high land. If you follow the direction of the northern road toward Richmond Hill, that would be a direction nearly parallel with the river.
- Mr. John Cleeve called in and examined:—
- Mr. J. Cleeve. 10564. *Chairman.*] You are a land agent and C.P.S. of the district? Yes.
- 7 April, 1886. 10565. From observation, I suppose, you know a great deal in connection with the settlement of the district? Not very much, because my work keeps me indoors; but I hear a great deal from people.
- Want of water. 10566. You know that the residents on the plains have suffered very much of late years from want of water? Yes, especially the farmers.
10567. Do you not think that a constant supply of water for the valley of the Hawkesbury would improve the condition of the settlers and re-establish the agricultural industry of the district? In dry seasons, such as we have experienced lately, it is actually necessary to have some sort of irrigation to make the farms pay.
- Windmills. 10568. Do any of the farmers make use of the water in the river? None, for farming purposes. There are a few windmills; but the water is raised simply for domestic and garden purposes, not for growing cereals.
- Want of irrigation. 10569. Can you give any reason for the apparent want of energy on the part of the farmers? My idea is, that, as the whole of our farming population belongs to the working classes, that is, men who employ little or no labour beyond their own and that of their families, they have not the means to go in for irrigation; and I am told that the landlords do not care about assisting them in that direction. We have no first-class farmers, that is, men with capital. All our farmers are working men, and they utilise the ground according to their own knowledge and ability.
- Farming. 10570. Do you think that if the holdings were larger in area, and that a proper system of farming were adopted coupled with irrigation, the country would be capable of producing much more than it does now? I think that, even with the present holdings, farming would pay much better if we had irrigation.
10571. What do you think would be the increase in productiveness if there were a constant supply of water? During the last few seasons the land has actually returned next to nothing. The farmers have been hardly able to pay expenses. If they had irrigation they would make a good living off the land.
- Water-rate. 10572. Do you think that for a proper system of irrigation these farmers could, without any hardship or difficulty, pay a fair interest on the outlay for irrigation works? I am quite certain of it.
10573. Are the people alive to the necessity for such a work? I have heard them speak about the good it would do, if they had a plentiful supply of water; but they had always represented their not being able to bring it on to the land themselves, and the owners were not willing to assist them. Our agriculturists, taken as a body, are not a highly educated class, not sufficiently well informed to do anything more than the seasons allow them; they depend almost solely on the seasons.
- Irrigation area. 10574. *Mr. Gipps.*] What area of land do you suppose would be benefited by irrigation? Certainly a couple of miles on this side of the river, and Emu Plains on the other side.
10575. Taking it as a whole, do you suppose it would be 20,000 acres? It all depends on how far back you go. If you go back from the river from Penrith towards Richmond, the land is of very little use for agricultural purposes, there being too much sand. When you get to Richmond, the country is quite different.
10576. I suppose there are fully 50,000 acres? I think so.
- Water-rate. 10577. Do you suppose that the tenant would pay 5s. or 10s. per acre per year for the advantages of irrigation? I could hardly say. I should think 10s. was a large amount.
- Rent. 10578. What is their rent? From 15s. to £1 per acre per annum.
10579. Suppose they got double the crop by irrigation, do you not think they would be willing to pay for it? I have no doubt they would willingly pay for it after they had been practically convinced of the advantage. The difficulty would be at the commencement.
- Manufactories. 10580. Do you think that, if motive power were available, manufactories would be established at Penrith? That and cheaper rates on the railway line, and more frequent transit than at present, would probably do so.
- Fruit. 10581. Is there much fruit grown in the district? A great deal—principally grapes, oranges, peaches, and apples.
10582. Do the orchards pay well? I think so.
10583. In all seasons? I am told that the grape-crop has been very fine this year. I have heard of £40 an acre being paid by Sydney buyers for the grapes.
10584. Do you not think that the vineyards would yield larger crops if they had irrigation? Certainly.
- Model Farm. 10585. *Mr. Murray.*] Do you not think that if we had a farm irrigated as an example, showing what could be done, the people would be likely to go in for irrigation? Yes; that would be a good idea. Our farmers like to be assured of the success of anything before they venture on adopting it themselves.
10586. Do you think that, if a supply of water were provided for the municipality, a large number of the residents would avail themselves of it for supplies for domestic purposes? Yes.
10587. *Mr. Donkin.*] How long have you lived here? Eighteen years.

10588. Do you think that the seasons are drier than they used to be? Certainly.

Mr. J. Cleeve.

10589. The grape-vine industry has only sprung up within the last ten or fifteen years? No; it was here when I came here, but it has been increasing every year lately.

7 April, 1886.

10590. What are the largest vineyards? Mr. Cox's and Dr. M'Kay's.

10591. The river does not open into flats until we get lower down than Penrith? The back country is Flats, good for light crops, oaten hay, and grape-vines.

10592. There is ten or twenty times a larger area of good land in the Richmond and Windsor district than there is here? I believe so.

10593. *Mr. Townsend.*] Do you think that if the uplands on the high ridge between the Nepean and South Creek, and between Rodd's Creek and Eastern Creek, Mount Druitt Range, and around that range on the other side to Eastern Creek, were watered, that the lands would be sufficiently enhanced in value to warrant the expense of bringing the water on to them for fruit-growing purposes? When you get a certain distance from here towards St. Mary's, the land is held in large holdings by a few people, and I do not think that the same advantage would be taken of the water as would if the land were held by a large number of people. No doubt, if the work were done, it would do a great deal of good to the district.

Distribution of water for fruit-growing.

FRIDAY, APRIL 16, 1886.

At Richmond.

Present:

MR. BARTON, M.P.,  
MR. DONKIN, J.P.,

MR. GIPPS, C.E.,  
MR. MURRAY,

MR. TOWNSEND.

RUSSELL BARTON, Esq., M.P., VICE-PRESIDENT, IN THE CHAIR.

Mr. Valentine John Stuart Blomfield called in and examined:—

10594. *Vice-President.*] What are you? I am an Associate Member of the Institution of Civil Engineers; I am Road Superintendent for this district.

Mr. V. J. S. Blomfield.

10595. How long have you been in this district? Between four and five years.

10596. Does your experience extend over the district for any length of time beyond that? No. I have visited the district before that; that is all.

16 April, 1886.

10597. During your experience, have you noticed any places that you think would answer the purpose of containing large quantities of water for the purpose of irrigation? I think that water might be stored in the Wheeny Creek, near the Kurrajong; but I cannot say for certain whether a survey has been made. I cannot give you the levels of the Wheeny Creek; that is the creek above Richmond Bridge.

Storage in Wheeny Creek.

10598. What height do you put it at above Richmond Bridge? 370 feet.

10699. Where Bell's line of road crosses Little Wheeny Creek, is that the site you would recommend? No; it would be lower down than that. Allowing 100 feet, that leaves a balance of 270 feet above the Richmond Bridge—that is a clear 200 feet above the floods.

10600. Have you made any calculation at all as to what quantity of water that would conserve? No, I have not. It would be a large reservoir; but I do not think the reservoir would be sufficient of itself for irrigation purposes. It would have to be fed by a stream such as the Grose or the Colo. The Colo, I think, might be utilised.

Feeding from Colo.

10601. In what way? It may be turned into the reservoir. I do not think that the area of itself would be large enough.

10602. And in what way could these other waters be utilised? They would have to be brought through the ridge by means of a tunnel.

10603. Otherwise, do you think the creek of itself is not sufficient for irrigation purposes? It would only be useful for a comparatively small area, because the demand on it would be very considerable.

10604. Is that the only place you know of? I know of one small place, but it is infinitesimal compared with this one. It is a small place named Clarke's Flat, near Riverstone, which might be utilised for irrigating the farms lying between Riverstone and Windsor.

Clarke's Flat.

10605. That is smaller than Wheeny Creek, then? Yes. It would do just to irrigate the farms about Riverstone and Windsor.

10606. What is the character of that place? It is a valley about  $\frac{3}{4}$  of a mile from Riverstone station. The bottom of it is about 100 feet above high-water mark.

Character.

10607. Do you know anything of the river between here and Penrith, or above Penrith? No, I cannot say that I do.

10608. Then you could not give any information as to whether it would be likely that we could take water from the river itself to irrigate the farms on each side by gravitation? No, I cannot say.

10609. Do you know of any place on the Grose River that might be made available for conserving large quantities of water for irrigation purposes? Only what we have seen to-day.

Grose River.

10610. At what part of the Grose River do you think we could get the best returns by damming—I mean, where the dams could be erected with the greatest economy and the largest amount of water obtained? I do not know anything about the levels. I scarcely think that where we have been to-day there would be fall enough; but that would all be settled by survey.

10611. Do you know anything about the rivers or the fall of them? No.

10612. Has anything been done in the district up to the present time by way of irrigation to any extent? There is a farmer named John Gow at Mulgrave who has irrigated the whole of his vineyard and orchard by means of pumping from South Creek.

Irrigation.

10613. Do you know what the result has been? The result has been very favourable; but in what proportion I cannot say. His orchard bears a wonderful comparison to the adjoining properties. Mr. Pitt, of North Richmond, has also a windmill, and he has laid the water through his garden; I believe also through his orchard, but I cannot say for certain.

10614. That is the extent, as far as you know, of attempts that have been made at irrigation in the district? Yes.

10615.

- Mr. V. J. S. Blomfield.  
16 April, 1886.
10615. Do you know whether there is a feeling in the district in favour of irrigation? I have heard it said by farmers that irrigation would be of great value to them in growing crops. In fact, I have heard some people say that the only thing that will save this district is a small flood. I mention that to show how dry the ground is.
10616. Have you ever heard people advance the proposition that Government in some way ought to construct large irrigation works for the benefit of the district? No; I do not think that I have ever heard that.
10617. Have you ever heard people express the opinion that, if large works were constructed, the people would be ready to pay for them? No, I do not think that I have heard that.
- Water-rate. 10618. Do you yourself think that they would pay a tax equal to the interest on the outlay—(say) 4 or 5 per cent.? There are, no doubt, a good many farmers who would be willing to do so, but I do not know whether the majority of the farmers would. They are very conservative in this district.
- Supply for stock. 10619. Do the people of this district generally depend upon the river for water for their stock and for domestic purposes? Generally. Some few in the towns have small tanks, but the majority depend entirely upon the river.
- Town supply. 10620. Have you ever thought of the question of the supply of water in the towns of Windsor and Richmond for domestic purposes? Yes. Various schemes have been proposed; but I have not thought it right to express any opinion on their relative merits, being a Government officer; but I know what the schemes are.
10621. What is your opinion of the scheme best adapted for the district? That is a question which I have not gone into sufficiently, and cannot express an opinion.
10622. I suppose every scheme that has been propounded must have been a pumping scheme? I do not think I have ever heard of a gravitation scheme.
- Droughts. 10623. Has there been any suffering here or loss through want of a sufficient supply of water in the district during the last drought? I do not think this district feels the drought very severely, except in the loss of crops. There is good water sufficient for the consumption of the people and for stock. With regard to Clarke's Flat, the comparative levels are:—Clarke's Flat, 106 feet; Riverstone, 78 feet; Windsor, 41 feet. The flood-waters are supposed to have risen about 7 feet above the rails at Windsor station, as the station-master informed me this morning.
- Levels. 10624. Have you had any experience here of the floods yourself? None.
- Hawkesbury river-bed and banks. 10625. *Mr. Gipps.*] What is the general character of the river-bed and banks of the Hawkesbury? Just above the junction of the Grose there is shingle; then, I think, nearly the whole way down the banks are alluvial, until you get below Pitt Town; then they come into rock again. Above, the river has been silted up for miles with sand—even below Pitt Town. Then you get into mud and rock.
10626. Then, do you not think a large proportion of the stream runs beneath the sand? I think a good quantity of water runs in the upper part of the river down as far as Windsor. It is tidal up to Windsor.
10627. Do you think a sunken weir would help to raise the water and increase the stream very largely? I could not say; I have not gone into that.
- South Creek. 10628. Do you know anything of South Creek? Yes; for some distance above Windsor it is deep water.
- Supply. 10629. Is there a constant stream running into it? The stream is very slight, but it is constant, except in a very dry season. It is tidal for some distance above Windsor.
10630. Are there any positions there for reservoirs? I have not gone right up the stream; I could not say.
10631. With regard to the Wheeny Creek at the junction, what is the character of the basin; does it consist of large flats with steep sides? I have never examined that creek thoroughly right down to the junction. I merely looked down the valley from the ridge above. It is sandstone country generally.
10632. You have no idea whether a dam could be erected at that spot? No, I have not.
10633. What distance would that be from Richmond? I suppose about 10 miles.
10634. You said you did not think there was sufficient watershed there to fill a reservoir, and you propose to divert the Colo River? That was an idea I had, but it might not turn out to be feasible.
- Diversion from Colo. 10635. In what way would you divert the Colo River? By making a dam across the Colo where it is suitable, at a sufficient height, then tunnelling through the ridge that divides the Colo from the Wheeny.
10636. You do not know what distance you would have to go up the stream to divert the water? No; I do not know that I can say anything about that, because I have not the levels.
- Movable weir. 10637. Do you think a moveable weir could be erected on the river which would preserve water which might be used for manufacturing purposes and water-supply in different parts? I have not gone into that question.
10638. Motive power could be supplied, I suppose? I do not exactly understand your meaning. Would you first explain what you wish to convey by the term movable weir?
10639. A weir that would keep up the water in dry times? Yes, I think so.
10640. You think a movable weir would be exceedingly valuable in dry times for the power it would afford for manufacturing and water-supply purposes? I think it would be very valuable indeed, but I do not know whether there is sufficient energy in the district to make use of it for manufactures.
- Site for dam on the Wheeny. 10641. *Mr. Donkin.*] The dam you propose as a site for a reservoir in the Little Wheeny Creek is about the junction of the two? I merely regard the Wheeny Creek as a probable site for a reservoir. I never fixed upon any particular site in my own mind.
- Extent of floods. 10642. How far from Richmond did these floods from the Hawkesbury come; did they first open out from the river below Penrith? I have never been up the river higher than where we crossed it to-day, but I believe that floods extend nearly the whole way to Penrith.
- Flood-level. 10643. Do you know what the average flood-level is above the Hawkesbury floods? No, I cannot say.
10644. It was said to be at Windsor Railway-station 7 feet above the railway; that would give 37 feet above Mulgrave? Mulgrave is shown on the railway time-table as 42 feet above the level of the sea, Windsor 41, and the flood-level given by the station-master is 48. Against that I have been informed that in the flood-time at Mulgrave they went in a boat over the top of the station-house. So you see there is a discrepancy somewhere. The flood-level was probably higher than that.
10645. Do they cart water for Richmond from the river? No; they pump it from the lagoon below the churchyard.
- Wells. 10646. Have you had any experience of any wells being sunk? There is a well at Mulgrave; there is one near Richmond which the Railway Department use.
- Supply. 10647. Do they get a plentiful supply of water? So I am told; Mulgrave, I believe, has an everlasting supply of beautiful water. 10648.

10648. Could they not make use of wells more largely? I believe you could sink wells in the flat between Windsor and Richmond and get water there. The water seems to run underground from above where we crossed in the coach to-day. It comes right underneath this common. Mr. V. J. S. Blomfield.
10649. *Vice-President.*] To what depth? I do not know; the stationmaster could tell. 16 April, 1886.
10650. *Mr. Donkin.*] You saw the Grose River to-day, and you know the Hawkesbury pretty well; which is the greater stream, the Hawkesbury, where we crossed to-night, or the Grose River? I have never seen it in flood-times. Grose and Hawkesbury Rivers.
10651. At the present time? I should think certainly the Hawkesbury.
10652. You do not know in what proportion? No; I may state, the stream has been reduced considerably by the dry season, and they have been draining off water above for Sydney. There is certainly less water in the river than there has been for some time at Windsor.
10653. Are there any other crops grown here besides maize? Yes, lucerne; I believe they have been trying wheat, oats, &c. Crops.
10654. *Mr. Townsend.*] The best place from which to take the water supply would be at Wheeny Creek? Yes, somewhere there; it would be an excellent place for a dam. I have an aneroid observation at the Blacksmith's Creek, but I have not got it here. Dam at Wheeny.
10655. That is 1½ mile beyond Tootie? Yes, there is plenty of fall in the river if it can be intercepted. Fall.
10656. Have you ever thought about what the expenditure would be of a sunken weir that would intercept the soakage which is proved to exist in the Nepean River? I have not given the matter sufficient consideration to answer this question. Sunken weir.
10657. What is the greatest distance that you know of a well that bottomed in drift from the Nepean? I do not know personally anything about these wells. I do well.
10658. If you had the command of the water, would you prefer to irrigate the river-flats or the high lands? I do not know that I should prefer to do one or the other; I should certainly do both if I had land. Mr. John Gow irrigates the high lands and the flats, the high land more especially, because it is the driest. Irrigation.
10659. There is greater necessity to irrigate the high lands than the flats? Decidedly so.
10660. *Mr. Murray.*] I believe there is a very large quantity of agricultural land in the district? Yes, a large quantity. Agricultural land.
10661. And that the ridges are rich as well as the low, level lands? Not all, some are very stony, some are sandstone, some clay and gravel mixed. Some of the ridges are very suitable for vineyards or orchards. Ridges.
10662. They are actually now under cultivation? Yes.
10663. You said a while ago that the principal crop was maize—what is the average yield in a fair season? I do not know. Yield of crop.
10664. You think that it would be very greatly increased by irrigation? Certainly; especially in dry seasons, because I have known the crops to be entirely lost in some places through the dryness of the season.
10665. Have you any idea of the yield this season? No.
10666. Is this considered a good or a bad season? I do not know.
10667. If the yield would be very largely increased by irrigation, and the farmers could see that, would they not agree to pay a fair percentage on the outlay upon a scheme of irrigation? I think that, ultimately, all the farmers would be only too glad to have it, but I think it would be a long time before many of them would be willing to pay for it. Water-rate.
10668. *Mr. Townsend.*] Instead of putting it as a percentage on the outlay, if you were to put it at so much per acre, would they pay for the conservation of the water for irrigation purposes—what do you think they would be prepared to pay per acre? Oh, I could not say: I have no practical knowledge of what the yield is.
10669. *Mr. Murray.*] Are the farmers on their own land, or are they tenants? There are both classes; there are a large number of tenants, but a good proportion are on freehold land. Class of farmers.
10670. *Mr. Gipps.*] Do you know of any trap basaltic outcrops in the country? The only outcrop of basaltic formation I know of is at Mount Tomah. Basaltic outcrop.
10671. Is that on this side or the other side of the river? On the other side of the river.

SATURDAY, 17 APRIL, 1886.

At Richmond.

Present:—

MR. BARTON, M.P.,  
MR. DONKIN, J.P.,  
MR. GIPPS, C.E.,

MR. MURRAY,  
MR. M'MORDIE, M.I.C.E.,  
MR. TOWNSEND.

RUSSELL BARTON, ESQ., M.P., VICE-PRESIDENT, IN THE CHAIR.

Mr. George Matcham Pitt called in and examined:—

10672. *Vice-President.*] How long have you been resident in this district? Since I was born, that is, since 1837. Mr. G. M. Pitt.
10673. Then of course you have had over 40 years' experience of the district? Yes.
10674. Will you tell us what has been the effect of the floods in your time here? The whole character of the river has changed. I took the level of the flood of 1867. 17 April, 1886. Floods.
10675. Was that the highest you know of? Yes, that was about 64 feet above the ordinary level of the river at that time.
10676. What was its duration? It did not keep up to the highest point very long; but it was an eight or nine days' flood. It was 52 feet above the deck of the Richmond bridge.
10677. Do these floods do much damage in the district? They do. The first flood was in 1857—the time the "Dunbar" was wrecked. From that time there were a series of floods up to 1867, and from that on again. The flood which did the most damage was the 1870 flood. It did not rise so high as the flood of 1867, but it came with greater force and rose more rapidly. Its velocity was 12 miles an hour at one time. Damage. Velocity.

- Mr. G. M. Pitt.  
17 April, 1886.
10678. What was the nature of the damage it did? It altered the whole river; in fact, nearly every flood had its own characteristics; one would silt in the river, and one would scour it out. In 1867, the river was nearly dammed at the Richmond Bridge; and in 1870, it washed away the banks and widened the river some three chains or more at the bridge, and a new channel was formed on the eastern side; and a few miles lower down the course of the river was entirely changed. Prior to that we had a tide at Richmond Bridge 18 inches to 2 feet, extending up to the confluence of the Grose River. There has been no tide since.
10679. That is in consequence of the river silting up? Yes; the body of the river is raised. We used to have beautiful deep water where now there is none.
10680. Have you had experience of any flood that has cleared the river? Yes.
10681. Then you think that other floods coming down might clear it out again? I do. When we have rapid floods it will clear the river. That is the only chance we are looking forward to.
- Benefit from floods.  
10682. Did these floods do great damage to the crops? No; I think a flood every three years is rather a benefit to the district.
10683. Does a flood benefit the land to a great extent? Considerably.
10684. You think then that the floods do more good than harm? I do.
- Irrigation.  
10685. Have you had any experience of irrigation in this district? No; I have not, except in a small way with my own windmill. I pump from the river and try to irrigate on the high lands, but when the ground gets so dry, it takes so much water to saturate it that I cannot carry out my idea without going to larger expense for pumping gear.
10686. Do you know of any other attempts that have been made at irrigation in this district? No.
10687. Then you could not give us any information as to what benefit is likely to be derived from irrigation in this particular district? I believe that on the high lands it would be invaluable.
10688. What about the low lands? I would not irrigate the low lands. I have been in communication with several gentlemen who have lucerne paddocks on the low lands, and who, if they could turn water on their paddocks, would be able to make sure of their crops, and they would pay a higher rent for the land. I have some high land which I would willingly pay a pound an acre per annum to have irrigated.
10689. What amount of water per acre do you consider you would require? I do not think it would want a great quantity if we could regulate the supply.
- Water-rate.  
10690. Do you think then that the majority of people residing in the district and owning property would be willing to pay something like 4 or 5 per cent. interest on the outlay on the construction of large irrigation, or how much per acre would they be willing to pay for having their land irrigated by some large and comprehensive scheme? The benefit would be incalculable; we can scarcely realise what the result would be if we could turn on the water as we require it.
10691. Would they pay something like 4s. or 5s. per acre? I am sure they would. They would be able to get crops of lucerne where now they can get none.
- Storage.  
10692. Do you know of any place suitable for conserving large bodies of water in this district so that it could be rendered available for irrigation at sufficiently high levels to enable us to irrigate by gravitation? We have only one or two places in these large gorges such as the Grose River and the Wheeny Creek.
10693. Is that Little Wheeny or Big Wheeny? Big Wheeny.
10694. Are those the only two places you know of? Those are the only two where you can erect a dam.
- Fall of river.  
10695. Do you know what the fall of the river is from here to Penrith? Only by estimate, but not accurately. A very elaborate survey of the contour of the 1867 flood was made by the Harbours and Rivers Department some years ago.
- Contour of flood.  
10696. And you have not made any estimate as to what quantity of water those places would be likely to conserve? No; I speak only from my own local knowledge; I think a very large quantity could be conserved.
- Irrigation by pumping.  
10697. Do you think that any plan of pumping the water from the river would be feasible for the irrigation of the lower or higher grounds? No, I do not see where you could pump from. The Government have started a scheme for supplying Richmond and Windsor with water. Half a mile above my house there was a place 18 to 20 feet deep and a quarter of a mile long—a magnificent sheet of water; they made a survey, and it was agreed to sell a portion of the Common to carry out the scheme; but there came a freshet and a flood, and the whole thing was put an end to in consequence of the basin silting up, and at the present time the whole is a bed of sand. The Grose would no doubt be a suitable place.
- Underground current.  
10698. Do you think there is a very large extent of water coming down and going away in underground currents, under sand and drift in the bed of the river? I think there is.
- Sunken weirs.  
10699. Do you think a scheme of sunken weirs on the clay or bed-rock would materially increase the quantity of water that would be available? I do not think it would. Another thing, I do not think the water would be so pure. As soon as ever the river begins to get low, the water gets a taint of some sort of chemical; it will even corrode galvanized iron; I think it is from the springs. At the sides of the river there are many springs; the lower it gets, the harder the water becomes.
- Springs.  
Wells.  
10700. Do you know whether many wells have been sunk in the district, and what their character is? There are several wells sunk down to the drift.
- Supply.  
10701. Have they a large supply of water? Some have, and some have gone dry lately which have not been dry before.
10702. You do not know any from which large quantities of water could be got for irrigation? There are one or two in the town which you could not empty.
- Depth.  
10703. What depth? I think they average about 60 feet. It is not soft water; it is not so valuable as the water of the Grose River for domestic purposes.
10704. Have you any idea of the quantity of arable land in the district that might be brought under irrigation? No; that could be calculated easily.
- Water-holding capacity of soil.  
10705. Is the soil sufficiently impermeable here for irrigation to carry the water over it so that it would not easily soak through and disappear? A good deal of it would be, but the nearer you get to the river the more the water would be wasted; still, I think not a great deal. The ground holds the water better than one would imagine; you see water lying on it long after the rains and floods.
- Formation of soil.  
10706. What is the character of the soil, is it alluvial or volcanic? There is no volcanic soil here; it is alluvial. There is a clay subsoil over the Kurrajong; it is a clay shale. Where my orchards are, there is a clay shale underneath.

10707. What are the principal crops that are grown here by the farmers? Indian maize and straw crops.
10708. More than lucerne? Yes; there were more crops of lucerne some time ago, but owing to the dry seasons and turning of stock on pastures, they have run out.
10709. What is about the average crop of corn here in a fair season? In a fair season I should put it down at about 40 bushels, considering the droughts and one thing with another.
10710. You never produce more than one crop in the year? No.
10711. Would you consider 40 bushels to the acre here would pay on the average? I think it would.
10712. What is the average price of that corn? From 2s. 6d. to 3s.
10713. What is the value of arable land in the district, on the flats or on the high lands? The value of the low land, according to a sale which took place the other day, is about £36 10s. to £37 per acre. I should put the average value at £30.
10714. What is the value of the high arable lands? It is difficult to form an opinion as to the value of the high lands? it was worth more than the low lands when we had so many floods, but now we cannot grow anything on the high lands for want of water. At the same time, however, I think it is worth half as much as the low lands, or £15 per acre.
10715. Are the watersheds of the Grose and the Wheeny extensive? Yes.
10716. Sufficiently extensive to supply water for the irrigation of the arable lands? Yes; the Grose particularly embraces a very large area; the Wheeny watershed is not so large, but still it is extensive.
10717. *Mr. Murray.*] You grow lucerne extensively? Not very extensively.
10718. How many cuttings a year do you get? I think about five.
10719. And on the average how many tons? About 1 ton to the acre; that would be 5 tons a year—that is, in good seasons.
10720. What sort of a crop is there this year? A poor one.
10721. What would be the average? I question whether it will amount to 2 tons per acre for the year.
10722. And the corn? Very poor.
10723. About how many bushels to the acre? I could not tell you exactly; I do not think it would be over 20 bushels to the acre.
10724. *Vice-President.*] In many cases there is no crop of corn at all? None at all; five acres of my own produce nothing.
10725. *Mr. Murray.*] Is there much cultivation further up? On the Kurrajong side there is.
10726. You stated that when the floods were frequent the value of the high lands was equal to that of the low lands? Yes.
10727. If you had irrigation, would it not bring the value of the high lands back again to what it was originally? I believe it would.
10728. You say the value is about £15 to the acre—would it not be doubled by irrigation? I am certain it would.
10729. *Mr. Gipps.*] How many crops of lucerne do you get in a year? As far as I know, from four to five crops.
10730. Can you give any exceptional cause of the height of the flood of 1867—was it due only to heavy rain-falls above Richmond, or to other extraordinary causes? It was due principally, in my opinion, to heavy falls of rain taking place simultaneously in different places and the water then coming down in a body.
10731. Was there no other reason—was there no high tide flowing in and a heavy gale blowing? I think not.
10732. There was nothing to back the tides up? I do not think that would affect it at all.
10733. You say that the current in 1867 was less than the current in 1870, that there was less water coming down? Yes.
10734. Consequently there must have been some cause? The heavy rain of 1867, and its raining longer.
10735. Still that ought to have given a larger current, which must have been backed up by the high winds below? I do not think so.
10736. What was the height of the flood in 1870? It was about 13 or 14 feet below that of 1867.
10737. What is the diameter of your windmill? 16 feet.
10738. Yet you find that of no effect? Not for irrigation.
10739. I suppose you have not estimated the horse-power? When we have a nice steady breeze I put it down at 2-horse power; during a gale it goes much higher.
10740. With regard to the site of a reservoir, have you examined Big Wheeny Creek? I know the place well.
10741. Is there a large area in the basin there, where a dam 80 feet high would impound water? It opens out in a sweeping ravine.
10742. Still there are narrow gorges? Yes, very narrow.
10743. Do you know anything of the fall higher up? No, I do not.
10744. Does the current show much velocity? Not a very great fall.
10745. 8 or 10 feet a mile? It may be a little over that.
10746. What do you think the fall is in the Grose River? I think it is less in the Grose; it is not so steep as the Wheeny; there are larger levels and stretches of water.
10747. Does that extend right up the river? Yes.
10748. And then small falls? Yes.
10749. Does the gravel or boulder drift extend far beyond the bank of the river? Yes; the town of Richmond is over the boulder drift. A peculiar drift of boulders is to be seen above the Lower Zigzag, on the Western line.
10750. But is there a regular boulder-stream right under the flats? Yes.
10751. Is that impermeable? I do not know. That is where they tap the water here.
10752. *Mr. Donkin.*] To what extent has the river silted up during the last ten years? The present level is, I should think, some 3 feet above its original bed. It has silted up to the extent of about 10 feet.
10753. Do you think it has been raised 10 feet? Where I live it must be 15 feet.
10754. And do you think that another flood will clear it out? One flood will scour it, another will silt up the stream; if we have a sharp flood, with a swift current, it will probably carry it away.
10755. You were speaking of the proposed reservoir at the Grose, is that where the first fall is? I take the top of the first level reach of water, which is somewhere about there.

Mr.  
G. M. Pitt.  
17 April, 1886.  
Crops.

Value of land.

Grose and  
Wheeny water-  
sheds.

Lucerne.

Value of lands.

Crops of lucerne.

Floods.

Windmill.

Dam.

Gorges.

Current.

Drift.

- Mr. G. M. Pitt. 10756. Do you think there is sufficient elevation there to bring it down by gravitation; what is the height, is it 150 feet? Less than that. That large basin would be a grand reservoir from which to pump water on the Richmond hills. I think it is the only place from which to get a supply for the town.
- 17 April, 1886. 10757. The big flood of 1867 was over Mulgrave Station? Yes.
- Height of flood. 10758. Do you know how it was with regard to Windsor Railway-station? Windsor and Richmond were completely covered, right up to the "Royal Hotel."
- Site for dam. 10759. *Mr. Townsend.*] Do you not think a better place for a dam would be below the junction of Little and Big Wheeny? I think it would be, to dam the water back and do nobody any injury.
- Compensation. 10760. Do you not think that would largely supplement the supply? Yes, it would.
10761. Have you any idea what the compensation would be for owners of land just around the junction; there are one or two blocks sold there? If you mean for being smothered out, I do not think you need trouble much about that. You could not make the land of any less value than it is at present. I should be very easily dealt with myself; the Government might give me some land elsewhere for that which would be flooded out.
- Macdonald and Colo Rivers. 10762. Do you know whether in 1867 the Macdonald and the Colo were in high flood at the same time? I believe they were.
10763. Would not that account for the backing up of the water in 1867? It may. I should like to mention one little thing which occurred during the last flood; I was standing near Richmond Bridge during the 1867 flood, the water having been 52 feet above the deck, and gone down about 15 or 20 feet; there was a sluggish current. All of a sudden, the bank on one side began to move, with a roar like the sound of artillery; there was a narrow opening through which about 2 acres of land kept sailing out, and this came bodily out of the opening of about 50 yards, at a depth of about 40 feet; and we could see the trees gradually disappearing.
- Soil. 10764. *Vice-President.*] What was the nature of the soil? All alluvial. It seemed as if some large animal, or else the water itself, was underneath carrying it out. It was a most remarkable thing to look at, and it was wonderful to see trees 40 feet high sailing out and gradually disappearing; I saw that twice. About 2 acres of land all came out through the narrow neck. The occurrence occupied about twenty-five minutes.

Mr. T. H. F. Griffin, manager of Commercial Bank, called in and examined.

- Mr. T. H. F. Griffin. 10765. *Vice-President.*] How long have you resided in the district? Only eight years.
- 17 April, 1886. 10766. And during that time you have had exceptional opportunities of judging of the prosperity of the residents? Yes, pretty good.
- Farmers. 10767. What is the general characteristic of the farmers here, are they prosperous—would you say this is a prosperous district? Yes.
- Floods. 10768. The farmers generally are well-to-do? Yes, they are fairly well-to-do.
10769. In your experience what effect have the floods had on the farmers generally? I have seen only one flood in eight years, and that was more than six years ago; the effect of that flood was not very severe. I was anticipating, when I saw the water coming up, that it would smother everything, and that there would be a great disaster. I found, however, that it was not so. The farmers were not very adversely affected; they lost their spring crops. Many of them told me that it enriched their land, and did a great deal of good. It was not a severe flood; the water backed up quietly and did not seem to do much damage.
- Droughts. 10770. What has been the effect of the late drought—has it militated seriously against the prosperity of the people? I do not think it has particularly; the rainfall has been pretty equal the whole time. The chief effect, in my opinion, is the draining of the underground sources of supply, the wells on the high land going dry. The lucerne crops do not get the supply which is necessary; lucerne strikes its roots to a great depth and the underground supplies which the roots used to reach have been drained away.
- Rainfall. 10771. How does the rainfall of the last few years compare with the average rainfall of the district? It has been considerably under the average, judging from Mr. Tebbutt's observations, for perhaps twenty years; the average is 26.137. The heaviest rainfall in the five years has exceeded 31 inches only by a little. The heaviest rain since Mr. Tebbutt has been taking observations—I think since 1862—was more than 70 inches, and that was in 1870. The rainfall of 1870 was rather more than that of the year 1867, the year of the great flood.
10772. Do you think that in dry seasons the quantity of rain falling at different times makes a considerable difference in the effect the drought will have—what I mean to say is, that, in seasons of drought, is it that the rain comes at a number of times in small quantities, or is it the reverse, that it comes seldom, in large quantities? No, it comes so seldom and in such small quantities. I may say that in the month of August, 1885, there was no rain at all, and the two previous months there was little more than 1½ inch. During the months of July, August, and September there was less than 1½ inch. (*Appendix C.*)
10773. In times of drought like this do you find that the rain falls at a number of different times instead of at one time: we find in the western district that, in times of drought, although we get nine or ten inches of rain, it is spread over such a number of times, and comes in such small quantities, that it is of no benefit? In 1884, although it was a very fair year, there were so many light falls of rain that it almost evaporated before it could penetrate the ground; it had no effect whatever. No doubt, we should have fine crops here if we had 15 inches of rain coming in large doses at proper intervals.
- Wells. 10774. Have you had any experience of wells in the district? I have only examined two wells that have been sunk here during my residence. They struck water at a depth of about 45 feet in clay or sand, but no boulders; there were a few small stones weighing perhaps an ounce or an ounce and a half. Two wells have been sunk recently in the ridge where this town stands, and a well has been sunk on the low land about a quarter of a mile from here in a straight line; the water was struck there in clay about 10 feet below the surface, and the supply was very good. This was on the property of Mr. Eather.
10775. Have you any reason to think they would get water at a shallow depth like that on the flats? Yes, I am sure of it.
10776. Where a windmill could be used? Yes. A well was sunk on the property of Mr. Bowman recently, and the miner sinking it, when he got down to a depth of about 12 or 15 feet, was loosening the clay with a crowbar, which he drove down into the ground at his feet; a rush of water then took place through the hole, and they had to abandon the well; the water shot up in a stream as thick as a man's arm.
- 10777.

10777. Is the water good, and would it be fit for stock? Very good for stock, but it is rather brackish. Mr. T. H. F. Griffin.
10778. It would not be suitable for irrigation? I could not say. I do not think it is sufficiently salt to be unsuitable for irrigation. All the wells here on the high and low ground are alike in that respect; they are more or less of a mineral character. 17 April, 1886.
10779. Do you think any comprehensive system of irrigation might be carried out by Government, or by a local Trust? Undoubtedly so. Irrigation.
10780. Do you think people would be willing to pay so much per acre towards the interest on the outlay? I think they would be very glad to do so. Water-rate.
10781. What is your opinion as to the best way to carry out such works—do you think that it ought to be done by the Government, or under a local Trust? I should think a local Trust. Trusts.
10782. And in your opinion there would be no difficulty, if the Government or a local Board were to levy such a rate upon the land in the district as would return a reasonable sum towards the interest on the outlay? I should imagine not, seeing what the results of irrigation in other countries have been.
10783. What experience have you had of irrigation in this district? Only Chinamen's gardens; they show what can be done by irrigation on a small scale.
10784. Has there been any scarcity of water in the district for stock in consequence of this drought? Undoubtedly; the lagoons and waterholes have almost dried up; wells in the town have gone dry in consequence of the continual droughts and the gradual slackening off of the rainfall. apply of water.
10785. *Mr. Gipps.*] What is the average depth of the wells on the high land? They vary very much; two I speak of struck water at from 45 to 50 feet, and there are others more than 60 feet deep. Depth of wells.
10786. Are those at 60 feet on the same level? No, rather higher.
10787. What I want to know is whether you can get water at the same level throughout? I imagine so.
10788. What is the stratum? In the last two cases the stratum was clay; there is nothing like drift, no boulders, but small pebbles. Stratum.
10789. Does it seem to be clay from decomposed shale? No, blue; inclined to white here and there.
10790. *Mr. Donkin.*] Which do you think would be the most feasible site for a reservoir, on the Grose or the Wheeny? I do not know much about the Wheeny; the Grose at present is scarcely capable of water storage. I should imagine that below the Vale of Avoca a dam 80 feet would be sufficient to irrigate all those flat lands. Reservoir.
10791. Do you know how the discharge of the Grose appears as compared with the Hawkesbury at the present time? No; of course, the watershed is much smaller than that of the Hawkesbury, and it is fed by nothing like the number of streams. Discharge of Grose.
10792. Is the water of very good quality? Beautiful water.
10793. *Mr. Townsend.*] Do you not think that the clay is clay that lies on the drift? I have no doubt this flood-land and the land behind it are of riverine formation; within a short distance from where we are now sitting there are large deposits of water-worn pebbles of the same nature as those you pick up on the river bank. Formation of drift.
10794. Do you know anything of the wells between Castlereagh and Penrith? Nothing. Wells.
10795. Do you know whether the water from the wells improves by use? I should not like to give an opinion. Generally, a well in constant use is said to improve; but I have no experience of wells; my own water-supply is from rain conserved in tanks.
10796. You have no means of knowing what quantity of land in the district could be improved by irrigation? No. I could only say that it must be a great many thousand acres.
10797. *Mr. Donkin.*] Ten thousand acres? Yes, quite that.
10798. *Mr. Murray.*] Are the farmers here mostly tenant farmers, or owners? Mostly tenants. Tenants.
10799. What is the average rental they pay? From £1 an acre for poor land up to £2 for good land. Rents.

Mr. Wm. Lamrock called in and examined:—

10800. *Vice-President.*] How long have you been residing in this district? For 44 years. Mr. Wm. Lamrock.
10801. During that time, of course, you have seen a number of floods? A great number. 17 April, 1886.
10802. What has been your general idea of those floods—that they were detrimental or beneficial to the district? The greater part I think have been beneficial. I was in Windsor at the time of the 1867 flood, and when I came home, I went up the bank of the river towards the Grose, and I saw that it had done a great deal of harm there to the farms. The silt went over the top of the fences; we could not see the fences of the farms, from the bridge up to Yellow Mundy. Floods.
10803. That was the only case in which severe damage had occurred? Wiseman's Ferry was very much silted up. Silt.
10804. But generally, floods have been rather beneficial than otherwise? When they have come to a moderate height, and left a coating of silt.
10805. Do you know of any particular reason why that flood was so high in 1867? There was a very heavy downfall of rain, and I have heard it said there was a very high tide at the mouth of the Hawkesbury, and the east winds were blowing so as to dam the water back. Causes of flood.
10806. And that flood silted up the river so much as to change its course? I do not think that flood did so much as subsequent floods. During that flood, I came in a boat from Mr. Town's place to the "Royal Hotel," after it had begun to subside.
10807. Have you ever thought out the question of irrigation, that is, as to whether it would be very beneficial to the district? I know that a good scheme of irrigation would be beneficial. Irrigation.
10808. Have you had experience that would lead you to think so? No; but I have the opinion of a practical farmer at Freeman's Reach, Mr. Conlon; like Mr. Pitt, he has a windmill, and he grows splendid crops. He grows more lucerne on 10 acres, than you would on 50 acres without irrigation.
10809. Therefore, you have come to the conclusion that it would be exceedingly beneficial to the district if any extensive system could be adopted? I have not the slightest doubt about it.
10810. Do you think there would be any difficulty in levying a rate to pay the interest on the outlay? I think people do not like paying taxes, as a rule; but if they were compelled to do it, they would soon get into the way. Water-rate.
10811. What quantity of land do you imagine there would be in this particular district that could be brought

- Mr. Wm. Lamrock. brought under irrigation? I suppose it would only be the low lands of the Hawkesbury; you could not irrigate the Kurrajong.
- 17 April, 1886. 10812. What quantity? I have not the slightest idea, but an immense area.
10813. More than 10,000 acres? Oh, yes; more than 50,000 acres on the Hawkesbury.
- Supervision of works. 10814. What principle would you favour for having large works of this sort carried out—should it be done by the Government, or by a Local Trust? I really do not know; I think it ought to be under a Commission appointed by the Government; local bodies do not act very well, except for particular towns or properties of their own.
10815. I suppose you have not seen any place, or had your attention called to any place which would be a good one for conserving large quantities of water? I could not add anything to what Mr. Pitt has told you.
- Wells. 10816. Do you know anything of the wells? I know there are wells in the town. Some 20 years ago, there was a well sunk at the back of the "Royal Hotel" in Richmond, and there was an oak log found, before they came to the water, about 20 or 30 feet deep.
- Supply. 10817. You do not know anything about the quantity of water tapped by that well? No; I heard that a well beside here, and several other wells in the town have been dry. There is good water in these wells, but it is not like rainwater; it is used in preference to the lagoon.
- Crops. 10818. What is about the average crop of corn to the acre in a fair season? I think Mr. Pitt's estimate rather low; I think 60 or 70 bushels in fair seasons.
10819. Mr. Pitt's estimate was that 40 bushels would be the average of good and bad seasons? Well, that is not far wrong; 60 bushels is a fair average in fair seasons.
10820. *Mr. Gipps.*] What crop at each cutting? A good crop is a ton to the acre.
10821. *Mr. Murray.*] What sort of crops do you grow? Oranges.
10822. Your land is on the Kurrajong Heights? On the slopes.
10823. Then, any irrigation system would not affect your land? No, unless it was from the Wheeny Creek.
- Wheeny and Grose. 10824. Would that supply your district with water? I think it would be made to supply it. The Wheeny Creek and the Grose River are the only two good sources of water on the Kurrajong that I know.
10825. Is any corn being grown on the Heights? I think not; I have grown maize, but it does not pay to grow corn.
10826. I suppose it is principally fruit that is grown on the Heights? Yes.
10827. *Mr. Gipps.*] Are the banks of the Grose alienated for any distance up? I do not know; I do not think so. A man had a place up near Blackheath. I think that the Grose starts from about 25 miles beyond Mount Tomah, that would be the head of the Grose.
- Alienated lands. 10828. Lower down, as far as boats can reach, is that alienated? The greater part of it is.
10829. And beyond that? It is Government land beyond.
- Timber. 10830. Has much timber been cleared off in this district? Yes, an immense quantity; they are taking timber now from the Kurrajong Heights.
- Rainfall. 10831. Does the destruction of timber appear to influence the rainfall? No.
10832. Does the rain come during several days, or does it fall more in thunderstorms? Last year, we had thunderstorms; this year, we have had none.
10833. Is there much fever in this district, or in the town? I do not know; I have heard that there has been typhoid.
10834. *Mr. Donkin.*] The rainfall in the Kurrajong is greater than in Richmond? It is, on the Heights—at all events, I think it is, as a rule.
10835. You were speaking of the Grose, the catchment area is reserved, is it not? I heard it was reserved for a railway route.
- Irrigation of orange-trees. 10836. Have you ever known the Kurrajong water to be used for the irrigation of orange-trees? No.
10837. You do not know what the effect would be? It would be very good, I have not the slightest doubt.
- Dairying. 10838. *Mr. Townsend.*] Do you think, if the water were applied in any quantity that the people would abandon crop-growing for dairying and fruit-growing? They might for fruit-growing; but as for dairying, there is such a scarcity of labour here, it is doubtful whether it would pay. Dairying ought to pay now better than growing crops.
10839. *Vice-President.*] You said that your principal crop was oranges, do you grow them to any extent? My son and I have 56 acres between us.
10840. Do you think it would be beneficial if you could irrigate them? Yes; some of the trees were without leaves before the rain came. It was only by keeping the land well cultivated and loose, that the trees have been kept alive.
10841. Do you know that a new principle has been adopted in America in irrigation, by means of which pipes are used, enabling good results to be obtained with the use of a very small quantity of water? No, I do not know anything of that system. I find that, by proper drainage, the more you drain land the more moisture you create.
- Value of orange crops. 10842. *Mr. Gipps.*] What is the value of the orange crop? I had 35 acres last year, and I got £600 for them. Mr. Cleeve had about the same quantity, but a better crop; he got £800.

Mr. Arthur Dight called in and examined:—

- Mr. A. Dight. 10843. *Vice-President.*] Have you been long residing in this district? Nearly all my life, within 1½ mile of Richmond.
- 17 April, 1886. 10844. Then you have had very considerable experience of the floods? I never took a note of them; I did not keep a diary. The only thing I made a note of was the 1867 flood; that surpassed all the others.
- Floods. 10845. Have you any idea as to what height that rose above the natural bed of the river? Mr. Tebbutt said it was 15½ feet higher than any previously recorded flood.
- Benefits. 10846. In your experience have the floods been beneficial to the district or otherwise? The land certainly is improved, but it is at the cost of the crop for a year. It is paying rather dearly for the good done. I had an idea of keeping a model farm, but the floods put me out of heart altogether.

10847. Then, as a general rule, there has been very much loss in consequence of the floods? There is no Mr. A. Dight. question about that.
10848. More than was compensated for by the benefits arising from the floods? Yes. During the last 17 April, 1886. eight years we have had no floods, and we have suffered from the other extreme.
10849. To the same extent? No, not to the same extent.
10850. What is the nature of the land in this district generally—is it rich alluvial soil? All alluvial on Nature of land. the flats. There is some good soil on the high land, and some very useless.
10851. Have you had any experience of irrigation? None whatever.
10852. It is your opinion that the land could be made to produce very much larger crops by irrigation? Irrigation. Well, on the flats a week after you had gone to the expense of irrigation you might very likely have a flood. Of course, that would not apply to the high lands.
10853. What are the crops grown in this district generally? Maize and horse-provender. Crops.
10854. What is about an average crop of maize? We consider 60 bushels rather above the average; still, Maize. I have seen 100 bushels.
10855. Has the quantity been materially lessened during the droughts? I think so.
10856. What would you think the average crop would be this year? I have not been amongst it; I cannot answer that question. I have discontinued farming.
10857. Have you heard that there have been many failures of the crops this year? I am told that the earlier corn is very good, but the latter crops are an entire failure.
10858. In consequence of the drought? Yes.
10859. What do you consider an average crop of lucerne here? I question whether, these last two summers, Lucerne. they have had much more than half a ton on the average.
10860. How much per annum? Four or five cuttings a year; from 2 to 2½ tons per acre per annum.
10861. What would it be in a fair season? From 20 to 25 cwt. each acre four or five times a year.
10862. More than double? Yes.
10863. You are of opinion, then, that the high lands would be more suitable for irrigation than the low lands? I think it would be more profitable.
10864. After the floods have left, has the land benefited considerably by their deposit? There is always a Flood-deposits. deposit which enriches the soil.
10865. Have you noticed that after the flood you have had better crops for several years running? It depends upon the tillage; you can go in depth and get fresh alluvial. If a person could arrange to have the land flooded every four or five years, especially if he knew when the flood was coming, it would be very beneficial.
10866. Do you think farmers here would join in a scheme for the irrigation of their crops? I think they Irrigation. will require to be educated up to it; each one will want to see the result of some other person's experiments.
10867. In spite of the floods and droughts, are the farmers here generally a well-to-do class? I think they are; they are a very frugal people; you rarely see an insolvent in this district.
10868. What is the rent of land for farming purposes? From 10s. to £2 an acre. Rent.
10869. What is about the size of the farms here? They are generally small farms. Farms.
10870. How many acres? All along the bank of the river nearly 30 acres; but the floods have swept away 3 or 4 acres. I think there are more farms from 20 to 30 acres than of any other size.
10871. Can a family make a living on 25 to 30 acres? Many are better off in service; but they are their own masters, and they manage to grub along.
10872. Is that the order of things here generally in regard to these small farms? As far as I am aware, it is.
10873. I suppose you could not give information as to the best sites available for the erection of dams? No.
10874. Do you know anything about wells in the district? No.
10875. *Mr. Murray.*] Are they mostly tenant farmers? Mostly tenant farmers. Tenant farmers.
10876. Who are the large landowners? Well, I think Town and myself are the largest holders of flooded Landowners. land within 10 or 12 miles of this place. Town occupies nearly all his land himself; he has a large stud of horses; but he rents other lands.
10877. If the large landowners saw their way to increase the value considerably, so as to get a higher rent, Water-rate. would they not pay the interest on the outlay? They would require to be educated on the matter. My opinions are rather crude on the subject; I felt diffident at giving evidence here at all.
10878. *Mr. Gipps.*] How many years did you say you had lived here? Ever since I was born.
10879. Are the droughts more frequent here of late years than before? No, I think not; when I was a Droughts. child, I recollect, there was not sufficient moisture for the people to grow wheat.
10880. You have known worse droughts than the present? I have known quite as bad, at all events; I have known that large reach near the railway bridge at Penrith very shallow, and covered thick with weeds.
10881. Has much timber been taken off? These flats originally were very heavily timbered, but in many Timber. cases they were let to little farmers for a certain number of years to clear, and everything was felled and burnt off.
10882. Is timber being taken now? There is very little left that is any good.
10883. Do you think the denudation of the forests has influenced the weather at all? No, I do not think so. Denudation of forests.
10884. *Mr. Donkin.*] Has the river altered its course to any extent? It has widened it considerably; the River. bank has been swept away; it is now nearly twice the width it used to be.
10885. And it has silted up? Yes.
10886. Do you think the next flood would scour it out? You never can tell; I should doubt it. I am Scour. told the tide used to run up to nearly 2 miles above the bridge, but that there is no tide there at all now.
10887. Do you recollect the year of the first flood in the Hawkesbury; the first description, I think, was First Hawkes- given in an illustration in the "Life of Margaret Catchpole"; do you recollect that year? I think that bury flood. was in 1809 or 1810, ten years before I was born.
10888. You recollect her living here? No, I do not; but she attended my mother at my birth, I believe.
10889. *Mr. Townsend.*] What is the character of the land you described as useless soil? A kind of pipe- Useless soil. clay and iron gravel.
10890. Is there a great quantity of loamy soil between here and Castlereagh? No; there is some particu- larly sandy land; I do not recollect any loamy.
10891. With water that land would grow almost anything, would it not? With water and manure; but it is poor itself.

- Mr. A. Dight. 10892. Do you not think that by the irrigation of the higher lands the low flats could be supplied by soakage? The foot of the ridge is lower than it is beyond.
- 18 April, 1886. 10893. Yes, but the water would soak along? Not without being conveyed.
- Drought in 1838. 10894. *Vice-President.*] Was that great drought you spoke of in 1838 or 1839? In 1838. Wheat went up to £1 a bushel. I might remark that the 1864 flood was the highest I had ever seen at that time. I saw Mr. George Bowman, and I asked him whether it was as high as the 1816 flood; and I recollect my father saying he had swum to the river, and that he could put his foot into the water at the back and front of his house, but it did not come inside. I asked a tenant whether it came into the house, and he said "No." I asked George Bowman whether it was as high as the flood of 1816, and he said, "When I get to my father's farm I can tell exactly;" but he said afterwards it was not so high by 6 or 7 inches as the 1816 flood; so the 1864 flood was the highest flood after that of 1816.
- Highest flood. 10895. Did that great drought of 1838 terminate in any floods in 1839? I cannot recollect; it was over my low lands thirteen times in one year.
10896. *Mr. Murray.*] Was the flood of 1864 higher than the flood of 1870? I cannot answer that question.

Rev. Dr. Cameron called in and examined:—

- Rev. Dr. Cameron. 10897. *Vice-President.*] Have you been long in this district? I have been here since 1856—thirty years.
10898. Then you have seen some of the floods that are so much talked about? Yes.
- 17 April, 1886. 10899. Is it your opinion that these floods are detrimental to the district? In the first instance they have been, but ultimately beneficial.
- Floods. 10900. You think there is more than a compensating balance? I think so; before I came here, I was told there had been no floods for fifteen years of any consequence. The 1864 flood was the first I saw, and the yield of the soil, which had been about 100 bushels per acre, had gone down to about 15 bushels per acre. After that series of floods, the soil came up to its original fertility, yielding as much as it had done before, from 80 to 100 bushels per acre.
10901. Was the reduction of the crops caused by the soil being worn out, or the want of moisture? I should think that it was due to the constant cropping without the soil being replenished in any way. I think floods have a marvellous effect in restoring the fertility of the soil.
10902. So that the farmers would look forward to a flood as improving their farms? It would do good, if they were prepared for it. Of course, the floods are very destructive in the first instance.
10903. Was the 1864 flood a very high flood? Yes.
10904. Not so high as the 1867 flood? I did not see that in 1867.
10905. What floods were there between them? We had a series of floods, sometimes two or three in one year. We had a sort of cycle of wet seasons that produced floods.
- Cycle of wet seasons. 10906. Do you look upon the farmers of this district as a thriving, prosperous class? I think they may fairly be regarded as such. I have heard that if they could calculate on good seasons—if they could get one good year out of three—they could do very well, the land is so productive.
- Yield of crops. 10907. Do you know what quantity of corn per acre they get on the small farms? I should think, in fair seasons, about 80 bushels per acre. I have heard of their getting 100. I do not know what is the average this year.
- Irrigation. 10908. Is corn more profitable to the farmer than lucerne? I could not say.
10909. Have you heard the question of irrigation mooted in the district? It has been more a question of water-supply for the towns of Richmond and Windsor; that is what we are more interested in.
10910. You have had no personal experience of irrigation? No, except of irrigation by Chinamen; they have given us practical experience of what irrigation will do.
- Wells. 10911. Do you know anything of the wells in the district? Yes.
10912. Do you know of large supplies of water having been made available from wells? This last year has told upon most of the wells; a great many that never went dry have gone totally dry during this drought.
10913. To what depth have the wells been sunk? 50 or 60 feet.
10914. Do you know of any shallow wells on the flats? Mr. Town recently put one down on Mr. Bowman's farm to a depth of about 30 feet.
10915. As far as you know, they have never been taken advantage of for irrigation purposes? No; the water is not particularly good, it is rather brackish.
- Town water-supply. 10916. *Mr. Gipps.*] What are the present proposals with regard to the water-supply of Windsor and Richmond? I have heard of four. I think there is the Government scheme, which is to pump water up into a reservoir near Clarke's Hill, then lay it on by gravitation to supply Richmond and Windsor and the intermediate district; then I have heard of another proposal, to pump the water up on this side, to save the reservoir, and lay it on in that way on a sort of arrangement such as they have in America, I understand—to pump it up into a tank and then let it flow from that; then there is the Prospect scheme, and the Grose scheme.
- Population. 10917. What is the population of Richmond? By last census the population of Richmond was 1,239.
10918. And of Windsor? I think about 1,900.
- Supply. 10919. How are they supplied with water at the present time? We have tanks underground and wells. A very large number of people depend upon that miserable lagoon there, which is really not fit for human use at all.
- Water-casks. 10920. How do they get the water? By pumping it into water-casks and taking it round.
- Water-rates. 10921. How much do they pay for the water? They get it free; the lagoon belongs to the municipality.
10922. You think that if they got a proper and sufficient water-supply they would be willing to pay rates for it? Yes; well, I would not say anything as to their willingness to pay rates, but I have not the slightest doubt that, if a good supply of water were furnished to the town, they would very soon begin to feel the benefit, and pay the rates ungrudgingly.
10923. How many houses are there in Richmond? I should say between 100 and 200.
10924. With an average of four rooms? I should say so.
10925. *Mr. Donkin.*] You know the Colo River and the Wheeny Creek and the Grose? I know Little Wheeny; I cross it every week.
- Little Wheeny. 10926. Which of those sources do you think would be the best for water-supply? It has often struck me, in crossing Little Wheeny, that there is sufficient water there to supply both these towns. It is a running stream of beautiful, clear water all the year round, and there is sufficient height there. No doubt, the Grose
- water

water is quite as good, and there is a large supply ; but I do not think you could get the elevation unless you went further up. I think we could more easily get the water from the Wheeny Creek than from the Grose. Rev.  
Dr. Cameron.

10927. I suppose you have known the Grose for many years? Yes. 17 April, 1886.

10928. Have you ever known it to be dry? Never.

10929. Would there not have to be a great deal of tunnelling to bring it from there? I suppose there might be.

10930. *Mr. Townsend.*] Do you know anything of Castlereagh? Yes.

10931. Do you know whether water from wells is used there for irrigation. I do not; I have not been there of late years.

10932. I want to know whether the water obtained there is fit for irrigation? I could not say.

MONDAY, 19 APRIL, 1886.

At Windsor.

Present:—

Mr. BARTON, M.P.,  
Mr. DONKIN, J.P.,

Mr. GIPPS, C.E.,  
Mr. MURRAY, M.P.

RUSSELL BARTON, Esq., M.P., VICE-PRESIDENT, IN THE CHAIR.

Mr. Benjamin Richards called in and examined:—

10933. *Vice-President.*] How long have you been in this district? All my life; I am now sixty-eight.

10934. Will you tell us what your experience has been of the floods since you can remember? I think it was about fifty-five years ago since the first flood of which I have any distinct recollection, viz., the early part of 1831. Mr.  
B. Richards.  
19 April, 1886.

10935. Was that a high flood? Not a very high flood; a fairly large one, but nothing like what I have seen many times since. Previous to that flood there was a three years' drought; after that we had several floods at short intervals. I cannot tell exactly the date, but in 1831 there was a flood, and in 1834, and in 1835, and another very dry season. Flood.

10936. Do you remember at any time several years passing without floods? Yes.

10937. Can you tell me about what time they were? I cannot tax my memory to that extent, but I think you will get that information from others.

10938. What has been your experience of the floods—have they been very destructive in the district? They have been destructive, but as a rule not so very destructive. The larger ones—such as those of 1857, 1864, 1867—were destructive. Effects.

10939. Those are the three largest you remember? Yes.

10940. Were they very destructive to the farmer? Yes.

10941. On account of the great height, and their coming at a time when the crops were nearly ripe? On account of the great height—the 1867 flood particularly. I cannot say the others did any great amount of damage.

10942. I suppose there were more crops on the soil in 1867 than in 1857? I will not say that; I question it, because I do not think that agriculture has been on the increase. I think, even as far back as 1835 and 1840, we produced as much in this district as we do now.

10943. It is only very high floods that do harm in the district? That is all.

10944. Is there any benefit derived from the floods? Yes, I think so.

10945. To fully compensate you for any loss, the crops being increased for the next few years? When the floods come, they injure the crops; but that is really no very great loss, because they improve the soil.

10946. Have you ever experienced as great a drought as this before? Yes; I think that from 1828 to 1831 was the greatest drought that ever I remember. I was very young, but I remember the circumstances of that drought; I know that no one had anything to feed stock with, and that they dug up the roots of the couch-grass to feed them on. Droughts.

10947. Was that a more severe drought than the drought of 1838 or 1839? I think so.

10948. How long did these droughts continue? I only go by what I have heard. The old hands call it the "three years' drought." One year we were devoid of a wheat-crop altogether, and next year it was only partial, but the rain came late in September, and it just brought about half a crop.

10949. Has there been much loss in the district in consequence of this last drought? I think so. Loss.

10950. Have there been any crops this year at all in the way of corn? I think about half a crop. Crops.

10951. What was it last year? It was better last year.

10952. And the year before? I think about three years ago we missed the corn crop.

10953. You think there has not been more than half a crop this year? I am positive not more.

10954. What do you consider a crop in a fair season? About 50 bushels to the acre; I think that a good average crop. Some of the flats may yield more, but these are exceptional.

10955. At that rate you would not have more than 25 bushels to the acre this season? I do not think so. That would apply to my own, and that is reckoned as good soil as any on the Hawkesbury.

10956. Has the lucerne been affected in the same way? Yes, more so; I do not think we have had one good cut this year.

10957. In fair average seasons, how many cuts of lucerne do you get? Four or five cuts.

10958. What is a fair crop? About a ton.

10959. *Mr. Gipps.*] A ton of hay, or of greenstuff? A ton of hay.

10960. *Vice-President.*] Have you had any experience of irrigation? I have not. Irrigation.

10961. And you have not seen it at all? Not to any extent.

10962. What is your opinion of it? I think it would be very desirable.

10963. Do you think it would enhance the value of the land by producing greater crops? Unquestionably.

10964. Do you think, from your experience here, that if the Government were to propound a scheme of irrigation, there would be any difficulty in levying a tax upon the land to pay interest on the outlay? I do not think so. Water-rate.

10965. What would be your opinion as to how it should be managed—do you think it should be managed by a Government Department or by a local Trust? I think a local Board. Local Trusts.

- Mr. B. Richards. 10966. A Local Government Bill has been before Parliament for some time—if that were carried, do you think it would assist to establish these local Trusts? I have not read myself up in that matter.
- 19 April, 1886. 10967. Do you think local government a good thing—where you can levy your own taxes, make your own rates, and spend the money yourselves? Yes, I think so.
- Irrigable area. 10968. Have you any idea as to what quantity of land there is in this immediate district which could be put under irrigation? I think nearly the whole of it.
- Storage. 10969. Do you know of any places where large dams could be constructed to conserve large quantities of water for irrigation purposes? I could not point out any places in particular, but I am certain there are plenty of natural reservoirs where water could be conserved.
10970. You do not know of any particular one? I think all our rivers and creeks could be dammed and made to conserve water. There is any amount of high land where there are natural watersheds and running streams.
10971. You have not gone into the matter sufficiently to be able to state that there are any particular places? No.
- Crops. 10972. I suppose maize and lucerne are the principal crops? Yes.
- Dairying. 10973. Is there much dairying done here? Very little, I am sorry to say. I think it would be a step in the right direction.
- Fruit growing. 10974. Is there any great quantity of fruit grown? Not a great deal.
10975. That is another thing that is neglected? Yes.
- Course of river. 10976. During your knowledge of this district, has this river altered its course very much in consequence of floods? Yes; there have been large landslips.
10977. The flood of 1867 is the one which silted up the river, is it not? Yes; it did the greatest damage.
10978. Had you ever known any large floods to silt it up before that, and smaller ones following and opening it out? No; I cannot say I have any distinct recollection of it.
10979. Is it your opinion that if we get a series of small floods it is likely the whole body of the river would change? I think it would take the proper channel.
- Tides. 10980. We have had in evidence that the tides, many years ago, used to rise as far as the Grose? Yes; the confluence of the Grose with the Nepean River.
10981. How far do they go now? I do not know whether it rises so far now.
10982. Can you give an opinion as to the cause of that very high flood of 1867,—was it simply in consequence of tremendous rains at the time, or was the water held up by strong winds and high tides? I could not say; we had very heavy rains at the time—the heaviest I ever experienced.
- Silt. 10983. *Mr. Murray.*] In the silting up, is the silt always of the same character? I think so. I have never noticed anything but sand.
10984. Any alluvial deposit? No; I have not noticed that.
10985. Is the sand beneficial to the land? No; it fills the bed of the river.
- Deposits on farms. 10986. Is the deposit which is left on the farm, as a rule, silt or sand? It is generally silt. In 1867, there were some spots where sand was left, which were very much damaged; that was noticeable about Yarramundi, but it is not very general. Many farms that were comparatively poor before the flood of 1867 have been good farms ever since, simply because of the deposit which was left. In one or two cases, where the land has been covered with raw sand, the farms have been of little value since.
10987. Are they principally tenant-farmers here? Yes, most of them.
- Rent. 10988. What rent do they pay? From 30s. to 40s.
- Landowners. 10989. Is the land held by a few or a great many landowners? By a great many; there are no very large landowners in this district.
- Water-rat 10990. Do you think those landowners would be willing to contribute towards the interest on the outlay upon a system of irrigation? I am an owner of land, and I should be willing.
10991. You think that irrigation would enable you to get larger crops? Yes; any one who would stand out and refuse to accept irrigation would have to give up farming, because he would not be able to compete with farmers on irrigated land.
10992. *Mr. Gipps.*] Where do you derive your water-supply from? The river.
10993. Is it ever brackish? Not to my knowledge.
- Wells. 10994. Are there many wells in the district? About the towns, but not very many; there are more in Richmond than in Windsor.
- Depth. 10995. What is the average depth? 40 or 50 feet in Richmond. Many people in Richmond have put wells down and they tell me they go that depth and, as a rule, get very good water.
- Stratum. 10996. In what stratum? Mostly on the boulder.
- Windmills. 10997. Are there any windmills in Richmond? I have one; I do not think they are much use.
10998. No good? They are good as far as they go, that is, when the wind blows; they are not regular.
10999. What is the size? From 12 to 14 feet.

Mr. J. B. Johnston called in and examined:—

- Mr. J.B. Johnston. 11000. *Vice-President.*] How long have you been a resident in this district? Since I was born, 1809.
- 19 April, 1886. 11001. What is your experience in reference to the floods—have you found that the high floods do considerably more damage than the smaller ones? There has only been one flood in my experience that did much damage; that was an exceedingly high one, the 1867 flood.
- Floods. 11002. Have the floods been rather beneficial than otherwise? In many places they have been very beneficial; for instance, I have a piece of land over the creek here, which is very low, in fact, it used to be always under water many years ago. Well, that high flood brought down silt and left it 2 feet deep all over it. That raised the land and improved it.
- Effects. 11003. Do you find, when there is a series of years without floods, that the land becomes poor? Well, it will not produce such large crops.
11004. But then it is enriched by the next flood that comes? Yes. Two years, last September, there was a small flood, it just went over the low land about the river; it went over that low land of mine across the creek. The consequence was, that during this exceedingly dry season, we have had five good cuttings of lucerne. Although the floods will damage the crops that are on the land, yet when they come, they prove beneficial in following years.
- 11005.

11005. As a general thing, have there been light crops this season? Very light in the neighbourhood of Windsor; down the river and that way, they have had good crops because they have had rain.
11006. Have you had any experience of irrigation? No, nothing worth speaking of, except with reference to Chinamen who water their gardens. It strikes me that plants require water above ground, as well as below the surface, to supply the deficiency of atmospheric moisture.
11007. Do you find that when irrigated the land produces much larger crops? Yes.
11008. Do you think that, if any scheme of irrigation were adopted over a large area in this district, it would be very beneficial? It would be very beneficial, if the people could be got to adopt the system and carry it out.
11009. Do you think there would be any difficulty about that? I cannot say.
11010. You think they would require educating up to it? I think so; people follow the old plan of growing corn and trusting to Providence for better times to come.
11011. I suppose that if it were shown to these people that, by a system of irrigation, they could produce three or four times the quantity of grain, or double the present quantity that they do now, they would be willing to pay for the privilege of using the water? One would think so.
11012. Do you think a system of irrigation would be managed better by a local Trust or by the Government? I should think by the Government; but, of course, local authorities would know better when the thing was required and when it should be applied.
11013. I mean, would it be better for the carrying out of large works, for the spending of money in the district, and for making laws to govern the system? That is a matter that requires a great deal of consideration. In the first instance, at all events, I think it would be advisable for the Government to carry out the works; then they might leave it to local authorities to use them. It is very questionable whether the people in the district would be disposed to contribute sufficient funds to construct the works in the first instance.
11014. Do you know whether there are many wells in the district? I think there are a few.
11015. You do not know whether they touch any large underground currents of water, from which supplies could be drawn for irrigation purposes? No; there is a well here, that I get a supply from; it is very good water, but the supply would easily be exhausted.
11016. Do you know of any depressions in the country, where, by means of dams, large quantities of water could be conserved? Yes, at Pitt Town common, a large amount of water could be conserved at a sufficient elevation to throw it over the land, and also over the Wilberforce side. I do not think there is much difficulty in finding places to construct reservoirs; the difficulty would be to get the work done.
11017. *Mr. Murray.*] Are you a large landowner? No; I have about 200 acres, and that is not all agricultural.
11018. Do you work it all yourself? I do not work any myself.
11019. I suppose you would be willing to contribute towards the interest on the outlay, upon a system of irrigation? I should.
11020. Do you think it would make a great revolution in the farming district? It would make a very great alteration; we could depend upon getting crops when we put in seed, unless floods came and took it away. It is 20 years since we had a great flood.
11021. Do you think that these reservoirs, if made, would be a preventive against floods, through being catchments for the water? To the extent of their capacity they would prevent the floods. Many people were under the impression that the Sydney water-scheme would take a great amount of water, but I do not think it would have any effect on the floods.
11022. *Vice-President.*] Have you not found that in consequence of the water taken for the Sydney supply the water in the river has decreased considerably? No; I do not think it has. In 1840 and 1841, we had three successive seasons of drought; the river was then salt, and the water could not be used, up to the Cattai Creek. I was living on the river at the time.
11023. How far is that below Windsor? About 8 miles.
11024. It was salt to there in that dry season? Yes; it is not salt now up to where I was living, nearly 20 miles below this place; it is not salt to within 30 miles of Windsor; it is a little brackish, but they use it.

Mr. John Tebbutt, F.R.A.S., called in and examined:—

11025. *Vice-President.*] I think you have a record, have you not, of the rainfalls and floods in the district for a long time past? I have a record of the floods since 1856—every flood and every fresh; also a record of the rainfall from 1862 to the present time. They have been published, with other meteorological results, in four parts, and there is another part in the press now.
11026. Will you tell us what has been your experience of the floods? I may say that, if a flood comes in June, July, or August, the destruction, so far as the crop is concerned, is not very great, because the crop is pretty well all gathered in; but in any other month of the year a flood is very destructive. I suppose that the flood of 1867 and one or two in 1870 were the most destructive.
11027. Were there two large floods here in 1870 and 1873? There was a high flood in April, 1870; on the 26th and 27th of February, 1873, the water rose above the flood-mark of April 29 and 30, 1860; the flood of April, 1860, was about 3 inches below the great August flood of 1857; the flood of February 26 and 27, 1873, was a very high flood.
11028. Do you think there is, as a rule, any compensating advantage from these floods, in the shape of improvement of the land? Yes, in some cases; but the drawbacks are perhaps quite as great as the benefits. A rich deposit is left in some instances, whilst in others we have the soil swept away and a sandy deposit left.
11029. Which is the more common of the two? I rather think the destructive element.
11030. Then you think it would be beneficial to the district if anything could be done to prevent these floods? Most certainly.
11031. We have it in evidence from many people that, as a rule, floods are beneficial rather than otherwise? There is one thing to be considered, namely: how would that be done—by embankments, or by clearing away obstructions to allow the water to fall away freely?
11032. Both by detaining the water at higher levels, and also by clearing the channel and removing obstructions? The engineering work would have to be very good, or, if it broke away, it would create more destruction than ever; it would be awful, the water would come down so suddenly.

11033.

- Mr. J. Tebbutt, F.R.A.S.  
19 April, 1886.  
Duration of floods.  
Course of river.
11033. Then you think, taking the floods as a whole, they have done more harm than good? I can hardly decide the matter. It is *in equilibrio*. The floods renew the soil, and we have better crops; but I rather think they have done more harm than good.
11034. What is about the average duration of the floods on the ground; do they vary much in the time they remain? I should say the time is from four to six days; altogether they may take two or three days to rise, and two or three to fall.
11035. Has there been much alteration in the natural bed of the rivers during your experience of the floods? Yes, there has been a considerable alteration; I suppose the channel of the river is changed in some places to the extent of 150 yards.
- Silt. 11036. Is it widened? It is in some places quite removed; the other side was formerly the middle of the river.
11037. Has the bed of the river silted up since you remember? Very much; the reach extending downward from Ben the Fisherman's Point was a splendid one. Regattas were held here; but now there is very little water.
11038. Have you observed that at any particular height of the floods the river was more likely to silt up than at others, or at any particular height to clear it out? No; it has not been cleared to my knowledge.
11039. There has never been any clearing of the river by the smaller floods? Not that I am aware of.
11040. We have been told in evidence at Richmond that the small floods would very likely clear the silt out; have you had any such experience? No.
11041. Do you think it has been a great drawback to the district that the river has been silted up? Yes, a very great drawback; it injures our trade. In the lower parts of the river we should have one or two steamers carrying passengers and cargo if it were not for the silting up of the river.
11042. To Windsor? Yes.
11043. And they cannot do so now? No; very recently a flat-bottomed vessel was in use.
11044. A short time ago steamers used to run up here? Yes; a very large vessel could go up at one time; it was very deep here.
- Droughts. 11045. What has been the effect of the droughts in this district; have they recently been as bad as they were formerly? There have been worse droughts in the past. Some forty years ago there was an extensive drought, and couch-grass had to be dug up and washed for the stock; that has not been done yet in this case.
11046. I suppose at that time there was not much crop in the district? The floods are very destructive; that has told its tale in the large amount of relief extended to the farmers in the district for their losses. We have had several Flood Relief Committees; I have been Secretary myself to two of them.
- Loss 11047. Do you think the floods here have been a source of greater loss to the farmers than droughts? I rather think so, as judged by that.
11048. Of course, whatever compensating balance there may have been in floods, there can be none in droughts? Very frequently we can grow crops here during a drought, the land is so low. On the high lands they suffer severely.
- Rainfall cycles. 11049. Has the rainfall materially altered in the district during your experience? It has been very variable since I commenced observations. I have traced a three-year period, but it has quite disappeared now; I cannot see any more of it. That period must be due to some minor cause. As regards any larger cycle, observations have not been sufficiently extensive to verify it; it is only in recent years that reliable observations have been taken in the Colony.
11050. How far back do your observations go? Only to 1863, as far as the rainfall is concerned; as regards floods, to 1857.
- Clearing of timber. 11051. Do you think that the clearing off of the timber has anything to do with the rainfall? That is a question I cannot decide; there has not been a sufficient number of observations to enable me to say yes or no to that question. I dare say it will be decided in America before long, perhaps in Germany also.
- Irrigation. 11052. Have you had any experience of irrigation in the district? Only as far as my Chinese tenants are concerned; they irrigate from the river, and it is wonderful what a change they effect in their gardens.
11053. By steam? Yes.
11054. Simply to produce vegetables? Yes; they do not go beyond that.
- Effect. 11055. What has been the effect of the irrigation? It is magnificent. Before the gardens were irrigated there was nothing to be seen in them; three days afterwards they were like a Paradise.
11056. Do you think it would have a beneficial effect on the district generally if some large scheme of irrigation were developed? I think so, but I do not know whether the profits would meet the expenses.
- Cost. 11057. Do you know what it has cost these Chinamen for irrigation? I believe the cost of their apparatus is £150 or £160. They have been irrigating four or five acres of land, and they have some more which they have not yet commenced to irrigate.
11058. Do you say the cost of the engine and appliances is not more than £160? That is what they told me.
11059. And that enabled them to irrigate four acres? Yes; the water does not stand upon the land as it does on the rice-fields; they pour it on.
11060. You do not know what the daily cost of irrigation is, then? I do not know what the cost is in the consumption of wood and coal. They had an engineer at £4 or £5 a week, but they soon dispensed with him.
11061. Do you think it would be possible for you to get that information for the Commission? I think I could manage that; I should be happy to supply any written information on the subject.
- Water-rate. 11062. Do you think from your knowledge of the district that, if large irrigation works were established, it would be beneficial to the locality—do you think there would be any difficulty in levying a rate upon the land to pay the interest upon the outlay? I am afraid that farming is not a very remunerative business at the best of times.
11063. Not if you could double the crops? I do not think you could double them.
- Increase of crops 11064. We have evidence from a gentleman here that he is satisfied it would increase the crops four-fold at least? Perhaps a little allowance must be made. In scientific matters we consider bias in a great measure.
- Management. 11065. Is it your opinion that any work of this sort should be under the control of a Government Department or under a local Trust? From my experience I do not believe in local Trusts.
- Local government. 11066. Then you are not of opinion that the proposed Local Government Bill will be of much benefit to the country? The worst of it is that we get so little for our money. If the money were properly expended we should derive a benefit, but it seems to me that local bodies spend more than they ought to do in arriving at a small amount of benefit.
- Wells. 11067. Do you know anything of the under-currents of water in the district? There is one well to my knowledge

knowledge in the town ; it is at the barracks, and I was informed just now by a very good authority that there is 36 feet of water in it. It is brackish, but I think you would find that to be the case with every well within the municipal boundary. If you sink a well on the peninsula, or on the low lands, you get good water.

Mr.  
J. Tebbutt,  
F.R.A.S.

19 April, 1886.  
Quality.

11068. Is the water you get on the low lands fit for irrigation purposes? Yes.

11069. It does not contain salts injurious to vegetation? I think not.

11070. Since the river has silted up are there any extensive waterholes in the river, from which supplies could be drawn, sufficient for irrigation? I have no idea what quantity of water would be required for irrigation. At one time, no doubt, there would have been a good supply. Waterholes.

11071. Do you think that by putting sunken weirs in the old river channel it would stop the flow of water under the gravel, and give us a larger quantity of water for any purposes we may require? I think so. Sunken weirs.

11072. You think there is a large underflow in the silt that filled up the river? Yes; and our rainfall itself might be conserved. An immense quantity of water falls every year upon our soil here. Undercurrent.

11073. What is the average? The average rainfall is 32·8 inches. I will give a statement of the number of gallons. (*Appendix.*) That makes the average slightly over 17 gallons to the square foot. 1884 was a very dry year, drier than 1865. That would amount to 742,000 gallons per acre, and that is an immense quantity of water. I have given the average for 23 years. Rainfall.

11074. Do you know the rainfall on the ranges, Kurrajong—is it much in excess of this? Oh, much. Comrie's is somewhere about 52 inches, I believe; it is pretty nearly the Sydney rainfall. The mountains intercept the clouds, and showers fall that we have not.

11075. Was that rainfall pretty evenly distributed through the district? I may say for 8 or 10 miles round Windsor. Mr. Griffin has kept a rain-gauge for five or six years at Richmond, and his rainfall is almost exactly the same.

11076. *Mr Gipps.*] Did it fall in heavy storms, or in light rains, or at any particular period? Chiefly in winter.

11077. Gradually? Sometimes in heavy falls we have 4½ inches in a day.

11078. *Vice-President.*] Do you find any great difference in the quantity of rain falling at any particular time in wet and dry seasons—suppose you have a rainfall of 30 inches in one year and only 20 inches in another, do you find the rainfall in the year you have had the most was in larger quantities, or that when only 20 inches fell it was divided into small falls that would do very little good? In heavy years the rainfall is made up of heavy rains.

11079. It is not merely a difference between the 20 inches and 11 or 12, but that the 11 or 12 is spread over such a number of light falls that it is of little benefit; this is our experience in the western district, and I was wondering whether it was the same thing here? These heavy falls come at the floods. My return shows for a time a greater quantity every third year.

11080. *Mr. Murray.*] You mentioned that the floods were more destructive than beneficial? I think they are. Effects of floods.

11081. I presume the floods totally destroy the crops, the droughts only partially so? Yes. Another consideration is that, if we have a pretty good flood and the ground becomes saturated, we can stand what we term a drought, on the low lands in particular, for three or four years. The reason why we call this a great drought is, that we have not had a flood for some years, and we have no supply of water laid up.

11082. You consider that this is some compensation for the destruction done by the floods? Yes.

11083. Was 1862 your earliest observation? I commenced in the beginning of 1863; one year's work was done at the Telegraph Office by the telegraph clerk; that was 1862; after that, I took up the work, and have continued it ever since. Observation

11084. There has been scarcely sufficient time to observe whether there has been a falling off in the rainfall? No; it would require a century's observations.

11085. Do you think there is a falling off within the last five or six years? There has been; but I imagine we shall have more rain during the next five or six years. That is the way it has been so far as we can trace it.

11086. What is the value of the land? The best land is, I suppose, £50 an acre. Value of Land.

11087. What rent do the tenant-farmers pay? About 30s., I suppose, up to £2. It is very little that I get £2 for. Rent.

11088. Why is it valued at such a high rate, if it brings in such a low rental? I do not know; if the best land were put up, it would bring from £40 to £50.

11089. Then the farmers must be doing well? Small farmers can do best; a little farmer with a few cows makes money where a large farmer cannot. Farmers.

11090. If these farmers had a certainty of water on their land, would they not be inclined to pay a higher rate; being liable to drought frightens them from giving a high rental, I suppose? No doubt, they would give a higher rent. Another thing I should very much like to see is a good market.

11091. Have you had any experience in lucerne growing? Yes.

11092. What is the average yield of lucerne in a good year? Four or five cuttings—about 8 or 10 tons per acre. Lucerne yield;

11093. So much as 2 tons to the cutting? More than that sometimes.

11094. What would the price be in the market? It varies very much, from 30s. up to £4. The yield of maize is from about 60 to (I have known) 100 bushels; but that is a very rare thing. I have had 90 myself, but I think the average may be taken to be about 70. Maize

11095. This is not a good season, I believe? No.

11096. What is the average this year? In the peninsula, it will be about 70; but those are the best crops in the district; over the river, it is not above 50 or 55 bushels.

11097. And the lucerne? I do not know what it is this season; I do not suppose they will get more than 2 or 3 tons this season off an acre.

11098. Is it your impression that if there were a system of irrigation established, it would be a great benefit to the district? I think it would. Irrigation

11099. Would it increase the produce in the district to a great extent? I think so. There is another thing I should like to speak about; of course, we have a good water-supply already, as far as domestic purposes and live stock are concerned. Our river formerly had very good water in it, and the creek also, but within the last eight or ten years, the water has been almost ruined by several establishments on the creek. There are two wool-washing establishments and a tannery, and they have been pouring their filth into the creek and spoiling the water—it is not fit for beasts, much less for human consumption. The argument used in defence of these establishments is that, if we object to them, we are driving trade away. I say, they should be compelled to deodorize the stuff, and use it for manure. Pollution of River.

11100

- Mr. J. Tebbutt, F.R.A.S. 11100. This is South Creek? Yes; it empties into the river. It is a tidal river, and a tidal creek.
- 19 April, 1886. 11101. It does not affect the water further down? Oh, yes; as soon as the polluted water escapes from the creek, it is carried to and fro by the tide. I think the tide goes as far as Freeman's Reach.
11102. *Mr. Donkin.*] The salt-water does not come near Windsor? It has been known to be brackish at Pitt Town during a long drought.
- Cycles. 11103. The salt-water does not come here? No. In dry seasons, it gets as far as Pitt Town.
11104. You said you had observed three-year cycles? Yes; it has disappeared now.
11105. From your experience of dry years, do you think that we are due now for heavy rains? Not for three or four years; but that is merely surmise.
- Navigation 11106. You said that some years ago navigation was carried out to some extent to Windsor? Yes.
11107. Did the inhabitants before the time of the railways depend upon the navigation for their supplies? From the lower part of the river. When my father and uncle were in business, they got thousands and thousands of bushels of grain from the lower parts of the river.
- Local Trusts. 11108. Speaking of local Trusts, you do not think they would answer to carry out a scheme of irrigation, how do you think it ought to be done? By the Government.
- 1867 Flood. 11109. You recollect the 1867 flood? Yes.
11110. How far was that above the railway-station? I cannot tell.
11111. You know it was above Mulgrave Station? Yes; I think it was over the roof. It was 62½ feet over the mean tidal level.
- Rainfall. 11112. Mulgrave is higher than Windsor? No; it is lower than some parts.
11113. What do you make the average rainfall during that number of years? 32·8 inches for the twenty-three years. The rainfall for 1882 was 19·2 inches, and in 1870, it was 62·5 inches. That is quite three times as much, but these are extremes.
- Extremes. 11114. Do you think it would increase the rainfall to plant the flats with timber? I cannot say.
11115. Mr. Russell said he thought trees were the result of rain, not rain the result of trees? Yes; but sometimes the trees may act again upon the rain; that is the point.
- Climate 11116. *Mr. Gipps.*] Have you noticed any change in the climate in your experience with regard to heat and cold? The change in the temperature is very slight.
11117. What is the average heat? The average temperature is 64 degrees for twenty years.
11118. Do you experience any frosts here at all? Yes; we have had the thermometer down to 19 degrees on the grass, and up to 117 degrees in the shade.
11119. Did that affect the vineyards or orange plantations? I do not think it did very much. The intense cold was in the winter.
- Sand deposits. 11120. Which floods bring down the most sand, those from the Grose or those from the Nepean? I think neither. It was in 1870 that so much sand was brought down, but I cannot say from what place.
11121. Which branch was in the highest flood in 1870? I do not know; in 1867 a great deal of water came from the western district through the Grose, and from the south, and we had an easterly gale. The three causes combined produced the flood.
- Population. 11122. What is the population of Windsor? Somewhere about 2,000.
11123. How many houses are there? I cannot say.
- Water-supply. 11124. What is the present source of the water-supply? The river.
11125. How do they get their water? It is brought by water-carts. For some time the water was pumped up by a small engine to Cadell's brewery; at other times it is brought directly from the river.
- Price per barrel. 11126. What is the price per barrel? I have not paid anything. I depend principally upon underground tanks. I think it is about sixpence a cask.
11127. How many gallons in a cask? 50 or 60.
- South Creek. 11128. Are there any large creeks or rivers in the vicinity? We have South Creek, which empties into the Hawkesbury.
- Storage. 11129. Are there any positions for storing water in it? I do not know about that; it would have to be stopped up at the mouth.
12130. Would that impound a large area? Yes; I do not know how many miles; there are two branches. We have another small creek emptying into that again. It was called Jacky Carr's Creek. A good deal of water comes into that from Killarney way. In heavy rains a great deal of water comes through that creek into the main one.
11131. Are there any rivers that flow into the Hawkesbury? The Grose and the Colo.
- Cattai Creek. 11132. Are there any other streams? Cattai Creek.
11133. Is that a permanent creek? I do not know much about that.
- Killarney. 11134. You do not know any position from which the country could be supplied by gravitation? The only place is Killarney; it is pretty high.
- Carr's Creek. 11135. That has reference to South Creek? Yes, it comes down that branch—Carr's Creek.
11136. What height is that above tidal level? About 50 feet above the mean tidal level.
11137. That would supply the flats? Yes, that would supply the low levels.
11138. You said that the water from the Barrack well was brackish? So I am informed.
11139. Is that constantly used? I do not know.
11140. What does it bottom on? Through shale, I expect.
- Soil. 11141. Is the valley permeable or impermeable on the flats? Permeable.
- Formation. 11142. What are the general geological features with regard to the rocks? Chiefly sandstone.
11143. Are there any basaltic dykes? Not in my experience.
- Analysis of water 11144. *Mr. Murray.*] Has any analysis been made of the water? Not that I am aware of, unless Mr. Moriarty made an analysis. He gave us a report some five or six years ago, and he drew attention to the state of the water, and I pointed out that it was affected by the refuse from the tannery and wool-washing establishments.

Mr. H. J. West called in and examined:—

- Mr. H. J. West. 11145. *Vice-President.*] I understand you are a delegate from the Riverstone Political and Local Improvement League? Yes.
- 19 April, 1886. 11146. What experience have you had in the district? Seven years. I was one of the early purchasers in the Riverstone Estate, when it was first subdivided. 11147.

11147. What has been your experience in reference to the last five years as to the crops in the district, during what they call the drought; has the district been much affected by the drought? Yes; it has been greatly affected. Mr.  
H. J. West.
11148. I suppose that is shown in the very small returns that are got from the land? Yes; the principal productions here are oranges and grape-vines, within a radius of 5 or 6 miles from the Station. 19 April, 1886.  
Drought.
11149. Have they been affected by the drought? Not so much as you might expect.
11150. Has the neighbourhood been short of water in consequence of the drought? It has been very short.
11151. Then I presume there has not been sufficient water in the district for irrigation purposes? Oh, yes. There is Eastern Creek, it would supply Riverstone, with a population of 40,000 people, and also meet all requirements for irrigation purposes in a well planned Government scheme. Eastern Creek.
11152. Is there any place where that creek could be dammed so as to supply water for the irrigation of the district? Yes; there are several places along the creek. There is the portion at the rear of Riverstone Meat Works, that could be dammed up for that purpose. There is another portion on the Grange Farm Estate, and several other places along the creek. Storage.
11153. Have you had any experience of irrigation at all except in that locality? No, except at the rear of my house. I have a creek there dammed up, and by means of a force-pump I raise water to rear a few vegetables for my own table. Irrigation.
11154. Do you irrigate the trees? No, I do not. I do not believe in irrigation for orchards or vineyards.
11155. Do you not think it would be beneficial to irrigate orchards? I do not think I would attempt it. I would not attempt to carry water to my young trees, I should just let them take their own course; they have taken their own course, and done well.
11156. What is your opinion as to the benefit of irrigation for farm produce? So far as the nature of the soil about there is concerned, it is better for oranges and vineyards, and not so much for farming. It would be beneficial to the district if we could get water for domestic purposes and for manufacturing purposes, local industries, such as meat works, or whatever may come into the district. That is why I think irrigation would be beneficial in Riverstone, not so much for market purposes as for manufacturing and local industries. Storage.
11157. Do you mean that a system of irrigation would be beneficial for supplying the water required for consumption or as a motive power? As a motive power, and to supply domestic requirements.
11158. You think then that any system by which large quantities of water could be stored up for distribution would be of great benefit in the development of the district? It certainly would.
11159. Do you think the large landowners would be willing, supposing their land were enhanced in value by a system of irrigation, to pay a rate towards the interest on the outlay? Yes. During the last five years, I suppose, there have been about thirty estates cut up. I suppose that the revenue to the vendors must have been £200,000. They have been cut up into blocks with 30-foot frontages to 5 or 6 acres. They have been sold and settled upon, especially the farming blocks, and there would be a large revenue from these estates. Water-rate.
11160. How much land in this immediate vicinity do you suppose has been brought under cultivation during the last four or five years? About 200 acres. Cultivation.
11161. Not more than that? No; that is chiefly in orchards and vineyards. The district is young; it has only lately been put into the market. I have 10 acres myself under cultivation.
11162. In orchards? A young orangery.
11163. You do not know of any case in New South Wales where irrigation has been tried for orchards? I do not.
11164. Do you know of any sites particularly adapted for reservoirs? There is a site supposed to have been selected somewhere at the rear of Mr. Parrington's residence. Reservoirs.
11165. If any work of this sort were carried out, what would be the best way of controlling it—should it be under Government engineers, or a Department, or a local Board? It should be under a local Board, most decidedly. Management.
11166. Do you think from your experience that there is any necessity for legislation in that direction to enable people to make dams and reservoirs for themselves, or for villages to do this? I think it is quite necessary, and should be done. The Local Government Bill provides for that, if I am not mistaken. Legislation.
11167. Do you think that a Local Government Bill on the lines of similar Bills passed in Victoria, Queensland, and South Australia, would be beneficial to the country if passed? I am not acquainted with the Bills passed in the other Colonies.
11168. But you think that a Local Government Bill, giving power to tax land in the immediate neighbourhood for improvements in the district, and giving local authorities power to spend money, would be an advantage? Most decidedly, a great advantage.
11169. Are there any wells in your district? There was a well close to Riverstone Railway station, formerly occupied by Mr. Barbour some years ago, and not a stone's throw from where the Cosmopolitan Hall is erected. There is a well there about 20 feet deep; the water is brackish. Wells
11170. Is that the only well you know of? That is the only one.
11171. Is there anything else that you would suggest to the Commission? I would mention that the Riverstone League is about to have a boring machine brought into the district. They have sent to the Under Secretary for the Department of Mines to ask that a site may be approved; so we mean business. We may find either water, coal, or gold. Riverstone  
League.
11172. Is it proposed to bore to any great depth? Yes; the Inspector will have to come first and examine the site.
11173. What is your object? To get what we can, either gold, coal, or water.
11174. What inducement have you held out to the Government to come and bore there more than any other part of the country? We think the natural position of the country justifies the application.
11175. *Mr. Murray.*] What is the nature of the soil? It is a kind of loamy soil.
11176. Very deep? 8 or 9 inches is about the average.
11177. What is the subsoil? Red and yellow clay.
11178. Do you think that irrigation would not be beneficial? I do not think it is necessary for surface working. Irrigation.
11179. We have had it in evidence, from others who grow oranges, that it is almost impossible to keep the young trees in leaf this season; do you not think that water would help them? It is a matter of opinion. Some think that on hot days water will have a tendency to injure them. My young orange-trees have been planted eighteen months, and they are looking well. I have not put a pint of water to any of the trees.

- Mr. H. J. West. 11180. Have you had any experience of orange growing? Not much. This is the first time, and I believe in surface working.
11181. Have you seen older trees shedding their leaves in a dry season? I have not seen it, but I have heard of it.
11182. What do you propose to pay the Government for the use of the diamond drill? I could not tell you till the matter comes before the League.
11183. *Mr. Gipps.*] What distance is Riverstone from Windsor? About 8 miles.
11184. Is Riverstone on the actual creek-flats or on the higher ground? One portion lies on the flats adjoining the Eastern Creek, and another towards the old Windsor Road.
11185. Is the Eastern Creek a constantly running stream? Yes.
11186. A small one? A very heavy stream in wet wether.

Mr. John Gow called in and examined :—

- Mr. J. Gow. 11187. *Vice-President.*] Where do you reside? At Mulgrave, 2 miles from Windsor.
11188. Have you been long a resident in the district? In the district, over fifty years; in my present occupation, over thirty years.
- Floods. 11189. Then you have seen some floods passing over the ground? Yes.
11190. Are you of opinion that these floods have done great damage to the district? They have acted both ways. In some places the damage has been serious, and in others the effect has been very beneficial. The floods have improved some land and destroyed other land.
11191. You could not say whether the benefit has been greater than the injury? Well, I think, taking the whole district, the floods are better than the droughts.
11192. Do you think the benefit of the floods arises from the irrigation of the land, or from the deposits which the floods leave? From both.
- Yield of crops. 11193. What would you call a fair average crop of corn in this district in a season of flood? From 50 to 100 bushels have been produced.
11194. What would be the average through the district this season? Well, I am not acquainted with it very much this year. Many crops have entirely failed, but early crops are fair. They might run something like from 40 to 50 bushels. My own will run about 60.
- Irrigation. 11195. I think you have some experience of irrigation? I have had one year's experience of it.
11196. In what way have you been irrigating? By means of a steam-pump.
11197. And how have you distributed the water? I have pumped it up to a higher level, to a tank; and from either side perforated pipes along the higher levels have distributed the water.
11198. And what has been the result? This year the result has been considerable; it has more than doubled the crop.
11199. Have you any idea as to the quantity of water that you have used in irrigating? For the vines we have used about 2 inches to 5 inches, about  $2\frac{1}{2}$  gallons to the foot.
11200. And on the oranges? I have not practised on the oranges; I have only just planted them.
11201. Your experience is chiefly with regard to vines? Yes.
11202. What effect has it had on the fruit-trees generally? A very good effect. Fruit which would have been utterly useless has turned out very good.
11203. Has it paid you for the labour? Yes, I think so.
11204. You are of opinion that, if some large scheme of irrigation were introduced, it would be generally beneficial to the district? Yes, I think it would. I think we stand at a great disadvantage here. The only place I know of which would irrigate the district generally is the Grose River. It would depend on whether that river could be sufficiently dammed to raise the water.
11205. Do you know anything of Wheeny Creek? Very little.
11206. Do you not think it possible to bring water from the higher levels to the Nepean? It would be possible, but very expensive.
- Water-rate. 11207. If it could be carried out at a reasonable cost, would it be beneficial to the district? Yes.
11208. Do you think the landowners would contribute to pay interest on the outlay? That would depend on the outlay.
11209. What do you think yourself the owners of the best lands in the district would be willing to pay per acre for a supply of water; you are getting 30s. an acre without water; what would you pay per acre if the same land could have a supply of from 5 to 10 inches of water to the acre? It would depend greatly upon the seasons. In dry seasons it would be very valuable; in ordinary seasons it would be worth but little.
11210. It would enable you to make sure of a crop every season, wet or dry? Yes, no doubt.
11211. Do you think it would be worth while to pay 5s., 8s., or 10s. for the use of the water? I think it would.
- Waterings. 11212. Is the quantity of water that you use upon your vines ample for them, or is that all you can give them? We had any quantity of water; we might have used a little more. Another year I shall commence sooner, and give three waterings instead of two.
- Cost of plant. 11213. What has been the cost originally for the plant? I only intended to water 10 acres when I first laid it down, and that cost about £250.
11214. From what depth have you to raise the water? About 55 feet.
11215. That is the greatest depth? Yes.
11216. From a creek? From South Creek.
- Cost of pumping 11217. What was the cost per acre for the pumping and distributing of the water? I have no estimate of that; we have done it among ourselves. One person could nearly always attend to it, both to the distribution and the pumping. You might say it occupied the time of one person, and about half the time of another person.
11218. And there is wood and coal to be added to that? Yes; that would not amount to above 5s. a day.
11219. Would 15s. a day cover the whole cost? Yes, about that.
11220. And how much would that water? It would only just water in the height of summer for particular purposes.
11221. Six months in the year? Oh, no; only about two months, using it altogether for grape-crops.
11222. Do you know of anyone else who is likely to follow in your footsteps in consequence of the experience gained by you? Yes; there are two or three persons, who were speaking to me about it. 11223.

11223. They are likely to do the same thing? I think so.
11224. What sort of pump do you use for forcing water? Shanks's pump. Mr. J. Gow.
11225. Has that given you satisfaction? Yes; entire satisfaction.
11226. What is the delivery of that pump? About 1,800 gallons an hour. If I were commencing again, I would have one that would throw 5,000 to 7,000 gallons per hour for 20 acres. 19 April, 1886.
11227. What size of engine have you? A 2-horse power engine; the grazing land would pay for it. Engine.
11228. Have you tried it in that way? Yes; I am sure it would pay over and over again.
11229. Watering on the ordinary land? Yes, with perforated pipes.
11230. Do you include perforated pipes in your £250 cost? Yes.
11231. Do you know anything at all as to the system prevalent in America of watering underground through the roots by pipes? No; I believe in it though; I believe it is the best system. My object is to put the water on in such a manner that it will penetrate 18 inches or 2 feet straight away. We found the correct way was to let it flow down the holes very slowly; perforated pipes underground would be an admirable idea. Surface watering is a most injurious thing. Underground watering.
11232. How many times do you require to saturate the ground for fruit-trees? About three times when it is excessively dry. Three good waterings with attention to the land afterwards are sufficient. Watering fruit-trees.
11233. *Mr. Gipps.*] What is the depth of water to each watering? About 2½ inches, about 2 or 3 gallons to the foot.
11234. Do you know much about wells in this district? Not very much; I know of one adjoining me.
11235. What has been the character of this well? Good water. Wells.
11236. Fit for irrigation? I do not think we have enough for that.
11237. What would be the depth? The well near me is about 10 feet.
11238. You are on low ground? Yes; I do not believe it is a living spring, but only soakage.
11239. *Mr. Murray.*] Is there plenty of water at South Creek for a large quantity of land? Yes. Supply in South Creek.
11240. Of good quality? Good enough for that.
11241. You irrigate 10 acres? Yes.
11242. Is your plant capable of irrigating very much more? It depends upon the seasons. I think it would manage 20 acres, working night and day.

THURSDAY, 15 JULY, 1886.

At Sydney.

Present:—

MR. BARTON, M.P.,  
MR. DONKIN, J.P.,

MR. FRANKLIN, C.E.,  
MR. GIPPS, C.E.,

MR. M'MORDIE, B.E., M.I.C.E.

RUSSELL BARTON, Esq., M.P., VICE-PRESIDENT, IN THE CHAIR.

Mr. W. T. Poole called in and examined:—

11243. *Vice-President.*] We wish to examine you in regard to your recent trip to Europe; but instead of putting to you the usual stereotyped questions, perhaps it will be better if we leave it to yourself to give us what information you may think useful to us and adapted to the colony? Yes; probably that will be the better way. I may say that, prior to my leaving the colony for Europe I received a communication from the President of this Commission, requesting me to obtain information on the subject of water conservation and irrigation in the various countries which I might visit. As far as my time would permit, I have done that. The first place which I thought would be instructive to examine was the well known plains of Lombardy, which have been subject to irrigation for centuries; and I made a trip through these plains from Venice right up to Milan. I may say that the first thing I was anxious to ascertain was the nature of the subsoil, and the soil itself. I found that from Verona to Milan, which is through the principal part of the plains, the plain itself is underlain with a free gravel-drift the whole way through. I had ample opportunities of judging of that from the formation in the railway cuttings. I do not recollect a single instance where there was anything but a gravel-drift. Mr. W. T. Poole.  
15 July, 1886.
11244. *Mr. Gipps.*] What depth? The soil itself? Irrigation in Lombardy.  
Subsoil.
11245. Yes; above the gravel-drift? About 18 inches. Depth.
11246. And how deep was the gravel-drift? I never saw the bottom of the drift.
11247. *Mr. Franklin.*] Were the side cuttings dry? Quite dry.
11248. There was no water-bearing gravel at that depth? No.
11249. *Mr. Gipps.*] The features of the country are level? Oh, yes; between Verona and Padua it is level, but much lower; but from there to Venice it may be described in the words of Dr. Lang as "drowned land." Now as to the system. I noticed that most of the subsidiary streams intersecting this plain have been raised; the banks have been raised artificially; in many cases the bed of the stream itself is above the level of the surrounding land. In a case like that, of course, it is easy to pierce these banks, and let the water flow by gravitation over the whole country within reach of it. Features of country.  
Subsidiary streams.
11250. *Vice-President.*] Nature has done exactly there what art has done in America? Partly nature, and partly art. The banks have been raised artificially by man's labour, and the continued flow of the water from the mountains downward has brought the gravel along and raised the beds. The whole country looks like a checker board, intersected as it is by these irrigation works. The holdings are very small. Banks.  
Holdings.
11251. *Mr. Gipps.*] What river do they draw water from? I cannot tell you that; but I noticed that lots of the subsidiary streams were in the position I have stated. The Po itself is not interfered with.
11252. I heard the Po was dry? It was not perfectly dry where I crossed it; but no doubt a vast quantity of water is diverted from it. So far as the reticulation is concerned, I noticed there were two sets of ditches. This bears upon the nature of the substrata. The delivery ditches were running full, and necessarily they had been puddled; and within 8 or 10 feet of them in most cases was a dry open ditch with gravel on the bottom. I concluded from these observations that the object of the dry ditches is to provide for local storm-water—practically, absorbing ditches. It does not appear to me that water runs through them; the irrigation-water, as it percolates through the upper soil, finds its way readily into the gravel below and disperses to its natural levels. River Po.  
Reticulation.  
Delivery ditches.  
Absorbing ditches.]

- Mr. 11253. *Mr. Franklin.*] You are speaking now of the main channel and the distributaries running at right angles, or at any angle from it—what sort of sluices have they? They are very rudimentary—that is, for the farm reticulation. It is just a simple wooden valve running across the ditches, and the ditches in most cases seem to have a cross-section about equal to our railway catchwater-drains.
- W. T. Poole. 11254. What I mean is, what are the sides-sluices like? They are lifting-sluices.
- 15 July, 1886. 11255. And the tow-paths are carried over these on arches? Yes; where there is navigation, but in most cases there is no navigation.
- Sluices. 11256. They do not go into elaborate brickwork? No; in the main openings, where the water is taken from a main river, the works are substantial; but on what may be called the subsidiary streams, the works are light, and what we would call temporary.
- Tow-paths. 11257. *Vice-President.*] How are these main arteries supplied? From the main rivers.
- Openings. 11258. That is, from constantly running rivers: they have no water in reserve in dams or reservoirs? I saw none. The formation of Italy is altogether different from that of this country; there you have a central backbone range that gives you water all the year round, either in the rainfall, or in melting snows.
- Supply. 11259. What water per acre do they put on the land for irrigation purposes? I do not know; I thought that was a matter which could be easily ascertained here. A detail of that kind, and also the cost of the works done, did not appear to me to be of very much value, because I know from long experience that the cost of works in Italy will be but a poor guide to us here; labour and everything else is so much cheaper in Italy.
- Cost of works. 11260. *Mr. Donkin.*] What is the crop under irrigation? Grass and every kind of crops. I would like to read an extract from my diary.
- Crops. *May 18, 1885.*—From Verona to Milan the country is one large garden, well watered naturally; and in addition, this portion of the beautiful plains of Lombardy is thoroughly irrigated, and the crops on every hand exceedingly good, especially the grass crops. The system of irrigation is very simple, and, I think, very effective. The soil all through is underlaid with a gravel drift.
11261. Do they flood the lands? You see the water creeping over; the ditches are kept just level full. Of course, the delivery ditches are not very far apart.
- Distance 11262. What distance? They did not appear to me to be above four or five chains, and sometimes less; between ditches. that, too, is determined by the smallness of the holdings. Italy, especially in this part, is broken up into small holdings.
- Irrigation 11263. *Mr. Franklin.*] Are the boundaries of these irrigable holdings protected by raised banks so as to hold a given quantity of water? No; the system seems to be this: the delivery ditches are running almost constantly, and when the farmer wants the water on to the land, he simply puts on the valves and raises it up; and when he does not want it, passes it on to somebody else.
- system. 11264. You did not ascertain under what system of supervision that is done? No, I did not. Every little holding is divided into little patches of beans, rye, grass-crops, and so on. It is very easy to ascertain a man's boundary; you will see it defined by a row of mulberry trees, and vines are festooned from the trees.
- Surface-soil. 11265. *Mr. Donkin.*] What is the surface-soil? The surface-soil is rather darker in its colour than (say) for instance, the soil of the Macleay River. It is a pure alluvial deposit; looking at it geologically, it is unmistakably alluvial.
11266. *Mr. Franklin.*] Had you an opportunity to compare any of the irrigated land with unirrigated land as to the crops produced? No; and I saw no land but what was irrigated, unless it happened to be a bit of rise, and in these cases it was gravel. This system continues to within a few miles of Milan.
- Works on Meuse 11267. *Vice-President.*] What was your next point? My next point was to visit the Meuse at Namur, River. Belgium. Feeling interested in what I saw there, I put myself in communication with the engineer in charge of the works as well as I could. He could not speak English, and I could not speak French; but I took the precaution to bring an interpreter with me from Brussels, and we got along very well together, the engineer being very courteous. I went first of all to the *barrage*, as they term the dam down below Namur, and had a look at it.
- Barrage. 11268. *Mr. Franklin.*] Those were the headworks you saw? No; there are a number of these barrages on the Meuse. I afterwards inspected another one; but they are both the same in principle; they are combined needle and automatic dams. First of all there is the lock or passage near one bank of the river, then the remaining portion of the river is divided into two sections, with a very firm and massive dividing wall between the two sections; one of these sections is fitted with an automatic system, and the other with the needles. The engineer was kind enough to call his men out to show me the action of both systems.
- Locks. 11269. *Mr. Franklin.*] You are referring to the movable weirs? Yes, to both the automatic and the needle systems.
11270. Before you describe the action of the two systems of movable weirs, please state how they prepare the foundation for the fixing of these weirs? In masonry.
- Foundations. 11271. *Mr. Gipps.*] Concrete, is it not? No, masonry.
11272. In every case you saw? In these two cases; but, I take it, there is no ready-cut-and-dried rule to provide for the foundations of expensive works of this kind.
- Crest-level. 11273. *Mr. Franklin.*] What would be the crest-level, taking the ordinary general level of the river; how far do they consider it proper to raise the foundation of this crest—you know, what we call summer level? Oh no, it is not summer level; it is not above a foot or eighteen inches above the bed of the river.
11274. It is all submerged work? Yes, what I saw.
11275. Any unwatered? No. At this point I would like to quote from my diary:—

*May 27, 1885.*—Took the train from Brussels to Namur; on arrival there, inspected first the weir below the town; found it to be partly needle and partly automatic; then went up the river, and introduced myself to the engineer in charge of the works, and with him visited the weir above the town; this, like the weir below the town, is an extensive and complete work, with a lock on one side for navigation; the weir is then divided into two sections, apparently about the same length each. One section, needles; and the other, the new automatic system. The engineer showed me the working of both systems; they are both excellent, but require extensive masonry foundations and dividing walls to render them manageable and safe. The engineer likes the needle system as the most economical in construction, and as forming a more water-tight weir, and the automatic as the safer system in times of sudden flood. The rise of water here, due to the weir, is 1·80 metres, and at the one below the town 1·50 metres. I incline strongly to the engineer's opinion that a compound automatic and needle system is the best; he has promised to send to London for me a complete copy of the detail drawings of the automatic system. Plans and details of the needle system I shall try and get in Brussels.

The divisions run on the longitudinal axis of the river.

11276.

11276. Are there shutters in the automatic system, and do they oscillate if the river rises over a certain level? Yes, they hinge over, as you will see in this plan (*Appendix E*). In these other plans (exhibited) you will see a section of the needle weir. At the time I was in Belgium there was a Commission of European engineers who came to examine these works. Mr. W. T. Poole.  
15 July, 1886.
11277. They pitch the needles do they not? Yes, into position. Working of needles.
11278. In putting the needles over the top of the crest, suppose they spread at the foot, what means have they of putting them on the crest? They cannot spread at the foot; there is no means of altering them when once they are in position; you can only throw down the locking bar and start afresh. Suppose there are two men pitching, and when the needles are up, there is not quite room for another one, they simply put down a covering needle, and the pressure of the water brings it up close. No doubt, some practice is required; of course, out here, men at first would be inexperienced with the weir; you would require some spare needles.
11279. Having raised the works by means of the weir, what do they do with that at the back of the weir, is there an off-take with revetment walls? No, it did not appear to me so. These works are not for irrigation, they are simply to raise the level of the water at various points for navigation; but, when once you raise the level of the water, you can devote the water to any purpose whatever. There are no irrigation works around Namur. Purpose of works.
11280. *Mr. Gipps.*] Is it all tidal works? No, it is not tidal water; you are a long way above tidal influence at Namur.
11281. *Mr. Franklin.*] Really, the object of raising the water over the large area of the river is that you keep a head of water, so that you can make your locks on one side; it reduces the current and gives you a certain series of falls? Yes; and they have the water for any purpose whatever. Of course, the tow-path is on the one side only of the river; there is no haulage on the opposite side.
11282. *Mr. Donkin.*] Have they trap-doors to open and let the water escape before it comes to the point of oscillation? Yes, by the central openings in the shutter itself. Trap-doors.
11283. *Mr. Franklin.*] They are provided to tide over threatened danger from a flood? Of course, they are the regulating medium. I intended to examine the enormous masonry work at Gileppe; but finding myself so near the coast, I was anxious to get across to London; and once there, I put myself in communication with the Agent-General, and asked him what he was doing or had done in the matter of your inquiry as to water conservation. Mr. Yardley told me he had, through the agency of the Foreign Office, collected all the information it was possible to obtain, something like half-a-ton weight, and had forwarded it on through our Government for the use of this Commission.
11284. *Vice-President.*] I should like to know where it is? I am only telling you what he told me. Naturally, I then felt reluctant to travel back to Belgium to seek for information which you would likely have.
11285. *Mr. Donkin.*] Do you know in round figures the cost of the weir you described? No; I cannot see what use that would be. Prices in Belgium are no guide for us here. Cost of weir.
- [The Vice-President retired, and Mr. Franklin took the chair.]
11286. *Chairman.*] Did any of the systems you saw in operation strike you as applicable to our rivers? Yes; it struck me that the combined needle and automatic system, or either one of them, would answer. And if you could once get over the difficulty of making the needles act automatically, I should say adopt the needle system on all the lower reaches of our rivers, but do not use them in the upper parts of the river where heavy timber is likely to be brought down. Where the current is slow and reasonably free of timber and rubbish, I would certainly be strongly in favour of this comparatively inexpensive system; but in other cases, where there is a great fall on the river (say) a flow of water 4 or 5 miles an hour, I should be in favour of fixed dams. Weirs applicable here.
11287. How do you think they could be applied (say) between Wilcannia and Bourke, supposing you wanted to raise the water temporarily to a certain height? I have never been in that district; but I take it, there is very little fall in the river. I ascertained the rate of the flow of water at Namur to be 1 metre per second—something like  $2\frac{1}{4}$  English miles per hour.
11288. If this system of movable weir were applied here in our rivers, such as the Darling, the conditions being appropriate, what sort of work would be necessary to protect the banks? At the site where the weir crosses? Protection of banks.
11289. Yes? It is shown in the plan I have produced.
11290. *Mr. Donkin.*] Do you not think it would be possible to have an automatic bar attached to the needles, so that when the water came up, it would raise each needle up? I should not advise that; I should advise certainly the letting down of the cross-bar and allowing that section of needles to go straight away; that would be the easiest way. Working of needles.
11291. Would wooden needles do? They are wooden needles, made of pine  $3\frac{1}{2}$  to 4 inches square. Size of needles.
11292. *Chairman.*] With regard to your general observations of the different systems, did anything occur to you particularly as perfectly applicable to our requirements here? As to being adapted for all cases.
11293. For the retaining and distributing of water? I have never seen any system of barrage or dam that would suit all cases.
11294. Or any cases? Oh yes, some cases.
11295. Have you fixed your mind on any part of the Colony where you might apply any of those cases you have stated? Well, take Gunnedah, on the Namoi; I should certainly consider that the combined needle and automatic system would be applicable there. Application to the Namoi.
11296. For throwing water back in steps up the river-bed? Yes; but do not make the steps too heavy. I think you should not go more than 8 or 9 feet from the sill.
11297. That would give in the ordinary fall of the Namoi about 9 miles of water? About that.
11298. *Mr. Gipps.*] Are you aware that the needle system is being used in America in greater heights and greater falls than you mention? I am not aware of it; but it seems to me that, if the velocity of the water in the channel is sufficient to move the gravel along its bed, that is not a position for a needle-dam. Needle system in America.
11299. You believe the proper position for a moveable weir is where the current runs slowly, and where plenty of time could be given by telegraph or otherwise to remove the needles? Yes.
11300. And that could be carried out from Bourke to Wentworth, from Wagga Wagga to Wentworth, and from Albury to Wentworth? Yes. As I said before, I consider this system applicable in all the lower reaches of our rivers, but not where you approach the mountain ridges. In those cases I should suggest a solid dam. The sections are divided into about 4 feet; the river is divided, for the purpose of barrage, into two. There is the lock outside; but that may be dismissed from our view just now. It may not

Mr. W. T. Poole. not be necessary in small rivers to divide them at all; and where there is a large opening, it may be necessary to have three or four sections. Because the Meuse is divided into two, I do not take that as a hard and fast rule. The reason for using the automatic shutters is to prevent damage to the barrage or dam in times of sudden flood, and not with a view to facilitate the navigation. The needles all across, or the automatic system all across, would provide for that just as well. The needles are very much cheaper than the automatic.

15 July, 1886.

Works on the Severn.

11301. *Mr. Donkin.*] Is the wood preserved in any way? No; it did not seem to be even painted.  
 11302. *Chairman.*] Have you anything to add? Not with respect to these. I examined the works on the Severn with a similar object, and I can give you some information on that point. At my request, the Agent-General caused a set of plans of the works at Diglis Locks to be drawn and sent to the Commission.  
 11303. *Mr. M'Mordie.*] The works on the Severn are for the purposes of navigation, and not of irrigation, are they not? They are for navigation; but it seems to me that if you raise the water by works, you can do anything you like with it afterwards.  
 11304. But there is a difference in the works required to be constructed? That may be.  
 11305. *Mr. Gipps.*] The works on the Severn are for drainage too? Not a bit. The Severn is like our Macleay in the formation of its banks.

THURSDAY, 22 JULY, 1886.

Present:—

MR. BARTON, M.P.,  
 MR. DONKIN, J.P.,

MR. FRANKLIN, C.E.,  
 MR. GIPPS, C.E.,

MR. M'MORDIE, B.E., M.I.C.E.

RUSSELL BARTON, Esq., M.P., VICE-PRESIDENT, IN THE CHAIR.

Mr. W. T. Poole called in and further examined:—

Mr. W. T. Poole. 11306. *Mr. Franklin.*] Referring to the works on the Meuse, what is the level of the crest above the bed of the river? By the crest do you mean the foundation of the masonry on the top of the needles?  
 11307. The level across the bed of the river on which the automatic weir is fixed—the sill? It seemed to me that, as much as possible, they carried heavy foundations; they do not raise up the crests more than is absolutely necessary.

12 July, 1886.

Level of sill.

Navigation.

11308. *Vice-President.*] Is the river open for navigation at this particular place? Yes. In all places that I saw, both in Belgium and in Britain, navigation is altogether apart from the works for the conservation of water; they are two separate subjects. They have works first of all, by fixed or movable weirs, to raise the water to some determined height; what is to be done with the water afterwards is another consideration. At the places which I visited in Belgium, the water is used principally for navigation purposes; of course, it is so in Britain; here is an example in the works at Diglis Locks, on the Severn, plans of which I produce; the water is used for navigation purposes, and also for the supply of manufactories along the banks of the river. In both cases, I speak advisedly, the water is not diverted for irrigation; it is there stored for any purpose for which it might be required. I do not think that there is any specific, fixed rule as to the height of the foundation or crest above the normal bed of the river; I think that that is a matter which is determined altogether by local circumstances.

Diglis Locks.

Foundation works.

Purpose of works.

11309. *Mr. Franklin.*] There is a very strong objection to raising permanent obstructions to any very great height in our rivers? I know that in both the weirs which I examined on the Meuse, the foundation works were entirely submerged; I could not see anything of them on the lower side of the dam, but they were certainly not at any very great depth below what we should term the summer level.

11310. You say that these weirs were constructed for the purpose of conserving water? Yes.

11311. Was it conserved with a view to its distribution for irrigation purposes? Not in these cases.

11312. Is it so in some cases? Not in any of the works of which I have submitted plans to you; the works are constructed merely to hold back the water.

11313. For what purpose? Principally for navigation, and for the use of manufactories along the banks of the river.

11314. When the obstruction was made by a movable weir, was there any advantage taken, by deviation of the river, in carrying navigation around the point of obstruction? Advantage is taken on the Meuse of the bends or peculiarities of the river; there is a navigable passage, as they call it. The crest of the works would be above the ordinary level of the river if it was left free; the water is held up to a height of 1·80 metres at the weir above Namur, and at the weir below 1·50 metres; the lock and navigation works are altogether distinct from the impounding works.

Locks.

11315. The downward navigation is carried on from the raised head of water above the weir? The upper water is the level of the lock when it is full, and when the lock is empty the lower flood-gates are lifted; where there is not a natural ana-branch they construct one.

Size of locks and passages.

11316. What are the sizes of the passages and the locks? In the case of the automatic systems there are two kinds, one large and one small; there is a navigable pass, so that a vessel of larger size than the lock is made to hold can go through; if they do not value the water, they throw down a considerable section of the automatic weirs, to allow the vessel to steam through; but she has to go through against the rush of water; they have this provision in case of extreme necessity.

Oblique weirs.

11317. *Mr. Donkin.*] Do they use oblique weirs in the Continent? Movable weirs do away with the necessity for that; as where they have needles or automatic weirs they can regulate the head of water so nicely by taking out sections of needles, or throwing down sections of the weirs.

11318. You have explained how they move the shutters from the automatic weirs; in the needles, I understand, they take a few sections out? Yes.

Working the needles.]

11319. *Mr. Gipps.*] They take one out? No; what is done is this: the whole length of the section of the weir—the needle section—is divided into about 4 feet lengths or bays, the cross-bar supports the upper end of the needle, the lower end being supported against the masonry work. On the foundation works there is a lock and hinges; the cross-bar comes across, and is locked on the other side. Suppose you want to throw down that section of needles, you simply unlock the bar and away they go.

11320.

11320. *Mr. Donkin.*] We have on our rivers overshot timber-dams of inch planking. Do you think that wooden needles would apply there? If your foundation is correct, I do not see why you cannot erect needles on it. What you have to provide is a cheek for the foot of the needles. I should be very unwilling to venture an opinion as to what is suitable for any position unless I knew the locality; but there is no magic in masonry, or concrete, or timber foundations, as long as they are sufficiently heavy and watertight—I have no particular choice. I should take whatever material was handy, provided it was suitable for the particular work.
11321. I think you said that they only carried out this needle or shutter system in large works? I have not seen any other works; of course I do not profess to give an epitome of engineering construction in relation to the conservation of water throughout Europe. I selected the places where I thought I should see good examples of the two systems—that is, of movable weirs.
11322. *Mr. Franklin.*] In any of those works in practical operation did you see any case which would apply to the friable banks which we have to contend with? The Meuse has alluvial banks. Cases of friable banks.
11323. *Mr. Donkin.*] Has the Severn also? Oh, certainly.
11324. How are the banks secured? They are just laced with rubble masonry. Protection of banks.
11325. *Mr. Franklin.*] In some cases it is necessary to do a work of this kind where there is not rubble at command within an easy radius; have you seen any works where the banks of the river and the flanks of the weir have been secured by such material as we have at command, such as wood? In none of the cases which I saw were the banks so secured, because it was stonework. If you were to ask if I thought such a system would be effective, where you had plenty of timber, I should have no hesitation in saying "Yes."
11326. As you know, some of our rivers are very deep in the banks; we should have to protect them to the full flood-height, and we have no local material except timber for the purpose. What I want to know is whether any of the drawings which you have represent the work done by timber? No; I do not think that there is an example of the ends of the works being secured by means of timber, because stone is general all over Europe—it is much more plentiful than timber.
11327. Are these rivers of greater velocity than our rivers generally—take the Meuse for instance? The velocity of that is about a metre a second, or  $2\frac{1}{4}$  miles per hour; but that is not its flood-rate. Velocity of rivers.
11328. Did you hear that where the off-take is made in the impounded water—whether the off-take is for irrigation or for navigation purposes—there is a large amount of silt settled at the point of the take-off? No; the Engineer of the Severn works never made the slightest complaint on that score. Silt.
11329. He never said that at any time they had to correct the work by bringing the regulator nearer to the off-take? He never made any complaint of that kind.
11330. *Mr. Donkin.*] It is a very low weir in the Severn? It is not high. Weirs in Severn.
11331. *Mr. Franklin.*] I am speaking of the weirs on the Meuse? No complaint was made to me on that point. The weirs on the Meuse are in straight reaches of the river, not in bends as on the Severn, and they are at right angles. Weirs in Meuse.
11332. On the upper side of the weirs, do they adopt any measure with respect to the banks of the river? They carry up what we should term hand-packed ballast in masonry for a short distance on the face of the banks.
11333. They do not raise the banks? No.
11334. Does the Meuse flood to any great height? The construction of the weirs is altogether different from the English system, it being automatic or easily movable; you can scarcely term the needles automatic, but the other portion is. The needles are so easily removed that what would be an obstruction in time of flood is readily taken away, and the river has its whole full cross-section for the discharge of the waters, with the exception of the small space occupied by the central dividing wall, which is a slight affair in relation to the total cross-section of the river. Obstruction to floods.
11335. Did you hear whether there had been any diversion of the stream above by the construction of the low weirs? No. I have received a letter from the Engineer of the Meuse works, in which he states that the barrage to which I refer is the sixth down from the French frontier. There are a number of others below that again, before you come to the Dutch frontier. Diversions.
11336. These six obstructions are in one river? Yes; in the part of it which runs through Belgium.
11337. They are under State management? Yes. State management.
11338. Did you hear of any objections being made by the people on the lower parts of the river, of the retention of the water in the upper weirs of the system? No; the river flows naturally, notwithstanding the slight obstruction. The system appears to me to be not to put too high a weir at any place, but to throw the water back in a succession of reasonably low steps by these comparatively inexpensive weirs—that is, inexpensive when compared with fixed weirs. System of low weirs.
11339. You have told us that the formation of the river-bed is somewhat raised, in consequence of the constant deposit of surface-material on its banks—that there is a natural fall away from the river on each side? No; that was with respect to the river passing through Lombardy; but, geologically, the whole of the valley of the Meuse at Nanur has been made up by the river, the same as other valleys are made up by rivers, as the Maccleay, the Clarence, and the Manning River flats, for example. Geological formation of Meuse valley.
11340. I want to know whether by the construction of these automatic weirs the water is at the command of any side of the country by gravitation? Not immediately opposite the weirs. Command of country.
11341. Or behind them? No; but you can command the country below with that water.
11342. That is, taking the natural fall of the country with the natural fall of the river? Yes.
11343. Would the water be taken off by off-takes from the back water of the river? I told you on the last occasion that there are no irrigation works on the Meuse; the works are for the conservation of water for navigation. If the people wanted to irrigate, they could do so.
11344. You think that where the country is suitable a head of water could be raised and distributed through canals for irrigation purposes? I say, that if you raised the water (say) 10 feet, you could afterwards use it for any purpose you chose.
11345. *Mr. M'Mordie.*] How long would the water last for irrigation purposes? I presume that would depend on the supply coming into the river and the acreage to be irrigated.
11346. But the capacity of the reservoir in the river would not be worth considering for irrigation purposes? If the cross-section of the river was half a mile or a mile, and the average depth 8 or 10 feet, you certainly could draw from that pretty considerably.
11347. Do you know of any cases where weirs are put across rivers, to conserve water for irrigation purposes? Weirs for irrigation purposes.

Mr.  
W. T. Poole.  
22 July, 1886

- Mr. W. T. Poole. purposes? I cannot refer to particular cases from memory, but there are cases where weirs are put across rivers to throw back the water.
- 22 July, 1886. 11348. By raising a head of water, so as to throw it out into the country? Yes; but not to irrigate in the immediate vicinity of the weirs.
- Storage reservoirs. 11349. You know of cases where river-beds are used for storage reservoirs? Yes; why not? If you have a river with a fall of 5 or 6 inches in the mile, and you constructed weirs—I am not wedded to any particular system (whether fixed dams, automatic or needle weirs), so long as it is economical and effective—and you throw water back to the foot of the next barrage, with a depth of 8 or 10 or 20 feet by half a mile wide, you would store a very large amount of water.
- Adaptability of the weirs to Darling River. 11350. *Mr. Franklin.*] You are aware that the Darling falls to a very low level, and remains at that level sometimes for many months—that it becomes so low as to render it dangerous for cattle to approach the small pools of water; do you think that by the automatic system we could throw back steps of water in the river, and make the whole frontage available at a safe level for stock? I think so. I have no doubt in my own mind that it would be an absolute certainty.
- Grand Junction Canal. 11351. Have you thought, in connection with that, that it would entirely stop navigation? Unless you provide for it. I have often thought, as a colonist and a politician, whether the water was not more valuable for irrigation purposes than for navigation, but I do not see any particular reason why you could not provide for both. Take the Grand Junction Canal, where I was brought up as a boy, on the summit levels, when you get up towards Tring. You are up almost on the summit, between Birmingham and London, where natural water is very scarce, and is of great value. There they have a system of side-locks.
- Side-locks. If a vessel is coming down the stream, the whole of the water is not allowed to escape to allow that one vessel to go through. The side-locks are constructed on the sides of the main lock, and a third of the water would be drawn off into the upper side-lock, and another third into the lower side-lock, the other third being allowed to escape. Take a boat coming the other way. The water in the lower side-lock was allowed to come into the main lock first, and from the upper side-lock second, and only the balance of one-third taken from the upper reservoir. These side-locks are of very simple construction, and are not costly. A puddle-wall all around them, some rough rubble masonry to line the sides, and a simple ratchet-valve are all that are required. This is the system all the way up and down that canal.
- Flood waters. 11352. Can you tell us what they do in Italy with regard to the waste waters—flood-waters, which are likely to submerge the works? You know that here we have very high floods, and if we could not control the river at the head, we should have to take large masses of water down over the works. The river Darling, for example, is liable to extreme floods, which would stop all operations of navigation through locks. Is there such a case as that in Italy? Of course, they are not subject there to such a tremendous range of rainfall; their rainfall is more regular; there are the summer, the spring, and the ordinary rains, and the snow-waters, and they know pretty well, in average seasons, what they will have to contend with. They are not subject to terrific downpours of rain in given districts in a few hours, as we are, and their works, naturally, are not constructed to provide for a contingency which, perhaps, does not happen once in fifty or sixty years.
- Height of needle weirs. 11353. *Mr. Gipps.*] To what extreme height, above the river-bed, can needle weirs be applied with advantage? I should be very unwilling to give an opinion as to the extremity to which the system can be carried. If you choose to strengthen the whole of the works, and cross-section the ironwork framing, and strengthen the needles themselves, you could then raise the height of the water above the barrage in a corresponding degree; but, with the section in use in the Namur Valley, I should say that it would be impossible—at any rate, it would be an unwise thing to attempt—to raise the weir 50 per cent. or even 25 per cent. higher.
11354. Are you aware that the French engineers state that the bar system can be applied up to 15 feet in depth? I am not aware of that from my own personal knowledge. I should say that it is quite possible. You would have to calculate the strain that the iron frame would be subjected to, and then you would have to design framing which would be sufficiently strong for the purpose. I see no insuperable difficulty in that.
11355. *Mr. Franklin.*] The works which you have seen are comparatively low-level works, and the frames which carry the needles are comparatively high? Yes.
11356. If the works were carried to a greater height, it would be necessary to have heavier frames? You would have to calculate the force of the water against the framework.
- Cost. 11357. *Mr. Gipps.*] What is the cost per foot of the needle weirs? I cannot tell you; my knowledge of contract-work here convinced me that it would be of no value to inquire as to what Continental prices were, as they would be no guide to us.
- Ratio of cost. 11358. Are you aware that the comparison of cost between needle weirs and masonry weirs, in the same proportion, is 20 to 50? I should be very reluctant to give an opinion as to the ratio of cost between the two systems in any and every position. If I had to construct a dam in a given locality, and there were abundance of stone at hand, and if I had to send 14,000 or 15,000 miles for iron framework, to construct a needle dam, it is likely if I were answerable for the cost of the work that I should use stone. But on our rivers, where, as a rule, there is no stone, and where material of every kind for constructive purposes must be brought a considerable distance, I should most certainly be in favour of the automatic and needle system, because the total amount of material is very small indeed, compared with that used in a fixed dam. All things being equal—that is, the position, and the facilities to get materials reasonably and quickly—I should certainly favour the needle system, or the combined needle and automatic system, where you did not want an excessive height—anything up to 14 or 15 feet.
11359. *Vice-President.*] What other inquiries did you make which would be likely to be of interest to the Commission? The plans which I produce of the several works give one of the best illustrations of the mode of using fixed weirs. The plans show the weirs and locks near Tewkesbury, under the supervision of the Severn Commission. Knowing that the feeling here was pretty general in favour of fixed dams, I thought that it was only right to get an example of that system from the English practice, as well as to get an example of the needle and automatic system adopted in Belgium. I put myself in communication with the engineer for the Severn works, and he wrote to me on the 11th July, 1885, expressing his willingness to accompany me down the river, and to prepare this set of tracings, for the sum of ten guineas. I saw the Agent-General, and represented to him that in my opinion the tracings would be of value here, and he agreed to purchase them, therefore they are Government property. The other plans I paid for myself.
- Weirs and locks at Tewkesbury. 11360. Did you examine any works designed for irrigation purposes only? Only those in Lombardy, which are

are considered the best. There are irrigation works in Scotland, but I did not think it worth my while to look at them. I should like to say again, that the geological construction of Italy is altogether different from that of this Colony. They have a central backbone range, and abundance of water, both from the sky and the melting of the snow. I should also like to refer to the enormous difficulty which any trust or company in England have to get an Act of Parliament dealing with any natural watercourses. They are not only tied as to the level, but are also under severe penalties if they throw the water back so as to interfere with the drainage of the land above. The engineer of the Severn works told me that they had great difficulties on that account. They had the whole of the farming body up in arms against them for attempting to raise the water at all. They declared that their land would be flooded, and their crops destroyed. But now there is a much better feeling; they are much more contented, and they approve of the works. Steps are being taken to raise the weirs and deepen the navigation right through—in other words, to conserve a greater quantity of water.

Mr.  
W. T. Poole.  
22 July, 1886.

11361. *Mr. Donkin.*] Were these works constructed by a private company? Yes.

11362. What is the water used for? For navigation, and for the supply of manufactories on the banks.

11363. How do they regulate matters; do they supply the water, and charge so much for it? Yes.

11364. Did you see any works that were carried out by the Government? No; I would point out this peculiarity. You observe the obliqueness of the dam across the river. You see that the river is widened above the dam on one side, and below the dam on the other. They are tied down by their Act not to lessen the cross-sectional area of the river; therefore in putting the weir across they have had to widen the river out, and only raise it such a height that the section across it would be equivalent to the cross-section of it in its natural state. Why I was anxious to get these plans was that I knew that one of the objects of the Commission was to report as to the best means of storing water for irrigation purposes. Once you have the water stored, you can do as you like with it. You will observe from the plans that in the Severn works the navigation is totally distinct from the weir.

Obliqueness of  
dam and widen-  
ing of cross-  
section.

11365. *Mr. M'Mordie.*] What is the width of the river Severn? Above the weir, about 165 feet. The weir line is about 500 feet.

11366. Is not the supply which could be given off above the weir only equal to what is coming in? Certainly. Supply

11367. The object of weirs for irrigation purposes must be to store water or to raise the level? It is to do both. If there were not a weir on the river, the water would flow down to the sea rapidly.

11368. *Mr. Franklin.*] You know that on our rivers in the interior there are large deep depressions corresponding with the general level of the beds of the rivers. If we had all these places stored with water it would be exceedingly valuable in times of drought? Yes, you could devote it to any purpose you required; I should say, as a general proposition, that not one drop of storm-water should be allowed to go to the sea until it has done duty somewhere.

Depressions.

## APPENDIX B

[To Evidence of Mr. J. B. Martin]

THE LATE FLOOD IN THE NEPEAN. ARE THERE NO MEANS AVAILABLE TO ABATE THE DESTRUCTIVE CHARACTER OF THESE INUNDATIONS?

*To the Editor of the Herald*

Sir,

Reliable information with reference to unusual occurrences, disastrous or otherwise, finding ready admission into your columns, I should make no apology for trespassing upon them, had I not an ulterior object in requesting you to give insertion to my communication

The late flood in this (Nepean) branch of the Hawkesbury was produced by rain over the basin of its upper waters, rather than by any considerable fall in this neighbourhood.

The entire quantity by rain gauge, from nightfall on the 13th instant to the same period on the 17th, amounted to 4·15 inches, of which 2·44 inches (comprising the only hard rain) fell during the last ten hours of the period, and after the flood had reached its maximum. The total rise of the water appears to have been about 47 or 48 feet, being within 5 feet of the maximum attained by the June flood of 1867, and 8 feet 6 inches below the great flood of April, 1860, the highest yet known on this part of the river.

The late flood could not be termed a very high one, yet through merely local causes it has been more damaging than earlier experience would have led one to anticipate. I will particularize we had exposed more or less to the action of the waters the following perishable crops—Maize, about 26 acres, the greater part a magnificent crop in full cob, barley, sown early last month to produce a late autumn crop of grain, 10 acres; potatoes, haricot beans, &c, 10 acres, mangolds and swedes, sown immediately after the first rain last month, and very flourishing, 24 acres, lucerne, fit for mowing, about 80 acres, low-lying pastures—a very thick sward of rich, succulent grasses above ankle deep, about 300 acres. They have fared as follows—The maize, excepting about 2 acres of late planted, which is destroyed, is uninjured, 10 acres of swedes, the same; 14 acres of mangolds, much damaged, several acres quite destroyed, the soil removed and deposited in heaps and ridges, 10 acres of barley quite killed, the season too far advanced to re-sow a crop before winter; 10 acres in potatoes and sundry crops destroyed, lucerne—the crop, over about 70 acres, quite destroyed, and the broad surface of luxuriant, rich pasture brown with muddy sediment, the very abundance of the grass being rendered a nuisance likely to cause the pastures to be unserviceable for a considerable time. Besides the above, there was in the vineyard a crop of grapes in prime condition, ten days ago estimated to produce, after fifteen or twenty days of moderately fine weather, about 10,000 gallons of wine. They have been so damaged as to lower the estimate to three or four thousand gallons of inferior quality. It was the rain of the last day especially which ruined them, the temperature, as indicated by thermometers exposed to it, having increased with the increasing copiousness of the rain from 60°–62° to 70°–72°. This last, however, is not to be placed to the score of flood.

The above constitute the major evils, the minor instances of damage branch into such a variety of detail that I forbear to state them. One's losses, however, are not to be repaired by grieving over them, so

we

we have not lost the fine weather succeeding the rains. By the help of the mowing-machine a goodly portion of the lucerne is cut down and being carted to the nearest muck-heaps, the wreck is being cleared off, the ditches cleared out and repaired. The horse-hoes and hand-hoes are effectively at work amongst the swedes and mangolds, and the fast rotting grapes are undergoing conversion into, I fear, no very near resemblance to "Johannisberg," nor even to "Camden Park" of 1858.

But it is not to parade our losses, or our diligence in repairing them, that I trespass upon your attention. We made no complaint on former occasions; and yet, in common with immediate neighbours, who were equally uncomplaining, we suffered very grievously in the flood of last June; but with an infinitely greater extent of disaster in 1860 and 1861, and again in 1864. Please bear these dates in remembrance.

I have had a long term of experience on this spot—more than fifty years. The flooded lands on this property are the nearest of any to its source on this side of the river. Higher up the stream, to its very commencement, the waters are confined between rocky precipitous banks, far above any floods. The first one I witnessed, as well as I remember, was just forty-nine years ago, being succeeded the same autumn by two more (all high) floods. The following year there were again three high floods, but all were ushered in by long periods of very heavy rains. They rose very gradually, continuing at their highest levels many hours, sometimes for days. They were serious matters in those times to trans-Nepean residents, and were apt to find out weak places in the commissariat, but they did not damage the land nor sweep away the fences in the fashion of later floods. From 1820 to April, 1830, there was no flood. Every year there were periods of heavy rain and corresponding freshes in the river, without extensive overflows; but in this year, and again in April, 1831, there were floods, about as high as the recent one. They did no damage (I hardly think they removed a panel of fence), although I remember to have thought the 1830 flood got up more rapidly, that is, with heavy rain of shorter duration, than I had been used to. Succeeding 1831, there was another long interval without flood, ending in April, 1842. From this time forward they have been greatly more frequent, being sometimes produced by very trifling rainfalls. Dividing my half-century into two periods of twenty-five years, I find that in the first there were ten floods, and in the second about twenty-seven, thus:—1819, 3 floods; 1820, 3; 1830, 1; 1831, 1; 1842, 2; 1843, 1; 1844, 1; 1845, 1; 1848, 2; 1850, 2; 1852, 1; 1853, 1; 1855, 1856, 1857, 4 (I was absent in Europe, but believe that more than I have specified occurred); 1860, 5; 1861, 2; 1864, 3; 1866, 2; 1867, 1; 1868, 1; total, 27. Besides, I may state from hearsay, that previously to 1819, and dating from the first occupation of a hut on the banks of the river, near the sill of the present Camden bridge, by constables Warby and Jackson, as far back as 1805, not more than two, or at most three, floods happened; yet no one supposes, the average of years being taken, that more rain falls now than formerly. I pass over the floods from 1843 until we come to 1860. This was a very remarkable year, with a greater rainfall than I had witnessed since 1819—producing five floods, two of them the very highest by several feet yet experienced. The first rose, after very little rain about this quarter, with unprecedented rapidity (it rose in six or eight hours), doing an immense amount of damage. I was desirous to mark in several spots the extreme level reached by the waters; but when the person employed proceeded to drive in with an axe the stakes which had been provided, he could not accomplish it, the ground beneath the surface being so dry and hard; it had not been moistened 6 inches deep.

Since 1860, we notice as a rule that the floods come up with greater rapidity. I can assert confidently that, besides their increased frequency, there is a marked change in their shorter duration, and in the rainfall requisite to produce them—that they rise and pass off with greater rapidity, and that the flood-waters instead of assuming the appearance, for several successive days, of tranquil lakes over the greater portion of their extent, now take the character rather of rapid currents, quick to rise and then disappear, but doing an infinitely greater amount of damage. I am aware that the clearing of the country, and the hardening of the surface by the trample of stock, may be alleged to partly account for the change; but these reasons are only to a limited extent applicable to our case. The basin of the Nepean lies chiefly on the flanks of barren sandstone hills and mountains, totally unoccupied by man, or by his flocks and herds, and presenting now much the same features as fifty years back.

But there is another change—one in the state of the channel of the river—which, although it has perhaps, been of slow progress, has become very marked when comparison is made of the present condition of certain spots with what they are remembered to have been thirty or forty years ago. The banks from immediately above the low level channel have become densely covered with trees and brushwood, so as very greatly to obstruct the flow of the water during freshes. After much reflection, I am inclined to attribute the marked changes in the floods chiefly to this circumstance. With your permission, I will revert to the subject in another letter, in which I will state what steps seem best calculated to stay the great and increasing destructiveness of these floods.

Camden Park, 22nd February, 1868.

WILLIAM MACARTHUR.

THE LATE FLOOD IN THE NEPEAN. ARE THERE NO MEANS AVAILABLE TO ABATE THE DESTRUCTIVE CHARACTER OF THESE INUNDATIONS?

*To the Editor of the Herald.*

Sir,

I resume the subject of my former letter upon floods in the Nepean, and the means calculated to abate their frequency and severity.

The bed of the river for the most part consists of loose, shifting sand, and the portions subject to overflow—the outer banks—consisting of light sandy loam, are usually from 45 to 55 feet above the bed. They in most places comprise a considerable area in proportion to the ordinary volume of the stream, being from 80 to 150 yards across. The water is fringed with trees growing close to its margin at low-water level (many of them of considerable size) of *Casuarina* and *Tristania* ("river oak" and "water gum"), which interlace their branches over mid channel. They must exceedingly check the flow of the current from the time the river begins to rise, but they have always existed; besides these, the whole of the great ravine between the outer banks has become much filled up by large sapling trees and brushwood—a tangled thicket generally of mingled wreck and rank vegetation, and altogether very different from the state in which I first knew it. This altered condition of the proper channel must tend to force the currents in flood-

time over the cleared and cultivated lands beyond the outer banks. If this channel were to be completely cleared from side to side of all obstructing vegetation, I believe the flow of water in times of heavy rain might be accelerated in the proportion of as much as six to four, and of course the capacity of the channel to carry off the accumulating waters be increased in the same ratio. The highest flood yet known attained the height of about 55 or 56 feet. Now, a rise of 40 feet hereabouts would do us no damage; even at 43 or 44 feet it would generally be of little consequence. It is the last few feet in high floods which do so much mischief. But, besides the main channel of the river, which I should propose to have cleared out, there are other channels—"races" they are often termed—taking usually alternate sides of the river, and cutting off the angles formed by its tortuous course. Opposite the greater bends these "races" are sometimes a mile from the river. They are the portions first covered with water when the rivers overflow, and are hardly ever susceptible of being cultivated, owing to the violent currents to which they are subject. They are frequently thickly clothed with brushwood, and in many instances have never been cleared. These channels, also, ought to be freed from every obstruction.

There are again several points, one especially, where the river is constricted between high rocky banks, the bed being a series of falls or rapids. In these places, also, it is believed that the waterway may be materially improved by clearing out the obstructing brushwood (which, it is hardly needful to repeat, should be cleared out wherever the current is obstructed), and probably by lowering or altering the channel. Indeed, it is asserted that in one place, by cutting a comparatively trifling channel on the Cumberland side, an immense bend of the river might be saved, and that an opening being once made, the waters in flood rushing over the increased declivity would soon establish a sufficient channel.

The foregoing proposals, as you may observe, are all with the view of preventing the too rapid accumulation of the flood-waters, by freeing the points most obstructed from whatever may impede the outflow. But higher up the stream than the first flooded lands, above Menangle viaduct, for instance, the more the channel could be dammed up or obstructed the better, as there are here no lands susceptible of injury from flood. I do not conceive any such measures would be requisite, but the nature of the channels of the upper waters favours the idea that their headlong course in violent rains might be greatly retarded by blasting the overhanging rocks at the numerous points where the streams change from comparatively tranquil reaches to foaming rapids. Nearly the highest and the most destructive flood we have known was apparently wholly caused by the waters suddenly pouring down upon us through these rocky channels of the river's head waters. It was not a distressing flood on the Hawkesbury, if even seriously felt, and here took only about six hours from the commencement of the fresh to reach its extreme point. There are places between the rocks where it must have been stopped back to the height of 70 or 80 feet. These rocky ravines are of very irregular width, but tolerably uniform in the height of their precipitous sides—usually from 200 to 300 feet. Numerous piles of rock, thrown by means of gunpowder across these channels at favourable points, so as to form rude dams, would have great effect in delaying the arrival of the flood-waters below until they could be more safely conveyed away. But, as I have said, I allude to this portion of the subject as only of secondary importance probably to the thorough clearing out of the channels lower down.

You will observe that hitherto I have dealt with the question only in a limited point of view, that of the proprietors on the Nepean, from Mulgoa upwards; but there is a much larger interest to be considered—that of the proprietors from Penrith downwards. The Warragamba falls into the Nepean at Mulgoa. The course of the former river, rising above 20 miles beyond Goulburn, is two and a half times longer than the Nepean, and the area of its basin must be more than five or six times as extensive. It would seem, therefore, to be the soundest principle, in dealing with the flood-waters of those rivers in the interests of the large agricultural population on the Hawkesbury, to hasten down those of the shorter river, and to hold back by all available means those of the longer. The measure of damming up the waters of the latter to a level high enough to reach Sydney by gravitation is, as you are also aware, one of the means of water supply under consideration. It is therefore on several grounds that I hope the bold proposal of my old friend Mr. Woore may after full investigation prove to be the most feasible. I shall rejoice in the hope of an unlimited supply to Sydney of the purest water, and that the intelligent mind which imagined this plan should meet with its just reward; but it will be an additional gratification to have the reasonable assurance that the same measure may be made a means of greatly mitigating the effects on the Hawkesbury of the flood-waters of its principal tributary. It must require the united flood-waters from both rivers to create a high flood below. The waters of the Nepean must be first down. I would hasten their arrival, while Mr. Woore's plan would hold back for hours the waters of the Warragamba. I am quite sure that hereabouts, at all events, it is often a mere question of an hour or two whether it is a flood or no flood.

But is there not also the probability of relief to the Hawkesbury low lands by reasonable outlay upon the course of the river below Windsor? I have always understood the channel about the Upper Portland Head to be exceedingly constricted, and at other points likewise. The tide no doubt must have great influence at times in checking the outflow. These are all questions requiring early and careful investigation: I think they are of importance sufficient to be referred by the Government to a Commission. The expense of the inquiry should be borne by the general revenue, but the expense of works to prevent or mitigate the great floods would fall most fairly upon the parties who benefit by them. Government might very properly undertake necessary works, taking power by Act of Parliament to levy rates upon the river-side proprietors to cover interest and gradually extinguish the principal of the outlay. For the relief of the Nepean, I believe that £100 to £200 per mile would be ample, and there are not, I think, above 30 miles of its course which require to be dealt with. Our share at Camden would be for the half of 13 or 14 miles; I would gladly compound for no flood by paying a much more considerable sum than at my estimate we should become liable for.

23 February, 1868.

W. MACARTHUR.

## APPENDIX C.

## APPENDIX D 1.

ESTIMATE of the Original Cost and Working Expenses of the Irrigation Appliances at the Chinamen's Gardens, the Peninsula, Windsor.

Original cost of engine, boiler, and pipes .....	£	s.	d.
Repairs soon after commencing to work .....	145	0	0
Fixing engine, boiler, and pipes .....	8	0	0
Carriages from Sydney, and other expenses .....	11	0	0
	20	0	0
Total cost of starting operations .....	£184	0	0
Cost of coal per week .....	1	0	0
Castor oil for engine .....	0	2	0
Chinaman's wages for occasional attendance on the engine during the week .....	0	5	0
Weekly outlay, exclusive of wear and tear .....	£	1	7

With the above-mentioned appliances my Chinese tenants effectually irrigate about 5 acres of land, and with an additional outlay of a few pounds they propose to extend their operations to about 5 acres more. It is extremely difficult to obtain a satisfactory statement from the Chinese, owing to their imperfect knowledge of English, but I have done the best I could for the Commission. The Chinese refused to draw their water supply from the Hawkesbury River, but two other gardens have been recently established by these foreigners on the South Creek. The water in this tributary of the Hawkesbury is said to be slightly brackish, but it is not known if its effect on vegetation is injurious. That question will doubtless soon be decided.

JOHN TEBBUTT.

Windsor, 23 July, 1886.

JOHN TEBBUTT.

## APPENDIX.

*Appendix to evidence of Mr. A. Dewhurst, given before the Commissioners, at Tamworth, 9 May, 1885.*  
(See *Evidence to First Report*, p. 149.)

Mr. District-Surveyor Dewhurst to The Secretary, Royal Commission for the Conservation of Water.

Sir,

District Survey Office, Tamworth, 1 November, 1886.

In compliance with a promise made to the Commissioners who honored Tamworth with a visit of inquiry, to ascertain facts in connection with Water Conservation and Supply, I have now the honor to enclose a tracing of a survey just completed (*vide* portfolio of maps and plans), showing the water catchment and approximate storage area at the locality which was officially inspected, and at the time (provisionally of course) approved as a suitable reservoir for the convenience of the town.

It appears that the whole catchment area does not exceed 850 acres, while the average rainfall over seven years equals 31 inches yearly; \* and the evaporation during summer (October to March inclusive), when the fall is greatest, equals 54 inches, and in winter 17 inches.

The country is volcanic, faulty, and porous to an unusual extent; and, although the enclosed letter from a resident of seventeen years discloses the information that during the period the gully ran down "several times," I am satisfied the stream was small, and only lasted an hour or two.

Under these circumstances, and taking into account the small watershed exhibited by the survey, I must respectfully withdraw any remarks which I made under examination in Tamworth favouring in any degree a scheme for the supply of water with this area as a factor, and retire upon the more reasonable scheme of utilizing the underground waters of the Peel valley.

May I request you will do me the favour to bring this matter under the notice of the Commission at their next sitting, and inform me at your earliest convenience, after it has been considered, whether any reason remains for locking up this area longer from sale and settlement.

I have, &c.,

A. DEWHURST, D.S.

If the Commission still consider this area should be reserved for the collection and storage of water, it would be evidently desirable to resume at once John Gill's 40 acres, being portion 3, parish of Tamworth, as it is the only site for the erection of a dam. The land is poor and stony; its market value is not more than 25s. per acre.—A.D.

\* The average number of days on which rain fell during twenty-one years is 71.

Mr. William Ahern to Mr. District-Surveyor Dewhurst.

Sir,

Dead Horse Gully, 29/10/86.

I received your note this morning, 29th instant, asking for information about the farm that I sold to Mr. Cohen. I resided on it for seventeen years. The creek which comes from the hills at the back; after heavy rain the creek comes down,\* and if the winter is moist remains for some time. At the head there is almost a permanent water-hole from a spring;† but there are some places where water could easily be obtainable from old springs.‡ The creek comes down after heavy rains; and it has been down several times in seventeen years, but the exact number I do not know. But should you require any further information, if you let me know when I am in town, I will call and give you all the information that I know.

I have, &c.,

WM. AHERN.

\* Every gully comes down after heavy rain.

† The spring has been dry for years, I understand.

‡ These are soakages from

the overlying soil—they have dried up years ago.—A. DEWHURST.

CORRESPONDENCE ON WATER CONSERVATION AND IRRIGATION IN EUROPE AND AMERICA, RECEIVED THROUGH THE COURTESY OF THE COLONIAL OFFICE.

Mr. Fenton to Earl Granville.

(No. 125.—Commercial.)

My Lord,

The Hague, 17 October, 1884.

I have the honor to acknowledge the receipt of your Lordship's despatch, marked Circular Commercial, of the 6th instant, instructing me to take steps to procure through the Netherlands Government, for communication to the Government of New South Wales, any available information on the subject of the storage, conservation, and distribution of water in this country.

In reply, I have the honor to state that, having made inquiries unofficially on this subject of Mr. de Willebois, and having also consulted a gentleman of my acquaintance, who is an authority in matters connected with water engineering, I have ascertained that no such information as that desired by the Government of New South Wales is to be obtained in this country, for the reason that, so far from there being any necessity for the adoption of measures for storing or conserving water in the Netherlands, one of the greatest difficulties the country has to contend with is that of getting rid of the large quantity of superfluous water which is to be found throughout nearly the whole length and breadth of the Kingdom.

I may add that Mr. de Willebois has also informed me that neither in any part of the Dutch East India Possessions do special works exist for the collection or conservation of water.

Under these circumstances I propose to abstain from addressing any official request to the Netherlands Minister for Foreign Affairs for information on the subject in question, unless I should be otherwise instructed by your Lordship.

I have, &c.,

H. P. FENTON.

The Hon. L. Sackville West to Earl Granville.

(No. 244.—Commercial.)

My Lord,

Washington, 2 November, 1884.

I have the honor to acknowledge the receipt of your Lordship's despatch, marked Circular of this series, of the 6th ultimo, relative to the wish of the Royal Commissioners in New South Wales, to be furnished with certain information respecting the method adopted in this country for conserving the rainfall and of developing the underground reservoirs of water, and to enclose to your Lordship herewith copy of a note which I have received from the Acting Secretary of State, together with copy of a letter from the Agricultural Department enclosed therein transmitting the accompanying documents.

I have the honor to submit to your Lordship that to collect all the information alluded to in the letter from the Agricultural Department would occupy even a competent person some months, and entail considerable expense.

I have the honor to be, with the highest respect, my Lord,

Yours, &c.,

L. S. SACKVILLE WEST.

The Acting Commissioner, United States Department of Agriculture, to the Secretary of State, Washington.

United States Department of Agriculture,

Sir,

Washington, D.C., 29 October, 1884.

I have the honor to acknowledge the receipt of your letter of the 24th instant, accompanying a copy of a note from Mr. West, the British Minister at this capital, asking for any available information this Government might possess in regard to the subject of the conservation of water, and of developing the underground reservoirs thereof for agricultural purposes.

In response I have the honor to report that this department has no further data at present than may be found in the enclosed report made by a commission appointed on artesian wells and their practicability, among the Colorado foot hills of the Rocky Mountain Range. I also beg to refer you for the information of Mr. West and the Government of New South Wales to a report made by Major J. W. Powell, Director of the United States Geological Survey, entitled, "The Arid Lands of the United States." Major Powell has probably other data in this regard, which would be of service to the Royal Commission of New South Wales. I beg leave also to refer to a report of the United States Commission of Irrigation in the Sacramento Valley, &c., &c., Cala. Pub. Doc. H. of R., 43rd Congress, 1st Ex. Doc., No. 290, no copy of which is, however, in this department.

There is a large amount of information scattered through the many reports of United States Explorations, Geological Surveys, and also in State and Territorial reports. At present this is not directly available. This department is, however, engaged in the preparation of a report on the questions referred to in the memo. of the New South Wales Commission. It will probably be printed during the ensuing winter, and will contain the data desired so far as it is possible to ascertain the same.

The general Government has not taken any positive steps towards any similar inquiry to that which is under way in New South Wales. Heretofore action has been had mainly by and through private enterprises in the establishment of land reclamation and irrigation works.

On the States and Territories of the United States affected by insufficient rainfall (which for full agricultural duty should not be less than 30 inches per annum,) laws and local customs, more or less insufficient in character, provide for the distribution of running and surface waters, and for the regulation of the amounts to be used by each irrigator.

In the volume referred to, "The Arid Lands of the United States," a good account is given of the system in use in Utah.

The State of Colorado has a code of laws designed to incorporate water companies, and to regulate the use, preservation, and distribution for farming purposes, of the waters of that state; an officer known as the State Engineer (Honorable E. S. Nettleton, Denver, Col.), is in general charge.

There are nine district judges having special powers to settle all water disputes. These districts are conterminous in area with the judicial districts of the State. Copies of the laws of Colorado on this subject may be found in the Law Library of Congress (General Statutes, State of Colo., pages 560 and 587). They are of importance, and contain features worthy of study.

The State of California contains extensive works for the conservation, storage, and distribution of water, chiefly from the mountain sources, while the watercourses of the State are very largely utilized for irrigation purposes.

These works have, in the first case, been constructed as aids to hydraulic and mining enterprises; they are, however, largely available for agricultural uses also. The surplus of water is entirely consumed in this way.

The irrigation system dependent upon the lakes and watercourses of late years has been almost entirely constructed by co-operative corporations of the farm owners organized under State law. For more direct and fuller information I beg to refer you to the reports of the State Engineer of California for the years 1880-81-82 and 1883, which, especially the first volumes, will be found full of important data. Mr. William Hamilton Hall, State Engineer, Sacramento, Cala., will undoubtedly forward the documents named.

The old Mexican local laws, as well as the miners' code, as to the use of water, both prevail in California, as also in Nevada and the Territory of Arizona.

In the latter, extensive irrigation works are now under way.

In Western Kansas and Western Texas private enterprise under State laws is now engaged in extending irrigation and water storage works. The detail of these efforts will, in some degree at least, be presented in the report now being prepared by this department.

I have, &c.,

E. A. CARMAN,

Acting Commissioner.

Department

Department of State, Washington, to the Honorable L. S. S. West.

Sir,

Department of State, Washington, 31 October, 1884.

Referring to your note of the 20th instant, requesting such information as may be available in relation to the subject of the conservation of water and of developing the underground reservoirs thereof for agricultural purposes, I now have the honor to enclose herewith the reply of the Commissioner of Agriculture, to whom the subject was referred.

The report of the commission appointed on artesian wells referred to in the note of the Commissioner is herewith enclosed.

The many other reports referred to are not now available.

The Department of Agriculture is, however, engaged in the preparation of a report on the questions referred to in the memorandum of the New South Wales Commission.

This report will be sent to you when printed, probably during the coming winter, and will, it is thought, contain the data desired, as far as it is possible to ascertain the same.

Accept, sir, the assurances of my highest consideration.

I have, &c.,  
W. HUNTER,  
Acting Secretary.

Mr. Locoock to Earl Granville.

(No. 23.—Commercial.)

My Lord,

Belgrade, 24 November, 1884.

I have been unable to obtain any information such as that sought for by the Royal Commissioners charged in New South Wales to inquire into the question of the conservation of water, and for which I was instructed to apply to the Servian Government in your Lordship's despatch, marked "Circular Commercial," of the 6th October.

The question of the water supply in Servia is not one which has hitherto occupied the Government, and the natural supply by streams and rivers, and by the pretty regular rainfall, is such that it is unlikely that it will ever be necessary to construct works of any importance for the conservation of water. The above refers to water for irrigation. In the villages and small towns any natural flow of water which exists is supplemented by ordinary wells, these also being used, where necessary, for the watering of flocks and herds.

I have, &c.,  
SIDNEY LOCOCK.

Sir H. Barron to Earl Granville.

(No. 14.—Commercial.)

My Lord,

Stuttgart, 29 November, 1884.

In obedience to the instructions conveyed in your Lordship's circular of October 6th, I have the honor to transmit herewith a Report on the Public Water Supply in the Kingdom of Wurtemberg, under the Government of King Charles, published by the Ministry of the Interior. This work seems exactly to meet the requirements of the New South Wales Government, as expressed in Mr. Secretary Robinson's letter of July 17th. The distribution of water for irrigation purposes has been brought to great perfection in the Black Forest region of Wurtemberg and Baden, and might be there studied with advantage. This branch of the subject is not treated in the accompanying report, but I beg to call particular attention to the description therein of the works executed for supplying drinking water to the arid highlands of the Suabian Alp, a novel and interesting work. No private or joint stock firms exist here which undertake to supply water to the public. This is a business of the communal authorities. In towns they have proved themselves quite equal to this task, but not so in rural districts. In 1865 the Government determined to aid the communes in their efforts by recommending to them a distinguished specialist, the Oberbaurat Dr. Von Ehmman, as a consulting engineer for the execution of hydraulic works. In 1869 the office of "Staats-Techniker" for the public water supply was created in favour of the same Dr. Von Ehmman. Henceforward he was obliged to give his advice gratuitously to those communes which might require it for carrying out any important water-works. An additional functionary was appointed in 1877 under the title of "Wasserbanispektor."

Stuttgart, 1881.  
Greiner and  
Pfeiffer.

This official and gratuitous organisation of the service gave a great impulse to the creation of new works. Down to the end of 1880 more than 200 such were executed, and many others were planned. New waterworks, with high pressure, and mostly with auxiliary steam power, have been erected in all the large towns, viz., at Stuttgart, Ulm, Heilbron, Esslingen, Ludinsburg, Tübingen, Friedenstadt, Cannstatt, and Reutlingen. The village of Nussdorf, standing on a waterless ridge 357 metres above the sea level, was the pioneer of this movement among the rural communes so far back as 1866. Availing itself of the new facilities granted by the Government, the corporation decided unanimously to erect a steam pump for the purpose of forcing spring water to a tank 120 metres above the valley. The work was rapidly, cheaply, and successfully completed at a cost of £3350, and acted as a powerful encouragement to other villages similarly circumstanced to adopt the same course.

Numerous communes of the Suabian Alp, in the same plight as Nussdorf, were debarred by their poverty from adopting the same remedy. This range of hills is composed of a porous rock, through which the rain-water percolates as through a sieve. Some few rivulets which arise disappears in the earth soon after their formation. For its water supply this population had hitherto been restricted to a scanty rainfall, collected in cisterns and horse-ponds. This repulsive water was, moreover, at times entirely deficient; in such cases the peasants had to send their carts many miles to fetch water from the valleys at immense inconvenience and expense.

In 1867 the Government determined to take this matter in hand on an extensive scale. The first scheme which suggested itself was to drain and collect all the surface waters which could be found into large

large tanks. This idea, evidently a mere development of the old system of cisterns, proved to be impracticable on a large scale for the following reasons:—

- 1st. The porous nature of the soil and the absence of clay hindered the collection of the water and the construction of tanks.
- 2nd. The water derived from surface drainage was objectionable on sanitary grounds.
- 3rd. The peasants were prejudiced against draining their lands.

It was determined, therefore, to raise the waters from the valleys by mechanical means. To execute such a design was palpably above the strength of the small, scattered, and isolated communities. It was determined, therefore, to carry it out on a broad and comprehensive plan, under the direction and partly at the expense of the State.

Such a plan was drawn up by Dr. Ehmann, founded on the principle of supplying the arid plateau of the Alp with pure water from the valleys by means of water power alone. The financial difficulty was got over by uniting several communes together for this particular enterprise into one group, similar to the body known in Flanders as a "Watering," each commune contributing to its expense in proportion to its population. The Government took upon itself the supervision of the works, all the preliminary expenses, and a large share of the expenses of construction. This undertaking was begun in 1870 with the first group, consisting of three communes, and was most successfully completed in 1881. The nine groups, comprising 102 communes, with 37,315 inhabitants, cover an area of seventy square miles.

The leading idea of the scheme was to divide the whole district into a certain number of independent sections, according to the topographical and hydrographical character of the soil, each section to be provided with one pumping station, which should force the pure spring or river water from the valley to one or more tanks on the high ground, the water to be thence distributed by its own weight through a network of cast-iron pipes to all the villages included in the section. The pumps are all driven by water power alone; but in some of the stations a small auxiliary steam-engine has been provided, which might be adapted to the pump if necessary in case of a long drought. This assistance has not yet, however, been found necessary. These works have, some of them, been in operation for thirteen years without any material repairs or any lengthened interruption of the supply having been found necessary, even during the severest winters.

The aggregate length of the cast-iron main and branch pipes is 223 miles; that of the wrought-iron house-pipes 87 miles. The number of house-pipes leading from the mains to private houses and stables is over 7,000. The nine water wheels employed in driving the pumps possess an aggregate force of 300 horse-power. By this means a daily supply of 1,100,000 gallons is forced up to heights varying from 115 to 305 metres. The normal supply of water in the sixty-two tanks is 4,400,000 gallons; the number of hydrants provided for extinguishing fire is 1,600; the number of street-pumps (in seven groups alone) is 178. The minimum daily supply of water provided is 75 litres (16½ gallons) per head of the population; but this might, if necessary, be largely increased.

The aggregate gross cost down to the end of 1880 of these nine waterworks amounted to £284,400. Of this sum £220,955 was borne by the communes, and £63,445 by the state. Some of the outlay was paid exclusively by the communes, such as branch pipes, street pumps, purchase of land, of water power, of fishing rights, and compensations for irrigation. Other expenses, such as those of surveys, estimates, and superintendence were borne exclusively by the State. The cost of erecting the works themselves was in a certain fixed proportion borne by the parties jointly, 20 per cent. being the proportion assumed by the State in the seven last groups. Some further trifling disbursements will bring the final aggregate outlay of the State up to £65,543. The gross cost of each of these nine several waterworks varied from £6,780 to £50,000. The capital charge falling on the communes varies from £4 5s. to £7 10s. per head of the population. Thanks to the exclusive use of water power, the working expenses are trifling, including only wages, grease, heating, and lighting materials. They are divided among the communes of each group in the ratio of their resident population. The amount of these expenses and that of the revenue derived from private consumers are not stated.

I have, &c.,  
H. BARRON.

---

Sir E. B. Malet to Earl Granville.

(No. 143.—Commercial.)

My Lord,

Berlin, 2 December, 1884.

On the receipt of your Lordship's Circular Commercial Despatch of the 6th of October last, relative to the wish of the New South Wales Government to obtain information respecting the conservation of water in this country, Mr. Scott lost no time in requesting the Acting Minister for Foreign Affairs to furnish him with any available information with regard to the storage and distribution of water in Germany.

In a note dated the 29th ultimo, Count Hatzfeldt informs me that Wurtemberg is the only one of the confederated states in which any such system is established to any great extent.

The system of water supply in the Rauhe Alp district was carried out during the years 1870-1881, and Count Hatzfeldt forwards for presentation to the New South Wales Government a work entitled, "*Die öffentliche Wasser-Versorgung im Königreich Württemberg*," by Dr. Von Ehmann, giving full details as to the system in question.

I have, &c.,  
E. B. MALET.

---

Mr. Jocelyn to Earl Granville.

(No. 17.—Commercial.)

My Lord,

Darmstadt, 26 December, 1884.

With reference to your Lordship's despatch marked "Circular" of this series, of the 16th of October last, with regard to the conservation of water, I have received from Monsieur Turban a reply to my request for information on the subject, a translation of which is herewith enclosed.

His Excellency in stating that the matter referred to in your Lordship's question has not been studied or reported upon in Baden has nevertheless afforded very valuable information as to the conservation

conservation of water with a view to the prevention of floods and its utilization for agricultural and other purposes, and the reports in illustration of it which I now have the honour to forward will doubtless be of service to the Royal Commissioners.

I have thanked Monsieur Turban for his courtesy in giving the above information.

I may mention that with regard to the Grand Duchy of Hesse I have learnt that no information whatever on the subject exists, the conformation of the country being such as to preclude all necessity for the conservation of water.

I have, &c.,  
N. JOCELYN.

(Translation)

Monsieur Turban to Mr. Jocelyn.

Karlsruhe, 19 December, 1884.

Sir,  
With reference to your note of the 8th ultimo, I have taken the necessary steps to inquire of the Department of Roads and Waterways what publications or private documents have appeared in Baden respecting the collection and distribution of water, and also what has appeared on the subject in neighbouring countries which might be of interest to Her Britannic Majesty's Government.

In reply to my inquiry, I have been informed by the above-named technical department that, with the exception of a short pamphlet on the stoppage of valleys to diminish the danger of inundations, entitled "The Floods and their Disastrous Consequences on the Rhine in November and December, 1882, by Honsell, Berlin, 1883," no publication of the kind exists.

The favoured situation and circumstances of Baden have hitherto given no cause to consider the question of the collection of water. On the other hand, the Government of Wurtemberg has conducted investigation as to the establishment of a chain of reservoirs, by means of which not only the prevention of inundations, but also the utilization of the collected water for agricultural and industrial purposes, has been kept in view.

The results of this inquiry have been made public in a memorandum on the "Diminution of Floods in the River Steinbach by the construction of reservoirs, Stuttgart, 1883."

The same theoretical principles that govern the successful endeavours to collect water in reservoirs are to be applied to the regulation of the outflow of a lake at a high level.

With regard to the majority of the Swiss lakes, reports referring to this subject are extant.

The most exhaustive of these, and having special reference to the retention of water in a great inland basin, is to be found in the publication "The Bodensee, and the deepening of its high water level," by Honsell.

In the hope that the above information, referring though it does to much that has been done in a neighbouring country, will prove of interest, I have the honour to transmit to you the accompanying copies of the works of M. Honsell above mentioned, who is the Chief Architect and Inspector of the Department of Roads and Waterways for the Grand Ducal Government.

I avail, &c.,  
TURBAN.

Mr. Sanderson to Earl Granville.

(No. 44—Commercial.)

My Lord,

Bucharest, 28 December, 1884.

With reference to your Lordship's circular of the 6th October, instructing Mr. White to procure through the Roumanian Government, for communication to the Governor of New South Wales, any available information respecting the storage of water, I have the honor to enclose a copy of the note I have received from Monsieur Stourdza in reply to that addressed to him by Mr. White on the 16th October last.

The Foreign Minister regrets that he can give no useful information on this subject as the matter is not provided for by legislation and no methodical system is applied in practice.

I have, &c.,  
PERCY SANDERSON.

[Enclosure.]

Monsieur Stourdza to Monsieur Sanderson.

Monsieur le Chargé d'Affaires,

Bucarest, le 15-27 decembre 1884.

En réponse à la note de la Légation de S. M. Britannique du 4-16 octobre dernier, No. 22, j'ai l'honneur de porter à votre connaissance qu'il n'existe, dans la législation ou dans les réglemens d'administration du Royaume, aucune disposition relative à la conservation des eaux pluviales et qu'aucune mesure, fondée sur un système méthodique, n'est pratiquée à cet égard dans aucune des localités du pays.

En regrettant de ne pouvoir fournir sur cette matière quelque indication utile au Gouvernement de la Nouvelle-Galle du-Sud, je vous prie, M. le Chargé d'Affaires, de vouloir bien agréer, etc.

D. STOURDZA.

Foreign Office to Colonial Office.

Sir,

Foreign Office, February 12th, 1885.

I am directed by the Secretary of State for Foreign Affairs to transmit to you, to be laid before the Earl of Derby, a despatch with its enclosures from Her Majesty's Ambassador at Vienna relating to the system adopted in Austria for the conservation of rain water; and am to request that the documents and drawings accompanying this despatch may be forwarded to the Government of New South Wales.

I am, &c.,  
PHILIP W. CURRIE.

Sir A. Paget, No. 7—Commercial.

[Enclosure.]

## [Enclosure.]

Sir A. Paget to Earl Granville.

Vienna, 9th February, 1885.

My Lord,  
On the receipt of your Lordship's circular despatch of the 6th of October of last year, I at once addressed a note to the Ministry for Foreign Affairs, communicating to his Excellency the wish expressed by the Governor of New South Wales in his despatch to the Earl of Derby, to be supplied with information on the subject of the system of conservation of water adopted in this empire.

I have now the honor to transmit, herewith, a translation of Count Kalnoky's reply in which his Excellency, after stating that the conservation of rain water is, as a rule, owing to climatic influences only found to be necessary in the southern provinces of the empire, has been good enough to furnish me with reports, accompanied by drawings, of the system adopted for the purposes in question in the provinces of Dalmatia, Istria, and Carniola.

I have, &c.,  
A. PAGET.

(Translation)

## [Sub-enclosure.]

In reply to Sir A. Paget's note of the 12th October of last year relating to the system adopted in Austria for the conservation of rain water, the I. and R. Ministry for Foreign Affairs, while calling attention to the fact that the conservation of water in question, is, as a rule, owing to climatic influences, only found to be necessary in the southern provinces of the empire, has the honor to place the following information at the disposal of his Excellency:—

- 1-5. Description and drawings of cisterns employed for general public use.
6. Description and drawings of the station cisterns in use on the State railways of Dalmatia.
- 7-8. Volumes V-VII (1878) of the Austrian Engineer and Architect's Journal, with a report on the supply of water on the State railways of Istria and Dalmatia.
9. A pamphlet published by the I. and R. Agricultural Society of Carniola relating to the collection, the purification, and the preservation of drinking water.

The undersigned for the Minister for Foreign Affairs,

SZÖGYÉNIJI.

The Principal Under Secretary to the President of the Water Commission.

Sir,

Colonial Secretary's Office, Sydney, 19 March, 1885.

January, 1885.

Referring to my letter of the 9th instant, I am now directed by the Colonial Secretary to transmit to you the accompanying copy of a further despatch that has been received by His Excellency the Governor, enclosing the documents specified in a schedule thereto annexed.

I have, &c.,  
CRITCHETT WALKER.

Mr. R. G. W. Herbert to the Officer Administering the Government of New South Wales.

My Lord,

Downing-street, 29 January, 1885.

I am directed by the Secretary of State to transmit to you, for communication to your Lordship's Government, the documents specified in the annexed schedule, which have been received from the Foreign Office.

I have, &c.,  
R. G. W. HERBERT.

## Description of Document.

COPIES of despatches from Her Majesty's Representatives at Rome, Dresden, and Paris, on the subject of the storage and conservation of water.

Sir J. Lumley to Earl Granville.

(No. 195.—Commercial.)

My Lord,

Rome, 19 December, 1884.

With reference to your Lordship's Circular Commercial of October 6th, I have the honor to forward the accompanying works, as per enclosed list, on the subject of the conservation of water in Italy, for the information of the Government of New South Wales. In transmitting these documents to me, the Italian Foreign Office informs me that certain of the books desired are not in the possession of the Ministry of Public Works; but that the "Report by Domenico Guglielmini on the Nature of Rivers" and the "Report on the Method of Regulating Rivers and Torrents," by Frisi, can be purchased at the booksellers in Rome. As, however, the library of the Ministry of Public Works contains most important treatises in hydraulics, the accompanying works are now forwarded, and the Ministry promises to add to them the acts of the Commission of the Cavour Canal as soon as they shall arrive from the Technical Office at Turin, which has been requested to send them to Rome as early as possible.

I shall not fail to transmit these acts to your Lordship, together with the works by D. Guglielmini and Frisi above-mentioned.

I have, &c.,  
J. SAVILE LUMLEY.

Mr. Strachey to Earl Granville.

My Lord,

Dresden, January 4, 1885.

In reply to my request for materials to enable me to furnish the information required on water supply by the Government of New South Wales, the authorities here have sent me the annexed "*Wasserwerk der Stadt, Dresden*," with an Atlas by the projector and constructor of the city waterworks. The book contains a variety of information on the various systems of water supply at present in use, to which I need not refer, as the facts in question are already well known to hydraulic engineers. But this capital is furnished with water on a plan which is comparatively little known, and I will therefore concisely sketch its leading idea and particularities.

The water which supplies Dresden is not brought, after the fashion of the ancients, in aqueducts, or derived from rivers like the Thames and Marne, and adapted for use by artificial filtration, or absorbed

absorbed by natural filtration from a river into a contiguous and parallel canal sunk at a lower level. The observation has been made that the water which rises from borings near a river sometimes has a temperature higher in winter, lower in summer, than the water near the banks. This and other circumstances indicate the existence of what the Germans call the "ground water" (so often mentioned in the sanitary discussions of Petten Koffer and others), or subterraneous supply, which is perpetually percolating the earth at certain depths below the surface. The essential assumptions for this are—a suitable alternation of porous and impermeable strata (the former to retain the water like a sponge, the latter to prevent it pouring away downwards), and a suitable dip, in the geological sense, so that the water available may be the drainage of a large area of sub-filtration. These conditions exist in the neighbourhood of Dresden. The Elbe cuts through layers of fine diluvial sand-grit and conglomerate, which rest on the outlying granite of the mountains of Saxon Switzerland and the Lausitz, the whole descending towards the river. The rainfall of this large plateau is absorbed by the sand, but cannot percolate the granite, and therefore flows to the valley of the Elbe, where, accordingly, a series of experiments, conducted over several years, showed that there was ground-water excellent in quality, and so abundant that the daily requirement of Dresden—1,326,000 Saxon cubic feet—is a mere vanishing fraction of the available subterraneous supply.

The water on Herr Salbach's plan is obtained as follows:—On the right bank of the Elbe, parallel to the stream, and sunk from four to five metres below the surface of the soil, is a conduit of slashed pipes of 55 metres maximum diameter, and 1,438 metres in length. This apparatus is bedded in and internally loaded with gravel; the pipes are always full of water. At intervals on the conduit are two wells, each 7 inches in diameter and placed 40 metres apart, into which the pipes discharge their contents. From the wells issue suction pipes, through which the water is pumped into the central cisterns of the works, whence it is driven by steam power to the main reservoirs on the Dresden Heath. The descent of water to the Elbe, its passage over the principal bridge of the city, and the arrangements of street and house distribution are details of the ordinary character into which I need not enter. I hope I have made it clear that this water of gravitation, as it has been called, does not come from the Elbe, and that it is not spring water, but that it comes rather from the mountains of Bohemia and the Lausitz. I ought to add that when the Elbe runs high above its normal level, its extra pressure checks the pour of the ground water into the river, so that at such times the water pressure in the collectors would tend to be low. That apparatus is therefore placed with reference to a level at which the subterraneous flow will usually have a higher tension than that of the Elbe as against the river's banks.

Perhaps it is superfluous to say that the city of Dresden did not hand over the water supply to private speculators. The cost of the works has been about £385,000. The pipes have a total length of about 156 kilometres. Last year nearly 6,000,000 litres of water were consumed for all purposes, public and private fountains, watering parks and streets inclusive. The charge to private persons is two marks per annum, for inhabited space, kitchen or bath-room, for closets, &c., six marks each. For manufactories, hotels, and other establishments where much water is consumed, the charge is, as a rule, by measurement, the minimum price being twelve pfennigs ( $1\frac{1}{2}$ d.) per cubic metre.

The water as obtained in the houses of the city inevitably differs in temperature and taste from the official descriptions of samples studied at the works. But it is vastly superior to the usual water of European cities, meeting chemically all the requirements of modern sanitary science.

If Dresden were supplied by "artificial" or "natural" filtration its drinking water would be heavily loaded with nitrogenous organic substances, nitric-acid, ammonia, magnesium-chloride, silica, clay, &c., &c., which reads like the familiar London catalogue. Such are the contents of Elbe water taken from above the city and properly filtered.

I have, &c.,

G. STRACY.

---

Lord Lyons to Earl Granville.

(No. 8.—Commercial.)

My Lord,

Paris, 9 January, 1885.

With reference to your Lordship's Commercial Despatch of the 6th October last marked "Circular," and to Sir J. Walsham's Commercial Despatch No. 306 of the 12th October last, I have the honor to inclose a copy of a note which has been addressed to me by the French Government, in answer to the application made to them, at the instance of the Government of New South Wales for information on the subject of the conservation of water.

I send also to your Lordship two parcels which accompanied the note, and which contain documents, the titles of which are mentioned in it.

I have endeavoured, but hitherto in vain, to obtain copies of the works which are, it is stated in the note, to be bought. I will forward these works hereafter, should I succeed in obtaining them; but I think it better, without waiting any longer for them, to forward now the documents sent by the French Government.

I have, &c.,

LYONS.

---

Sir J. S. Lumley to Earl Granville.

(No. 3.—Commercial.)

My Lord,

Rome, 14 January, 1885

With reference to my despatch of this series, No. 195, of the 19th ultimo, I have now the honor to forward the "Report by Domenico Guglielmini on the Nature of Rivers," and the work "On the Method of Regulating Rivers and Torrents" by Frisi, therein referred to in connection with the information required by the Government of New South Wales on the subject of the conservation of water.

I have, &c.,

J. SAVILE LUMLEY.

---

Mr.

Mr. Vivian to Earl Granville.

My Lord,

Brussels, 2 April, 1885.

With reference to your Lordship's Circular, marked "Commercial," of the 6th of October last, I have the honor to enclose copy of a letter from the Minister of Foreign Affairs, stating that the accompanying report on the reservoir of La Gilleppe, which was prepared by the Department of Public Works for the Belgium National Exhibition of 1880, is the only official work published in Belgium on the conservation, storage, and distribution of rain water; but that as reservoirs have lately been constructed in connection with the new barracks, he has asked the Minister for War to furnish some information respecting them, which he will furnish to me later on.

I have, &amp;c.

C. VIVIAN.

[Enclosure.]

P<sup>er</sup> de Caraman to Mr. Vivian.

Bruxelles, le 31 mars 1885.

M. le Ministre,  
En réponse à la lettre que la Légation de Sa Majesté Britannique a bien voulu adresser à mon Département, sous la date du 10 octobre dernier, j'ai l'honneur de transmettre sous ce pli à votre Excellence une notice sur le lac réservoir de la Gilleppe. Cette notice est le seul ouvrage publié par l'Administration des Ponts-et-Chaussées relativement à la question de l'emmagasinage et de la distribution de l'eau de pluie.

Des réservoirs d'eau fluviale ont été exécutés dans ces derniers temps à proximité des nouvelles casernes. J'ai prié M. le Ministre de la Guerre de m'adresser des renseignements au sujet de ces installations; j'aurai soin de transmettre à votre Excellence, dès qu'elles me seront parvenues, les indications qui m'auront été fournies par mon collègue.

Je saisis, &amp;c.

P<sup>er</sup> DE CARAMAN.

The Marquis of Lansdowne to Earl Granville.

My Lord,

Canada, Government House, Ottawa, 3rd April, 1886.

With reference to Lord Derby's Despatch (No. 164) of the 30th September, 1884, relating to information desired by the Government of New South Wales on the question of the conservation of rainfall and the development of underground reservoirs of water, I have the honor to forward to your Lordship herewith a copy of an approved Report of a Committee of the Privy Council, embodying a Report from the Minister of Marine and Fisheries on the subject, as it relates to the Dominion.

2. It will be seen that no systems of Irrigation or Conservation of Water for agricultural purposes are necessary in the Dominion, except in British Columbia, in regard to which a report from the Acting Director of the Geological Survey of Canada is appended to the enclosed Minute of Council.

I have, &amp;c.

LANSDOWNE.

[Enclosure.]

CERTIFIED Copy of a Report of a Committee of the Honorable the Privy Council, approved by His Excellency the Governor-General in Council on the 27th March, 1886.

The Committee of the Privy Council have had under consideration a despatch, dated 30th September, 1884, from the Right Honorable the Secretary of State for the Colonies, transmitting a copy of a Despatch from the Governor of New South Wales respecting the desire of the Royal Commissioners appointed in that Colony in connection with the question of the conservation of water, to obtain information as to the best method of conserving the rainfall and developing the underground reservoirs of water.

The Minister of Marine and Fisheries, to whom the despatch and enclosures were referred, reports that so far as agricultural necessities are concerned, Canada is happily situated in regard to water. The distribution of rainfall throughout the season is, in the older settled portions of the country, sufficient in ordinary years to maintain continuous growth of plants, and the observations taken for a limited period in the North-west Territories show the same result, so that no systems of irrigation or conservation of water are required in the agricultural interests of Canada, and that with respect to British Columbia he appends herewith a Report from the Acting Director of the Geological Survey, referring to means taken for irrigation of a section of British Columbia where the rainfall is insufficient for the growth of crops.

The Minister observes that there are, however, large works consisting of dams, bulkheads, and slides, constructed in the interests of the lumber trade for the conservation of water in the streams to enable them to be utilised for the purpose of floating lumber and logs, but information in regard to the construction of these works does not appear to be called for in the interests of the Commission.

The Committee recommend that your Excellency be moved to inform the Right Honorable the Secretary of State for the Colonies of the efforts made by the Minister of Marine and Fisheries to collect any information that would be of service in promoting the object of the Royal Commission appointed by the Government of New South Wales.

All which is respectfully submitted for your Excellency's approval.

JOHN J. MCGEE,  
Clerk, Privy Council,  
Canada.

[Sub-enclosure.]

The Geological Survey Department to the Deputy Minister of Marine.

Dear Sir,

Geological Survey of Canada, Ottawa, March 18, 1886.

In answer to your question as to irrigation in British Columbia, I may say that irrigation is practised over a considerable part of the southern interior portion of that province where the rainfall is insufficient for the growth of crops.

The main region in which irrigation is resorted to may be described as extending southward from the 51st parallel to the international boundary, and being limited to the east and west respectively by the mountains of the Gold and Coast Ranges. A second subordinate dry region is separated from this by the Gold and Purcell Ranges, and lies between the last named and the western base of the Rocky Mountains proper, along the upper portions of the Columbia and Kootanie Rivers, extending northward from the 49th parallel for about 100 miles. As this last mentioned region is comparatively restricted in area, &c., little land has there yet been brought under cultivation, it need not be further alluded to.

In the region first described the arable land is as a rule confined to the valleys of the larger streams and rivers, which are generally wide and trough-like, with flat bottoms, or series of terrace flats ("benches") at various elevations, and traverse a country which may be characterised as a high broken plateau, a hilly region. The principal valleys in which agriculture with irrigation is now carried on are as follows:—

Fraser Valley (in part), Valley of the Main Thompson River, and of the south and part of the north branch of the same stream; Nicola, Okanagan, Similkameen, and part of the Kettle River Valleys. Ditches of several miles in length have in several places been made for the purpose of conveying the water to and distributing it over the cultivated lands, and trestles supporting "flumes" or wooden troughs are employed in crossing ravines or passing round bluffs. No machinery has yet been employed as far as I am aware for the purpose of raising water from lower to higher levels, and the whole method

method in use is so simple and obvious (besides being practically identical with that used over great areas in the Western States) as to render it unnecessary to describe it in detail.

I have, &c.,  
 GEORGE M. DAWSON,  
 Acting Director, Geological Survey.

Earl Granville to Governor the Right Honorable Lord Carrington.

My Lord,

Downing-street, 14 July, 1886.

With reference to previous correspondence respecting the conservation of water, I have the honor to transmit to you herewith, for the information of your Government, a copy of a letter from the Foreign Office, with a despatch from Her Majesty's Ambassador at St. Petersburg on the subject.

I should be obliged if you will enable me to reply to the inquiry in the Foreign Office letter, as to the wishes of your Government in regard to the translation of the report referred to in the papers at an estimated cost of £30.

I have, &c.,  
 GRANVILLE.

The Foreign Office to The Colonial Office.

Sir,

Foreign Office, June 24, 1886.

I am directed by the Secretary of State for Foreign Affairs to transmit to you, to be laid before Earl Granville, with reference to previous correspondence, the accompanying despatch and two enclosures, as marked in the margin, respecting irrigation. Sir R. Morier.  
No. 62.—Com-  
mercial.

And I am to inquire what his Lordship wishes with regard to the question of translating the report.

I am, &c.,  
 T. V. LISTER.

[Enclosure.]

Sir R. Morier to Earl Rosebery.

(No. 62—Commercial.)

My Lord,

St. Petersburg, 16 June, 1886.

On the receipt of your Lordship's Circular Commercial Despatch of October 6, 1884, Sir Edward Thornton addressed a note to the Russian Government, asking if they would kindly furnish some details with regard to the storing of water and the system of irrigation at present carried out in this country, for the information of the Government of New South Wales.

In reply to this communication, I have received the enclosed Memorandum on the system at present adopted in the southern and south-eastern regions of Russia, where, owing to the long seasons of drought, irrigation is carried out on a large and extensive scale.

In addition to the Memorandum I also have the honor to enclose the Report which was published by the Imperial Society of Engineers in 1882, giving full details as to the irrigation works in the Caucasus.

I have caused a translation to be made of the above-mentioned Memorandum, but as the enclosed Report is a more serious undertaking, I would submit to your Lordship that, should the Colonial Office consider it desirable, I could easily find a person capable of making a translation of this work at a cost of £30.

The portions of the Report which bear on the main question of inquiry instituted by the Government of New South Wales will, however, be found all carefully marked in the index.]

I have, &c.,  
 R. B. D. MORIER.

(Translation)

[Sub-enclosure.]

The necessity of adopting measures for the accumulation and storing of water arises chiefly, owing to climatic conditions, in the southern and south-eastern regions of Russia, also in the Crimea and the Caucasus.

In these parts of the Empire the atmospheric precipitation is very inconsiderable (about 200 mm.—about 8 inches—per annum) and moreover, the greatest rainfall takes place late in the autumn and winter (about two-thirds of the whole quantity); in the summer and spring, when there is an almost entire absence of rain, while heavy dews prevail, attaining, for instance, in the south-eastern Steppes of Russia 160 mm. (about 6 inches). In the month of June it is necessary to have recourse to artificial measures for preserving the water for agricultural requirements as also for purposes of irrigation.

In the Caucasus, where there are numerous rivers which are fed by the waters that issue from the snow-capped summits of the main chain of the Caucasian range of mountains, from the smaller Caucasian heights and other elevations, the greatest abundance of water occurs during the dry season, namely in June, July or August, covered or open water-courses are constructed for a regular distribution of the water. Owing to the great incline of the rivers, which frequently exceeds one fathom (fathom or sagène=7 feet) per verst (1 verst=½ mile English) the current is rapid, and constructions are made in the rivers which direct the stream towards the head of the water-courses, the water in which, in its turn, is regulated by sluices. The water is then conducted through main and subsidiary water-courses to plots of land under irrigation to water-mills and villages. Moreover, in some localities in the Trans-Caucasus, which are less bounteously supplied with water, reservoirs are formed by damming up small streams, the walls of the dams being from 3 to 4 fathoms high.

In the waterless Steppe portion of the Crimea, and in the province of Ekaterinoslav, also partly in that of Kherson and in the southern portion of Kharkoff, water reservoirs are formed in dales and along the courses of small rivers and brooks.

For the formation of such reservoirs the water is generally confined by walls from 3 to 6 fathoms high, constructed of earth; simple arrangements are at the same time made for allowing the superfluous water to escape and for feeding the main and secondary irrigating courses which distribute the water over the surface of land requiring irrigation.

There, where the water supply is derived from springs, the water reservoirs are replenished several times during the summer, and the water, besides being used for domestic purposes and for cattle, &c., is also employed for the irrigation of fields and meadows. In the waterless Steppes the water reservoirs are generally filled only once a year, and the supply is furnished by melting snow. The water so stored is used for the irrigation of meadows and arable lands. By means of such a reservoir as many as 400 dessiatins (1 dessiatina=2.70 acres English) of meadow and arable land may be irrigated.

The Steppe country of south-eastern Russia has a clay soil and subsoil, the latter being sometimes from 8 to 14 fathoms in depth. The soil is impregnated with various salts which are injurious to vegetable life, and which form so-called salines. Over the whole extent of this country but few rivers and rivulets occur, and there is also a total absence of springs in this region. In order, therefore, to accumulate water for agricultural purposes, artificial reservoirs are formed in dales and along river beds, which are plentifully supplied during the season of spring by the melting snows. Dams, with walls from 3 to 6 sagène (7 feet English) high are constructed for the formation of such reservoirs, and in connection with these there are also contrivances for letting off superfluous water. In these reservoirs there is water all the year round, the loss from filtration and evaporation not exceeding a column of water of about 1 fathom in height. In many parts of the province of Samara beyond the Volga, and in the northern portion of the province of Astrakhan, from the River Samara to the basin of the River Eruslan inclusively, the peasants erect in the earthen hollows and depressions dams over an extent of several hundred fathoms, the walls being generally from 0.50 to 1 fathom high. By means of these constructions, and after a plentiful fall of snow in winter, a considerable quantity of snow-water is accumulated and, forming a so-called "liman," inundates areas of land of about 500 dessiatins.

Latterly, in order to irrigate considerable extents of meadow land and to disalkalize the saline soil, the water derived from melted snow is used to great advantage in the south-eastern plains and waterless regions of the Empire. The method employed consists of erecting an ordinary earthen dam from 4 to 6 fathoms high across the bed of a river or hollow, the crest of the dam rising considerably over the surrounding plain. From this dam down the course of the river or hollow, longitudinal embankments are erected. In spring, during the melting of the snow, the water collecting at the dam flows along canals to the part of the Steppe destined for inundation, and by means of earthworks or embankments is distributed over the various land plots. Generally speaking, these plots are kept three weeks under water, and they afterwards yield rich growth of grass.

Wells lined with timber are also sunk in parts of the country devoid of water, and these wells are from 8 and not unfrequently 20 fathoms deep, with a diameter of half a fathom.

ZIELINSKI,  
Major-General.

#### NOTES AND MEMORANDA REGARDING THE NEPEAN AND WARRAGAMBA RIVERS.

THE Warragamba scheme of Mr. Thomas Woore was intended not only to supply Sydney with water but also to provide for the irrigation of a large extent of land in the county of Cumberland. Mr. Clark examined the scheme so far as related to the former object, but did not consider its merits in connection with the latter. Mr. Woore's proposal was to construct a dam in the Warragamba, near its junction with the Nepean, and thus to intercept and, to some extent, render available for use the drainage of 3,247 square miles. The dam proposed by Mr. Woore was to be 170 feet high, and composed chiefly of boulders, but rendered watertight by a vertical wall of masonry running along its centre. Mr. Clark showed that in order to fulfil the objects aimed at it would be necessary to provide a dam 214 feet high, instead of 170 feet, and that the cost of the waste weir alone would be over a million and a quarter sterling. These drawbacks, added to the risk attendant on the construction of a dam of such height, and the risk and expense of carrying the supply across the Nepean, were sufficient to condemn the scheme.

The attainment of the second object aimed at in Mr. Woore's scheme does not seem to be beset by any such serious difficulties as those mentioned. But the supply to the low lands along the valley of the Nepean can be more easily obtained than by damming the Warragamba. From levels taken by the Harbours and Rivers Department, in connection with Mr. Clark's report, it was found that the summer level of the Warragamba near its junction with the Nepean is 45 feet above Sydney high-water mark. At Penrith, the valley of the Nepean throughout a width of 2½ miles is under 86 feet above the same datum, and beyond that place it has a fairly steady fall in the direction of the river. It is evident, therefore, that a dam of moderate height in the Nepean would render it possible to irrigate the low-lying land by gravitation. As the Nepean, down to about 3 miles from Penrith, flows within steep and rocky banks, only a short dam would be required; and if a suitable site can be obtained at the place where the rocky banks disappear, a supply of water could be diverted into an open cutting, and the necessity of tunnelling would be avoided. As the summer level of the river at Penrith is only 1 foot lower than that at the junction with the Warragamba there would be nothing to gain, so far as the levels are concerned, by taking out a supply higher up the river than the place suggested.

Another method of providing a supply of water for irrigation, as well as for domestic and stock purposes, along the valley of the Nepean is by pumping direct from the river, and delivering the water at such height as would enable it to flow over the plains by gravitation. The information collected for the Lower Nepean scheme for the supply of Sydney throws some light on this project. In Mr. Clark's report on the Lower Nepean scheme it was admitted that there is such extensive natural storage in the Nepean that no dam was required in connection with that scheme. Throughout the 10½ miles from the railway bridge at Penrith to the junction of the Nepean with the Warragamba the depth of water below summer level varies from 30 feet to 100 feet, and there is deep water to a distance of several miles up the Warragamba. The pumping station proposed in the Lower Nepean scheme was 2½ miles up the river from Penrith—that is, near the place where the banks cease to be high and rocky, and where the alluvial banks begin. There is every reason to believe that this would be the best site for a pumping station for the supply of water for irrigation. As the height of the lift is a very important factor in connection with the cost of pumping, it should be stated that the maximum range of the river-level at Penrith is 42 feet; the highest flood-level, according to the records of the Railway Department, being 86 feet above Sydney high-water mark, while the summer-level, according to the information supplied by the Harbours and Rivers Department to the late Mr. Clark, is 44 feet above the same datum. The range of surface-level at the proposed pumping station would exceed that at Penrith; but the excess cannot be great, as the difference in the flood section is comparatively trivial. The range of the water-level in the Warragamba, according to information received from the Harbours and Rivers Department, is 70 feet; but this is easily accounted for by the small sectional area through which floods have to pass below the junction of the two rivers.

As the Commissioners have now seen these rivers, and are in a position to appreciate the importance of the supply carried by them, it is perhaps needless for me to point out the necessity of having a gauge in the Nepean at the Penrith Bridge

I have, &c.,  
H. G. MCKINNEY, M.E., M.I.C.E.,  
Engineer to the Commission.

Penrith, 7 April, 1886.

#### MEMORANDUM OF THE LEVELS OF THE HAWKESBURY.

ALTHOUGH no surveys, so far as I have been able to ascertain, have been made with a view to determine the practicability of utilising the waters of the Hawkesbury on the plains adjoining it, still much light is thrown on this subject by the surveys and levels which have been taken by the Department of Harbours and Rivers and the Department of Railways. The most important record regarding the levels of the Hawkesbury District is a plan prepared under the directions of Mr. Moriarty, Engineer-in-Chief of Harbours and Rivers. This plan shows the extent of land covered by the flood-water of the Hawkesbury in 1867, or more correctly that portion of the flooded area extending from the mouth of the Grose to Pitt Town. In this

this length the flooded area shown in the plan is little short of 40 square miles in extent, and the town of Windsor is represented by two islands, which together include an area of only about 340 acres.

The height of the flood of 1867 at Richmond above high-water mark at Windsor was 65.49 feet. The high-water mark at Windsor would appear to be slightly above the high-water mark at Sydney, judging by the fact that, the level lately taken by the Railway Department on the Southern and Northern Junction Railway, the high-water level at the site of the proposed Hawkesbury Bridge was found to be 1.81 feet above the Sydney high-water level. It would therefore seem sufficiently accurate for present purposes to assume that high-water at Windsor is 2 feet above high-water at Sydney. This would give the flood-level of 1867 at Richmond as 67½ feet above the latter datum.

The section along the line of railway from Blacktown to Richmond shows that to a distance of nearly 11 miles from the latter place only three comparatively narrow ridges of land rise above the flood level of 1867. Omitting a ridge about a mile and a-half in width, situated at a distance of about 8 miles from Richmond, the average level of the ground throughout the 11 miles mentioned is only from 40 to 50 feet above Sydney high-water mark.

In a previous Memorandum it was mentioned that the highest flood-level at Penrith is 86 feet above Sydney datum. The distance by river from Penrith to Richmond is only about 15 miles, so that the rate of fall in the surface of the river during a very high flood is about a foot and a half per mile. If a canal from Penrith to Richmond were proved to be otherwise practicable, it appears that the levels of the land, so far as data are available, are highly favourable. If it were necessary to give such a canal a course even more tortuous than that of the river the rate of fall would still be ample. In fact a large extent of land between Richmond and Blacktown is only slightly above the summer level of the Nepean at Penrith, and in several places portions of the railway line are even below this level.

In connection with the Grose River there was a scheme for the supply of Sydney from that source, but Mr. Clark showed that to give the necessary head the supply would have to be taken from a point about 15 miles from the mouth of the Grose. The scheme on this and other grounds was rejected. More recently it was proposed by the Engineer-in-Chief for Harbours and Rivers to draw a supply from the Grose for the towns of Richmond and Windsor. In this case there was to be a reservoir on the top of Pitt's Hill, at an elevation of 152 feet above Windsor high water mark. The subject of utilising the waters of the Grose for irrigation does not appear to have received serious consideration though the present large supply naturally stored could be greatly increased, and though, as pointed out by Mr. Donkin, a good site for a weir is available.

Richmond, 17 April, 1886.

H. G. M'KINNEY, M.E., M.I.C.E.,  
Engineer to the Commission.

## UPPER DARLING (BARWAN) SURVEY.

### REPORT No. 1.

The Engineer-in-charge, Darling River Survey, to The Secretary of the Royal Commission on Conservation of Water.

Sir,

Collarindabri, Barwan River, May 10th, 1886.

I have the honor to forward progress report having reference to sites for schemes of water conservation in the counties of Finch and Benarba. The explorations, reconnaissance, and trial surveys and levels connected with these have not been extended beyond a limit of 20 miles on either side of the main drainage channel of the Barwan or Upper Darling. The fall of this main drainage in the districts under consideration appears to average somewhat under a foot per mile. Numerous reaches of still water occur throughout. These are impounded at a low level by natural bars. The depth at many points is considerable, and the water may, in most instances, be considered as permanent. The low level at which it lies, relative to the surrounding country, is, however, an obstacle to its being used in any way except for stock-watering purposes. The soil along the banks and in the immediate vicinity of the main channel is, for the greater part, unproductive—not apparently from any inferiority in quality, but from its very porous nature, which rapidly absorbs the water, and returns it to the river by percolation. The generally friable nature of these banks would probably render abortive any attempt to maintain the water at a high level by the construction of weirs, as the river would have a tendency to form new channels at points above these works.

The tributaries to the main stream in these counties are the Mooni, flowing from Queensland in a southerly direction, and the Gwydir, or Meei, draining a large extent of country to the east. Ana-branches, known as the Boomi River and the Ballone Creek, also pursue a course, mainly parallel with the river, on the south-east side. The books containing field-notes of trial surveys and sections made on these streams are forwarded. The Mooni River, after rainfall over its watershed in Queensland, brings down a large supply of water, none of which is apparently at present turned to account. I have marked a favourable site for a dam at the surveyed township of Gundabloui. This might be carried to a height of 18 feet above the summer-level of water, the storm-channel and by-wash above its site being regulated to within 2 or 3 feet of the crest of the embankment. The 16-foot contour which I have carried for about 7 miles up the stream on both sides shows a large reservoir of water impounded, and which would extend beyond the furthest point surveyed, probably to the vicinity of the Queensland border. There are considerable areas of naturally fertile land on portions of both sides of this proposed reservoir which, if irrigated, might be profitably cultivated.

South-west of the channel of the Mooni there is an extensive district totally devoid of any defined watercourses leading towards the river Barwan. The main fall of the country is south-west, and the various drainage channels or warrambools flow, in wet seasons, in courses nearly parallel with the Barwan. Much of the water which would be impounded in proposed Mooni reservoir would be available, at little cost, for the irrigation of portions of this area. This object could be attained by pumping to a small height, and thence distributing; or by shallow cuttings regulated by sluices made at certain points, such as that where the watercourse known as the Mungaroo Warrambool approaches the site of reservoir.

A work subsidiary to the foregoing might be constructed on the Mooni about half a mile above its junction

junction with the Barwan. A dam at this point would render the water available for certain areas of good land on both sides of the lower reaches of the river. But as to this latter, no special survey has been made, beyond cross-sections of both rivers at the junction. The banks of the Mooni are generally retentive of water, and large permanent lagoons exist at various points of its course.

As already stated, there are no streams of importance below the Mooni flowing into the Barwan from the north-west; and no direct affluent is found throughout the whole of that region until the Bokhara is reached. The drainage system throughout follows courses roughly parallel with river, uniting ultimately with the Big Warrambool which joins the river at a point nearly south from Narran Lake. There are numerous positions on these shallow watercourses or warrambools where water might be conserved over considerable areas, but at no great depth. This has been already effected on a small scale by some of the pastoral tenants.

On the south-east side of Barwan I have directed my attention to the Ballone River, or Creek, an ana-branch connecting with the Boomi River near the lower junction of that branch with the Barwan. The Ballone channel extends southerly for about 24 miles, having generally well-defined and sound banks throughout. Near Collymongoul Station it divides into two arms, which, as they approach the Barwan, join the river by various channels. The plan will indicate two positions I have selected as suitable for overshot dams, one on each main branch. That on the north arm will be 14 feet above level of water in lagoon, and on the south arm 13 feet. These dams will impound water to a depth varying from 16 feet to 32 feet, for almost, if not altogether, the entire length of main channel, and also along the Banarway branch, which goes off, as shown on plan, towards the Barwan in a northerly direction. It seems unnecessary to interfere with the levels of the upper inlets of these channels at the Barwan. In rainy seasons the Ballone, in addition to the flood-water from the Barwan, receives considerable drainage from the country eastwards by watercourses, such as the "Big Leather" and "Gingham."

The materials for constructing the overshot dams on the Ballone are to be obtained at the sites of the works. A hill which occupies the country lying between the two is formed by the upheaval of cretaceous strata, consisting of sandstones and impure limestone. Excavations made contiguous to the works would doubtless disclose materials suitable to be laid in cement for the faces of the dams.

A short distance south of the lower mouth of the Ballone the river Meei or Gwydir enters the Barwan. There has been apparently very little water flowing down this channel for a considerable time, and it is at present dry. The usual flood discharge has been, I understand, diverted at a point in the upper channel, where a natural embankment has been formed by fallen timber, &c. The Barwan, when in flood, backs up the Gwydir channel for several miles, but no water is retained after the subsidence of the flood, there being no waterholes of any dimensions in the channel. So far as regards the formation of the banks, there are numerous sites where an overshot dam might be constructed to retain the local drainage. That indicated on plan is situated below the junction of the Moomin with the Gwydir. It is, in common with the Ballone dams, connected with the Barwan by a line of levels. Contour lines are run along lower portions of Gwydir and Moomin 16 feet above bed of river at site for dam. This would throw the water back in both streams for many miles—probably from 15 to 17. Suitable materials for construction are not present on the surface in the vicinity of the site.

Considerable areas of naturally fertile soil occur on both sides of these rivers, a large proportion of which might be irrigated at little cost from the proposed 16-foot level of the water.

The raising of the permanent water-level on these and other channels would render necessary the resumption of small portions of the purchased and selected areas, which occur at intervals along the banks.

As regards the unalienated blocks on the resumed parts of the pastoral runs, it is obvious that reserves would be requisite over certain areas the value of which would be so largely increased by the facilities for irrigation which the contemplated works would provide.

I have, &c.,

JOHN B. HOTSON.

#### UPPER DARLING (BARWAN) SURVEY.

##### REPORT No. 2.

The Engineer-in-charge, Darling River Survey, to The Secretary of the Royal Commission on Conservation of Water.

Sir,

Walgett, Barwan River, 16 June, 1886.

In continuation of the report transmitted in May, I have now the honor to direct the attention of the Commissioners to the features presented by a bar of rock which exists in the main channel of the Barwan, at a point situated about 60 chains above the junction, already described, of the river Gwydir or Meei.

Immediately above this bar the water, at summer level, is about 40 feet in depth. The position is known as "Werribilla Waterhole." The natural features existing here, and in the district westward of it, lead me to the conclusion that the objections which are in force as to the construction of weirs in the Barwan on most parts of its course may in the present instance be set aside. A suitable site for a substantially constructed weir is to be found at a point where the course of the main stream has been gradually altered by erosion of the rock, leaving apparently solid abutments on the banks. One effect of a weir in this position would be to cause an almost constant flow by way of a channel or depression running in a westerly direction. It would be necessary to raise the permanent level of water sufficiently to command for irrigation purposes the now waterless plains to the north and west of Collarindabri.

This appears also to be the most favourable route by which to convey a portion of the surplus water of the Barwan, across the country, in a generally westerly direction; so as to unite with the line of drainage formed by the shallow Warrambools already alluded to in a former report. The district through which these flow during wet seasons appears to have its lowest level at an average distance of 17 miles north-west from the river. In order to convey the water over this intervening space it would be necessary to cut through the slightly elevated ridge which divides these drainage areas. The greatest depth at any point

point would probably not exceed from 9 to 12 feet. The line of cutting would be some 4 or 5 miles north of Collarindabri.

It was my intention to have taken cross-sections of the river at the points now under consideration, and to have carried a line of levels westward along proposed channel, but the heavy and continuous rains of the past month, followed by a high flood, which is only now beginning to subside, rendered any such work impracticable. I must, therefore, at present confine myself to indicating approximately the nature of the works suggested. The height from rock to crest of weir may be taken as upwards of 25 feet, and the length as about 130 feet. The question as to the interruption to navigation need not arise, so far as regards these upper reaches of the river, there being no traffic by water, except for merely local purposes.

The construction of this weir would render unnecessary the two overshot dams in the branches of Ballonne River, previously reported on, as the raised river level would maintain the various Ballonne and Banarway channels permanently full. A detailed survey over a large area in this locality, along with an extended system of levels, is requisite in order to indicate the precise nature and extent of the above works, and the advantages they would entail. It is, however, evident that by irrigating portions of the plains referred to large areas of good soil would be rendered capable of profitable cultivation, which, in the absence of permanent water, at the required level, cannot be attempted. The small enclosures made at wide intervals by some of the settlers, and which have been watered by pumping from existing lagoons and water-holes, have been in every case, so far as my knowledge extends, in the highest degree productive. The gradual disappearance of the water from which these supplies were raised had, previous to the recent rains, caused most of the cultivated areas to relapse into a barren state.

Ten miles below Collarindabri, the Grawan Creek enters the Barwan, having a main branch channel named the Meaki, which falls into the river 3 miles higher, at a point opposite Bundinbarrina. In addition to these main channels there are others which do not flow except in cases of high flood. In that event a portion of the flood-waters of the Gwydir or Meei, and of its ana-branch the Moomin, overflow to the Grawan channels. The inlet channels of the Grawan, situated between Collarindabri and the mouth of the Meei, are apparently at a height above ordinary river level sufficient to prevent the reflux of water entering them during floods. This water may be impounded by overshot dams at the lower ends of the Grawan and the Meaki channels. On the former stream, and indicated on the general map, are two surveyed sites for dams. The upper of these, about 3 miles above junction with Barwan, is the more favourably situated. The position for dam on Meaki can at present be indicated only approximately as from 40 to 60 chains above junction. The flooded state of the country at the date of attempted survey in that direction precluded any reliable data being obtained. The height of the dam in Grawan would be 19 feet above bottom of channel at that point. That in Meaki would be similar, or possibly somewhat higher. The assumed height above datum of the water thus impounded in the various channels is 473 feet. The relative heights of the land between the Grawan and Thalaba are shown upon sections which have been taken across that area. The positions of these sections are indicated upon general map.

These works upon the Grawan and Meaki will necessarily be supplemented by a similar work at the lower end of the Thalaba Creek, near to the point where the Pagan Creek is formed, and also by another dam situated several miles up the Thalaba, at a point above the entrances of two channels, which in times of flood communicate with the Grawan.

It would have been desirable to have had the necessary surveys made in these localities, and I have endeavoured to reach them previous to the preparation of this report. The great height of the water has, for some weeks past, rendered this impossible, and the description of the works required must be deferred until the water is greatly lowered in level.

The large area of land lying between the courses of the Thalaba and Grawan is, in general, of good quality for agricultural purposes. The irrigation of the greater portion of it can be accomplished by pumping to a height of from 10 to 12 feet above the proposed raised level of these channels. The total rise of the Barwan in this part of its course, during the present flood, has been about 32 feet. It has at this date (June 16th), fallen 4 feet, and the subsidence still continues. The flooded state of all watercourses, together with the unfitness for traffic of the unsubmerged land after the heavy rainfall, have delayed the progress of this work for several weeks. The obstacles to any advance during that period will be understood by all who have had experience of this part of the Colony during a wet season.

I have, &c.,  
JOHN B. HOTSON.

### UPPER DARLING (BARWAN) SURVEY.

#### REPORT No. 3.

The Engineer-in-charge, Darling River Survey, to The Secretary of the Royal Commission on Conservation of Water.

Sir,

Sydney, July 20th, 1886.

I have the honor to report my return to Sydney, in accordance with instructions received to suspend proceedings, in consequence of the high floods prevailing on the Barwan and its branches.

On a date subsequent to the dispatch of my general report in June, I proceeded to survey and examine the upper inlet from the Barwan to Pagan Creek, situated 4 miles below the position marked "Brothers," in county Denham, on general map. The river and the inlet to Pagan were then in high flood, and the actual channels of latter, and those of Thalaba and Pagan, were indistinguishable. It is, however, evident that for water-conservation purposes the Thalaba and Pagan must be regarded as one stream; the inlet referred to being regulated so as to cause the Thalaba water to continue its flow along the Pagan channel, at periods when local rain has caused a rise in the Thalaba, the Barwan being at the same time low. This result is to be obtained by the construction of self-acting gates on the inlet mentioned, admitting a portion of the Barwan water when high, but preventing its return when the relative levels of the river and the watercourses under consideration are reversed.

The water would be impounded at a lower part of the Pagan by an overshot dam, situated about 16 miles below the work described, at the most favourable site to be obtained for construction below Eurie Eurie. The height to which this dam ought to be carried would probably be about 20 feet, but precise

precise levels, &c., cannot be obtained until subsidence of floods. These have also rendered impracticable any attempt to indicate the best site for weir on the Barwan below Walgett, or to obtain levels and other data respecting the effect of such a structure upon the Barwan and Namoi Rivers. One result, however, would be the maintaining of permanent water in the Pagan channel below the dam suggested below Eurie Eurie.

The country between the Pagan and Pian Creeks is level across, and the soil is generally of good quality. The position of a considerable portion of it is favourable for irrigation being applied from either the Pagan or Thalaba.

In the lower portions of the channel of the Pian Creek one or two shallow earthwork dams have been put in by pastoral tenants. Proceeding up the creek towards the Namoi, a few points present themselves where overshot dams, constructed of ironbark or other suitable and available timber, might be constructed with advantage. The height of these would not, however, be great—say from 7 to 10 feet. Below Gorian, a dam site occurs, on which a timber overshot of 12 feet would impound flood-water between well-defined banks for several miles. A similar position which may be pointed out is near the present crossing of Pian Creek by main road, at about 10 miles west of the Namoi crossing, near Wee Waa.

Proceeding towards Narrabri from the last-named point, a large extent of high-class land presents itself, bordering the Gunnedra ana-branch of the Namoi. This area, which embraces portions of great natural fertility, is, in general, waterless, with the exception of the inadequate supply obtained from a few wells.

A suitable position for an overshot dam, formed of ironbark, is to be found on this Gunnedra branch about 11 miles below the point where the flood-water from the Namoi enters the channel. The height of dam would be approximately 16 feet, and the length 100 feet. It appears probable that a portion of the flood-water impounded above the dam could be diverted into a cross-channel situated somewhat under 2 miles higher up, and which leads to the upper channel of Pian Creek. The work in question would be of the greatest advantage to the settlers on these creeks, but a special survey would be necessary before the details of the scheme could be obtained. The information on the subject which I have been enabled to gather was got merely in passing through the district on my return route to Narrabri.

I have, &c.,

JOHN B. HOTSON,  
Engineer-in-charge, Darling River Survey.

#### UPPER DARLING (BARWAN) SURVEY.

##### REPORT No. 4.

The Engineer-in-charge, Darling River Survey, to The Secretary of the Royal Commission on Conservation of Water.

Sir,

Sydney, July 23rd, 1886.

I have the honor to submit for the information of the Commissioners the following abstract of work done by me during my recent survey of the Barwan River and its branches, over the portion of its course embraced between the boundary of Queensland and Walgett.

The progress of the work was, as you are aware, subject to constant interruption and delay by the very heavy rains and consequent floods which commenced soon after my arrival in the district, early in April, and continued throughout the months of May and June. More than half of my time during these three months was unavoidably lost, although every endeavour was made by me to overcome the obstacles to progress by which I was surrounded.

The following are the works referred to:—

- No. 1.—Cross-section of Barwan below Mungendi, at Queensland border, plotted and submitted. There is no gauge yet fixed at Mungendi. The levels taken along river downward from above section need not be plotted, as they would serve no useful purpose.
- No. 2.—Cross-section at mouth of Mooni River, also of Barwan immediately below that point. Cross-section of Mooni River, at site of proposed dam at Gundabloui township. These might be plotted to scale of 40 feet horizontal and 4 feet vertical to inch. Traverse and contour lines along course of Mooni River above site of proposed dam. For useful purposes these might be plotted to a scale of 5 chains to an inch. The proposed works on this river would secure a great permanent storage of water, available for irrigation and other purposes. (See my report of May 10th, 1886.)
- No. 3.—Cross-section of Barwan at Mogil Mogil. May be plotted to scale of 40 feet horizontal and 4 feet vertical to inch. There is no gauge yet fixed at Mogil Mogil.
- No. 4.—Sites for two overshot dams on branches of Ballone Creek. The cross-sections of these may be plotted to scale of 40 feet horizontal and 4 feet vertical to inch. Traverse of two arms of Ballone Creek, with traverse and contour lines extending to inlet of Banarway Creek. It would be of advantage to have all this work plotted to scale of 5 chains to an inch. Large permanent storage of water obtained by the two dams referred to. (See my report dated May 10th, 1886.)
- No. 5.—Traverse of Meei or Gwydir River and Moomin branch. Site for dam below junction of these streams, with contour lines along both streams. May be plotted to scale of 5 chains to an inch. (See report of May 10th, 1886.)
- No. 6.—As to proposed weir in Barwan above Collarindabri, and the results to be obtained. (See report of June 16th, 1886.)
- No. 7.—Cross-sections of Grawan Creek, the upper of which, for site of proposed dam, may be plotted to 40 feet and 4 feet to inch. Traverse of Grawan Creek and branches, with levels throughout, partly contoured, until flood rose above position of contour line. Surveyed lines of levels across from Grawan Creek to Thalaba; also traverse and levels across to Mcaki-Creek from Grawan Creek. All above might usefully be plotted to scale of 5 chains to inch, and reduced levels noted at the station points along lines. (See report dated 16th June, 1886.)

No. 8.

No. 8.—Traverse and levels of upper inlet to Pagan Creek, connecting also with Thalaba, might be plotted to scale of 5 chains to inch, with levels noted on plan. No detailed survey of Pagan Creek could be made, owing to the very high flood. (See report, July 20th, 1886.)

The foregoing is a summary of the work actually done, with references to reports in which details will be found.

I beg also to direct the attention of the Commissioners to the map of the north-east portion of Western Division of Colony, upon which I have indicated the sites of the various proposed works now referred to. This map, along with the parish maps used by me, are now returned.

Any further information which the Commissioners may wish, and which it may be in my power to supply, will be submitted to them whenever required.

I have, &c.,  
JOHN B. HOTSON,  
Engineer-in-charge, Darling River Survey.

#### MEMORANDUM ON THE CLARENCE RIVER AND ITS CATCHMENT AREA.

COMPARED with the western and south-western rivers of this Colony the course of the Clarence is short, and its catchment area appears small in extent. On this account the importance of the Clarence is not understood, except by those who have seen it or have studied its conditions. In order to obtain a correct conception of the relative conditions of the eastern and western rivers it is necessary to bear in mind that the latter flow for hundreds of miles through districts which scarcely ever contribute to the discharge of the rivers, and in which the rivers diminish steadily in volume as they flow towards the ocean. On the other hand, the plain country on the eastern coast is comparatively small in extent, so that practically the whole of every large catchment area may be classed as "effective." Another point which operates in favour of the eastern catchments is their high rate of rainfall. At Grafton, which occupies a fairly central position in the Clarence basin, the mean rainfall is about 34 inches, while the mean rainfall on the Upper Murrumbidgee is only  $21\frac{1}{2}$  inches. Thus, although the effective catchment area of the Murrumbidgee is 11,900 square miles, while that of the Clarence is under 8,400, the quantities of rain falling on those areas are in the proportion of 256 to 286, or approximately as 8 to 9. This would practically mean that if equal proportions of the rainfall were carried off by the Clarence and the Murrumbidgee the discharge of the former at its mouth would exceed that of the latter at Wagga in the proportion of 9 to 8. But the Clarence basin, as the smaller area may naturally be expected to lose less by evaporation, percolation, and absorption than the basin of the Murrumbidgee. From a rough measurement of the velocity of the Clarence at Copmanhurst, added to information obtained from Mr. E. J. Statham, assistant engineer of the Roads Department, I conclude that the discharge of the Clarence seldom falls below 1,000 cubic feet per second. So far as can be judged from the few observations already made, the corresponding summer discharge of the Murrumbidgee at Wagga is about 600 cubic feet per second. These figures confirm the suggestion that the proportion of rainfall discharged from the Clarence basin is greater than that from the basin of the Upper Murrumbidgee.

Regarding the flood discharge of the Clarence, no detailed observations have been made, but Mr. Statham, who has kindly furnished me with a cross-section of the Nymboi taken by him, has made some experiments to determine the velocity of that river during high floods, and he has come to the conclusion that the flood discharge of the Nymboi below its junction with the Little River is over 270,000 cubic feet per second.\* The maximum discharge of the main northern branch of the Clarence is believed by Mr. Statham to be considerably greater than that of the Nymboi. Taking this fact into consideration, and bearing in mind that the Orara, the second large southern tributary, has a mean width of about 80 feet during floods, and a depth of from 25 to 30 feet, it will readily be understood that a flood in the Clarence attains to enormous proportions.

Owing to several causes, the importance of the Clarence for other purposes besides navigation has hitherto received little or no attention. So far as regards irrigation, this is not surprising, as, in the first place, only a short period has elapsed since the district was settled; and, in the second place, the rainfall in ordinary seasons is sufficient to ensure fair crops. Still, the statistics which will be placed before the Commission, as well as the evidence of witnesses, will show that the diminution of produce in the Clarence District in dry seasons is a serious matter. Nor is this in any way remarkable, for the rainfall, though relatively great, is frequently unseasonable; so that all the bad effects of a scarcity of water for agricultural purposes are felt, while the rainfall would be more than sufficient if it occurred when required. In northern Italy, where the rainfall is 20 per cent. in excess of that at Grafton, irrigation is extensively and successfully practised. The case of the Dehra Doon Valley, in Upper India, affords a much more striking comparison, as irrigation has long been carried on there on a considerable scale, though the mean rainfall is more than two and a half times greater than that at Grafton. A direct proof of the advantages of irrigation in the Clarence Valley is afforded by the Chinamen's gardens, which are irrigated from wells, with the usual satisfactory results.

The utility of irrigation in the basin of the Clarence is beyond dispute; but the question of carrying out irrigation works on anything like an extensive scale is surrounded with serious difficulties. In the first place, the river, when low, is affected by the sea-water to Copmanhurst, which is about 30 miles by the river upstream from Grafton. The immediate consequence of this is that any supply of water taken from the Clarence for the irrigation of the delta land would have to be drawn from the river at or above Copmanhurst. As the conduit would, under these circumstances, pass through 15 to 20 miles of irregular and hilly country, it would necessarily be very expensive.

Another very serious difficulty in the way of diverting a supply of water from the Clarence is the great height and high velocity of the floods to which the river is subject. While the great flood of 1876 rose to 23 feet 8 inches above high-water-mark at Grafton, the corresponding rise at Moleville, 10 miles above Grafton, was 34 feet, that at the mouth of the Orara, 11 miles further up the river, was 62 feet, and at

\* NOTE.—This discharge appears almost incredible; but Mr. Statham has explained how he arrived at this conclusion and has shown me a tracing of the cross section of the Nymboi at Buccarumbi when in flood. According to Mr. Statham's levels and measurements the water section there during a high flood is 21,880 square feet, and the velocity about 8 miles per hour; and from these data the discharge was calculated.—H. G. MCK.

at Copmanhurst, 30 miles above Grafton, 77 feet. It follows from this that in time of flood the fall in the surface of the river from Copmanhurst to Grafton is about 54 ft. more than when the river is at ordinary level. Mr. Statham found that during a high flood the velocity in the contracted portions of the river from Copmanhurst to Moleville is from 11 to 13 feet per second. At such times the banks are overflowed in many places, and the flood-water frequently crosses the necks of bends, thereby increasing the effective fall in an important degree. It was owing to this cause that in 1876 the flood-water passed with a dangerously high velocity across the bend on which the town of Grafton is built. Provision for floods of that description would be a serious item in connection with the distribution channels, as well as with the head works of any irrigation scheme.

Another serious obstacle to the constructions of extensive irrigation works is the irregularity of the delta land and its division into islands. The action of the Clarence in regard to the accumulation of alluvial soil differs materially from the process going on in the case of the rivers of the west and south-west of the Colony. Such rivers as the Darling and its tributaries flow with moderate velocity in flood-time as compared with the Clarence; and while their alluvium is deposited over wide areas, and is very little subject to subsequent disturbance, the alluvium of a large portion of the Clarence delta bears the appearance of having been deposited in large quantities, and of having been greatly altered by eddies and changes of current. Though the general conditions of the western rivers differ widely from this, parallel cases may in some cases be found at the point of emergence of these rivers from the hilly country. The best instance of this with which I am acquainted is that of the Macquarie at Dubbo, where a deposit many feet in depth is sometimes left by one great flood, and subsequently removed or altered by another. Owing to such cases much of the alluvial land of the Clarence has an irregular and ridgy outline. Besides, the lower portion of the delta is practically cut off from the upper by the hills, which arise almost from the brink of the river at Rocky Mouth or Maclean. These hills would form an expensive barrier to the irrigation of the alluvial land between this place and Clarence Heads.

There is yet another point which would demand a heavy outlay in connection with any large irrigation work in the Clarence Valley. This is the presence of tracts of low land which would require to be provided with a system of drainage in conjunction with the irrigation works.

The conclusion to which I have been obliged to come is, that while irrigation in the delta of the Clarence would in many cases be decidedly beneficial, the obstacles in the way of utilising a supply of water from the river for this purpose are of serious importance. Under these circumstances the question of irrigation from wells is one deserving of consideration. An abundant supply of water suitable for irrigation has in several places been found at depths of from 20 to 30 feet; but hitherto only Chinamen appear to have made use of it. It seems highly probable that as the cultivation of the alluvial land extends, and agricultural competition becomes more keen, a demand for the complete investigation of the practicability of an extensive system of irrigation will arise. Meanwhile it is necessary to indicate the measures which should be taken in order that the prospect of utilising the available supply in the river should not be marred.

The most important point to be attended to is the reservation of all probable sites for storage reservoirs, especially where such sites are at a considerable elevation. It frequently happens that the best sites for reservoirs are rich alluvial flats surrounded by hills, and unfortunately comparatively few such places remain unalienated. The reservation of the valley above and below such places would, however, be useful; and in the case of possible sites which yet remain unalienated it would be advisable to have special surveys made to determine their merits. I understand that the Surveyor-General has devoted special attention to this question in connection with the country west of the Dividing Range; and I have no doubt that in regard to the Coast District, it has only to be brought to his notice to receive similar consideration.

It is not irrigation alone which has to be considered in dealing with the supply of water in the Clarence and its tributaries. The presence of one of the largest supplies of water in the Colony within the bounds of an extensive gold-field is a very suggestive coincidence. Not only is the supply abundant for sluicing purposes, but the rapid fall in the tributary rivers affords the means of obtaining power for working machinery on a large scale. An example of what can be done with the water-power in such a river as the Clarence is furnished by the case of the Connecticut River in the United States. The catchment area of this river is slightly less than that of the Clarence, but it is made to yield 15,000 horse-power, and thereby returns a revenue of about £20,000 per annum.

I attach hereto a sketch map showing the coast river-basins from the Nambuccra to the Tweed. This map was very kindly supplied to me by Mr. Statham, Assistant Engineer for Roads, who also gave me rough copies of cross-sections of the Nymboi, Blick's River, and Whiteman's Creek, and from whose experience I obtained much useful information when inspecting the southern tributaries of the Clarence.

Grafton, 23 October, 1886.

H. G. MCKINNEY, M.E., M.I.C.E.,  
Engineer to the Commission.

## REPORT ON THE DISTRICT BETWEEN THE LACHLAN, BOGAN, AND DARLING RIVERS.

V. Czarlinski, Esq., M.E., C.E., to The Secretary, Royal Commission, Conservation of Water.

Sir,

Sydney, 27 January, 1887.

I have the honor to present the President and the Members of the Commission with my Report on the district between the Lachlan, the Bogan, and the Darling Rivers, which I visited under instructions contained in your letter of April 30th, 1885, as also instructions received from the President verbally.

I have, &c.,

V. CZARLINSKI, M.E., C.E.,  
Assistant to the President.

### 1.—OROGRAPHICAL DESCRIPTION.

The country bounded in the north-west by the Darling, in the north-east by the Bogan, and in the south by a portion of the Lachlan River, and its effluent the Willandra Billabong, occupies the most central position in New South Wales, and its area is equal to about 46,000 square miles. Position and area.

The surface configuration of this triangular tract of country may in its general form be described as that of a tetrahedron, formed by the remnants of what was once a range of some magnitude,\* and which, from its position in the Colony, may be designated by the name of Central Range. Surface configuration.

The position of the summit of this tetrahedron range is fixed by the junction of its three main ridges on Nangeribone Run, where the Crawl, the Nangeribone (head of the Panjee), and the Tarran Creeks take their rise and run towards the Darling, Bogan, and Lachlan Rivers respectively, defining in that way the directions of the general fall of three of the sides of this tetrahedron, while the position and fall of the plane forming the basis are defined by the position and the fall of the rivers which bound the tetrahedron.

The south-easterly ridge, starting from the range at the head of the Bogan River, at a point which determines the division of the Bogan, Lachlan, and Macquarie River watersheds, runs in a north-westerly direction, keeping parallel with, and almost equidistant from, the courses of the Bogan and Lachlan Rivers, till it reaches the summit of the tetrahedron, nearly opposite the points where the Bogan trends towards the north and the Lachlan to the south-west. Ridges dividing main water-sheds.

The altitude of the points composing this dividing line, if peaks existing here and there are excepted, remains almost constant at a height of about 1,200 feet above sea-level, on the portions from the summit at Nangeribone (1,265 feet) to near the head of the Bogan proper, on Coradgery Station. There is however, a slight fall towards the centre of the line about the heads of Murga Creek, as Melrose Plains homestead, situated right on the dividing line, is at an elevation of 1,195 feet only. The elevation gradually increases as we go nearer the summit on the Macquarie watershed division, where it attains about 1,700 feet. This line, though well defined in its whole length, seldom appears as a sharp ridge of steep inclined slopes, and, with the exception of both ends, it mostly occurs as a slight undulation, on a high table-land gently descending towards the main drainage channels on both its sides.

The ridge separating the territories of which the Lachlan and Darling Rivers are the main drainage channels, runs from the summit at Nangeribone towards Wilcannia, in the same westerly direction as the dividing line between the Bogan and the Lachlan, and of which it is a continuation. But it soon loses its well-defined character, as when from the extremity of the granitic outcrop it trends with the Devonian to the south, it abuts at North Peak on to a table-land, which is like a depression of the crest of the two watersheds.

This plateau, inclined towards the west, or, in other words, following the direction of the main crest of the old Central Range dividing the great River systems of the Darling and the Murray, and which here has been flattened, is in the south and the north skirted by chains of low ridges. The southern ridge is crossed twice by the Forbes-Wilcannia Railway survey, at an altitude of 329 and 309 feet respectively. To the west it gradually and almost unnoticeably goes over into the plain of the Darling Valley, opposite Wilcannia, and its eastern limit is formed by a range extending from Mount Hope in the south to the banks of Crawl Creek in the north. Two other lines of ridges running transversely to the length of the plateau divide it into three portions. It will easily be understood that such configuration forms of the two upper or easterly portions almost enclosed basins in themselves. They comprise a sort of neutral zone between the watersheds of the Darling and Lachlan, from which the escape of the rain waters in any direction is rendered difficult by nature. However, the ridges bounding in the north having a decided slope to the Crawl Creek, which belongs to the Darling watersheds, though its waters might never reach the present surface drainage channel of that river, and the tendency of the few creeks on their southern side being to flow in the direction of the Lachlan, the higher gradients of this table-land may well be considered as lying within the Lachlan basin.

The third main dividing line is that which causes the rain waters to flow on the eastern side towards the Bogan, and on the western side towards the Darling.

Running from the summit due north after leaving the porphyritic outcrops at the head of Mulga Creek, it trends to the north of east, narrowing the area of the slope which sheds its waters to the Bogan, by approaching that river to within 12 miles. From that point it takes a north-westerly direction parallel with the river course, reaches Mount Oxley, and finishes with a granitic hill in the corner formed by the Bogan and a Darling ana-branch called the Dry Bogan. This

\* First discovered by Mr. C. S. Wilkinson, Government Geologist, and referred to in his evidence given before the Commissioners in their First Report, Minutes of Evidence, Q.Q. 942, 971, 975.

This ridge is easily discernible on its whole length by prominent peaks of 1,400 to 1,500 feet high, remaining witnesses of a grand range which once existed here, but through deficiency of accurate surveys all its minor bends cannot be fixed on the map. In the first part there are few variations in the altitude of this line—I mean a line passing through the lowest points on the ridge of the range. Starting at Nangeribone, 1,265 feet high, and crossed by the Nymagee-Nyngan road, at the head of Nymagee Box Creek, at 1,200 feet, it maintains about this height to the head of the Mulga, whence the ridge begins gradually to lower till it descends to the level of the flooded valley of the Darling, which is about 360 feet, the surveyed line for the Cobar Railway crossing it at 955 feet, the Nyngan-Bourke line at 781 feet, and the proposed Byrock-Brewarrina line at 690 feet above sea level.

Slopes

The position of the summit in relation to the main drainage channels, and the nature of the rocks about the summit and the ridges, furnish by themselves to some degree an explanation of the present configuration of the three main slopes, and the distribution thereon of more recently formed deposits.

This culminating point is about equidistant from the Lachlan and the Bogan, as in a straight line about 48 miles separate it from both rivers. The nearest point of the Darling is however 160 miles distant. The fall from the summit in those straight directions to the rivers can be taken as a gauge of the mean declivity of the slopes. The total fall towards the Lachlan being 665 feet, the declivity of the slope is 14 feet per mile. The Tarran Creek takes a course following closely that shortest line to the Lachlan. On the Bogan side the total fall amounts to 627 feet, giving a mean fall of 13 feet per mile, which is most nearly approached by the Panjee Creek.

In the direction of the Darling the tendency to follow the shortest route is for a considerable distance marked by the Crowl Creek. The total fall from the summit to the nearest point on the Darling being 960 feet, the declivity of this slope is equal to only 6 feet per mile in average.

As a result of the eccentric position within the area encompassed by the main rivers, of the summit, where the named creeks rise, steep slopes to within a short reach of the rivers mark the watersheds of the Lachlan and the Bogan, while the waters shed to the Darling descend over a slope gently inclined almost throughout. Steep slopes engender torrential watercourses, but as in the Bogan and the Upper Lachlan basins down to Euabalong the watersheds are narrow, their occasional torrents are short, and so deposit but little of the debris of rocks brought down from the hills, carrying the great bulk to the main channels or their immediate shores. The consequence is that on the respective sides, and along the rivers, alluvial plains do not extend far back from the banks; this is especially true in the case of the Bogan. The basin of that river being too limited and the nature of the rocks at the heads unfavourable to furnish material enough for the building up on its left bank of extensive plains from alluvial deposits; their extreme width does not exceed about 5 miles. Moreover, the tributaries to the Bogan and the Lachlan compelled by the contours, results of old convulsions of the earth's surface, to wind their courses through wider depressions and gaps, have ridded their waters from silt, ere reaching the rivers. They filled first the enclosed depressions, and to such an extent that in the so formed flats it is now often a difficult matter to discover and trace the beds of the tributaries. However, they do reappear, and the junction of most of them with the recipient river is marked by channels cut deep and wide enough to make it evident that at times they discharge down the hills great volumes of water with tremendous force.

On the Darling side, the mean fall being less and the distance greater, the creeks, though torrential at the heads in times of rainstorms, die out in the alluvial plains which they helped to form, but which were mainly built up by the Darling itself. So far away from the Darling do these creeks die out that no one can positively tell the spot where the river receives their waters, if it receives them at all.

After this general description, in which I have endeavoured to exhibit the general similarities and differences in the surface character of the sides of the tetrahedron, it will be convenient, for the consideration of features characteristic only to each of the three areas, to treat them separately.

#### THE BOGAN SLOPE.

**Area.** The side sloping to the Bogan occupies an area of about 7,000 square miles, or only a little over 15 per cent. of the whole area, and is the smallest of the three watersheds.

**Aspect of surface.**

The range bounding it in the east, the central part of which is known as Harvey's Range, has a very abrupt flank towards the Bogan and stands like a wall dominant above the adjoining western table-land. The ridge of this range being highest, about 1,700 feet, at the division point of the Lachlan, Bogan and Macquarie basins declines towards the north, descending to about 1,000 feet, a few miles to the west of Dubbo.

**Gaps and table-lands.**

Three gaps, the Burrell in the south end, the Gingham in the centre, and the Gundong in the north, give access from the Bogan watershed to the high table-land of the Macquarie on the east side of the range. This table-land slopes, in a general sense, in a north-easterly direction or parallel to the course of the Macquarie, that is to say, the general position of Lewis Ponds Creek is more elevated than that of the Bell River, which is higher situated than the Little River. At the opening of the Gingham gap the Macquarie table-land is about 200 feet higher than that of the Bogan, which, through that gap, is reached by a very steep descent. The sill of the gap is 1,200 feet above sea-level, and about 10 miles to the west of it a surveyed railway line crosses the Ten-mile Creek at a height of 945 feet. The table-land of the Bogan preserves a character of undulations, interspersed with small open and almost level plains; and it would present no superior difficulties to the construction of canals, even if they were to run on the higher parts along the southerly dividing range, as the spurs from that range subdividing the watershed into secondary drainage areas are neither formidable in height nor precipitous in shape, and suitable places on the many depressions of their ridges would afford easy passages to lead the canal from one into the other of these minor basins.

**Panjee and Trowel Creeks basins.**

A more rugged appearance is presented by the country where the slope bends from the north-west to the full north, and where consequently the waters of the Panjee and Trowel Creeks flow in a north-easterly and easterly direction respectively; but whereas the hilly country above the Bulbodny Creek extends to within a short distance from the bank of the Bogan, the broken country of the Panjee reaches only to about half-way between the high edge of the slope and the river, the greatest irregularities of the surface occurring naturally in the neighbourhood of that edge. Within the basin of the Trowel Creek the pronounced mountainous character about the heads changes towards the lower course into gentler undulations, which extend again to about 5 miles from the river about Nyngan.

Referring

Referring to the annexed geological and hydrological map, it will be noticed that the Bulbodny Creek forms a sharp angle with the Bogan. Within that angle runs a ridge almost parallel to the Bogan, forming the division between the river and the creek, and limiting the Bogan valley proper. This ridge, originating on Coradgery Station, runs at the back of Crowl or Sandy Creek, along the north-eastern boundary fence of Burra Burra, forming there a gap through which the Bullock Creek passes, thence, running at the back of Middlefield block, it extends over the Albert Waterhole block, and follows on Orange Plains, close to the north-eastern boundary of that run. The eastern flank of that ridge sheds its waters direct into the Bogan, giving rise after heavy rainfall to watercourses of only a few miles length. There is nothing in the way of natural difficulties to prevent the leading of a canal on to this ridge and along it, from which higher position both sides could be commanded.

No very distinctive features—at least, so far as my knowledge goes—occur below the basin of Trowel Creek, with the exception of the New Year's Range and the Pink Hills, marked on the map close to the river. The decreasing height of the main divide, and the narrowing area of the slope, explain the absence of any important water-channel, though the undulating character is maintained also in this lower portion of the area drained by the Bogan.

#### THE LACHLAN SLOPE.

The tract of country tinted in yellow shades on the geological and hydrological map comprises that portion of the northern watershed of the Lachlan which is drained or otherwise affected by the central part of the course of that river.

The area is equal to about 14,000 square miles, of which, however, 5,000 square miles are occupied by the enclosed plateaux on the crest of the Dividing Range, contributing no water to the river, and about 3,000 square miles receive at flood-times water from the river; so that the area actually drained is reduced to only 6,000 square miles.

On the whole the drained portion, from the heads of Goobang Creek to near Mount Hope in the west, and from the Dividing Range to the river's bed, may be described as generally undulating, similar to that on the Bogan side. This slope is, however, distinguished by a series of ranges, running north and south across the valley of the river, and which are continued on the southern bank. Some of them are bold, as the Grudgery Range, which is pierced alike by the Goobang and its tributary, the Gunningbland, as by the Lachlan. Upon the waters of the Lachlan it has acted as a natural formidable weir, rising as it does wall-like in the midst of the almost level plain of the banks. If, for information on the country situated west of Yarrabundry Creek, we refer to existing maps, the profuse number of dots over that portion would lead to the wrong impression that this country is a plain with isolated, unconnected, and unsystematically situated hills, whereas in fact they represent the highest peaks of ridges dividing well-defined watersheds. With regard, however, to the northern end of the Bogandillen or Manna Range, prominent on the south side of the Lachlan, the task of tracing the ridge would be difficult, as the action of denudation and of pressure of water on the barrier which once existed there has been so effective as to leave only landmarks, such as the Wollamundry, the Wollawigany, Wollongong, and Derriwong Hills.

Another line of demarcation starts from the main range with the Boona Mountains, conspicuous by abrupt cliffs of the old red sandstone, and which, passing over the Condobolin Hill, of similar formation, and the Tuga Hill, abuts as a yet elevated ridge on the river at Condobolin. Here a reef crossing the bed shows its continuation on the southern bank, but without any trace of it on the surface.

A well-marked and extensive upheaval occurs between the Nangeribone summit and a point on the river, where it has caused the Lachlan to bend from a north-westerly course to the south of west. It is a true mountainous piece of country, extending over a large area in all directions. The ridge from which on the eastern side flows the last well-defined tributary, divides the southern side of our tetrahedron into two distinct halves—the eastern capable of discharging its waters to the Lachlan; and the western, which, producing on the higher ground only a few insignificant and short rivulets whose waters can never reach the river, is, in its lower reach bordering the Willandra Billabong, subjected to floods.

Mount Manara is a prominent link in the chain of sandhills extending southwards to the Culparlin Range. Limiting in the west the area drained or commanded by the Lachlan, these sandhills are said to form the only obstacle to the meeting of the Lachlan and Darling flood-waters.

With regard to the country east of Tarran Creek, it is remarkable that the peculiar sections into which this part of the slope has been divided are the result of a subsiding at one time of a stretch of country in the region of the present river-bed. The visibly-sharp broken-off sides of the narrow portions of Devonian sediments, which remained relatively undisturbed to form the divisions, bear testimony to such an occurrence. The volcanic cones and dykes about Parkes and Euabalong exhibit the cause of the cataclysm. The waters gathering behind the outstanding barriers of rock would find no difficulty to force a passage where the gigantic shaking, producing crevices and chasms, had already materially weakened the power of resistance of the barriers. These natural dams, with apertures as fixed points where the bed of the then forming river would have to pass, helped at once the water to rebuild what the fiery element had just destroyed, by compelling the stream to deposit what material it brought down from the hills. The field from which to gather being extensive, this material was abundant enough to fill the lower portions of the sections till there were created the present plains of the valley. At the present day the water, continuing its levelling action, does not confine itself to one channel, but, breaking through the friable loam of the banks, has created networks of depressions, lagoons, and ana branches. A slight fall from the river back of the wide plain is the cause that most of the tributary creeks, with minor watersheds, have not been able to cut a channel right through to the river, but empty into swamps as much as 10 miles away from the Lachlan channel.

#### THE DARLING SLOPE.

The portion drained towards the Darling of the district defined by the three main rivers and a line which would strike the Darling if the Willandra were prolonged in the direction of its course to the west, covers an aggregate area of about 25,000 square miles, made up by about 12,600 square miles of mountainous and generally undulating country, 4,400 square miles of a low plateau, transitory between the hilly portion and the plain of the present valley, and the valley itself which embraces an area of about 8,000 square miles. In this valley all watercourses, lakes, and depressions are exclusively supplied from floods, and the valley is occasionally exposed to total submersion.

Considering

Surface appearance.	Considering the modulation of surface of the higher or hilly part, it may be described as a generally rolling country. In appearance, if a narrow strip of mountainous land, consisting of deep gullies and precipitous flanks, and extending from the summit by Nymagee towards Cobar, be excepted, the monotonous regularity of the undulations is only diversified by some isolated peaks and bluffs, remains of broken-up ridges. Each undulation of the ground is separated from the next by a depression of a corresponding shape, but reversed, the width of the flat bottom of the one being almost equal to that of the flattened top of the other.
Sub-divisions.	The whole area is subdivided by ridges of more or less prominence into separate drainage areas, some of which are extensive. A prominent range, leaving the eastern main divide near the head of Yanda Creek, runs to the north of west, and passing at the distance of about 4 miles east of Cobar joins after some bends Rankin's Range, which is almost on the bank of the Darling. It divides the sub-drainage areas into two distinctive groups: those sloping to the north-west, and those inclined to the south of west.
North-western slope.	The north-western slope comprises the larger basins of the Mulga Creek (2,700 sq. miles), the Yanda Creek (2,500 sq. miles), and the smaller basins of Kerrigundi and Gundabooka Creeks together (1,050 sq. miles). The Gundabooka mountains, connected on one side with the Dunlop Range by a ridge of low hills, and in the south with the main dividing ridge, separates the Yanda watershed from a series of minor basins, of which the Kerrigundi Creek has the largest. Outside of hills which form part of watershed divisions occurs the isolated Tindarey chain within the basin of Yanda Creek.
South-western slope.	The south-western group of basins includes the extensive basin of the Crawl or Sandy Creek (5,550 sq. miles) and the limited area (800 sq. miles) of the western flank of a ridge which, extending from Rankin's Hills by the boundary of Pullpulla and Wuttagoona stations, runs south to Barnato, and gives rise to a number of small watercourses. These disappear as soon as they enter the most permeable soil of the plateau at the foot of this elevated chain.
Low plateau.	This very absorbent, spongy, and sandy stretch of country, in which the Crawl Creek also loses its channel, is chiefly characterised by low sandy ridges and small swamps. It is separated from the inundated plains of the Darling by a chain of sandy ridges extending from Mount Manara and Macculloch's Range in the south, to Greenough's Hills north of Lake Poopelloc, and Rankin's Hills. Other low ridges extending from Mount Manara by the Neckarboo Range towards Barnato form its eastern edge, and divide it from the drained portion of the Crawl Creek basin.
Crawl Creek basin.	In connection with the extensive basin of the Crawl, it has to be noticed as a remarkable feature that the main drainage channel, through its close position to the southern limit of the basin, draws its supply from only one side. All the tributaries come in from the northern watershed, and with the exception of a high spur intervening between the Nymagee Box Creek, and the upper course of Crawl Creek, their respective drainage areas are formed and divided by undulations of but medium prominence. Still, of a more mountainous character is the land between the gully in which Cobar is situated and the Buckwaroon Creek, where some valleys of amphitheatrical shape have been formed by erosion. On the Box Creek, about 10 miles below Nymagee, two high spurs, coming within a short distance of each other on the opposite banks, and encircling as they do an extensive plain, offer the only instance to my knowledge where a large storage reservoir could be made within this district.
Valley.	The black-soil plain along the course of the Darling opposite Bourke, about 12 miles wide, is reduced to a narrow neck by the Dunlop and Rankin's Ranges; it then widens out again; when past Macculloch's Range its breadth takes an excessive development. This is the area, at times almost completely covered by floods, in which the river has in the course of more recent ages been shifting its bed, with the result of creating a network of large and small billabongs, lagoons, and innumerable depressions called lakes. As is usual for most of the lower courses of Australian rivers, the bank falls slightly back from the river.

## 2. GEOLOGICAL FORMATION.

The flow and escape of the rain-water from the surface are regulated and governed by the physical properties, disposition, and apportionment of the component parts of the ground. It is therefore, in a hydrographical study, essential to the acquisition of a true understanding of existing conditions, and especially of those affecting the circulation of water underground, that we should add to our geognostic knowledge an inquiry into the geological changes undergone by the country under consideration.

The Government Geologist, Mr. C. S. Wilkinson, has, in his evidence already referred to, made a general statement as to the substances of rocks of the Old Central Range and its surroundings, their lithological conditions and proportions of superficial extent. It is therefore unnecessary to dwell here upon those subjects; but since that time the character of large portions of areas marked on the maps with the First Report of the Commissioners as "not geologically examined" has been recognized, and accordingly those portions have been attributed to the basins of corresponding geological origin. As the field for research of artesian water is indicated by the character and confined to the area of particular formations, this modification of limits is important. In compiling the accompanying geological and hydrological map regard has been paid to these recent alterations as shown on a map prepared by Mr. Wilkinson for the Colonial Exhibition in London, and which he kindly put at my disposal.

The discovery of cretaceous beds between Bourke and Wilcannia on the left bank extends the possibility of striking artesian waters to the eastern shore of the Darling. So far a tolerably extensive patch of country about Bourke, and the land lying between Acre's Billabong and the Darling, have been found to be of cretaceous age. It may also be expected that, with the exception of what has been recognized as Devonian, the intervening country and further down to the dividing Devonian outcrops opposite Wilcannia will also prove to be of similar formation; but the recognized development of the area occupied by paleozoic rocks forbids the expectation of finding the cretaceous beds to extend much in width.

It has been ascertained that the silurian deposits reach a long way further north, and there is little doubt that they will be found beyond the limits ascribed to them at present in the west of Cobar. The disposal of the patches known to belong to the Devonian class of rocks indicates the existence of a considerable basin of that origin, although in places it is covered by recent or pleistocene deposits of shallow depth. There is information to hand indicating as an approximate position of the shores of the paleozoic mass a line passing outside of Mount Oxley, the Gundabooka Mountains, touching the Darling with the Dunlop and Rankin's Ranges, which thence takes a turn to the south, skirting the foot of the Devonian range extending towards Barnato, and of Neckarboo Range; it turns there by the north by Macculloch's Hills towards

Wilcannia

Wilcannia. This is of course an outline from which there are departures in the form of indentations occupied by more recent deposits, as also of Devonian outrunners, promontories in the cretaceous ocean, of which it marks the south-eastern shore in this region. These primary sediments extend also in the south over a field larger by far than has been hitherto allotted to them. The largest portion of the country between that massive barrier of porphyry and Devonian rocks, extending from the junction of the Nymagee Box Creek down to Mount Hope, and the Devonian dyke, called the Grudgerly and Gunningbland Ranges, is composed of Devonian rocks. In the valleys and occasional hollows the old rocks have been covered with tertiary and recent alluvial deposits; but even there silurian and Devonian schists appear frequently in the banks, and at the bottom of the creeks, and of the Lachlan. The Devonian formation extends also for some distance in the west of the porphyritic outburst near Mount Hope.

Within the basin of these old sediments the occurrence of granite and porphyry is mostly confined to the main dividing ranges. Through the agency of these early eruptions has been determined the still prevailing divisions of watersheds, and was shaped the original configuration of the country. But a ceaseless action of denudation, the disintegration of *debris*, and settling of deposits, have since softened the ruggedness of surface and angularity of outline, and reduced the elevation of prominences. In speaking of elevation I have in mind the difference of levels between the top of the hills and the bottom of the valleys, for the absolute height above sea level varies from one geological epoch to another through its dependence, not only on the destructive action of atmospheric influences, but also on the alternate upheaval and subsidence experienced by whole parts of the continent.

The basaltic outburst, which we find to have taken place at the heads of the Bogan, near Parkes, and below Euabalong in the Lachlan watershed, as also near the northern course of Mulga Creek, producing merely local effects, cannot have much changed the original surface arrangement of the whole.

The schists, mostly of a micaceous nature, frequently intersected by quartz reefs, form the bulk of the hills, where they appear exposed on the surface or are covered with a few inches of soil, the result of their own disintegration. Some of the hills, principally between Cobar and Nymagee, are covered to such an extent with small, round, waterworn nodules of ironstone that not a blade of grass or other herbage can pierce the black coating which glitters under the rays of the sun like a mirror. To this peculiarity is due the name of "buckshot country," which it locally bears. This shows the sterility of the hills for agricultural and pastoral purposes. But immense mineral riches, hidden in their bowels, wait for the development of mining industries. Although the Cobar, Nymagee, and Mount Hope copper mines have a world-wide fame, and gold is occasionally extracted near Byrock, on the Nyngan-Cobar and the Nyngan-Nymagee roads, these minerals are so profusely distributed over the whole of the primary basin that the wealth of it may be said to be yet untouched. Hopes may also be entertained for the discovery of silver, as there is no want of indications in that direction.

The depressions and valleys towards the heads of the creeks and watercourses are filled with alluvial soil 6 to 8 feet deep, but at the lower ends, as the valleys widen out, the depth of deposits also increases, and the rich fertility of these red plains is well known.

The red sand-hills, characteristic of the country at the foot of the basin, of older impermeable formation, are of Eolian origin, and due to the disintegration of their Devonian neighbours. They are scattered over a chiefly flat and permeable soil, interspersed with clay pans, where the drainage of local rain causes the formation of swamps.

The materials which have settled over an older valley bottom of the Darling and Lachlan Rivers, forming the present undatable black soil plains, has been made up from *debris* brought down by the floods of those rivers. Both sand and black soil are capable of great fertility when water is abundant. A deep deposit of alluvium, chiefly of clay, covers also the layers of rock over a narrow belt of land, averaging about 4 miles in width, on the west bank of the Bogan.

The most common kinds of trees covering the country are the mulga, pine, yarran, and mallee, the box, coolabah, belar, ti, and common gum trees. Valuable timber is scarce, and good sound box is generally confined to forests on the higher ridges. These forests have generally an undergrowth, in which the currant bush is foremost. The higher plains are mostly overrun with yarran and pine, which last seems of late to take the place of whatever other disappeared essence. It grows as a dense scrub, and is rarely found in useful size and quality. Extensively spread out is also the mallee and ti-tree scrub, mainly over the sandy permeable soil of the level plateaux. The low lands and the banks of the Darling and the Lachlan are open, the surface being only covered by low cotton bush and salt bush, and roley-poley: all the main river beds and every flood channel that leaves them are fringed with a line of gum-trees. On the Bogan the bush extends right to the edge of the river, and open plains exist in isolated patches in various parts of the basin, right up to the heads of the Bogan proper.

### 3. HYDROGRAPHICAL CONDITIONS.

The hydrographical features of a country differ from one part to another, the variation being caused by dissimilarity of certain conditions. Special modes of escape of the rain water from over the surface are determined by peculiar shapes of contour and the nature of the soil.

It will be discharged by defined channels, gather in certain points and evaporate, sink in the ground, or disappear by any combination of two or all of these means. But any particularly prevalent state of surface conditions will determine upon the prevalence of one or the other mode, and as similarity of causes provokes analogous results a natural classification of territories according to similar hydrographical conditions is rendered possible.

#### A.—SURFACE WATERS.

Districts formed of impermeable rocks are generally marked by a multitude of watercourse beds, as at times of rain the bottom of every fold of the surface is turned into a rivulet or small torrent. This is also what happens on the surface of the paleozoic basin on the west side of the Bogan. But here a severe action of denudation and accumulation of debris has levelled down original asperities, and totally filled minor depressions. Channels of small feeders have completely disappeared, except in the more rugged, elevated, and steeper inclined regions at the heads. As a consequence a greater proportion of rain water, deprived of proper channels which ensure quicker discharge, permeates the soil, and loses itself in the fissures of the substrata to the detriment of supply in the main drainage channels. But the larger valleys themselves have received deep deposits of soil of various natures, and the bed of their watercourses have been raised with the general surface of the valley, so that the soakage waters rarely get the opportunity of reaching them from underground.

A main feature of all beds of the creeks rising on this paleozoic ground is, that appearing as well defined deep cut trenches towards their heads, they become almost untraceable, even in their upper course, whenever their valley attains a great width, except by the growth of timber. They reappear with high banks in the lower course, where the valley is more contracted. The sluggish waters that build up the plains of the larger depressions, in more readily depositing the silt carried in suspension lost the power to keep themselves open a channel; but when a contraction of ground forced the volume of water that rolled in a thin sheet over these plains to gather again, and assume a greater depth, endowed with new power, it preserved a clear way through the narrows.

Formation of  
gilgies.

Over the whole area of this hilly and impermeable country the occurrence of swamps or deep and extensive depressions which would hold larger volumes of water is rare. But in the level made up ground of the flats, where they are composed of loose soil, groups of small round depressions have been formed which are known by the name of "gilgies." The cause of their formation seems to be the washing out of the soluble salts of lime and magnesia, by the water freely soaking through the loose surface soil. In consequence empty spaces would be formed on the bottom of the permeable and above the surface of the underlying impermeable stratum, provoking a subsequent falling in of the ground. Considerable quantities of water are absorbed in these holes. The existence of the little mounds between the small depressions, and surrounding each of them, may be accounted for by the swelling of the calcareous matter previous to its disintegration and removal. So there would be first a lift of the upper ground, followed by a partial settling.

Lower plateau  
swamps.

There are some small swamps on depressed portions of the crest of the main divides, and they are the sources of several of the watercourses. The lower almost level plateau bordering the older formation affords the greatest facilities for the formation of swamps. There the numerous clay-pans gather the local downpour, which is dissipated into the air. The formation of water channels of any size was rendered impossible through its orographical conditions and the great proportion of very permeable soil. All the water received even through channels of the impermeable strata, disappearing here completely, is absorbed as it spreads out.

Valley.

All the great depressions of lakes and channels within the plains of the valleys of the Lachlan-Willandra and mostly occurring in that of the Darling owe their existence to the action of the shifting course of flood-waters, and are therefore the recipients of flood-waters only, without possessing any drainage power or area of their own.

#### WATERCOURSES TRIBUTARY TO THE BOGAN.

Although this inquiry is restricted to the western watershed it is convenient with regard to the heads that the eastern watercourses should be mentioned, for all the head feeders come in from that side, and besides these there are lower down no tributaries self-existent from own watersheds, as the channels emptying on the eastern side below Brady's Cowal bring in flood-waters from the Macquarie basin.

The Bogan proper rises on Coradgery Run, at the back and south of Coonumbra Hill, in limestone country. It has a well defined bed, which it preserves throughout until it passes Muddall. It winds its course, with a moderate fall, through undulating country and open plains alternately; the banks and the bottom are chiefly of clay and loam. It receives, on Coradgery Run, the Timaldrie Creek, another small stream, and the Cookapoie Creek, which is a deep and important feeder. The insignificant Cargi Ponds come next in.

Eastern creeks.

The Burril Creek, rising in Burril Gap, after at first a rapid descent, soon widens out into shallow flats. The Ten-mile Creek is an important torrent of the steep western flanks of Harvey's Range, originating in Gingham Gap. Shut in between narrow gorges, and falling in cascades, sometimes at the bottom of a precipice, its channel is clean, in solid rock, or now and then encumbered with boulders, rubble, and coarse gravel; of similar material also has it built up its banks when, freed of the ties of the granite walls, it enters the wider silurian valley, but always keeping a distinct bed to the junction with the Bogan.

The Tomingley and Gundong Creeks, being watercourses also springing from the granite range, present, in their upper courses, a similar disposition, but the distance from their heads to their natural outlet being greater, and the lower country they have to pass through being of a less undulating character, their waters lose the power to force an open bed through the deep alluvial deposits. On the contrary, continuing at every rush of water from the heads to carry down sand and other loose debris, they have the tendency to efface the last vestiges of their ancient courses. Large holes that existed forty years ago in Tomingley Creek are now filled up. Gundong Creek, although a head branch of the Tomingley, takes, when in flood, a short cut to the Bogan, over a flat, emptying near Bulgandramine homestead. There also comes in, by another depression, some of the flood-waters breaking out of Tomingley Creek, some distance below the junction with Gundong Creek.

Brady's Cowal, the last of the eastern creeks, rises on Wallaby Run, and its still less distinctive lower course discharges high flood-waters into the Bogan, a few miles below the mouth of the Tomingley.

All these watercourses from the Burril, originating in granite, form one distinctive class, having this in common that all of them have springs as sources. They are the most precipitous and the only real mountain streams within the basin of the Bogan.

Western creeks.

Returning to the area on which this investigation bears in particular, the first creek joining in the west is the Back or Genarin, rising from several branches on Tomilico block of Coradgery Run. It follows a straight direction due north, but having lost a proper channel on the plains of the Curra and Tolma blocks, it gains again a deep bed some 12 miles before joining, as such, the Bogan, on Wallenbillen Run, about 20 miles above Dandaloo.

The Birchen or Bullock Creek heads in the west corner of Burra Burra, in the ironbark country of the tableland of the main divide. Fed by several branches from generally undulating country, which extends to within a few miles of the river, it grows into an important watercourse and empties with a deep and wide channel, 10 miles above Dandaloo, or half a mile south of Alagala homestead, opposite Derribong. 2 miles above its mouth it receives the Cowl or Sandy Creek, heading from a ridge at the back of Curraweena block. This creek has an equally deep channel, and at flood times it assumes a width of about  $\frac{3}{4}$  of a mile.

The Bulbodney Creek, the upper course of which is also called Boburdanell, rises from a yarran flat on Jumble Plains, near the north-eastern boundary of Burra Burra; but a few miles from the source

source its valley, in which there are numerous gilgies, widens out into very extensive alluvial plains, so that almost from the very heads the channel of the creek presents a frequently disconnected line, or rather a chain of holes. With a larger watershed than Bullock Creek it has a worse channel, and receives a smaller number of feeders. From the ridge, running along the western boundary of Orange Plains, and which forms its divide from the Bogan, several gullies without defined channels empty into the lower course.

The Panjee, Sandy Crowie, or Grahway Creek heads as Nangeribone Creek from the summit of the main dividing ridges, and is by far the most important of the Bogan tributaries. The Nangeribone Creek is formed by a great number of small gullies and channels in the corrugations of granitic ground. But in consequence of having undergone a greater denudation this range does not present the wild and bold appearance of that other range, from which spring the previously described group of creeks of granitic origin. Here the debris of broken up peaks filled in the precipitous gorges with deep deposits of gravel and sand, which form the bed of the present watercourses. The fall of the main creek is about 200 feet for the first 4 miles from the head; it decreases then to an average of about 12 feet per mile for the next 16 miles, and of 7 feet per mile for the further 18 miles. From Panjee head station to the mouth of the creek, for a distance of 40 miles, it falls from 4 to 3 feet per mile. Though running out several times the Panjee Creek has, on the whole, a very good bed, in places by far exceeding in width and depth that of the Bogan itself. At the Panjee homestead it is 8 feet deep, and when floods break over the banks they assume a width of over 1 mile. At the woolshed, 4 miles east of the bank, rock (silurian slate) is met with at 3 feet below the surface, whereas an alluvial deposit of 60 feet in depth intervenes between the bottom of the creek and a layer of sandstone.

The Trowel or Whitbarrow Creek is the last of the tributaries of more extensive basins that are worth mentioning. Heading about 10 miles north-east of Nymagee, in a somewhat rugged part of the main dividing range, it empties a little south of Nyngan. It loses itself several times. Small watercourses, as Stoney and Shallow Creeks, having well defined beds, with banks 3 to 6 feet high in the upper courses, and with stoney and gravelly bottoms, but hardly noticeable in out-widened gullies, send flood waters into the Trowel in streams 30 to 50 yards wide, and in the centre about 3 feet deep, and with force enough to uproot the fence posts.

#### WATERCOURSES OF THE LACHLAN SLOPE.

The Goobang Creek, having gathered the waters from an extensive mountainous basin, enters the plain of the Lachlan Valley through a break in the Grudgery Range. But following an almost parallel course it only joins the river at Condobolin. The Goobang, rising at an elevation of about 1,700 feet, has the considerable fall of about 700 feet to Parkes, which lies about midway between the heads and the gap in the Grudgery. From Parkes to this gap it falls 300 feet, and the incline from there to the junction, nearly double the distance, is only 80 feet. Halfway on its course through the plains the Goobang receives the Gunningbland Creek, which also breaks through the same Devonian barrier. A few miles lower it is joined by the Yarrabundry Creek, which has only a very limited gathering ground about the heads. The shifting beds of the Goobang and Gunningbland Creeks have left in the plains, as vestiges of older courses, some swamps and useful lagoons. One of such, about 4 miles long, near Burrawang homestead, has been turned by a small dam into an almost permanent water reservoir, from which about 200 acres of land are irrigated by a 4-horse power engine and centrifugal pump. The channels of both creeks, although very much silted at places, are generally deep and well defined. At Condobolin the Goobang channel exceeds in importance that of the Lachlan.

Creeks contributing to the supply in the Lachlan.

The Murrumbogie Creek empties also into the Goobang, but draining a very small area it is insignificant.

The Murda Creek rises on Melrose Plains, and has a comparatively large but not throughout well-defined basin. It winds its course on a tableland between low undulations. The bed is easily traceable to Mowabla, but nowhere attaining larger dimensions, yet its valley discharges at times streams 150 yards wide and 20 feet deep. It empties into the Lachlan Valley, about 12 miles below Condobolin, without any channel being traceable.

The Tarran Creek: With regard to the designation of this drainage system, which is locally known by the names of Sandy and Crowie Creek, I have chosen the name of one of the most important head creeks, to avoid confusion with the Crawl or Sandy running towards the Darling, and the Sandy or Nangeribone Creek running as the Panjee Creek to the Bogan, all these three systems diverging from the same point on the dividing Range. The course of Tarran Creek runs parallel with the crest, and at the foot of the eastern slope of the range which extends from the summit southwards to the bank of the Lachlan. It receives the waters of this slope through a number of well-defined creeks. Although some watercourses leave the Yellow Range, there are apparently no important channels coming in through the plains extending on its eastern bank. The Tarran empties into Morumbil or Flanigan Swamp, a little below the southern boundary of Palisthan Run, about 12 miles from the Lachlan, which it is said to have reached during the flood of 1870.

This completes the list of creeks which do contribute at times to the supply in the Lachlan. All the watercourses rising on the western downs run out to nothing scores of miles away from the main river.

The Berthong Creek, rising on the opposite side of the head of Eremeran Creek, and after running for some distance west, takes a turn to the south and runs out on Wirchelliba.

Creeks not contributing to the main river.

The Marobee Creek spreads out over the plains of Tara and Coan Downs in the west of Bogallo Peak.

Within the plateau a few creeks—on Lachlan Downs, Thule, and Keginnie—disappear in sandy ground after running a few miles.

The Willandra Billabong is an effluent most probably marking the direction of a course followed in older times by the Lachlan itself, which through its own deposits, and the formation of sandhills, has been forced to cut a channel more south.

The Kiarcathur and Booberoi Creeks are important ana-branches within the flooded zone of the Lachlan.

Conoble Creek runs out of the Willandra, and turns back into it by North Abbotsford.

#### WATERCOURSES

## WATERCOURSES OF THE DARLING SLOPE.

The western flank of the old Central Range is divided, as has been shown before, by a ridge leaving the northern branch of the main divide above Nymagee, and extending to the Rankin Hills, into two main slopes. On the northern side of this ridge the waters are gathered in the following creeks:—

Creeks running north.

The Mulga, which rising on porphyritic ground, and with the upper bed very much silted up with sand, runs out repeatedly in the flats of its generally wide valley. The waters from the slopes are brought in by gullies without marked channels. It is believed to empty on Jandra Run, but long ere reaching the Darling Valley its course becomes a mere depression marked only by a more prolific vegetation.

The Yanda Creek, rising near Nymagee, in the corner of the two creeks bounding the northern slope, is of a similar character. Its channel, 8 to 9 feet deep, and in places 20 to 30 yards wide, is already in its upper course on the Nyngan-Cobar road, only remarkable by the growth of gum saplings over a belt of about 50 yards in width. It has not run through for the last fifteen years.

A few watercourses descend from the Gundabooka Range, which run out after a short distance.

The Kerrigundi Creek comes down, a steep torrent, from the range on Pullpulla Station. It after good rains, 10 to 12 feet deep, and sometimes 3 miles wide.

Creeks running east.

The southerly portion of the south-westerly slope constitutes the great watershed of the Crowl or Sandy Creek. The main drainage channel of this basin has, as the name indicates, a bottom filled with sand throughout. From a deeper drift filling an older bed beneath, water may be drawn at any time by piercing a layer of cement intervening between the two strata of sand. The creek is said to run out on Moira Plains—some pretend that it reaches only Kew—but it must oftener happen to lose itself in the very permeable soil before reaching Tiltagara. At any rate there is no traceable channel lower down. It has almost no watershed on the southern bank, on which side there is a complete absence of feeders. From the north it is joined by the Box Creek, coming down as a well defined channel from the granitic mountain beyond and round Nymagee. Lower down it receives another Box Creek, which is merely a wide gully gathering the waters from round Cobar, and from a creek originating at Buckwaroon Hill. Between the two Box Creeks there is a number of gullies, formed by low spurs from the range extending between Nymagee and Cobar. At the bottom of all these gullies is a shallow deposit of soil, rarely exceeding a depth of 6 to 7 feet, and after heavy rains there come down streams of water up to 300 yards wide, but only 2 to 3 feet deep. Yet in many cases these waters filter into crevices not apparent on the surface, as they are filled with loose soil, for they mostly disappear after a short run.

In the northern portions of this slope a number of creeks rise on the western flank of the Devonian chain of hills, which shed the waters from their north-eastern side to the Kerrigundi, and from the south-eastern to the Buckwaroon affluent of the Crowl. Steep and stony at their heads, they lose themselves in sandy soil at the foot of the range. An idea of their incline may be gathered from the fact that a dam on one of them, the Cameron Creek, 30 feet high, backs up the water only 1 mile when full.

## B.—UNDERGROUND WATERS.

However hard a rock may be, it is, properly speaking, never absolutely impermeable. A portion of rain water is absorbed by filtration in the crevices of the granite; some is absorbed by the superficial detrital stratum of the stiffest of clays, and some between the interstices left by the grains of sand of the arenaceous grounds.

The subterranean water accordingly will occur in limited contracted veins or diffused sheets. Those nearest to the surface are due to local rainfall. Deeper ones, often of great extent, are separated by impermeable strata. The higher position of infiltration can always be found by a research on a geological map of the country of the corresponding acquiferous stratum, but not always can be detected the inferior line of discharge.

We can also imagine a series of strata disposed in a huge natural saucer, on the horizontal border of which the rain permeates. When the empty space forming a reservoir in the permeable strata gets filled, the water stops motionless, and any surplus must overflow. If a hole is bored to the bottom of the saucer an artesian jet of water must rise, which will be followed by a certain current of the subterranean water.

In some, the underground waters may be stagnant or flow like rivers; springs might rise from the sheets, imprisoned between impermeable strata, or flow out at the surface on the basis of the permeable stratum.

Underground water in the paleozoic formation.

In reference, under this respect, to the district between the Lachlan, Bogan, and Darling Rivers, it is in the granitic and porphyritic portions that the water circulates, in narrow veins, and where occur superficial springs. Such are known to exist at the heads of the Tomingley and the northern branch of the Nymagee Box Creek.

We cannot look to the great paleozoic basin for any important underground sheets of water, as filtering in between the dislocated layers of schists they can have no depth and they must be unconnected; moreover, the water is generally of bad quality, as the minerals it meets render it in the best cases brackish. We find there, also, no surface springs. The waters following the incline of the slates sink deeper than is the case in the granitic ground. In Barton shaft, at Cobar, water was tapped at 601 feet below the surface, or about 110 feet above sea level.

Sheets of water extend at the bottom of the alluvial deposits within the valleys. They belong to the class owing their existence to local rainfall, and are, therefore, not reliable sources for any greater demands. This water is often salt, except in the sand deposits in the immediate neighbourhood of the watercourse beds, where they are almost always to be found. Mr. Gordon, on Alagala (opposite Derribong), excavated a tank on the left bank, and about 200 yards back from the Bogan. When he reached a depth of 9 feet through clay, he met with drift from which water bursted out with such force that he had to stop work. The river was, at the time, perfectly dry.

Springs from gilgias.

There are a few springs breaking out near the creeks and originating from gilgias. An important one of this class exists at Kerriwah Station on the Bulbodney Creek, where 3,000 sheep are constantly watered.

The

The cretaceous beds occupying the Valley of the Darling on the eastern bank contain several over-lying aquiferous strata. Those nearest the surface contain the soakage from local rain. They are mostly unconnected, the waters gathering in portions of older river-beds and occasional hollows which are now filled in. The next in depth from the surface have their line of infiltration along the flank of the paleozoic mass, only a short distance away from the river, and they discharge into the river in the form of small springs from the side of the bank, or bubbling up from the bottom. Some are salt, some fresh, according to the minerals they meet in their course. The water in wells tapping these underground currents would rise moderately, as the line of infiltration occupies a position not much higher than the outlet.

The deepest aquiferous strata have not yet been reached on this side of the Darling, although their existence under the cretaceous sandstone is undoubted. They have not been looked for, as the discovery of the cretaceous origin of the left bank of the Darling is so recent. These strata draw their supply from a belt of country extending along the north-western limit of the Darling watershed in Queensland. Ammonites, belemnites, and fossils of the saurian species characteristic to the oolitic floor of the Jurassic formation have been found all over the intervening country between the Nive River—one of the Warrego heads—and the Wallambilla Creek emptying in the Condamine above Surat. The southern limit of these eminently permeable oolitic beds is approximately indicated by the disposition of the rivers. The bearing of geological formation on hydrological features is so intimate that both are often valuable guides in a reciprocal research. I take it that the line of this limit passes from above the heads of the Paroo, by Mangalore, round the heads of the Nebine, Mungallala, and Wallam Creeks (which, originating on the lower impermeable cretaceous beds, disappear in the upper cretaceous sands), down to the junction of the Maranoa with the Condamine, which flows along the eastern edge of this formation. North of this line is the infiltration ground of the waters finding their way under the older cretaceous deposits. In seeking to discover the whereabouts of discharge it must be remembered that the cretaceous sediments were here, as usually, deposited in a deep basin encompassed by land, and that consequently we are here in presence of the case of the imaginary saucer, wherefrom the waters imprisoned between the various strata cannot escape, unless by overflow. It is here the covered Devonian range that passes across the Darling about Wilcannia, which prevents these deep artesian water-veins from continuing their course further down in the direction of the waters flowing over the surface. It has been contended that these waters must find their way to the ocean, for otherwise, however great the underground reservoir might be, it would in time get filled and the waters would overflow; and so in fact they do overflow from time to time, and would continually do so were the supply kept up by continuous rains around the border of the enormous basin. But we know that the rain is far from being regular and copious (see on diagram of rainfall over the basins of the tributaries of the Darling within Queensland the records relating to the Warrego, Paroo, and Bulloo Rivers). We know also that through capillary action the water, especially near the upper line of infiltration, is drawn to the surface, and there absorbed by direct evaporation and through the medium of vegetation, principally all the thirsty varieties of the eucalyptus family. Subsequent rains must, therefore, be of sufficient copiousness to make up all the loss in the superficial ground before a fresh over-saturation can produce a new overflow. This takes place in rainy seasons, and causes occasionally the great floods on the upper courses of the Queensland tributaries to the Darling. A further proof of the correctness of this view is supplied by the series of mud springs, where the water under the great pressure from beneath forces itself outlets to the surface by not finding any lower down. This opinion is confirmed also by the great variation in the supply of all the artesian wells on the north-west side of the Darling, which, overflowing or reaching within a few feet of the surface, subside invariably in a few days after they have been tapped. It would be interesting and valuable to be enabled to connect by accurate records the variation of height and yield of the existing artesian wells with the rainfall over the infiltration area, as the result would show the importance and reliability of supply from this source, and thus would be decided the question whether the incurrence of expense in that direction would be advisable. I would suggest that arrangements be made to secure the keeping of trustworthy records, such as (1) height of water in, and yield of, wells; (2) quality of water in hydrotimetric degrees; (3) state of rivers in infiltration area; (4) rainfall. A comparison of the diagrams of these records would also directly suggest the source of each well.

From these artesian veins water-supplies might be obtained on the eastern bank at not too great a distance from the river, and at a moderate depth of about 700 feet, as we are here close to the edge of the cretaceous basin.

On to the southern flank of the Devonian barrier lean the tertiary and pleistocene deposits. Water is and will be obtained in them, but it can neither be of an artesian character nor of great supply within that portion of the Darling basin, as we are there too close to the edge of the drainage-ground, and the rainfall is the smallest. I refer of course not to portions in the neighbourhood of the mouth of the Darling, where artesian veins may be met with, finding their supply from the basin of the Murray system. We must, as a matter of fact, look to the heads of the Murray as the source of the underground rivers in the limestone of the coast about Mount Gambier.

Ordinary wells might yield strong supplies of water within the tertiary area bordering the Lachlan and the Willandra. They are, however, invariably salt, whereas, on the southern side, unlimited quantities of fresh water have been found.

Within the plateau one can count upon only the unreliable sources of well-water from the scant local rainfall.

#### 4. RAINFALL.

The amount of rain that falls on an average over this district has been stated in the First Report of the Commissioners in the descriptive parts of the basins of the Darling, the Bogan, the Lachlan, and of the Manara County drainage areas. The map of the rainfall which I submit with this report represents how the average rain varies from one part to another within this district, so that from it an idea might be gathered of the supply available to feed the various watercourses and the springs and wells bottoming in the strata saturated by percolation of a portion of the local rainfall only. The information contained in that map might also prove useful to the settlers in that part of the country for fixing the holding capacity to be given to tanks, knowing in each case the area from which the tank may draw its supply.

Within the area represented on the map meteorological observations are recorded on eighty-seven stations. The largest number of these have been established only within the last two or three years, so that the averages have had to be arrived at from a smaller number of older stations, and the delimitation of areas upon which generally obtain the same conditions of rain has been fixed by comparison of the results registered in corresponding years at the older stations and at those of more recent date.

As the question has been raised by witnesses of the practicability of drawing a supplementary supply of water into the Bogan from the Macquarie, I have thought it useful to illustrate also the rainfall over the neighbouring portion of the Macquarie basin.

The irregularity of the rain seasons generally, as of the distribution of the scanty downpours making up the yearly totals, and all other particulars with regard to meteorological phenomena over this district, have been fully described in the First Report, and the accompanying map will supply sufficient details without needing any lengthy explanation.

## 5. CONSERVATION OF WATER.

### Existing Works.

All the works for the conservation of surface water in this district have been undertaken almost exclusively for the purpose of securing a supply for domestic use and for watering stock. The only instance where the stored water has been applied to cultivation is that already mentioned on Burrawang Station, in the Lachlan District, and on a very small scale irrigation has been attempted by Mr. C. J. Wallace, on the Priory, between Cobar and Nymagee. The irrigation at Winbar is carried on by drawing water from the Darling without any special arrangements for storage.

### Tanks and dams.

The wants of domestic consumption and of stock have largely been provided for all over that country by means of tanks excavated in the soil and dams thrown across the watercourses. With regard to tanks, the injudicious choice of sites is apparent in many places, especially remarkable for this fault being those established by the Government. In this case the chief aim seems to have been to place them close to the roads without regard to the surface configuration, and to whatever might have been the difficulties of making the water converge towards the excavations. It will suffice to state that as most of the roads follow close to or even on the crest of dividing ridges, the tanks situated so near the upper edge of the watersheds cannot possibly get a supply adequate to their holding capacity. They ought to have been made at lower levels, and the roads diverted accordingly, which in many cases would have also entailed considerably less expense. The dams on the creeks are often faulty in construction, through not having been sunk deep enough into the impermeable basis of the ground. However, the tanks and dams, such as they are, on the stations provide ample water for drinking purposes, and the complaint invariably met with throughout the driest district round Cobar relates only to the want of grass. In consequence of the absence of sufficient resources of water within this large district itself, extensive irrigation for the purpose of satisfying this want is out of the question, unless, indeed, it were possible to bring the water by means of canals from basins better favoured by nature.

### Irrigation.

### Practicability of supplying the district from outside basins.

The Upper Macquarie basin, through its higher position, is conveniently placed for such diversion into the Bogan basin, and with a thorough system of works for the conservation of water executed in the regions of the head tributaries, where the average rainfall ranges from 22 to 36 inches, not only would a greater and more regular supply of water be ensured to the settlers in that basin, but a surplus would be available for those on the Bogan.

### Diversion from the Macquarie to the east bank of the Bogan.

Concurring absolutely with the opinion expressed by Mr. H. G. M'Kinney, M.E., M.I.C.E., in his "Report on the Macquarie River and the district between the Macquarie and the Bogan Rivers" (annexed to First Report of the Commissioners, pp. 134-136) on the practicability of supplying and distributing the Macquarie waters on the right bank of the Bogan by diversions from Narromine down, I have been led to the conclusion that, considering the natural facilities of that country, the necessary works would be relatively inexpensive, and the capital returned in a remarkably short time. Over a hundred thousand acres of the plain between the two rivers could be irrigated, and if a charge were made of ten shillings per acre for water the yearly sum obtained (£50,000) would, at 5 per cent., justify the Government to spend on such works one million pounds sterling—a sum by far superior to what would be required.

### Diversion to the west bank of the Bogan.

My inspection of the Upper Bogan country, and the tributaries of the Macquarie from the Little River to the Molong and Bell Rivers, has also convinced me of the possibility of bringing a supply of water through the Gingham Gap on to the ridge between the Bogan and the Bulbodny Creek in the western watershed of the Bogan, by means of a canal gathering the waters of the tributaries mentioned, on a higher level than is done at present by the Macquarie. However, though I have no doubt about the possibility of carrying out such works—and the levels inscribed on the map will bear out the justness of that opinion—yet the difficulties in the way of constructing the canal are such as to relegate the recommendation of its undertaking for centuries to come, when, through want of room for an overgrown population, it will have become a necessity.

### Diversion towards Cobar impracticable.

Proceeding now to the suggestion contained in Question 1339 (Minutes of Evidence, First Report), as to the possibility of dealing "with the head waters of the Bogan, so as to send water down from Mudall towards Nymagee, between Nymagee and Cobar," I think it unnecessary to waste many words about it. The orographical description of the main dividing ridge between the Bogan and the Darling, and the relative situation as regards levels of the whole course of the Bogan from its very head, show conclusively the absurdity of the idea, for it would mean the bringing of water from Mudall *up* hill—not down. It is therefore clear that this portion of the Darling watershed must rely upon the resources that may be rendered available from its own basin.

### Diversions from the Darling.

Whether or not it would be practicable to tap the Darling above or about Brewarrina, the diverted water could never be led into the portion of country designated in this report as the hilly part, formed of primary rocks. There are sufficient levels known and marked to show as much. The canal could only follow the edge of the valley, which is either on a level with banks of the river or lower, and it would be impossible to lead water from that source into the most moisture-needing plateau between the Lachlan and the Darling.

It is also very questionable whether it would be possible to bring Darling water across the country from Wilcannia to the Willandra Billabong, even should the piercing of the intervening sandhill chains not

not make the expense an extravagant one, as it would seem, from the flood-levels on the Willandra country and at Wilcannia, that the extremity of the traceable channel of the Willandra is rather higher situated than the bank of the Darling at Wilcannia.

It remains now to be seen whether, with any advantage to pastoral interests, the local rainfall might be conserved in a larger measure than is done at present. It being established that domestic and stock wants are sufficiently secured with present arrangements, an increased supply would have the object to serve irrigation purposes.

Conservation of local rain for irrigation by improved methods of gathering.

It has been affirmed by several witnesses from that dry country before the Commission, and to me when travelling there, that although the total rainfall per year is small, it would, where it reaches 12 inches, cause an abundant growth of feed were it to come down four or five times a year in falls of from 3 to 2½ inches each. The question in that case is reduced to a proper distribution of water with regard to time, and it would be solved by gathering the rain-water and distributing it artificially at need and will. As only a portion of the rain can be saved, it is evident that only to a portion of the area over which it falls can be extended the boon of an artificial watering. But the aim should be to make this fraction as important as possible by reducing the effects of the causes which make the gathering of the water only a partial one. Such result would be obtained by withdrawing as much as possible the rain-water from the effects of evaporation and percolation by ensuring a speedy discharge over the surface into the storage reservoirs. To effect this, recourse must be had to a *proper* system of drainage, by making inexpensive trenches and races in every fold of the ground, which would end in tanks properly situated. Where the storage is provided for by dams and creeks, a small channel should be kept open and clean by means of plough and scoop in the bed, throughout the length of the watercourse and all its feeders, in addition always to a network of drains leading the water from the field to these natural waterways. At Glenariff Station, where such improved system has lately been introduced, the effect has been most beneficial. A dam on the Mulga Creek, previously dry for years, has been filled, so to say, in no time. In this way, even in so dry a country as that between the Lachlan and the Darling, sufficient water could be stored for irrigation, were it only of a few acres on each holding, to make provisions of fodder in silos and stacks for more valuable stock in times of excessive drought. But the establishment of even so simple a system of water conservation demands technical skill and instruments mostly unprovided for by pastoralists. They should, therefore, in their interest, have recourse to advice from qualified persons, which no doubt they would have every facility of obtaining should the proposals recommended in the First Report of the Commission, with regard to local water authorities, ever enter the phase of accomplished facts.

Necessity for professional advice.

Much improvement would also result from the destruction of scrub and all that growth which is neither grass nor timber—and there is almost none worth the name of forest—as a portion of the moisture now absorbed by noxious vegetation would produce valuable feed, while the remainder would be able to reach dams and tanks more readily. But such an achievement is for the present rendered impossible by the provisions of the Land Act and the Forest Regulations.

Improvement through destruction of scrub, &c.

V. CZARLINSKI, M.E., C.E.,  
Assistant to the President.

## REPORT ON THE DARLING RIVER.

To the President and Members, Royal Commission, Conservation of Water,—

Gentlemen,

We have the honor to report that, in connection with our examination of the Darling River in flood, we left Sydney for Bourke on Saturday, 18th September, and on the 20th proceeded down stream by steamer. As fully as opportunity permitted, we investigated the river to its junction with the river Murray, a distance of about 1,100 miles by water, or about 440 miles by road, the stream, as compared with the road, being as about 2½ to 1. A remarkable circumstance in connection with the Darling is, that from Bourke to Wentworth, a distance of 1,100 miles, the river does not receive a single affluent of any importance, except the Warrego River, and it is only on rare occasions of high flood that the waters of the Warrego reach the Darling. We examined thirty-seven witnesses, minutes of whose evidence are attached hereto.

The time at our disposal being limited, we were unable to make a thorough inspection of the lake system along the course of the river, but we succeeded in visiting some of the more important lakes near Menindie. Instrumental examination will, however, be necessary to determine accurately the value of these lakes as reservoirs; but the evidence placed before us justifies our expressing the opinion that very large bodies of water can be permanently conserved in these depressions at a comparatively small expenditure. It is estimated by the Road Superintendent of the district, Mr. W. J. Hanna, C.E., that the water in Menindie Lake and Cawndilla Lake, which covers an area of over 60,000 acres, could be retained at a cost of about £700. Several witnesses asserted with confidence that Menindie Lake, in discharging its waters back into the river, suffices to maintain the navigation of the Darling from that point downwards for a period of three months longer than would be possible without such an augmentation of the volume of the stream. From the accompanying plan (Appendix No. 1), showing the lake system in the vicinity of Menindie, it will be seen that after the flood-waters of the Darling have filled Menindie Lake they are still further backed out into Cawndilla Lake, a large depression containing 21,836 acres, and into Speculation Lake. Appendix No. 2 will convey an approximate idea of the body of water in Menindie Lake at the time of our visit. By means of a dam erected on the Teryaweynya Creek by the owners of adjoining stations, the flood waters of the Darling have been directed on the east bank as far as Lake Bullabulka, filling a system of about twenty-two lakes, comprising an area of about 52,000 acres.

As an instance of the significant results which may be achieved at a small cost, it is only necessary to cite the case of Mr. J. W. Brougham, of Outer Netallie Station, near Wilcannia, who, by an expenditure of £10, succeeded in retaining a considerable body of water in Lake Woytchugga for nearly two years. This lake, which is now nearly full, has a depth in places of 10 feet, and covers an area of fully 4,000 acres. This witness also asserts that an outlay of £100 would be ample to secure the retention of the lake in its present condition. A view of the lake is presented in Appendix No. 3. The

The question as to the possibility of erecting weirs in the Darling engaged a large share of our attention. We elicited that at intervals of from 10 to 20 miles along the whole course of the river from Wentworth to Bourke there exist bars of rock, which would afford excellent foundation for any works in the nature of a weir. In the vicinity of some of these bars sufficient building material is to be found suitable for the construction of masonry. The Jandra Rocks, about 40 miles by river below Bourke, are a striking case in point. A view of this remarkable outcrop is shown in Appendix No. 4. The evidence adduced by us seems to preponderate in favour of the opinion that properly constructed works would not induce erosion of the banks.

The absence of a constant stream in the Darling has been very prejudicial to the interests of the settlers in the western part of the Colony. Sometimes barges laden with wool and general merchandise have been detained for twelve months awaiting even so slight a rise in the river as would permit navigation for steamers drawing 3 feet of water. This detention has not only caused the deprivation of a year's interest on the capital lying idle, but has involved a direct loss through deterioration in the quality of the merchandise. One instance was brought to our notice of a steamer laden with goods which occupied over three years (May, 1883, to June, 1886) upon the journey from Morgan to Bourke.

The only means by which Sydney can secure a large accession of trade and consequent revenue would seem to be found in the extension of the railway to Wilcannia or Menindie, and the maintenance of a permanent stream, by locks or weirs, between Bourke and the railway terminus that may be established down the river. The residents themselves concur in this opinion.

The fact that great bodies of water from time to time are discharged down the Paroo and Bulloo Rivers only to spread out aimlessly into polygonum swamps and clay pans, and then to disappear rapidly by percolation and evaporation, would seem to justify a contour survey of that region to determine to what extent the flood-waters might be concentrated in the natural depressions which are known to exist. Private enterprise has done a great deal towards ascertaining whether an artesian supply exists west of the Darling, but in many instances energy has been misapplied. A number of shallow wells have been sunk, and the pastoralist has had the mortification of obtaining salt water, or an indifferent supply of fresh water, whereas one well or bore carried to a depth of 1,000 feet to 2,000 feet might perhaps have determined at one stroke the possibility of obtaining an artesian supply. The subject bears forcibly on the future of that part of the Colony, and the question might well arise as to whether it would not be a wise course to devote national funds to the purpose of dealing with a problem which individual effort has been powerless to solve. It was stated to us in evidence that water might probably be diverted from the upper portion of the Paroo towards the South Australian border near Silverton. The respective levels, it is said, will permit of such a project, but further investigation must determine whether the scheme, even if possible, be advisable in other respects.

At Winbar and Tapio we witnessed the effects of irrigation applied with intelligence and method and in each case the result was an undoubted success. At the former station the manager is so satisfied with the result of his experiment on 7 acres that he intends to extend his operations. He obtained 30 tons of lucerne hay per annum at a cost of little more than £3 per ton, during a drought when £23 per ton was paid for chaff delivered at the station. He calculated that by means of irrigation he had saved £1,000 in one year. At Tapio 22 acres were under irrigation, and the growth of lucerne, &c., was so luxuriant that eighteen sheep to an acre were maintained in splendid condition. These results were achieved on soil that during the drought would not have grown a blade of herbage. Mr. N. Sadleir of Albemarle, kept 8,000 sheep on an irrigated patch 3 square miles, in the middle of summer, and the lambing was good. He asserts that the same piece of country, if it had not been irrigated, would not have supported 1,200 sheep. Every witness examined was prepared to admit the benefits of irrigation, but some appeared to doubt whether the system could be adopted with profit. The fitful supply of water, and the insecurity of land tenure, seem to be the considerations which operate most forcibly in deterring the pastoralist from experiments in irrigation. The mortality in the flocks has been terrible. One station lost £12,000 worth during the late drought, on another property 6,000 head of cattle perished; and within the sheep district of Wilcannia the losses in sheep in 1884 were, according to the statement of the local Inspector of Stock, probably 400,000, or equivalent to £100,000. The loss on three stations in two years was over a quarter of a million sheep, irrespective of the loss of lambs. Hay and chaff were sold at £50 a ton, and flour at £40 a ton. These appalling figures cannot but convince the pastoralist that something must be done to provide against such calamitous droughts; but it may require action on the part of the Government to persuade him of the vast possibilities of water conservation and irrigation. This action might well find expression in the establishing of an experimental irrigation farm under Government control, and in the offering of bonuses for the purpose of stimulating the art of cultivation with water.

Great diversity prevails along the river in the methods of noting the heights of floods. For example, the record of the height at one point bears no relation to that at any other point. Readings appear to be taken variously as from the bed, navigation level, and summer level. Considerable confusion arises from the laxity of the methods employed, and a record on the upper river does not enable a resident on the lower river to foretell with any degree of precision what rise he may expect in his locality. At Bourke the height of a flood is read from a datum called "summer level," which is 6 feet above the bed; at Louth the readings are also taken from "summer level," but in that case the term is applied to the bed of the river. Most of the witnesses seemed to concur in the opinion that it would be best to adopt the height of some well-known flood as a datum, and, taking that as zero, to read all future floods downwards from it. The records would thus bear an absolute relation to each other. The flood of 1864 seems to have been the highest of which we have any knowledge, but being an incident of a generation almost passed away there might be considerable difficulty in determining its height along the river. For this reason it would appear advisable to adopt the present flood as the datum. We, however, incline to the opinion, also freely expressed, that the datum should be registered at that discharge of the river when the water is barely flowing over the rocky bars. Appendix No. 5 shows the town of Bourke at the time of our visit. By instrumental examination we found that a further rise of about 3 feet would cause the whole town to be submerged. The danger to life and property involved through an absence of trustworthy intelligence as to the height of a flood in its progress down stream is illustrated in Appendices 6 and 7. The former represents Yanda Station, around which a dyke 3 feet high has been thrown to keep out invading waters; and the latter picture is a view of a homestead on Toorale Station which would have been inundated had the river risen 6 inches more.

Leaving

Leaving Wentworth by steamer for Morgan (S.A.) we had the opportunity of seeing the Lower Murray, which, even for small steamers, is not navigable for about three months in the year. A noteworthy feature of the river at that part is the spurs or wings which have been constructed by the South Australian Government, for the purpose of nullifying the effects of the sand-bars and other obstructions to navigation in the river. There are three series of works, namely—four spurs at Hart's Island, three at Pyap's Reach, and two at Pensey's Reach, and their cost of construction has been about £2,750. The object of this simple and ingenious device is to check that portion of the stream which would otherwise spread over the sand-bars, and to divert it with increased velocity in order by its own action to dredge the deep channel still deeper. The works therefore not only serve the purpose of maintaining a permanently navigable depth of water in the river, but they act as beacons by denoting the position of the bars. Each spur consists of two rows of round piles driven into the bed of the river, the space between the rows being filled up with the limbs and branches of the gum-trees which supplied the piles. The spurs project from the bank of the river, at angles varying from 25° to 85° with the current. So far as these works have been carried to completion they have been found to fully answer the purpose for which they were designed.

During our inquiry we ascertained from witnesses that the waters of the Willandra Billabong, an affluent of the Lachlan, do not reach the Darling. They approach to within 35 miles of that river, then take a sudden turn, and, after filling Lake Gol Gol, empty into Manie Creek, which is a billabong running from the Murrumbidgee into the Murray.

The opinion which has hitherto prevailed to some extent that the climate of the extreme west of New South Wales might be tempered, and the humidity of the atmosphere intensified, by leading the waters of Spencer's Gulf into Lakes Torrens and Eyre, is now found to be untenable. We are indebted to Mr. J. W. Jones, Conservator of Water, Adelaide, for the information that recent investigations have proved the northern end of Lake Torrens to be 100 feet above sea level.

In conclusion, we would recommend that all lakes and depressions throughout the Colony of sufficient depth and capacity to conserve water permanently should, at once, be reserved from sale. Otherwise, we are of opinion that considerable difficulties will present themselves when the national question of water conservation receives attention.

We have, &c.,

JOHN B. DONKIN,  
FREDK. B. GIPPS, C.E.

Sydney, 17 March, 1887.

#### FURTHER REPORT ON THE DARLING RIVER, BY MR. F. B. GIPPS, C.E.

I FOUND that the height of the flood-level at Bourke was 37 ft. 3 in. above summer level, whilst an instrumental examination showed that an additional 3 ft. would submerge the principal streets. In this condition the river Darling resembles a fan, having its apex or handle at Wentworth. A short distance below Bourke the flood-waters covered the country for 5 or 6 miles beyond the banks; but gradually they contracted, as large streams were drawn off by tallywalks or ana-branches to fill extensive lakes and shallow depressions on both banks of the river, until, at a few miles below Menindie, they were confined to the channel, which in places was little over 200 ft. wide. A few miles above its junction with the Murray River, at Wentworth, the channel widened out to 400 ft., but it was only 15 ft. 7 in. above summer level. The velocity of the stream in the channel, as measured by one of Stanley's tachometers, was half a mile per hour less at Wentworth than at Bourke.

Though there are several creeks draining large areas, notably Yanda and Kerrigundi, discharging into the river on its left bank, between Bourke and Wilcanuia, they do not appear to have much influence on the flow of the river, except after heavy local rains, when, according to evidence, they have caused a rise in it of several feet. Their streams are backed up for many miles by the river when in flood. The Warrego and Paroo are the only tributaries of importance that discharge into the river between the same points on the right bank. The former unites its waters with the Darling in a distinct but shallow channel; but the latter has rarely been known to flow further than Lake Perry—a large shallow depression about 40 miles from the right bank of the Darling—where it sinks into the flat rotten bed of the lake. The flood-waters of the Darling cover the country for many miles towards the same lake, and returning by the course of what is known as the Paroo channel, have frequently been mistaken for the Paroo River.

Throughout the whole distance, from Bourke to Wentworth, the river is very tortuous, having but few straight reaches more than a mile long; and it measures about 3 miles by its course to every straight mile by land. The bed of the river is chiefly composed of stiff gypseous clay covered with alluvium, except where crossed at rare intervals by rocky bars of conglomerate and sandstone. It has no regular grade or fall for any distance, but is divided into shallow falls and deep waterholes. Its banks, with exception of the rocky spurs which crop out at long intervals, are composed of black alluvium where low, and of beds of gypsum, and gypsum marls, covered by a top stratum of fine red sandy loam, where high. The high banks vary from 6 to 20 ft. in height above the flood-level; they are seldom opposite, but form long bends or elbows in the river. A wide belt of gum and box trees generally skirts either bank, so that the river, in flood, reaching up to the lower limbs, has the appearance of a narrow stream winding through an interminable forest. The flood-water is very muddy, and, if left standing, quickly deposits a thick coating of very fine silt.

The Darling River, in high flood, supplies a large system of lakes contiguous to and at considerable distances from both banks. Some of these are only shallow depressions covering large areas, whilst the deepest have a maximum depth of only 20 ft. The high flood-water of their shores may be easily distinguished by a belt of stunted box-trees which invariably surround it. Their shores are surrounded by sandhills, varying from 20 to 60 ft. high, except at the point they receive their supply, where the bank is broken away for some distance, and the country seems almost level. They receive and discharge flood-waters by the same channel. In every instance that came under my observation their supply streams had to surmount a rim, just at their point of discharge into the lakes, which intervened between the deepest point of the channel and lake.

From the limited experience gained by our hasty journey down the Darling, I am not prepared to formulate exhaustive proposals as to its future treatment, which only extensive and accurate surveys can properly determine; but I would beg to submit the following suggestions as worthy of consideration, and as bearing more particularly on the line of action that should be pursued for the proper development of  
this

this river. For this purpose it seems to me necessary to ensure: 1st. The canalisation of the river to provide for irrigation and navigation at all seasons. 2nd. The conservation of water in the deepest lakes at as early a period of floods as possible, that they may be drawn on for a regular supply to the river to account for loss from navigation and irrigation. 3rd. The settlement of a peasant proprietary on the rich deep alluvial soil of both banks.

The character of the river banks, together with the large deposits of silt by floods, prohibits the adoption of fixed weirs in its channel for the canalisation of the Darling, and favours the construction of movable weirs. The width of the channel at base rarely exceeds 80 ft., except at waterholes; and the banks rise abruptly to within a few feet of the top, where they are much broken, partly from the wash of the steamers, but chiefly from the surface drainage of the surrounding country. In considering the type of movable weir most suitable for the damming of the river, guided largely by Mr. Poole's evidence as to his experience on the Meuse River, I am inclined to prefer the Poirée needle weir and the improved shutter weir. The Poirée weir is simple and economical in construction, and can be rendered quite water-tight by a canvas curtain in front. It can be manœuvred with facility, and can be raised and lowered in a few minutes. It also provides a footway across the river. I advise the trial of one of these weirs at the rocky bar at Wilcannia as soon as the flood subside sufficiently for the laying of its foundations. I have selected this town as some such work is urgently required there, because its water supply is pumped direct from the river, and suffers considerably, both as to quality and quantity, when the stream is low. By placing two such weirs, 200 or 300 ft. apart at each station, provision could be made for the navigation of the river without any expensive locks. When down, these weirs would not in any way interfere with the flood discharge of the whole sectional area of the channel, so that there would be no increase of deposition of silt and erosion of banks to fear. The average length of the crest of these weirs, with 12 ft. rise of water, would not exceed 150 ft. Their cost, therefore, at £30 per foot, would average £4,500. They would back the river up over 30 miles, and would impound a large volume of water. The actual loss of water, each time the weirs were lowered to allow of the passage of steamers and barges at any station, would be only about 1,000,000 gallons.

I would here draw attention to the urgent necessity of legislation to prevent the drainage of town sewerage and of wool-washing establishments into the river, as at present such drainage is very deleterious to the health of those who are compelled to drink the water in dry seasons, and renders it quite unfit for the supply of towns.

I recommend instrumental surveys;—1st. Of the river and its neighbourhood, from Bourke to Wentworth, to fix stations for the movable weirs, and to determine where and to what extent it will be necessary to raise the low banks in order to prevent the dispersion and prevent waste of flood-waters, and to divert them more directly into the deeper lakes. 2nd. Of the Warrego and Paroo Channels, to discover if they might not be diverted so as to discharge their streams into the deeper lakes and depressions in the country they traverse, instead of wasting their waters as at present. 3rd. Of the Yanda, Kerri-gundi, Cowal, or Pine Creeks, and the ana-branches and tallywalkas on the left bank of the Darling. 4th. Of Lakes Wangalara, Poopelloe, Woytchugga, Tandure, Pomamaroo, Menindie, Cavndilla, Tandou, Nettlego; and also of the principal lakes supplied by the Big Tallywalka on the left bank, and by the Big Ana-branch and Paroo River on the right bank, for the purpose of showing what depth of cutting will be required to connect the deepest part of each lake on a certain grade with the channel which supplies it, and to fix points in the channel for the construction of sluice-gates to regulate the influx and efflux of flood-waters.

With regard to the large shallow depressions, with their flat rotten beds, more fitted for evaporating and absorbing pans than for conservation of water, owing to their exposure to a hot, almost tropical sun, and to high winds which at times have been known to blow their water from one end of their beds for over half a mile beyond the other end, I would advise that small works should be constructed to prevent floods entering them until the deeper lakes are filled.

Having provided a sufficiency of water in the river, for irrigation on a moderate scale, to allow of cultivation independent of the seasons, and for continuous navigation to allow of produce being easily and economically conveyed between our different railway termini, having also large inducement to offer in the rich deep soil of the banks and adjacent country, it requires only a little careful legislation secure the settlement of the whole river frontage by a peasant proprietary. In order to encourage such settlement, I suggest that Government should reserve special blocks on the river frontage, and offer small selections, varying from 20 to 100 acres on 20 years' lease, to employees on the different works on the rivers or lakes. This would allow them to form homes and cultivations by means of their wages, so that at the end of their employment they would be in an independent position. Californian experience has shown that a few acres in such a position, cultivated in vines, orange, walnut, and other fruit trees, would ensure a man a more regular income than most of the large squattages at present provide, and without any of the anxiety. The water necessary for irrigation would have to be lifted from 10 to 20 ft. from the channel to top of bank, either by steam-power or windmills. In the former instance several settlers might combine and purchase the necessary plant and pay for its working expenses; in the latter instance the settler would, in most instances, be able to purchase the necessary plant without co-operation and erect it himself.

FRED. B. GIPPS, C.E.

Sydney, 20 January, 1887.

EVIDENCE TAKEN BY COMMISSIONERS DONKIN AND GIPPS ON  
THE DARLING RIVER.

SEPTEMBER-OCTOBER, 1886.

TUESDAY, 21 SEPTEMBER, 1886.

At Yanda Station, Darling River.

Present:—

MR. DONKIN,

MR. GIPPS.

Mr. D. W. F. Hatten examined:—

- Mr. Donkin.*] You were examined before the Commission some time ago? Yes; I gave some evidence at Bourke last year. Mr. D.  
W. F. Hatten.
- That was in the height of the drought, before this recent flood? Yes. 21 Sept., 1886.
- How long have you been resident on the river? Thirty-one years—since the latter end of 1855. Floods.
- How many floods have you known since your residence here? The floods in 1863, 1864, 1870, 1879, and the present one.
- When you came here in 1855, was the river then in a state of flood? No; it was very low.
- Have you seen the river lower than it was during the last twelve months? The only time was in 1862; then it was dry for miles. Last summer it was dry for miles, with the exception of a few little pools. All the straight reaches were dry.
- Were you the first to form this homestead? It was formed by Mr. T. A. Smith, of Bathurst.
- Mr. Gipps.*] Was there any under-current in the river during the drought—could you always get water by sinking? Yes. Under-current.
- Was it fresh? In some places it was fresh, and in some it was as salt as brine. Between here and Jandra there are a number of salt springs in the river. Some of them bubble up several inches in height.
- Is there any rock with which those springs are connected? In some places we meet a kind of rotten rock.
- Mr. Donkin.*] What have you been in the habit of reading the height of the river from—have you any zero? None whatever; we judge by the ordinary marks on the trees which the flood leaves.
- Mr. Gipps.*] What were the relative heights of these floods above what you term summer level? I should think the 1864 flood was 45 feet above. The next highest flood was that of 1870, which was about 43 feet above. Of course I only speak from the marks on the trees. Heights of floods.
- Mr. Donkin.*] What do you mean by summer level? I suppose summer level is the bed of the river. Summer level.
- What would you consider the best guide to read the river by, by a previous well-known flood, or by the bed of the river? By a well-known flood, I should think.
- What flood would you take as a guide? The 1864 flood; that was 4 feet higher than the present.
- Then the whole of Bourke must have been under water in that flood? It was under water.
- Mr. Gipps.*] Do you think the flood level of 1864 would be sufficiently defined in order to locate it exactly? I think so.
- Mr. Donkin.*] There is no doubt in your mind that great confusion has arisen through taking summer level as a guide? There has been great confusion.
- Is it possible to have a flood as high as the 1864 flood? Quite possible, if the rivers were all to come down at once.
- All the way down the river there is a high bank on one side and a correspondingly low bank on the other side? Yes, but when you get below Wilcannia the banks are low on both sides.
- What is the average width of the river now? I should say 6 miles. Width of flood.
- Do you know of any large depressions on the Darling where water could be conserved? Below Wilcannia there are several lakes—Lake Poopelloe, for instance, on Cultowa Run.
- Mr. Gipps.*] During the flood of 1864, was there a general rain throughout the country? No; it was one of the driest seasons we had. On the lower end of the Darling there was no rain at all. The floods arose from the rains in Queensland; we had no local rain. From Wilcannia down there was no rain. The rainfall was so slight that had it not been for the flood all the stock would have died at the lower end of the river.
- Mr. Donkin.*] You know Lake Poopelloe? Yes. Lake Poopelloe.
- What depth of water would it average? About 12 feet. The bottom is nearly level.
- Are there many rocky bars across the river? Yes.
- You think then that it would be possible to erect weirs or locks across the river? I think it would.
- Do you think it would pay the country to go to the expense of erecting weirs or locks? I think it would pay better than the railways. Weirs.
- And what do you think the water should be used for? For irrigation and for general transit.
- Could any great body of water be conserved in Yanda Creek? No; it is almost a dead level. Yanda Creek.
- Mr. Gipps.*] Where does the Yanda Creek rise? Near Cobar.
- Is there a rocky channel? A very deep defined channel.
- Is there generally much of a stream in the creek itself? It had not run for fifteen years until February, 1885.
- Then it ran because of local rain at its source? Yes.
- Was it very deep? There must have been an average of 10 feet of water. It carried away every dam with the exception of one of ours.
- What is the average depth of the bed of the creek? I should think about 8 or 9 feet.
- With steep sides? Yes.
- Do you think a dam at the mouth would throw back much water? I am sure it would.
- To what distance? To several miles. And

- Mr. D. And of what width? Not very wide. I suppose the creek itself is not more than from 20 to 30 yards  
W. F. Hatten. in width.
- 21 Sept., 1886. Would the impounding of the water in the creek be of much benefit? It would benefit all that tract  
of country between here and Cobar, about 100 miles.  
Has the creek a regular fall? A very slight fall. We have a dam in the creek now, and it is full.  
There are 3 miles of water in it. At the deepest part there would not be more than 8 or 9 feet.  
Do you think that water could be diverted into any large depressions on its course? No, because the  
country falls gradually towards the river.  
Not even down south? There are no depressions that would hold great quantities of water. You could  
only dam the creek.  
It could not be thrown into Lake Poopelloe? No; there are too many ridges intervening.
- Dunlop's Range. Mr. Donkin.] Is Dunlop's Range isolated? Yes; there are a few little spurs, but there is no extent  
of rangy country.  
Do you think that if a weir were thrown across the Darling that the small ana-branches could be made  
use of for navigation? I am sure they could.
- Tanks. Mr. Gipps.] How do you supply stock with water? By means of excavations.  
What is the average depth of the tanks? From 15 to 20 feet.  
And the average capacity? From 10,000 to 20,000 cubic yards.  
Have they ever been filled? They are all full now.
- Evaporation. What amount do you reckon you lose by evaporation during the year? I have never reckoned it, but I  
am convinced that fully a third of the water is lost every year. We have 291,491 yards excavated.
- Cost of excavation. Mr. Donkin.] What is the average cost of excavation? 15d.; some tanks cost 18d. a yard.  
Rainfall. That does not take into account your own supervision? No.  
What has been the average rainfall here? 13·58 inches for six years.  
What was the lowest rainfall? 6·11 inches, in 1884, and the highest was 22·57 inches, in 1882.
- Mr. Gipps.] Do the rains fall in heavy storms? Yes; we had 11 inches and some points in February  
in a very few hours.  
What are the winds? East winds.
- Irrigation. Mr. Donkin.] With so much water in the river, have you ever tried irrigation? No.  
You know it has been tried at Winbar? Yes.  
Was it a success there? Yes, but I doubt whether the outlay would counterbalance the large  
expenditure for machinery and preparing the ground.
- Wells. Mr. Gipps.] Have you any wells sunk? One.  
What distance from here? 40 miles.  
What is the character of the country? It is red soil.  
What depth is the well? 110 feet.  
Did you get fresh water in it? Yes, at 36 feet.
- Strata. What is the character of the strata you passed through? It is a kind of rotten rock.  
The whole distance? Yes. At first we went through clay, and we got water in the coarse gravel and  
water-worn pebbles. This was on the top of rotten rock. We went 70 feet into that, and only got a  
small supply of fresh water. We got some very salt water.
- Salt water. Did the salt water rise? Yes, to 80 feet; but as we used it and kept on sinking the water increased  
very much. It came in so strong that we could not keep it down with horses and a whim.  
What was the diameter of the well? 6 feet by 3 in the clear, timbered with sawn gum slabs and centred.  
Was there a large supply of fresh water? Only 7 feet. We put a drive of 20 feet on each side,  
but the water did not increase.  
Mr. Donkin.] You think that by going deep enough water could be obtained on this back country? Yes.  
Mr. Gipps.] You say you have seen fresh- and salt-water springs in the bed of the river? Many of them.  
Did you notice the difference of the strata? No; you would see them boiling up in the same kind of  
rock within a very few yards of each other.  
Mr. Donkin.] With your long experience here, have you come to any conclusion in your own mind as  
to how this large body of water could be conserved? I have not.  
You see no means except by the natural depressions? That is all.  
Would it involve a large cost to conserve the water in Lake Poopelloe? No; a small expenditure would  
keep it filled.
- Paroo River. You know the Paroo, does it ever join the Darling? Yes, when the Darling water backs out to meet it;  
but there is no defined channel.  
Could any large body of water be retained in the depressions on the Paroo? I think so, and at a small  
cost. There are two or three lakes on Tongo Run, Mr. Rankin's, that could be so dealt with.
- Depth of tanks. Have you ever tried covering the tanks? No, but I am convinced of the great benefit to be derived  
from such a course. I may mention that a tank 10 feet deep is of no use. To stand a drought the  
tanks must be from 15 to 20 feet deep.  
How long will it take the water in the river to subside to its ordinary level? About three months,  
I suppose.
- Lakes. What are the names of the lakes below Wilcannia? Lake Poopelloe, Lake Woytchugga, and others.  
And how far are the Paroo lakes from Wilcannia? There are lakes on the Momba Run, no distance  
from Wilcannia.  
How far is it to Mr. Rankin's? About 90 miles from Wilcannia.
- Bad water. You did no deep sinking here? No. Several wells have been sunk round the mountain, but the water  
is so bad that the cattle cannot drink it. If you poured water on the ground it would leave a crust that  
you could not break with your boot.
- Herbage. Do you find after the past long drought that the herbage has come back again? Yes; the herbage  
is as good as I ever saw it.  
You think the country has not deteriorated? It has as regards carrying capabilities. The shrubs are  
eaten down and the branches broken off, and the country will not carry stock as in its maiden state.  
If you spell the country it will improve. The salt-bush will never come back; it has been eaten out.
- Soil. Which do you find best for cultivation, the red soil or the black? The red soil. It is not so porous  
as the black, and the growth is quicker.

Mr.

*Mr. Gipps.*] Have you tried lucerne-growing? It has been tried with great success on several places around here.

How many cuttings do they get? I could not say.

*Mr. D.  
W. F. Hatten.*

21 Sept., 1886.  
Lucerne.

*At Gundabooka Station.*

Mr. William Harrison examined:—

*Mr. Donkin.*] How long have you been on the Darling? Seven years at Gundabooka, and about two years at Wilcannia.

*Mr.  
W. Harrison.*

Is this the largest flood you have seen in the river? Yes.

21 Sept., 1886.

What do you go by here as to the height of a flood? We have no guide but the marks on the trees. How do you determine the height of a flood, from the bed of the river, or summer level? By the spread of the water.

Summer level.

The flood of 1864 was the highest, was it not? Yes, according to the tradition of the blacks.

Flood of 1864.

What is the difference between the 1879 flood and the present one? About 6 inches, that of 1879 being the highest.

Does the flood-water of the Darling, on Gundabooka, find its way out back;—have you any ana-branches? No.

Is it all dry bank? Yes.

River dry.

Was the river dry between 1879 and the present flood? Yes, within six months ago.

Was the river absolutely dry? Yes, absolutely.

Water-holes.

There are large water-holes in the river, are there not? Plenty of them.

Do you know a place in the river known as Jandra Rocks? Yes.

Is the river very deep there? No; it stopped running altogether. There is a rocky bar across the river.

Rocky bars.

Are there any other bars that you are aware of? Yes, the Toorale Rocks below here, above the junction of the Warrego.

Of what nature are the rocks? Sandstone, rather harder than the stone at Gundabooka Mountain.

Do you think there would be any great difficulty in erecting weirs across the river at these rocky bars? I fancy not.

There is no actual drop in the river, as at Brewarrina? Not that I know of. The water finds its way through until it stops.

When the river was dry the whole communication by river was stopped? Yes, for eighteen months at least.

Which do you think would be of the greatest importance to the country in conserving the water in the river, irrigation or navigation? Navigation.

Navigation.

You look upon navigation as necessary to the settlers on the Darling? I do.

Do you think that if stone weirs were erected on these rocky bars across the river the short ana-branches could be made use of as water-ways to take the traffic through? No.

You have the railway to Bourke now, and there is the probability of its being taken to Wilcannia; do you think that carriage by rail will do away with the water carriage—in fact, that the railway can compete against the river? I think so.

Railway.

If that be the case there is scarcely any necessity to keep up navigation? We only require navigation between the railway points.

You think that if weirs were erected between Wilcannia and Bourke sufficient means would be afforded for the conveyance of produce on the river between those points? Yes, if at stated intervals and good long distances.

Do you know of any large depressions in which the water might be retained at a moderate cost? Yes. Stony Creek.

There is Stony Creek, which comes out of the Kerrigundy Creek.

Has it a deep channel? Not very.

What height would the river require to be before it would discharge into it? Within 2 feet of its present head.

Then a slight dam at the off-take from the river would hold back a large quantity of water in the creek? I think so.

Do you know whether the Warrego has been in flood since 1879? The waters of the Warrego have not joined the Darling from 1879 till the present time.

Warrego River.

What do you think is the width of the river now between here and Wilcannia? 6 or 7 miles.

There is not much current away from the actual bed of the river? Very little.

Have you tried irrigation at all? No.

They have at Winbar? Yes.

Was it a success? Yes, but it was an expensive arrangement.

You have a great deal of red soil which seems splendid for growing cereals; do you not think it would pay to irrigate that now, considering the quantity of water you have and the shortness of lift? I think it would.

Irrigation.

Do you not think it would be advisable for people who have water to try it over small areas? Yes, but you must bear in mind the time the river is down, when you have to lift 60 feet.

Do you not think that the irrigation of a few acres in cases of great necessity would save your stud stock? I do not think it would; I do not think the soil is good enough.

Soil.

How do you supply the back of your run? By tanks.

Have you any wells? No; the water is all salt at any reasonable depth.

Wells.

To what depth have you gone? 100 feet.

You have no deep wells? No.

Do you think if you went far enough you would get fresh water? I dare say.

Has there been any cultivation here at any time? No; it has never been tried on the station.

*Mr. Gipps.*] What is the average width of the river between its two banks from here to Wilcannia? I should guess about 100 yards.

Width of river.

What is the average depth? To the bottom it is a good 50 feet.

And how much higher is the left bank than the right? About 12 feet I should say.

What strata do the banks show? There are two banks that are composed of old soil, then comes the strata. gypsum, about 2 feet underneath, and then that continues until you come to the rock.

Does

- Mr. W. Harrison. Does the country rise from the left bank of the river towards Gundabooka Range? Yes, gradually for the first 10 miles, then rather quickly after that.
- 21 Sept., 1886. What would be the height of the first 10 miles, 50 or 60 feet higher than the bank? Yes.  
Gundabooka Range. Is the Gundabooka Range connected in any way with the Cobar Range? No.  
Or any other range? No. It is simply an isolated range.  
Then beyond the Gundabooka Range the country sinks again? No; it keeps on rising until it runs into half a dozen ranges.  
There would be no means of carrying a channel across country between the Gundabooka Range and Cobar? No.
- Soil. What is the character of the surface soil? Red loam.  
What depth does it go to? The country is undulating out there. There are stony rises and dips in between. In places the red loam goes from 2 to 5 feet, and on the ridges stones are sticking out.  
There is no sub-soil.  
Is it gypsum underneath? Yes, and sandstone.
- Yanda Creek. Do you know anything of the Yanda Creek? It passes close to the back of our run.  
Does it run frequently? It has run twice during seven years to my knowledge.  
Is there any under-current? Yes, but only after heavy rains, like the drainage from all those mountains. We have some dams close to the mountain, and as long as there is a soakage from the mountain our dams remain perfectly good. Directly the under-current becomes exhausted the water goes away from the dams. At times you could sink down 10 or 12 feet and get water; at other times you would sink 600 feet and not get any.  
Always fresh? Oh, no.
- Springs. Are there any springs in the Gundabooka Ranges? Only soakages.  
Are there any springs in the river bed? Always running springs, both fresh and salt.  
Have you noticed any difference in the character of the strata with regard to the fresh water and the salt? You may see them alongside each other and not tell the difference.  
What is your idea with regard to these springs? I hardly know. I suppose the river leaves a deposit behind and it oozes out again. The wells we put down alongside the river have no connection with the river.  
Are the sandstone rocks bedded or tilted? They are bedded.  
Have you ever found any fossils in the sandstone rocks by which you could distinguish their age? No.
- Wells. Have you sunk any wells? Two, to a depth of 100 feet.  
What was the character of the strata passed through? A peculiar sandstone, something between gypsum and sandstone.  
Do you get water at the bottom of the wells? Yes, salt water; we could not use it.  
Did you try drawing from the wells? Yes; but it is impossible to get better water.  
Did you notice whether there was any current in the salt water? There is no current; the water just oozes from the sides.
- Tanks. What is the capacity of your tanks? From 9,000 to 22,000 cubic yards.  
And the depth? They average 15 feet.  
Are they full? To the top.  
How long would they last if there were no rain? They would last nine months without rain.
- Evaporation. How much would you lose by evaporation? I should think a third, but that is only a guess.  
How do you get the water into the tanks? By properly constructed drains. The drains lead into a silt tank, and then into the main tank.  
Are the tanks lined? No.  
What slope do you give the sides? At the ends, 8 to 1; at the sides, 2½ to 1.  
Is the fall of the country in any one direction, say, from north to south, regularly, or from east to west? No.
- Brackish water. Does the soil hold the water well? Yes; not on the surface, but a foot from the surface.  
Does the rock make the water brackish? No; the gypsum does, but the sheep drink the water all the same.
- Irrigation. Mr. Donkin.] According to your statement the people on the Darling depend simply on the river, and nothing can be done by irrigation? I think it would not pay financially.  
If you do not get irrigation it means starvation? That is so. We have the mulga to fall back on.  
That will not last for ever? It will not be cut down in our grandchildren's time.  
Is the mulga sufficient to keep you through a drought? Yes, if we get plenty of it.
- Rainfall. Mr. Gipps.] What is the rainfall? In 1884 we had 8 inches; in 1885, 17½ inches; this year we have had 8¼ inches up to the present.  
Mr. Donkin.] Is the mulga spreading? It is, but not to a great extent.  
You think it is a grand stand-by if you had plenty of rain? It is the only thing that has kept us from starvation.
- Loss in sheep. Have you lost many sheep here during the last year or two? Not so many as our neighbours. During the last six years we have lost as many as 50,000 sheep.
- Price of chaff. What would their value be? About 5s. per head, or over £12,000. I may mention that in one year I spent £1,000 for horse feed. I was paying £35 a ton for chaff.

WEDNESDAY, 22 SEPTEMBER, 1886.

At Gundabooka Station.

Present:

MR. DONKIN, | MR. GIPPS.

Mr. John Mackay examined:—

Mr. J. Mackay.  
22 Sept., 1886  
Floods

Mr. Gipps.] What is your occupation? Grazier.  
How long have you been on the river? Since 1862.  
How many floods have there been since your residence here? The first high flood was in 1863, and the second in 1864. There was a bit of a fresh in 1866, and then the river ran in a good stream from the

the end of 1869 till 1873 or 1874. The 1864 flood was the highest flood, and it was 6 feet higher than this flood. The last flood previous to the present one, when the river overflowed its banks, was in 1879.

What is the width of the river now? I suppose about 4 miles.

What is the width between its banks? About 100 feet.

And its depth within the banks? About 27 feet.

Have you ever seen the river dry? The river stopped running here on 6th November, 1885, and commenced to run again on 23rd December following, between which dates is the only time I have ever known this to occur. River dry.

How do you get your water then? There is a large hole here about  $2\frac{1}{2}$  miles long and from 8 to 14 feet deep. The water is always fresh.

When the bed of the river is dry, do you see any springs? I have not noticed any. In these high banks there are springs. Springs.

Are the springs fresh or salt? Mostly fresh. Some of them are salt.

Do you notice any rock where the springs occur? No; the only rock is the ferruginous clay. Wells.

Have you ever tried sinking wells? Yes.

To what depth? There is one on Gundabooka Mountain that I sank 175 feet. I sank 140 feet and drilled 35 feet.

Did you get water? Plenty water, but it was so salt or mineral that nothing could drink it.

Do you know of any lakes or billabongs in this vicinity where you could conserve water? It is all billabongs on the other side of the river.

Which is the longest one you know of? The Taloula Billabong. It breaks out from the Warrego about 3 miles above the junction of the river, and goes away down the back country. Taloula Billabong.

How many miles? I suppose it is continuous down to Campadore. Below Dunlop they call it Mundy Creek.

Has the channel any breadth? In some places. There is one hole called the Taloula Waterhole about 3 miles from here. In ordinary times that hole is never dry. It is silted up a good deal, but it is perhaps 8 or 10 feet deep.

The river has to be in flood to fill it? Yes.

Has it any direct channel to discharge into the river? No; it is just a network of channels.

Have you tried irrigation at all? Only for the garden. Irrigation.

Does it seem to increase vegetation? The soil will grow anything if watered.

*Mr. Donkin.*] Have you sheep or cattle? Both.

How many acres on an average do you allow for a sheep during all seasons? I should say about 6 acres to keep them in condition.

Do you not think this soil will grow lucerne? I do. Lucerne.

Which soil do you prefer, the black or the red? The red soil.

You think that if people had an example of what can be done by irrigation they would be inclined to try it? I think so. I know the soil will grow anything if watered. I know that hay could have been grown splendidly this present season. I put some wheat in, which grew splendidly. Excellence soil.

How long is it since the waters of the Warrego joined the Darling before the present time? It must be about eighteen months. I believe it has not joined of late years because there are so many dams on the Warrego.

This flood has washed the dams away? I believe so.

You depend for your supplies on the river? I used to do so, but I can send to Bourke now.

Have you lost many of your stock since you have been here? A good many.

Have you any suggestions to make? No; I have often thought that the lowness of the river must be caused by so many dams above. I do not remember during my earlier residence on the river of its ever having so small a volume of water running as has been the case on several occasions during the past six years, although the rainfall in this quarter has, I believe, been fully equal to the average formerly falling. Effect of dam on river.

#### *At Sunnyside.*

Mr. Henry Gillett examined:—

*Mr. Donkin.*] How long have you been on the Darling? About thirty-four years.

Where did you come to? I was about fourteen years with John McKinley, the explorer.

Where was he? He used to own nearly all the Darling country at that time.

Where were you living? At Weinteriga.

How far up do you know the river? I am not acquainted with it further than Fort Bourke.

In what year were you up there first? In 1853.

Who was living there then? Nobody but blacks.

In what state was the river when you came? It was dry. We used to sleep in the bed of the river.

Just about that time the river came down one night while we were sleeping in its bed. We heard a roaring noise which we thought was caused by the blacks. It was the river coming down. We ran on to the wrong side of the river, and in the morning we had 8 feet of water to go through. Sudden flood.

To what height did that flood rise? About 10 feet.

When was the next flood after that? There were a number of little ones. The 1864 flood was the biggest. It was about 6 feet higher than this flood. Flood of 1864.

What height was the 1879 flood? I do not know much about that. The 1870 flood was nearly up to that of 1864. It only wanted a few inches of it.

What do you go by as to the height of a coming flood? By telegrams; we have no other warning.

What do you call summer level here? I call it about a couple of feet deep in the shallow places.

Have you tried irrigation, besides what you have done in your garden? No; but I know that any mortal thing would grow here if you watered it. Irrigation.

Why do you not try an acre or two of lucerne? A man wants means. If I had laid out money in an engine when I first came here I would have done well.

You are satisfied that irrigation would pay? There is no mistake about it; you cannot beat it.

Mr. J.  
Mackay.

22 Sept., 1886.

Taloula Billabong.

Irrigation.

Lucerne.

Excellence soil.

Effect of dam on river.

Mr.  
H. Gillett.

22 Sept., 1886.

WEDNESDAY,

WEDNESDAY, 22 SEPTEMBER, 1886.

At Louth.

Present:—

MR. DONKIN,

MR. GIPPS.

Mr. Thomas Francis Josephson examined:—

- Mr. Donkin.*] You live at Pulpulla? Yes.
- Mr. T. F. Josephson. How long have you been in the district? On this occasion I have been here since 1881; I came to the district in 1866-1867.
- 22 Sept., 1886. Where was that to? To Jandra, on the Darling.
- How long were you there? About eight or nine months.
- What condition was the river in at that time? It was in flood; the steamers were running.
- Flood of 1864. That was after the big flood of 1864? Yes.
- And the river had kept up all the time? I do not know whether it had kept up, but I saw steamers running when I was there in June, 1867.
- Height. Do you know how the 1864 flood compared with this present one? As far as I can judge, it was 5 or 6 feet higher. The marks were shown to me, and were then quite distinct 18 inches above the floor of the Jandra house.
- When you were there, did they gauge the heights of the flood by summer level or from the bed? They used to go by the height the floods rose upon the trees on the banks.
- Summer level. There seems to be considerable doubt in the minds of many people on the river as to what is summer level, and the heights to which the floods have come; do you know of any plan which could be adopted? I should think that summer level would represent the amount of water in feet flowing over different falls in the river at that time. I should say summer level would be when there were about 2 feet of water flowing over the falls.
- Do you not think it would be better to gauge the river by some well-known flood, and take that as zero, in order to send information down the river about coming floods? I should think so.
- Do you know of any large billabongs or ana-branches where any quantity of water could be conserved? Not in this neighbourhood. There is one billabong on Jandra, which runs out 7 miles straight into the run, but in the 1864 flood the Bogan broke over at Mount Oxley, and it ran in just above Yanda Station.
- Breaking out of Bogan. That would be through Jandra Station? Yes.
- How many miles out from Bourke was that water? About 6 or 8 miles.
- Then you think that shows conclusively, judging from the trend of the country from the Bogan, that water could be diverted from the Bogan all over Jandra black soil? Most certainly. The black soil is the limit of the flooded country in the highest floods. The red soil is said to be never flooded.
- In fact you can judge by the class of timber as to whether the soil is liable to inundation? Yes, generally. The mulga, for instance, is never flooded.
- Rocky bars. You know there are rocky bars in the river; do you think there would be any great difficulty in constructing locks or weirs on these bars? There are numerous rocky bars. From Curranyalpa up there are sufficient bars to lock the river, if it were possible to put locks on to them. There are sufficient materials for construction.
- Mundy Creek. Do you know the large billabong on the other side of the Darling, through Toorale, known as Mundy Creek? Yes; I have been across it.
- Do you think any large body of water might be conserved there? Yes; it could be conserved if it were possible to make use of it, but it would be just as easy to conserve water in the river itself. The creek is no great distance out.
- You make use of the river, do you not, to send your produce to the seaboard? Only occasionally; I would not do so if I had the railway.
- Navigation and railway. Which do you think would be of the greatest benefit to the country, to consider the advantages of navigation, or to conserve the water of the river for the purposes of stock and irrigation? I believe, as a commercial undertaking, a railway along the course of the Darling would give better results for the outlay than a series of locks in the river. I believe there are other water-channels where the purposes of irrigation might be served without the risk to be encountered in stopping the flood-waters of this river.
- Have you seen irrigation tried on the Darling? I have seen the irrigation at Winbar since it was started. At Pulpulla it is entirely dry country, there is no natural water? No natural water.
- Is there any natural water between the Bogan and the Darling? The only permanent natural water I know of is a spring at Nymagee. There are soakages on Pulpulla.
- Roughly speaking, how many miles would you call it straight across from the Darling at this point to the Bogan or the Lachlan? About 250 miles to the nearest point of the Lachlan.
- Extent of dry country. And there is no natural water over that tract of country? Not that I have heard of. There are several wells.
- There is no surface permanent water? No.
- Tanks. What do you find to be the best size and depth for your tanks? It all depends upon the area of country to be watered, and also the stock coming to the water. About 2 cubic yards excavation should be allowed per sheep. It also depends very much on the quality of the catchment area more than on the size of the tank.
- What is the shallowest depth you make your tanks? Ten feet.
- Evaporation. Do you find the evaporation great? Yes. It is considerable in summer during the months of December, January, and February.
- Have you any idea as to what proportion you lose by evaporation from a tank say 10 feet deep? It entirely depends upon the stock. The stock make more difference in the depth of the water than evaporation. A flock of thirsty sheep will lower a tank 6 inches in a day in summer, consequently a large area of water is of more consequence than depth, provided the catchment is good. It depends also on the water itself; clear water will evaporate more quickly than muddy water or clayey water.
- How do you account for that? The sun penetrates deeper into clear water and warms it. Also, an exposed tank which is open to the wind will evaporate more than one which is not so exposed; the waves beating up on the side of the tank increase the loss through the earth soaking up the water and evaporating it, therefore steep batters are advisable wherever possible.
- Have

Have you tried to cover in any of the tanks to keep off the wind and sun? No, except the tanks for domestic purposes. Mr. T. F. Josephson.

After this last severe drought, I suppose most of the herbage—cotton-bush, &c.—has been eaten out; do you find it has recovered after this good season? Cotton-bush recovers; salt-bush does not. 22 Sept., 1886.

Do you think the country has improved for pastoral purposes since stocking was introduced? No, on the contrary. Clayey soil becomes so hard through stocking that nothing will grow on it. Sandy soil improves under stock. Soil.

It is not so rich as in its average state?—It is richer, but there is not the same quantity of grass there used to be. The sweeter varieties being eaten out, and the coarser ones neglected, there is a natural tendency towards the increase of the latter.

You know the range running out from here called the Dunlop Range? Yes. Dunlop Range.

Is it continuous? That goes from Gundabooka Mountain down through the Rankin's Hill blocks, and down to Barnato.

You say the water came in through Jandra? The Mulga Creek comes down along the course of the railway, and runs in nearly at Jandra Station.

In speaking of the Dunlop Range, do you think the water could be brought across country through the back of that creek and some miles out so as to water some of the back country? No; there is rising ground between all these creeks. There is a watershed between Yanda Creek and Mulga Creek.

And does the Dunlop Range form a watershed between Yanda Creek and this lower country? I do not know exactly which is called the Dunlop.

These hills near Louth? They are merely isolated. There is a watershed between Yanda Creek and Kerrigundy Creek, which is the next drainage creek below us here, and runs in at Stony Point just below Winbar. Gundabooka Mountain lies between Yanda Creek and Kerrigunda Creek. Neither of these creeks is of any consideration.

Do you think something ought to be done to retain the water in the river? No; there is quite sufficient water for stock purposes in the river.

But not for irrigation? No; but I do not think the time has come for that yet. Irrigation.

Have you put down any wells on Pulpulla? I have wells which have been sunk by other people—one 80 feet, and one 60 feet. I have put down several trial shafts without success. Wells.

Do you think fresh water could be obtained if you went deep enough? I have fresh water in the soakage springs. There is 28 feet in one, but the well is not reliable in drought.

*Mr. Gipps.*] What is the character of the falls in the river that you made mention of? The river when it is at what I call summer level consists of long reaches of deep holes with a distinct fall between. Of how many feet? For instance, there is a fall of about 6 inches at the crossing here, and so on every half mile or so. Falls in river.

Therefore the bed of the river, instead of having a regular inclination, is formed by a distinct series of falls with deep holes in between? Yes.

Are these falls rocky? Not all of them; in some cases they consist of little shingly gravel.

How do you account for the formation of the deep holes? I should think they were scoured out by the current running round the curves in the river, because on the inner elbow of every curve there is a deposit of sand, while the outside of the elbow is always scoured out. There is generally a hole in the outside of the elbow.

Does the river appear to you to be changing its course in any way by making its way towards the east or west? No; there is very little alteration. In the heaviest flood in the river there is very little cut away.

Do you know of any bars of rock crossing the river? There are numerous bars of rock. There is one at Yanda, one at Toorale, one at Curranyalpa, and I think there is one at Campadore. Rocky bars.

And can you see these bars of rock cropping out in each bank? Yes, distinctly cropping out, and about half-bank high.

What is the nature of the rock? Most of it is a sort of indurated clay, as far as I can make out. Some of the rock is sandstone.

Is it gypseous rock at all? A little in some cases.

I have noticed in the Murrumbidgee that the bars are formed of gypsum? Those at Curranyalpa were, so far as I can judge, of indurated clay, nothing more; but there are sandstone rocks here at Louth.

Do the conglomerate rocks which form Dunlop Ranges cross the river at any point? No; I have seen no conglomerate near the river. Out on Rankin's Hills there are conglomerate rocks.

At what point of the Bogan did the river leave its channel and make across the country? On one of the Beemery blocks opposite Oxley's Tableland. Breaking out of Bogan.

What was the height of that flood? It must have been 6 feet above the present flood.

Then the whole country was in flood at that time? All the rivers came down at once.

Did the water come straight across country in a sheet, or follow any channel? It followed the channels, certainly.

There was a distinct channel? The river was as it is now. Of course more land was submerged, and the stream was wider. In fact the flat black-soil country between the Darling and the Warrego was one sheet of water. The river was 7 miles out from Jandra on this side, and the people at Jandra were camped out at the Saltwater Well, 7 miles from the station, and had to go in in a boat.

What is the average rainfall at Pulpulla? It is from 12 to 14 inches per annum. Rainfall.

Does the rain fall in sudden storms or in a continuous fall? In storms; we have very little continuous rain. The body of the water falls generally in heavy thunderstorms.

What winds bring up these storms? A northerly wind shifting to north-west, and then south-west. Winds.

Are these storms local? They are very patchy.

It does not follow then that if there are continuous rains in Queensland they will come down here? We look for the tail end of the Queensland tropical rains in February, but we do not always get them.

With regard to the springs, have you ever tried opening them up at all? I have sunk to various depths upon them, down to 28 feet. Springs.

Did they rise above the ground? They rise after wet weather to the surface.

Do the springs go right down into the ground, or do they come laterally from the rock? My belief is that they are accumulations of water in the crevices of the rock. These springs are all on the westward

- Mr. T. F. Josephson. westward slope, consequently I think the water is collected between layers of rock, and where there is a fault there the water springs up.
- 22 Sept., 1886. What is the inclination of these rocks? About 20 degrees.
- Character of rock. And what is the character of the rock? Chiefly altered sandstone.
- Fossils. Very hard, indurated? Yes, metamorphic, having been under the action of fire.
- Have you discovered any fossils in them, or been able to distinguish their age? I found a recent fossil of a fungus, but that was not in the rock. I found on the tops of the hills numerous layers of rock with impressions of water waves. It is a very common thing here. They may have been formed by wind, but still they are the marks of waves in the sand before the rock was formed.
- Volcanic action. Are there any indications of volcanic action in the country? None whatever.
- No basalt, no trachite? Nothing of the sort; nothing but these conglomerate rocks, which contain rounded quartz, which has evidently been carried a long way. The quartz is round like eggs.
- There is nothing to account for the tilting of the rocks? Not on the surface. They have evidently been upheaved, but not with sufficient force to bring any volcanic rocks to the surface.
- Wells. How many wells have you on Pulpulla? I have two, 60 and 80 ft. deep, but dry. I have three shafts of 28 ft., one of which has water in it, and there is one shaft of 20 ft. with water in it from the springs.
- Did you never get any water in the 60- and 80-ft. dry wells? No. The rock was so hard that the men would not go on with the work for the price. It was deep red sandstone with nodules of quartz in it.
- Was it bedded or tilted? Flat, in beds.
- The rock was so hard that you never tried to go deeper? I did not sink these wells; my predecessor did.
- Do you not think that by going deeper there would be some chance of getting water? I would not like to try myself. I would sooner put down a tank than go on sinking wells.
- There are no borings in that country? No?
- Sandstone ranges. Are there any sandstone ranges at all? Yes, there are well-defined sandstone ranges.
- Bedded, I suppose? Yes, they are all tilted to an angle of about 20 degrees.
- I suppose it is all broken country? Yes; there are flats running between these ranges of no great extent, a mile or 2 miles wide.
- Tertiary strata. As these ranges run out, is there no indication of any tertiary strata then? It is all tertiary.
- It can hardly be tertiary if it is tilted like that? No?
- There is no volcanic action in the tertiary? Well, there are no volcanic rocks on the surface.
- Winds. With regard to the winds here, are they regular in summer? Yes.
- Sufficient to drive a windmill? Yes, quite, most days in the week.
- Tanks. Mr. Donkin.] In making your tanks, what time do you reckon will elapse before getting them filled in ordinary seasons? If a man is lucky he may get a tank filled the day it is finished. Sometimes I have waited two years.
- In some cases people have to wait longer than that? Oh, yes; some wait for years.
- There is no certainty as to the time of waiting after the tank is excavated? No.
- What length of drains do you make to your tanks? I have drains 3 and 4 miles long to a tank.
- Mr. Gipps.] The tanks are always located in depressions? Yes, so that one can obtain water over the excavation if possible, but always having regard to the catchment area.

Mr. James Ramsay examined:—

- Mr. J. Ramsay. Mr. Donkin.] At present you are living at Wuttagoona? Yes.
- 22 Sept., 1886. How long have you been residing there? About two and a half years.
- Were you in this district previously to that? Yes; I was on Tindayrey for four years.
- That is near Cobar? Between Cobar and Bourke.
- Have you any knowledge of the Darling River? Very little.
- Wuttagoona has not a frontage to the river? No.
- So the flood does not affect you? No, not as to a supply of water.
- What do you depend on for your water supply, there being no natural water? There is no natural water whatever, so we depend on tanks and dams.
- Waterless country. Do you know of any natural water between the Bogan, the Darling, and the Lachlan? I do not know of any permanent water.
- Then there is a tract of country of 200 or 300 miles in extent between those three rivers without any permanent water? I do not know of any except in small crab-holes, which only last a few months.
- Tanks. What size do you generally make your tanks to be efficacious? I look on the tank as a necessary evil to procure material for my dam, and sometimes I can make a very effective dam with a very small excavation—say 5,000 or 6,000 yards.
- You have some shallow watercourses? We have two creeks running right through the blocks.
- Actually you combine the tank and dam together? I never make a tank unless I can save a large quantity of water on the surface.
- But do you not find that the dams wash away sometimes in heavy floods? Dams do wash away, but I think it is for want of selecting a suitable site for them.
- What depth do you make your tanks? They vary from about 10 feet to 18 or 20 feet.
- Evaporation. Do you find you lose much water by evaporation? I think there is a great loss by evaporation.
- Have you ever recorded the quantity? No.
- Have you ever tried irrigation? No.
- Wells. Have you any wells on the station? There were two wells—one on Wuttagoona, and one on this end.
- Do you get good water? No.
- At what depth do you get the water? About 140 feet.
- Do you know of any deep bores being put down to test the country? None whatever.
- Do you think there is a possibility of getting fresh water if you went deep enough? I think we would get a supply.
- Soil. What is the character of the soil out back? Mostly red soil, with a few white flats, but not many.
- What you call mulga country? Yes.
- How many acres do you allow to a sheep? Seven. It is not safe to stock over that. Have

Have you had any losses in stock? Not many since I have been here there were a great many before I came, both of cattle and sheep. Mr. J. Ramsay.

You do not know what the losses were? I could not say. When I came here I did not find half the stock I expected on the station. 22 Sept., 1886.

Do you think anything could be done artificially to preserve the stock against these droughts? I think the only means is to spare portions of the country. I consider one-third of the run ought to be always in reserve. I have watched the thing very closely, and I think that by preserving one-third of the run always idle we might save the stock. Besides it is necessary to do that for the sake of saving the country itself. I notice that we have lost many of the most nutritious grasses which are annuals. These are fast disappearing, and unless a portion of the country be spared it will be impossible to save them. Losses in stock.  
Spelling country.

Do you know of any instance in which that plan has been adopted? I have never seen it adopted. It has been my wish to do it, but I have never been able to do it.

It can be done now that you have fixity of tenure? I do not see any obstacle, except the expense of making paddocks.

Are you trying the plan of preserving part of the run? I have not the means of doing so; I am trying to work up a station, and I cannot put sufficient outlay on it to do so.

How many years experience have you had in grazing? I suppose for the last twenty-five years.

And that is your opinion as to sparing a portion of the run? Quite.

You were in the Mirool country before you came here? Yes. Mirool Creek.

Is the country similar to this? Yes.

The Mirool heads at Temora, does it not? Pretty near there.

Do you know the creek? Tolerably well.

Do you know where it discharges? I have not been much below the Warre block, within 25 miles of Narrandera.

It has a sandy bed? Yes.

Does the water percolate to any great extent in the Mirool Creek? Yes; it scarcely remains any time.

More so than in any other creek? More so than in any I have had to do with.

What scrub do you depend on here in bad seasons to keep the sheep alive? Principally the mulga, leopard-wood, white-wood, belar, cotton-bush, and a bush whose name I do not know. They call it blue-bush. Edible scrubs

With plenty of water, do you think the mulga is sufficiently nutritious to keep sheep alive during a drought? Only for a term. I should not like to feed them on it for a couple of months if they had to live on the mulga alone.

Mr. Gipps.] Your station is situated on the left bank of the Darling? Yes.

How far distant from the river? The nearest point is about 19 miles.

What is the character of the country with regard to its physical features; is it rolling country or plain? It is undulating. There are little rises on the portion near the river, and the other part of the run is very rough.

Are there many trees in that country? A good many trees.

Of what kind chiefly? We have the mulga and iron-wood, and two sorts of box; one is called gum but it is really box. They are the red box and white box, known as coolabah and bimbah. Then we have a number of other trees, the mallee scrub in places, the belar and the sandalwood, and a white wood which is very good for stock, and leopard-wood.

Are the trees scattered or pretty close together? The mulga country is very close.

Are you cutting down or ringbarking any trees? None at all.

Does grass grow well? In the opener parts.

Do any of those trees indicate the presence of water beneath them? I could not say. On the course of the creek we have the real gum. Trees indicating water.

That is a sure indication of the course of the creek? Yes, and the white box or the bimbah. You can trace the creek by noticing where this bimbah grows thickly along its course.

Have you many dams on your run? A good many. Dams.

What is the average height? I suppose, counting from the lower side, they would average 14 or 15 feet.

Are they in the beds of the creeks? Some of them.

What creeks? One we know as Wuttagoona, and there is Kerrigundy. Creeks.

Do these creeks flow into the Darling? Yes, they come in about 3 or 4 miles below Louth.

They rise at what distance from the river? As the crow flies I suppose it would be about 40 miles.

Are these creeks frequently running? Only after heavy rains.

Do floods in the Darling affect them in any way by backing up the water to any distance in the creeks? Yes, but only near the river. The creeks in time of heavy local flood are very deep.

For what distance? I think the dams have perhaps affected the creeks, but in the open creek, where there is no dam, the waters would back for 10 or 12 miles after heavy rain. Many times, after heavy rain, we cannot cross the creek at Kerrigundy.

What is the average depth of the bed of the creek? It varies much in different places. You might ride over the creek in some places without knowing it. At times the water rises to 10 or 12 feet.

Then the flood throws out a very large expanse of water? I have seen it 3 miles wide.

Was that from the flood on the river itself? No.

Was it a flood in the creek? It was a flood in the creek itself. It made a little rise in the river here.

How many dams have you on the creeks? About eleven in all.

Does every one of them conserve water? Yes, over a considerable distance; some of them for about 1½ mile in the course of the creek.

Then there is a good fall in the creek? A great fall. Fall in creek.

Right down to the river? I do not know it beyond the blocks I am on, but it was sufficiently strong to wash our fencing up.

Are there any springs on the run? They speak of a spring or two in the hills, but I do not put much faith in them.

Any mud springs? No.

Have you tried any well-sinking? I tried a well at Tindayrey, but it was not carried on.

Mr. J. P. Morrison examined:—

- Mr. J. P. Morrison. *Mr. Donkin.*] How long have you been in Louth? Thirteen years.  
 22 Sept., 1886. What have you been engaged in? In contracting and fencing.  
 Have you had any experience of the floods here? A little.  
 Which was the first flood you remember? The highest I saw was in 1879.  
 Was it higher than the present flood? Far higher; it must have been fully 5 feet higher than this.  
 Mundy Creek. Do you think a large body of water could be conserved in Mundy Creek? Yes; the creek is deep in parts.  
 You can see it from the Dunlop Hill? Yes.  
 Navigation stopped. How long has the river been dry sufficient to stop navigation? For two years at a time to my knowledge.  
 One steamer was stuck here for eighteen months.  
 At Louth, here, what do you depend on as your means of transit, river or railway? We depend mostly on the river, but by railway it has much improved.  
 Do you think it would be sufficient for the general purposes of the residents here if there were means of communication between the railway termini, say Bourke and Wilcannia? Yes, by water-carriage.  
 Do you know any large lakes or depressions in the back country where water could be conserved? On the other side of the river, but not on this side.  
 What depth of water could be conserved in the lakes on the other side? There would be 14 or 15 feet of water in the centre.  
 Irrigation. Have you seen irrigation tried on the river? Yes, at Winbar, and it was a success. I am sure it could be more generally adopted.  
 Have the selectors and small holders suffered much loss through the drought? Very much so.  
 Homestead leases. Under the new Land Act, have many homestead leases been taken up? A great lot of country has been taken up on all the runs.  
 Do you think the people will be able to succeed without adopting some artificial means of raising pasture by irrigation? I do not think it.  
 Wells. *Mr. Gipps.*] Are there any wells in this town? I have one about 44 feet deep.  
 Is it fresh water? Yes. It rises 3 feet, and I get an unlimited supply.  
 What is the character of the strata you went through? It was clay the whole distance down for about 40 feet, then we came on to about 3 feet of drift, and then on to a sort of white sandstone.  
 How far is the well from the river? About 200 or 300 feet.  
 You do not think it is soakage from the river? No, it is not soakage from the river; it comes in from the back country. The well does not rise or fall with the river.

Mr. Peter Matthews examined:—

- Mr. P. Matthews. *Mr. Donkin.*] How long have you been residing here? About twenty years. The last four or five years I have been in Cobar, but previously to that I was living here.  
 22 Sept., 1886. Do you know the Darling well? I do; between Bourke and Wilcannia.  
 Flood of 1864. Do you remember any flood in the river? The 1864 flood is the one I know most about.  
 How much higher was that flood than the present one? Louth was entirely under water. It was about 6 feet higher than this flood.  
 Are there any marks on the trees to indicate its height? No; but the water went right out on the plains.  
 Bogan water. Do you know whether the water from the Bogan in the 1864 flood came across the back country through Jandra? It did not, but only through those plains from Bourke out.  
 How long will it take the river to run down to its usual height? It depends on how the Murray is situated.  
 Dry river. What is the longest time you have known the river dry? I have never seen the river so dry in my life as it was the past season.  
 Does the river ever cease running? It never actually ceases running; it goes underneath the sand.  
*Mr. Gipps.*] Do the floods come down suddenly in a wave, or gradually? I have seen the river rise 3 or 4 feet in a night, but generally it rises gradually.  
 Dunlop Range. Does Dunlop Range continue on to Cobar Range? No; there is a range below here which goes in a broken sort of way towards Cobar, but it runs right on to the Lachlan, and leaves Cobar a long distance away.  
 Does not Dunlop Range keep on rising? It is only a small range by itself. At the back of it the country is low again. It runs into flats.

Mr. A. D. Turner examined:—

- Mr. A. D. Turner. *Mr. Donkin.*] You are the Post and Telegraph Master here? Yes.  
 22 Sept., 1886. How long have you been in Louth? Eight years.  
 Rainfall. Have you kept a rain-gauge since your residence here? Yes, the whole time.  
 How does this year compare with previous years? I have only kept the record from day to day up till the beginning of last year. The rain last year and this year has been exceptionally heavy. Total rainfall for 1885 was 18.75. Total rainfall for 1886, up to the 1st September, was 11.04. (*Appendix to Report on Darling River, No. 8.*)  
 When does the heaviest rain generally fall? Last year's fell in January, and this year's in July.  
 River gauge. What floods have you seen? Only the 1879 flood.  
 Do you keep any gauge of the river? There is no Government gauge; it is all guess-work on my part.  
 How did the 1879 flood compare with the present flood? It was from 14 to 18 inches higher than this one.  
 What do the other stations above you read their gauge from, is it summer level? I do not think they have any standard.  
 Summer level. What do you call summer level? The information about the river is telegraphed to the head office every morning, but I do not think you can come to any summer level in the river. Last year the river was running all the year round, and this year it was not running at all.  
 What do you take it from when you send it down? From the bed of the river. Even that is not correct, because this waterhole at the back has filled up tremendously since the 1879 flood. If

If you take summer level from the bed of the river, and higher up the river they take it as 2 or 3 feet above the bed, would not that mislead people lower down? Some of the stations read from navigation level. Mr.  
A. D. Turner.

Are the Government aware you have not a proper gauge here? My department is aware of it. Before the flood of 1879 I applied for a gauge, and I received instructions to have one erected, but I did not receive the instructions until after the flood came down; so I was unable to have the gauge erected. After the flood disappeared I reported the matter to the department, but I have not yet received word to erect a gauge. 22 Sept., 1886.

What length of time have you known the river to be dry since you have been here; that is, unnavigable? For over two years. Dry river.

Suppose there were a 5-foot rise at Bourke, what rise would you expect here? About 4 feet.

*Mr. Gipps.*] Have you kept any record of evaporation? No.

*Mr. Donkin.*] With regard to summer level and navigation level, what would you suggest should be taken as a standard by which to read the different floods; should it be the bed of the river, or summer level, or navigation level, or the height of any known flood? I should say there ought to be some standard for summer level all through. For instance, here the river has to rise 6 feet before you can call it proper navigation level, that is, to enable boats to pass down from 100 yards up stream.

If you wired to Menindie "river is 2 feet below 1879 flood," would they understand you? No. They do not know the river as regards previous floods? No. At Bourke they send from navigation level. I send from the bed of the river. I judge by the rocks.

FRIDAY, 24 SEPTEMBER, 1886.

At Winbar.

Present:—

MR. DONKIN,

MR. GIPPS.

Mr. J. C. Paterson examined:—

*Mr. Donkin.*] You are storekeeper of Winbar Station? Yes.

How long have you been here? Between five and six years.

Have you seen the Darling in flood before the present one? No. This is the first big flood I have seen. What was the state of the river here before this flood? It was perfectly dry in many places. You could walk across it. Mr.  
J. C. Paterson.  
24 Sept., 1886.

Are there any deep holes in the river? Yes, there is here, and one at Campadore.

Is that close to the station? Yes.

What depth of water was there in that hole in the last drought? Perhaps 12 or 13 feet.

You had plenty of water? Yes.

You have tried irrigation at the station? Yes.

Irrigation

How long is it since it was first started? In the beginning of 1884, I think.

That was right in the middle of the drought? Yes.

Was there sufficient water in the river to continue irrigation? We would have had to cease if we had not had a fresh.

There was not sufficient to keep up irrigation? I think not.

How many acres had you under irrigation? Seven acres.

What size of pump did you use to lift the water? A 10-inch centrifugal pump.

What was the lift? About 40 feet from the bank to the water.

What system did you adopt for laying out the ground for irrigation? We laid the ground out in squares, about eight squares to the paddock, and ran a main drain through, which we dammed all round. We ran the water into one of the squares, and as soon as that was thoroughly irrigated we opened the dam or check and let the water run over another square.

How do you check the main drain? We simply dam it up with earth.

What did you put in as the first crop in 1884? Lucerne.

Lucerne.

Had you any difficulty in ploughing the land before flooding? Yes; the ground is very sticky; it is a black loamy sort of soil.

How many floodings did you give it for a crop? In summer we flood when the crop is taken off, and again about a fortnight before cutting. In winter we give one flooding after cutting. Flooding the soil.

About how many inches to each check? I should say about 6 inches of water. About a fortnight before we cut the crop we thoroughly flood the ground.

What quantity of lucerne per acre do you generally take off? About a ton.

Quantity of lucerne per ton.

How many crops do you get per annum? About five crops. We flooded the present crop in June, and it is ready for cutting now.

As soon as you have cut that you will flood the ground again? Yes.

Do you expect to get five crops this year? Yes.

Number of crops.

Have you ever tried to preserve the lucerne in silos? Never.

How do you make use of it for food? We use some of it green, but we stack most of it, and cut it for chaff.

What do you use it for? For horse-feed only.

Not for stud sheep? No.

What do you think is the most profitable crop to grow? Lucerne is the most profitable.

Have you tried prairie grass? Yes; we tried a small patch, but it did not answer. We also tried sorghum, but we were not satisfied, although it grew well. We thought lucerne was the best crop. Prairie grass.  
Sorghum.

Many stations here have paid large sums of money during the drought for horse-feed? Yes.

Do you think this experiment of yours in growing your own crop has been successful? Yes; it has saved us £1,000 since we began. Success of irrigation.

You feel justified then in continuing your experiments? Yes.

Do you think it would pay to irrigate for keeping stud sheep alive in times of great drought? That is hard to say.

- Mr. J.C. Paterson. You know many stations have paid large sums for feed; do you not think it has been a saving to you to have grown the feed? For horses most certainly. It has been a great saving. We must feed the horses at any cost.
- 24 Sept., 1886. You know the expense of your irrigation, and that you have kept your horses by means of it; what would have been the difference if you had had to send for chaff as the other stations did? It would have cost us, I dare say, £1000 more than it has done.
- Soil. Which do you think is the best soil to irrigate, the soft black soil or the red? We have never seen the effect of it on the red soil.  
The red soil is better to work for cultivation, is it not? I should say so.  
Are there any depressions on Winbar where any large quantities of Darling flood-water could be conserved? Only small billabongs.  
You have no large channel like the Talyawalka? No.
- Weirs. Do you think it would be possible to construct weirs across the river from 8 to 10 feet high to retain the water in the Darling? I dare say it would.
- Rocky bars. Are there any rocky bars on the river? There are several bars.  
And plenty of stone? There is no stone just on the river, but at no great distance from the river on the upper part of it it may be found.  
Do you think anything ought to be done towards conserving water in the river; would it be a national benefit? I think so.
- Stock. Which do you think would be of most importance to the country, to conserve the water for irrigation purposes or for stock? For stock, I think.
- Irrigation. Do you think if there were plenty of water in the river the residents would utilise it for irrigation? I think they would eventually.  
How is it that you first came to try irrigation? We found the expense of buying the feed was so heavy that we determined to try what we could do ourselves.  
Do you find the locusts and grasshoppers destructive? No; we do not suffer from them here.
- Wells. Have you any wells on the station? We have two.  
What depth are they? One is 220 feet, and the other is 140 feet.  
Have you got good water? Very good water.  
What do you depend on for your water supply out back? Principally tanks.
- Tanks. Of what depth are your tanks? From 12 to 15 feet.
- Boring. Do you think an abundant supply of water could be obtained by boring deep? I think in most places water could be obtained.  
Which do you prefer to depend on, tanks or wells? I think tanks are best. With the wells there is a difficulty in raising the water.
- Cost of irrigation. Can you give us an approximate estimate of the cost of irrigating the six acres, say, for one season, that would be for five crops? I should say it cost £100 a year to keep the paddock going.  
Then there is the cost of the plant? We had the plant on the station.  
You think you can keep it going now for £100 for five crops a year, that is 30 tons of hay a year? Yes.  
That would make it a little over £3 a ton? Yes.  
You cannot get hay delivered here at that price? No.
- Cost of forage during drought. Did you buy any forage during the drought? Yes.  
What did it cost you a ton? Carriage is very high. We paid £16 a ton for carriage from Nyngan.  
Chaff costs about £23 a ton.
- Success of irrigation. Speaking from your experience with irrigation for five years you think it has been a decided success? Yes, a great success. I think it is one of the best improvements on the place.
- Navigation. Do you think if navigation were kept up by means of weirs between the railway points (say) Bourke and Wilcannia, that the wants of the residents on the river would be met, or do you look for through navigation down the river? Through navigation would be more to our advantage.
- Wool to Adelaide. Where do you send your wool to now? To Adelaide.  
Is there any great difference in the cost of transit comparing Adelaide with Sydney? I do not know the cost to Sydney.  
What do you pay to Adelaide? £5 10s. per ton; that covers insurance.  
You have not been able to send your wool to Adelaide for some years? Not for the last five years.
- Wool detained by drought. How long have you had wool on the station waiting for a river? We sent one year's clip away and part of the following year's at the same time.  
If you had a certain river between the railway points you would be enabled to get it away at once, would not that be an advantage? It would be an advantage certainly.
- Rainfall. Mr. Gipps.] What is the average rainfall on the river at this part? About 12 inches.  
Does the rain fall in regular continuous quantities or in heavy storms? Generally in heavy storms.
- Winds. What are the rain winds? The westerly winds.  
What wind brings up continuous rain? West to east.  
Are the winds pretty regular here during summer time? No; they are very irregular.  
Which is the prevailing wind? It changes about all day long. Whirlwinds generally prevail.  
Are they constant enough from any one quarter to permit of the use of windmills? I do not think so.  
They are not constant at all.  
We have been told you have winds all day? It blows all day, but it chops round.
- Windmill. Is there enough wind to keep a mill going? Generally speaking. We had a mill at the station, but it was of very little use.  
What is the horse-power of the windmill? I could not say.  
Do you know the diameter of the wind-sail? No.  
Was the river very low last drought? Very low.  
Did it cease running? Yes.  
Where did you get the water for your irrigation? There was a large hole at the station.  
What is the height of the bank to the surface of the water? About 40 feet.
- Pumping. How many hours a day did you pump the water continuously? About ten hours a day.  
Was that every day in the week? Sometimes we pumped for four days. We have irrigated the paddock in four days.  
Did the pumping seem to affect the level of the water in the hole? I think not.

Do you think there is an under-current in the bed of the river itself? I do not know.

Are there any creeks on the run coming from the hills? There is one fair creek out back called Cameron's Creek. Mr. J. C. Paterson.  
24 Sept., 1886.  
Cameron's Creek

Where does that join the river? I do not think it joins the river at all. It runs out in the sandy country.

What is the length of it? I do not know exactly how far it runs out.

In what locality does it rise? In the range out back.

Have you a dam on the creek? Yes. Dam.

What is the height of it? About 30 feet from the bed of the creek to the top of the dam.

How far does that throw the water back? At the present time it is thrown back for about three-quarters of a mile.

How high is the water now on the dam? I could not say.

How far will the water be thrown back when the dam is full? Over a mile.

Can you not follow the course of the creek after it flows into the swamp? No; there is no channel whatever.

What is the character of the rock you went through in the wells? I do not know; they were put down before I came.

Are you getting fresh water? It is good stock-water, but not exactly fresh.

How high does the water rise in the well? It does not rise high at all. Water in well.

What do you use the water for? For sheep.

Does pumping seem to affect the level at all? One of the wells you can bale out in two or three days' continuous baling with a whim. The other one we have never bailed out.

Did you reduce the level at all? Not to a great extent.

How many gallons do you think you pumped out at a time? I could not say.

*Mr. Donkin.*] You said whirlwinds are very prevalent; is that during drought or during bad seasons? Whirlwinds.

Nearly every summer they are very bad.

Are they destructive at all? Oh, no.

In speaking of the level of the river, what do you gauge it from—do you take it from summer level, or the bed, or the height of any well-known flood? We judge it by a mark on a tree which has the feet noted on it all the way up. Summer level

For instance, in obtaining reports from up the river as to this present flood, what were you guided by; were you able to prepare for the flood from the information you received? From the information we received we knew pretty well what the flood would be here.

What do you think would be best to adopt as a zero by which to read floods from—what would be more generally understood along the river, the bed of the river or some well-known flood-mark? I think navigation level would be the best thing to start from.

What would you call navigation level? I could not say that.

Do you think that is well known and defined? I think anyone who has been on the river would know what is intended by navigation level. Zero for gauge.  
Navigation level.

Do you not think it would be simpler to read from the rocky bars in the river, or else from a well-known flood, and say the river was so much above or so much below that? That would be a good plan.

Navigation level is not trustworthy, because so much depends on what the steamers draw? That is true.

*Mr. Gipps.*] How far do these plains extend back from the left bank of the river? In some places about 5 miles. Plain country.

Then what sort of country follows; is it rolling country? No; it is scrubby, irregular country and sandhills.

Are these spurs from any range? No; the hills are isolated.

*Mr. Donkin.*] Had you to discontinue pumping for irrigation because of the low state of the river? No; we had always enough water. Rise of water for irrigation.

Were there any complaints as to your using the water? I heard that a few people complained, but I do not think our using the water affected anybody.

How many horses and cattle on the station did you keep during the drought with the food grown by irrigation? We kept all the horses we had working. We have not had to buy any food since we took our first crop off. Cattle kept by means of irrigation.

When did you take that off? About the middle of 1884.

You say you saved a thousand pounds through adopting irrigation; that would be since the middle of 1884? Yes. Of course that saving was principally in the first year; since then we would not have had to lay out much money for horse-feed.

You may say you saved a thousand pounds in twelve months? Yes.

Have you had many losses on the station? Yes. Losses in sheep.

Can you give a rough estimate? Over 50,000 sheep.

In what time? In 1884 principally—the end of 1883 and 1884.

Do you think any means could be adopted to avert the frightful loss in stock? I do not think so.

*Mr. Gipps.*] What was the heavy loss due to, to want of water or want of feed? To both.

*Mr. Donkin.*] It has been proverbial on the river that it has been from want of feed especially? Yes.

Have you tried the plan of spelling part of your country? We have spelled some. Spelling country.

Suppose you were to spell a third of the run, would not that overcome the difficulty? The feed does not last. The rainfall is so small here, and we are so long without rain, that the feed dries up.

Whether the country be stocked or not? Yes.

*Mr. Gipps.*] Are there any springs in this part of the country? I do not know.

*Mr. Donkin.*] Have you any minimum depth for your tanks? No. Tanks.

What depth do you find will hold out through a drought? About 12 feet is a fair depth.

Any less depth than that would not be a safeguard? No; that is as low as you can make them.

*Mr. Gipps.*] Have you known any of the creeks to run into the river in heavy floods? The Morbilly Creek. Morbilly Creek

What induced that to run? A very heavy rain. We had 5 inches of rain in a couple of days.

Was there a large volume of water? Yes.

About what width? I could not say; I was not here when it was running.

Is it a deep bank at its entrance to the river? Yes.

What depth are the banks? About 20 feet. What

Mr. J.C. Paterson. What width from bank to bank near the river? About 60 feet.  
 During that flood, did it run over these banks? I could not say; I was not here.  
 24 Sept., 1886. Mr. Donkin.] Do you think it made much difference to the level of the river? No.  
 Mr. Gipps.] If a dam had been thrown across the mouth of the creek, would it have conserved a large quantity of water? It would have backed the water up.  
 Mr. Donkin.] Is it a well-defined channel? Only just over the river.  
 Could you ride over it without knowing it? There are people who would.

*At Curranyalpa.*

Mr. M. H. Seale examined:—

Mr. M. H. Seale. Mr. Gipps.] How long have you been here? Five years.  
 Have you had very dry weather lately? Yes. From January, 1885, till last June we had only partial rain.  
 24 Sept., 1886. What was the condition of the river during that time? Perfectly dry at times.  
 River dry. Were there no waterholes? There was a stretch of 3 miles here without water with the exception of one little drop in a hole just here, about 50 yards long, 6 yards wide, and 2 feet deep. But that water was not fit to use.\*  
 Banks of river. Are there any springs in the bed of the river? None whatever here.  
 What is the character of the banks of the river, rocky or alluvial? On this side of the river it is rocky.  
 What kind of rock? It seems to be a rotten kind of ironstone.  
 Does it appear to cross the river? It goes right across in the beds.  
 You do not see it in the bank? No.  
 Watering stock. How did you water your stock in the interior of the run during the dry season? By wells and tanks.  
 Wells. How many wells have you? Three.  
 How far apart are they? About 8 miles.  
 What strata did you pass through in sinking? Alluvial for about 40 feet, then hard rock.  
 Sand. For what depth? We had about 40 feet of pretty hard rock, and finally we got on to sand-drift.  
 How deep was the sand? After the sand we got on to another kind of stone which was harder.  
 What depth of that was there? It was running in veins.  
 What did you bottom on in the end? Sand.  
 Tight sand? No; drift sand, quite loose.  
 What was the depth of the well? The wells are of different depths; our deepest is 120 feet.  
 Did you get a continuous supply? There is a continuous supply.  
 Any current in the water? None that you can see.  
 How high did the water rise? It did not rise at all.  
 Windmill. Can you pump the well dry? We have not done so; our only power is wind.  
 How many gallons can the windmill raise? About 500 gallons per hour.  
 What is the diameter of the windmill? 16 feet.  
 What horse-power do you reckon it is? I really do not know.  
 Salt water. Is the water clear? Perfectly clear.  
 And pure? No; it is salt. We have no fresh water in any of the wells. There are two that none of the men attempt to drink from. Stock drink the water. There is not fresh water in any of these three wells, but we have one shallow fresh-water well on the Billabong with a very small supply.  
 Is the water changing in its character? In one well it is getting better; it is not so salt. That well is 110 feet deep.  
 Tanks. Can you mark the position of these wells on the map? Yes.  
 How many tanks have you got? Twelve.  
 What is their average capacity? They are from 3,000 to 14,000 cubic yards.  
 And their depth? To 14 feet.  
 Do you batter the sides to keep them up? Only in the first instance.  
 You do not puddle the sides? No.  
 The character of the soil is sufficiently impervious not to need it? We have some that do not need it.  
 What do you do with those? We have done nothing with them. The water comes in, and in a short time goes away. We have three that will not hold water. One of the tanks of 3,000 or 4,000 yards has not held water more than a week.  
 Evaporation. Do you lose much water by evaporation? I do not think so.  
 Rainfall. What is your average rainfall here? About 11 inches a year.  
 Does it fall in storms or in continuous rains? In storms chiefly.  
 Winds. What winds bring these storms? The storms come with west and north-west winds.  
 Windmills. Are these winds sufficiently continuous to allow you to avail yourselves of the windmill? In summer-time they are, that is for six months in the year.  
 Would it not be possible to have windmills on the bank of the river to pump up the water? What would you use it for?  
 For irrigation? No.  
 Is there not enough wind? There is enough wind, but you could not get enough water. We have a small garden, and a windmill always at work on it, but we cannot keep enough water on it in summer-time. As fast as you put it on it goes straight down.  
 Irrigation. Have you tried irrigation at all? Only in the garden.  
 Can you raise any kind of vegetation with the water? Yes; we grow vegetables enough for the station.  
 You have never tried to grow feed for the horses? No.  
 Do you know Winbar Station? I do.  
 Soil at Winbar. Is not the soil here similar to that of Winbar? It is not like it at all. I do not think you could find one place on this station similar to Winbar.  
 The soil from Winbar up river is less permeable than the soil from Winbar down? I believe so.

Have

\* NOTE (on revision):—Referring to this, it was in November and December, 1884, and part of January, 1885.—M.H.S.

Have you any large creeks on the run? We have one; it is called the Billabong; it runs out of the river and enters it again at Nelyambo.

Mr.  
M. H. Seale.  
24 Sept., 1886.  
The Billabong.

What is the distance it covers altogether? Fifty miles frontage by the river. It would be about 80 or 100 miles to follow it round.

What is the depth of its bed? If filled it would hold about 12 feet,

And the width of the channel? An average of 40 yards.

What is the height of the bed above the bed of the river? Twenty-five feet, I should say.

Does there appear to be a good fall? A very good fall.

Do you think it would be possible to conserve much water in this billabong? Yes; it will hold a lot of water.

Have you ever tried damming it? We have a dam on it.

Dam.

What is its height? About 15 feet, I suppose.

And what distance does that throw back the water? I could scarcely tell you, as the country is all under water just now from here to the dam.

How far would that be? Thirteen miles.

*Mr. Donkin.*] Have you tried red soil for cultivation at all? No.

Red soil.

Do you think it would answer for irrigation? I dare say it would; the grass grows on the red soil.

How do you take the height of the river here? We have no gauge at high flood.

Do the floods affect you seriously? Only at shearing time, when we are cut off from our sheep in the paddocks. On our lower station, Budda, which is 35 miles down the river from here, we have not been able to keep any sheep since June, because the country is so low that the greater portion has been under water, also a great portion of Curranyalpa. The frontage is useless to us in flood-time, being all covered with water.

Floods.

What do you gauge the height of the river by? By guess. The river is about 40 feet from the bed to the bank, and we guess the height of the water up the bank.

Height of river.

What do you think should be the zero to read the river by, an old flood-level, or summer-level, or the bed? I should say the bed.

Zero of gauge.

Had you to go to much expense for the horses during the drought? We spent very little, because we could not get the feed here.

Do you not think you could have grown enough if you had had a pump? Not on the white soil. I saw it tried at Winbar. They were pumping for three weeks at the rate of 60,000 gallons an hour, and the water did not go 400 yards from the pump, and it did not spread 200 yards. It was pumped by a 12-horse power engine, with centrifugal pump and 10-inch pipe.

Poorness of white soil.

Do you think the pumping at Winbar made any difference in the river when the river was low? I do not know whether the pumping at Winbar did. The river stopped for a few days, and then commenced to run again.

Pumping at Winbar.

It did not seriously affect you? Oh, no.

Are there any rocky bars in the river on which weirs might be constructed? It is hard for me to say whether weirs could be constructed, but there is a splendid foundation and plenty of material. There is a rocky bed here for a mile and a half along the course of the river.

Rocky bar.

Do you find that these bars affect the river at all by causing the banks to scour away? No.

Is there any soakage from the river? None whatever. We sank a well 40 feet below the bottom of the river and could not get any water. We had to put a tunnel into the river to get water in the well.

Soakage.

If the river were made navigable between the railway termini of Bourke and Wilcannia, which route would you make use of for the conveyance of your produce to market, down to Adelaide or by Bourke to Sydney? We should go up the river.

If the river were weired across and communication retained between the railway termini, that would be sufficient for the residents here? I believe so.

Weirs.

Do you think it would be of benefit to retain the water in the billabong you spoke of, or would the cost be too much? It would be of benefit.

What would be the cost of an earthwork dam on that billabong? I think the greatest cost would be in making the by-wash; making the dam would not be very costly. With the quantity of water running now our by-wash has cut within the last few weeks very nearly equal to another creek, and the get-away was a natural one to begin with. I suppose we have a channel 5 ft. deep and about 50 yards wide.

Dam on the Billabong.

Do you not think it would be better here to adopt overshot dams? Yes, if we could get them to stand.

Overshot dams.

Have they been tried? Not to my knowledge.

If you had always a full river like this, do you not think you would be inclined to try irrigation? No; the soil would never pay for it.

In the drought, does it not mean actual starvation to the horses and stock on the station without feed? You could save your horses, but if you could not save your sheep what is the use of it?

Losses during drought.

Have you tried the plan of spelling part of the run? We cannot afford it. The country is not good enough. If we were to spell part of the run we could not carry enough stock to make it pay. The only way we can work is not to overstock the paddocks, but never to have them empty.

Spelling country

Do you not think you could carry more stock by relieving some of the paddocks? Not any more. In this part of the country if the feed in a paddock is once eaten down it will not grow again till you get a heavy rain. It might be six or twelve months before you would get sufficient rainfall to make more feed. Some have to guard against not eating the paddocks down.

How do you account for the fearful losses in stock, is it through overstocking? Just from the want of rain.

What have the losses been due to—want of grass or want of water? Want of grass.

Want of grass.

Have you had water? We have had water. We can always have sufficient water, but no grass.

FRIDAY, 24 SEPTEMBER, 1886.

At Kallara.

Present: —

MR. DONKIN,

MR. GIPPS.

Captain Thomas Johnston examined:—

- Captain T. Johnston.** *Mr. Donkin.*] How long have you been on the river Darling? About twenty-six years.
- 24 Sept., 1886.** Have you been trading up and down the river? Yes. I first came on the Murray with Captain Cadell. From there I went to the Murrumbidgee, and thence to the Darling, when it was first opened. I started with Captain Cadell in 1854.
- Floods.** Where was he running to then? To Albury.
- How far up the Murrumbidgee did you run? As far as Wagga Wagga.
- And how far up the Darling? Not beyond Brewarrina.
- Floods.** You know pretty well all the floods that have occurred of late years? Yes. I know the floods of 1864, 1870, 1879, and this year.
- Which was the highest? That of 1864.
- Height of flood of 1864.** Do you know what height it registered? I could not say, but I think that flood must have been fully 5 feet higher than the present flood. It was up to the window-sills in Bourke.
- The whole of Bourke was under flood? Yes.
- Were you there at the time? The water commenced to fall when we got there, but we experienced the height of the flood down here.
- Gauge readings.** Does "5 feet" at Bourke read "5 feet" at Wilcannia? I should think so. At that time the water was all level.
- Do you think a 5-foot rise at Bourke now would mean 5 feet here? It would come close to it, I think.
- Have you noticed much difference in travelling up and down? I think it is about the same.
- Does not the river spread more here, near Wilcannia? There is more spread, but the reading on the gauge is the same. I have noticed that when the river is half a banker it runs into the billabongs, and does not reach here.
- How did the 1870 flood compare with that of 1864? It was about 4 feet lower.
- Floods.** And the 1879 flood? That was a foot higher than this one.
- Velocity.** Was the velocity of those floods about the same as that of the present flood? About the same.
- What do you consider it is now? On an average not more than 2 miles. In some places where the water is confined it may be a little more.
- How have you been accustomed to gauge the floods in the river? We know by the stations and townships we discharge at.
- What I mean is, what have you been accustomed to read from; do you take navigation level, summer level, or the bed of the river? We take the top of the flood.
- Summer level.** But the telegraphic news is from summer level? Yes. We hardly know what summer level is, there is such a difference of opinion. What I would call summer level is when the river is snagged and a boat drawing 2 feet 6 inches or 3 feet can go over the bars freely.
- Zero of gauge.** What do you think should be adopted as zero in telegraphing a rise in the river? I would take it at 3 feet from the bed. That would allow a light-draft boat to work.
- But does not the bed shift? There are three or four bars in the Darling higher than the bed. For instance, that at Curranyalpa is fully 4 feet above the bed.
- You think it is about the same as the bar at Brewarrina? About the same.
- Bar at Curranyalpa.** If the water is running over the bar at Curranyalpa, would the river be navigable to Bourke? I think so. I do not think there is another bar from there to Wentworth, except the one at the Coach and Horses, which is just above the Mount Murchison woolshed, about 10 miles this side, and below Cultowa a good distance. There is a difference of 4 feet between there and Wilcannia. They call the place Kennedy Reef.
- Weir.** Supposing a weir were erected 3 or 4 feet above the rocks at Curranyalpa, would that make the river navigable at all times to Bourke? No. There is another bar at O'Shannassy's boundary.
- Gauge readings.** You said that in your opinion the datum to read floods from should be about 3 feet from the bed? I think so.
- Do you not think it would be better to take it from some well-known flood? Perhaps that would be as well. Which point would be best known along the river, a well-known flood-mark or 3 feet from the bed? I think 3 feet from the bed would be best.
- Do you know of any other bars in the river except those you mention? Not on this side of Bourke. There are rocks in the way, but there is a channel between them.
- Foundation for weirs.** Do you think it would be a difficult undertaking to erect weirs or dams across the river to raise it a few feet at these bars? I do not think it would be difficult, because where there are bars you have a good foundation.
- Locks.** Do you think the banks would cut away? If there were locks I believe the banks would cut away in high-water.
- But with an ordinary dam or weir? They might stand. With locks, unless they were strongly built, the weight of water pressing against them would make a fresh channel at the side.
- Fresh channels cut by river.** In your experience of the Darling, have you known it to cut a fresh channel? Yes. We go through channels now where there were none before. When the water is over the banks we go through. In fact there is no channel in the old river in some places.
- Duration of flood.** How long do you calculate it will take this river to run down, saying there is no fresh rise in the river? It depends upon rain. If there is no more rain I think the present river will last three months.
- And what will it go down to? I suppose to summer level.
- Woytchugga Creek.** You know the river well from the Murray to Brewarrina; do you know of any creeks along the whole of that course which empty any water into the river from local rain? A lot of water comes down Woytchugga Creek, below Wilcannia.
- Where does that rise? The junction of it is about 4 miles from Wilcannia.
- Is it not an ana-branch? No.

- Do you think the creeks which empty into the river make any perceptible difference in the height of the water from Brewarrina down? I do not think so, but I think the small rivers do, such as the Culgoa and the Bogan. And I have seen the Cato come down very strong. Captain T. Johnston.
- The Cato is only an ana-branch? I suppose it is. 24 Sept., 1886.
- Do you think a large body of water could be conserved in the Cato Creek by a weir or overshot dam? I could not say. I have not had enough experience there. Cato Creek.
- Do you know of any other billabongs or ana-branches down the river? There is the Great Ana-branch which runs into the Murray. The Great Ana-branch.
- Is that navigable in flood time? There is too much timber in it, I think.
- Is that the largest channel you know down the river? The largest on the Darling.
- Do you know any of the inland lakes? I have been on Lake Menindie. I suppose there are 20 miles of water there now. Lake Menindie.
- What would be the greatest depth? I suppose there are now about 30 feet of water.
- Does the water find its way into the river? Yes. The creek is about 2 miles below Menindie.
- Could not the creek be easily dammed? Very easily.
- Do you think there is much water lost in the river through soakage in the bed? I do not think so.
- You think it would not be advisable for the Government to erect locks in the river, because the banks would fray away? Unless there were plenty of masonry work. There is plenty of good foundation. Danger of locks.
- Do you know the character of the rock; is it ironstone? Above it is ironstone, and so it is down at Weinteriga. Rock.
- Mr. Gipps.*] What was the principal cause of the 1864 flood, was it heavy rains? Yes. Flood of 1864.
- And local rains besides? I do not recollect that we had much local rain.
- Were the Murray and Murrumbidgee in flood? Not so much as the Darling. Those were within their banks.
- They served to back the Darling up a little? At Wentworth.
- They are in flood now? Their banks are not flooded, but I think there is 14 or 15 feet of water.
- That would allow the Darling to get away more quickly now than in 1864? But that does not affect the water up here.
- I suppose you have seen the bed of the river when it has been very low? I have seen it dry. River dry.
- Have you seen any springs along the course of it? No, except a little soakage in the banks. It is a dirty-coloured water.
- Which are the prevailing winds here? The south-west wind, I think. Winds.
- Is that all the year round? I cannot say for this part of the country. I know where I came from it is about nine months in the year.
- Is it a high wind generally; does it blow continuously? In winter the winds are high, but not so much in summer.
- Do you know of any point on the Darling where some of the western ranges cross, they say there is a divide of the Lachlan across the river somewhere near Wilcannia? I have never been out that way. Range crossing the Darling.
- There are no points on the Darling itself where you would fancy a range crosses? No.
- Do you know anything of the Talywalka ana-branch? I know it is a very large one and runs back 20 miles. The Talywalka.
- For what length? It runs in 30 miles below Menindie. Menindie Creek will keep the river for three months, from Menindie to Wentworth.
- What is the width of the channel from the point of off-take of the Talywalka? Quite as wide as the Darling, and very deep.
- What would be the depth? I could not say. I think as deep as the Darling in places.
- It would give you the impression that at one time it may have been the channel itself? It looks as like the river as the river itself in many places. At the back of Murtee it is just as big as the Murrumbidgee.
- Are there any depressions or lakes on its course? I cannot say. I know the boats have gone 20 miles back and loaded wool.
- What is about the fall, is it the same as the Darling? It must fall the same. Fall.
- At the point of discharge into the Darling, is it as wide as the point of off-take? There are two entrances there, both of them pretty wide.
- Do you think there would be any means of conserving water in it by dams? I think so.
- Mr. Donkin.*] How is it the navigation in the river is considered so dangerous, and that so high a rate of insurance is charged; have you had any accidents? I have had none, exception one occasion when a barge made a little water unknown to me. I think the shrimps must have eaten the oakum out of the seams of the vessel. Dangers of navigation.
- Was there not a barge wrecked the other day? A steamer went down, but I do not know the cause of it. She went down at Netley, but no one knows how she sank. Steamer sunk.
- What is the longest time you have known a vessel detained here through the river being too low for navigation? I have been detained eighteen months. Vessel detained through drought.
- In one place? No; I moved five times, but it was eighteen months before I came home. We went from Wentworth, and were stopped at the Rocky Waterholes, then to Tilpa, then to Curranyalpa, then to Louth, then to Bourke. It required five floods to take us through, and my vessel was only drawing 4 feet of water when we started. At the last we were only drawing 3 feet.
- There is no certainty as to navigation in the present state of the river? No.
- Mr. Gipps.*] In the high flood of 1864, was the Paroo running? It must have been running. Paroo.

Mr. David Brown examined:—

- Mr. Donkin.*] You are manager of Kallara Station? Yes. Mr. D. Brown.
- How long have you been here? Since 1878.
- How many floods have you known on the river? There was the flood of 1879, which lasted till 1880, and there is the present flood. 24 Sept. 1886:
- How long did the 1879 flood last before the river came back to summer level? A long time. The highest point of the flood was about November, and the river was navigable till the following March. It went down very fast in November, so fast that we could scarcely get our wool in from the shed 3 miles back. Duration of 1879 flood.

- Mr. D. Brown. back where it was stored. The river fell so rapidly that by the time the flats were dry enough to allow of carting the wool the river was all but too low for navigation.
- 24 Sept., 1886. How did that flood compare in height with the present flood? It was about 9 inches higher here.
- Height. Has the present flood reached its maximum height? It has just reached it to-day.
- Information as to floods. Do you think it is rising? I think it is standing still now.
- How do you receive information as to when a fresh is coming down? By telegraph from Bourke, Walgett, and other stations.
- Is the information reliable? None of the information except from Walgett is reliable.
- Datum. Do you know what datum they take? I do not. I know that at Brewarrina this year the level changed in two days about 10 or 12 feet. It was reported as 35 feet one day, and as 24 feet the next day, according to telegraphic report. I should like to say with regard to Bourke that the information from there this year has been fair enough. There was a change made from summer level to navigation level in the mode of reckoning, and that threw me out 3 feet in my calculations. Consequently the flood was 3 feet higher than I expected.
- Is it of serious importance to you that you should have correct information as to the height of the floods? It is a matter of extreme importance.
- What would you suggest as a datum? I think we should have some gauge relatively fair; that is, a certain height at Walgett would give a certain height at Brewarrina, the height at Brewarrina would represent a certain height at Bourke, and so on down the river to Louth, Tilpa, Wilcannia, Menindie, Pooncairie, and Wentworth. If the highest point of any given flood were taken the best plan would be to mark that as zero on the gauge and reckon downwards.
- Zero of gauge. Do you think that the highest point of the present flood of 1886 would be recognized all along the river? I do. I know the highest point of this flood is relatively fair with regard to Walgett.
- Would a rise of 4 feet at Bourke mean 4 feet here? Not necessarily. The last fall of the river was 3 feet at Bourke, and the corresponding fall was only 5 inches here. The reason is that the water as it flows down the river is caught by the following flood. There has been no fall at all at Wilcannia, but a steady rise. The same thing has occurred here, but not to the same extent. There was a considerable fall at Bourke, but none here.
- Would the Warrego water coming in below Bourke make some difference? No doubt.
- Warrego River. Did the Warrego water join the Darling in 1879? Yes.
- Has it been raining since? Yes, once or twice. It rained in 1882, in January, 1885, and December, 1885.
- Width of flood. What is the average width of the Darling here at Kallara in flood? The steady south-western flow goes out in our direction 3 miles wide north-west from the river bank.
- Is there much current at the back or edge of the flood? A considerable current, about a third of the velocity of the river.
- Cuttaburra Creek. You know the Cuttaburra Creek? I know what is called the Cuttaburra. It is an outflow from the Warrego, and joins the Paroo. The lower portion of the Cuttaburra is often filled with Paroo water.
- Paroo River. You know the Paroo River? Yes.
- Has it been in flood before the present flood? Since 1870 the highest flood previous to this was in 1877. I did not see it, but I know the record of it. The Paroo has run on Goorimpe on an average about once in eighteen months. The next to that of 1877 was in 1882, and this last flood has been the highest of the three. It has been within 2 feet of the 1870 flood, judging by flood-marks.
- Have you been down the course of the Paroo from Goorimpe to Wilcannia? Not to Wilcannia, but as far as Momba.
- Do you know whether the Paroo water ever joined the Darling? I know it has, or rather the Darling water has joined the Paroo.
- Has the present flood-water joined the Paroo? Not yet, but I believe it will. There is a flat on this run where the water goes out between two hills, and if it runs long enough it runs into Peery Lake. I believe that during the heavy rain in January, 1885, Paroo water ran into the Darling.
- As a matter of fact, the height of the Darling is not affected by the Paroo River? No; practically the Paroo never reaches the Darling.
- Lakes on the Paroo. Do you know of any other lakes besides Peery Lake? Yes; there is Tonga Lake, which has a depth of about 6 feet when full; Yantabangie, about 12 feet; and Peery, about 8 feet.
- What is their length and width? Tonga is about 8 miles long with an average width of about 2 or 3 miles; Yantabangie, about 3 or 4 miles; Peery is about 5 or 6 miles each way.
- Is there an outlet from Yantabangie? Yes.
- Would there be any probability of damming it? I do not think so.
- In any of the lakes on the Paroo, could water be conserved? I do not think it.
- Speaking from your knowledge of the Paroo, do you think it is possible to conserve any large body of water in it? I think not, because the Paroo channel, at all events on Goorimpe, is really no channel. It is a mere succession of flats. In high floods the Paroo is only 5 feet at most.
- The Talywalka. Are there any large ana-branches on the run? There is one, the Talywalka.
- Which Talywalka? It runs in on Dunlop and comes out here.
- What is the length of it? 40 miles.
- What is the average depth? 12 to 18 feet.
- Could it be easily dammed? Yes; it has three or four dams on it. There is a dam on our portion of the Talywalka which cost £1,600. This was made for the purpose of forcing the Darling water out to Peery Lake. It was made in 1874, and when the flood of 1879 came the water went round the end of the dam, and a channel deeper than that of the Talywalka, the creek itself, was cut in twenty-four hours.
- Overshot dams. Have you tried overshot dams? No.
- Would they answer? I cannot see that they would be applicable to this part of the country; the country is too flat for them.
- Are the dams in the Talywalka still standing? Yes.
- Failure of dams. Have you any other dams? Not here. There were dams out on the Paroo which were put at the end of natural waterholes previous to 1878, but the silt and dust have filled up the natural waterholes, and the dams prevent the scour. Dams are perfectly useless on that portion of the Paroo.
- Does the wind, by blowing the earth in a dry state into the channel, affect the position of the water-course at all? No.

Do you know of any other large ana-branches of the river? There is one on the other side, Acre's Billabong.

Has that a deep channel? About 16 feet deep.

Could any large body of water be held back there? The water is held back all along it by dams.

How do they answer? They seem to answer pretty well.

Do you know what distance any one dam throws the water back? I do not; perhaps 7 or 8 miles.

You have known water to be in the billabong when the river was actually dry? Yes.

Do you think the billabongs could be made of any great service to the district if the water were con- The Billabong  
served? I think everything has been done by private enterprise that can be done.

With regard to the river itself, you say you have known it to be dry;—was that for any distance? For River dry.  
three-quarters of a mile at a stretch.

Was it dry during the last eighteen months? Yes, twice.

What could be done with the river? I think it would be possible to put locks on the bars in the river Locks.  
for the purpose of navigation.

Do you think it would be sufficient if weirs were erected where the bars cross the river, and naviga- Market for wool.  
tion kept open between the railway points, say Bourke and Wilcannia? It would be a great con-  
venience to the residents. At the same time, if the river were navigable downwards, I believe the wool  
would go down to Adelaide. I do not believe that locking the river or any other process will induce  
people to send their wool by the dearest road: and wool can be taken more cheaply to Adelaide than to  
Sydney by the present system.

What is the difference between the two routes in cost of carriage? The cost is on an average £3 10s. Rates of  
per ton free on board; with the insurance it would be £5 10s. carriage.

What is it from Bourke to Sydney? From Bourke to Sydney, £5 11s. 6d.; agency in Bourke, 5s.;  
river to Bourke, £1 5s.; insurance to Bourke, 12s. 6d. Total, £7 14s. At all events there is a  
difference of from 30s. to £2 10s. per ton in favour of Adelaide.

Do you not think that a weir of a few feet high to preserve navigation between the points of the railway  
would be of much greater advantage to the residents and producers than to allow the river to remain  
in its usual state? Certainly.

At present you have no certainty as to when produce can be sent away? By river there is no certainty;  
and not even locking would make it certain, because the river ceases to run at times. There is another  
point: there are a great many springs along this portion of the river, and my impression is that the Springs in the  
higher you raise the water by locking or damming the more the water will go away in the banks. If you  
sink a well on the banks while the river is up you will find that well will rise and fall with the river until a  
certain point, and then it will not rise and fall; it will give you a large supply below the level of the river.

Our evidence to-day has been that a well put down close to the river bank is not affected by the river? Wells.  
Wells vary. All wells are affected by a high river if they are close to the bank. After the river goes  
down to a certain point it ceases to affect the wells, and they give their own supply. All wells are  
not alike. There are some that depend entirely on the supply from the river, and there are some whose  
supplies are distinct from river water.

What distance is your run back from the Darling? From here to the corner of the run is 90 miles.

What is the area? A million acres.

How do you supply water to the stock in the back parts of the run? By tanks and wells.

Which do you find of the greatest service? Wells, if they can be got. No matter how large tanks are  
made in this part of the country, they are not reliable. One reason is, that you cannot make them deep.

If you go more than 9 feet you reach the salt water. You cannot make some more than 3 or 4 feet deep. Depth.  
Some you may sink 12 feet, but it is at a risk.

Have you not found that after the tanks have been constructed the sheep make the sides of the tank  
almost impervious? I have not found that. Tanks which do not hold at first never hold well. Some  
will hold fairly well from the beginning, and continue to do so.

What size do you make your tanks? From 10,000 to 20,000 cubic yards of excavation; but the capacity  
of the tank is much greater. It varies from 30,000 to 60,000 cubic yards. Capacity.

What time do you reckon to elapse after making a tank before you have it filled? We cannot give an  
average. I have known it to be twenty-three months.

Are they all full? Not now; they are fairly supplied.

What wells have you sunk here? Wells and bores, about 150 holes.

What depths are the wells? They vary from 40 to 720 feet. Wells.

Have you obtained fresh water? In some cases.

What was your experience with the 720-foot well? We sank the shaft 200 feet, and bored from that  
bottom; at 430 feet we got a small supply of fresh water; we continued to 720 feet, but got no more.

We had a succession of accidents, and just now it is impossible to proceed further with the work.

What has been the expense of boring, &c.? The actual expense of sinking the well has been little  
over the mere labour employed; the cost will be about £1,400 or £1,500.

Have you tubed the well? Yes, down to the water at 430 feet.

What means do you adopt for boring? The Chinese method in this well: percussion by drills hung from Means of boring.  
the end of a rope.

What other apparatus have you used? Wright and Edwards' boring machine, and the Pennsylvanian auger.

Have they turned out a success? The American has, as I can do faster work with that than with any  
other instrument.

To what depth have you bored? 600 feet. We do on an average about 50 feet a week. Depth.

Have you succeeded in striking water? Yes, at 600 feet. The supply at 100 feet is 10,000 gallons  
a day. If I pump from 300 feet I can get as much as I want. Water rises to within 7 feet of the surface.

It is almost an artesian well? Almost.

What was the width of the bore? 4 inches.

And the cost? The first cost was the cost of sinking a shaft 100 feet. Then we put 300 feet of the Cost.  
bore down by the old plan, and it cost between £600 and £700. It was nearly all through blue clay  
with layers of solid bluestone, exceedingly hard. When we put the American machine on we started at  
300 and went to 600 feet at a moderate cost.

Which is the machine best adapted to this dry country for tube wells? I use a combination. I use the  
American

- Mr. D. Brown. American with the rods attached as far as I can go. I have not been successful in boring from the surface, the difficulty being to keep the hole straight. I suppose this is due to my want of experience.
- 24 Sept., 1886. Have you had an experienced well-driller? Never.
- Have the Government put down any deep wells? Not in this neighbourhood.
- Do you know of any other wells deeper than the one you speak of? I know of no well as deep in this neighbourhood. We have another bore down to 600 ft. which gives a supply equal to about 3,000 gallons per day, but it is of no use. I am still boring at this place.
- In those wells which are not artesian, how do you raise the water to the surface? As a rule, by whim; I intend to apply steam.
- Windmills. Would not windmills answer the purpose? Windmills do not give a satisfactory result in my opinion unless the depth from which you require to raise the water is very small. Where the depth is not more than 100 ft. they are good. When you have to go lower you require such a heavy wind to drive the mill that you cannot rely upon it.
- Artesian water. Do you think that by boring 1,000 ft. artesian water could be obtained? Probably; that is, water which would rise to the surface. From my observation in the district I do not think it likely that a strong flow could be got at the surface. The flow appears to be fairly good at 200 or 300 ft. down, but decreases as it reaches the surface.
- Tube well-boring. You recommend for a permanent supply tube well-boring? Certainly.
- Do you think the Government should be advised to test the Paroo and western country as to artesian supply? That is a difficult question. For what purpose?
- Boring by Government. To test if there is a supply? If the Government were prepared to go 1,000 or 2,000 ft., and pass the comparative surface supplies which we have already proved, the experiment might be worth while.
- If water were discovered at that great depth, would the expense be too great? Probably too great for any benefit to be derived from it, because there is a limit to the expense to which you can go in order to supply water to stock.
- The Government have numerous tanks at Mount Browne and Silverton? Yes.
- Government tanks. Do you know whether any of them are permanent? The two Government tanks I know are not. They are made on the channel of the Paroo, and I have known both to be dry twice.
- Wells. Do you intend to carry on your well-sinking in preference to making tanks? If I spend any money at all in the way of water conservation I shall spend it on wells.
- Number of stock. What number of stock do you carry on this run? We average 150,000 sheep.
- On how many acres? 1,000,000 acres.
- Loss during drought. Have you any idea of your loss during the last drought? We lost 56,000 sheep in the season of 1883-84.
- The loss was made in 1884.
- Can anything be done to avert the fearful losses in stock? I do not think so, for this reason: if this country is stocked as against a bad season it will never pay to hold it. You must stock it as against an average season, but every now and then you get a bad season, which is so much worse than the average that you cannot avoid losses.
- Grass and herbage. Is it possible to reserve part of the run—are the grasses and herbage of such a character that you could keep a certain area of the country in reserve? There are three classes of feed which grow here. There is the winter herbage, and a grass which grows in October and November, if rain comes, and a grass which grows in March or April, if rain comes. Each of these lasts its own season, but no longer. The winter herbage perishes whether used or not, and then blows away; the October grass goes away in the summer; the March grass lasts till the winter, and disappears with the frost. It would do no good to reserve any country; and the only use in very lightly stocking would be to save the bushes, but the number of sheep which will live on the bushes is exceedingly small.
- Reserving country. What are the edible bushes? Nearly every bush that grows, with the exception of the turpentine.
- Hop-bush. What is your mainstay? Hop-bush. It is not feed for sheep in every part of the country, but it is feed for sheep here. I suppose it depends upon the constituent parts of the soil. Hop-bush will keep the sheep alive here, but will not fatten them.
- Rainfall. Have you kept a rain-gauge since you have been here? I have.
- What has been the average rainfall? From 1877 to 1885 it has been 12.92 inches per annum. The lowest yearly fall was 9.96 inches, and the highest 15.61 inches. This was at Kallara. I keep five gauges on this run; but the gauges away from the river agree nearly with the gauge at Goorimpa on the Paroo. Much more rain falls along the river than out back. I cannot account for the difference. The highest fall at Goorimpa has been 15.36 inches, and the lowest 5.22 inches, the average being 9.69 inches. I notice that the longer I keep the average for the months the more the months assimilate, and in fifteen or twenty years I think each month will have its own inches of rain for an average, or nearly so. (*Appendix to Report on Darling River, No. 9.*)
- You think the rain is being more equally distributed? There is no month in which you can be sure of getting much more than in another.
- Tropical rains. Was it not considered your rains fell after the tropical rains in Queensland? I do not think that will be borne out by statistics.
- Loss of sheep. You have lost 56,000 sheep here, was that through want of grass or want of water? Through both. There was one period here when for nineteen months 8.9 inches was the fall. That was during 1875, 1876, and 1877. This last time we had twenty-three months during which period not one inch of rain fell in twenty-four hours. That was during 1883 and 1884.
- Light rainfall. What do you consider is sufficient rainfall here in the year? It entirely depends on how the rains fall. The general falls are so slight that they do no good. Two hours afterwards you could not see them.
- What register of rain do you consider sufficient at one time? In winter an inch of rain is useful; in summer 2 inches are useful. Anything less than that is of no use if the ground is dry, as it generally is.
- What would be the yearly average that you think sufficient? It depends entirely on how the rain falls, and the season of the year when it falls. If it comes in 20 and 30 points at a time it is perfectly useless, as it is not sufficient to wet the ground or start the bushes or scrub.
- Do you think the seasons here are changing for the better? I do not. So far as I can learn from older residents than myself there is no change, and there is not likely to be any change.
- What is your average elevation here above sea-level? I cannot tell you; I suppose about 350 feet.
- Have

Have you tried any irrigation? No, except in the garden.

Had you to buy feed during the drought? I never bought feed. I could not do it. It would pay better to let the horses die than to buy food for them. None did die, however. We had 120 miles of carriage at £10, £15, or £20 a ton.

Would it not have been practicable to have grown sufficient feed to keep the sheep alive by pumping the water from the river? It would have been; but during the worst of the drought the river was not running; and if we had pumped the water from the river we would have dried our home water-supply.

If there were a permanent supply in the river, would you use the water for irrigation? I would not, because I consider it would cost less to import the feed from those places where it can be grown more cheaply and more favourably than here. If you irrigate and grow crops you must store them, so I consider it wiser to take advantage of such opportunities as present themselves to obtain feed at a reasonable rate and store it. You can do the work cheaper by buying feed than by growing it. That is my opinion.

You have never tried to preserve feed here by ensilage? Never; I do not think it would answer. It might answer to preserve a small quantity of feed for valuable stock, but certainly it would not pay to provide feed in that way for a considerable number of sheep.

But could you not grow feed here by irrigation more cheaply than bringing it here? For what purpose; for a few horses?

For working horses, cattle, &c.? No. It means raising the water 40 or 50 feet, and applying steam. It is more costly to do the work here than elsewhere.

*Mr. Gipps.*] What is the average depth of Peery Lake? I can scarcely answer that question correctly. I can only guess it at 9 feet perhaps.

I see by the map that there are some low ridges marked about 30 miles below Lake Peery; would they allow of the conservation of any water in the channel of the Paroo, towards Wilcannia? I should think not. There is a ridge behind Peery on one side, but the flooded course of the Paroo is on the left-hand side of these ridges. I know there is no considerable ridge within some miles of the ridge behind Peery.

Is there any difference in the strata of the wells sunk near the Darling and those sunk near the Paroo? To some extent. It has never been necessary to go to the same depth on the Darling as on the Paroo. There are no wells on the Darling below 70 or 80 feet that I know of.

What is the nearest well to the Darling? The nearest well is 22 miles, the nearest shaft 9 miles, on this run.

What is the depth of the 22-mile well? It is an artesian well, 140 feet deep.

Is it bored? Sunk and bored.

What depth was it sunk? That is beyond my knowledge, as it was sunk in 1864. I think it was sunk about 100 feet. I began to work at that shaft in 1878; it was filled up to within 70 feet from the surface. I sent a man down to clean it out, and he sent up sand and then big boulders of hard clay. He said the shaft was sound all the way up, which struck me as peculiar, because these lumps weighed several hundredweight when unbroken, and were surrounded by a sound shaft. Evidently this had been sent up the shaft by a burst of water much stronger than anything we were dealing with. The supply was about 500 gallons per day. After sinking as far as possible we started boring and got a considerable supply, equal to about 120,000 gallons per day. But a large quantity of sand came up with the water, and continually choked the bore. Now we have a small flow of clear water equal to 8 gallons a minute.

What was the character of the strata passed through from the surface? Impacted sand.

What was the surface of the soil? Clay-pan. Not far from it there is a mud spring.

Below the first stratum you came on sand, and then on heavy drift? The sand was coarse from the time the flow came. Sand and pebbles came up with the flow. We tried to sink to the rock, but could not, owing to the rush of water. The water ran 16 feet above the surface, and there was no perceptible diminution in the flow.

Is the flow increasing now or decreasing? I can get a strong flow at any time by pumping out the sand, but you cannot use the water until it settles. I have a bore inside the shaft and a bore outside, and I work the two in connection with each other. The bore inside the shaft flows 8 gallons a minute. I require say 20,000 gallons per day. I must supplement the flow, and therefore I bale from the shaft. This baling from the shaft draws the sand towards the bottom of the shaft, and in time the accumulation prevents a free flow of water, and I can no longer bale as much as I require. I then use the bore alongside, and by removing the sand accumulated in the pipe, start the flow in it; that flow draws the sand from the shaft and once more clears it, so by the time the strong artesian flow ceases I can again raise as much water as I require from the well. One acts upon the other. The bore, which is 8 or 10 yards from the well, when it is running draws the water from the well, and the well does the same to the bore.

What diameter is the bore? It is 4 inches.

Do you think by putting down a large bore you could get more water? I do not think it is possible to beat the drift.

How far distant from the Darling is the next well? We have another about 14 miles over. The flow decreases tremendously as you rise. The level does not appear to be the same. Although the flow at the surface is equal to 10 gallons per minute, the flow 3 feet up is less than 9 gallons per minute. It decreases rapidly, and there is no sand in it.

How far do the artesian wells continue from the Darling? These are the only artesian wells I have.

How far distant from the Darling have you tried? I have one bore about 65 miles out.

Is there any water in that? That is, the one down 720 feet.

What strata does the 720-foot well go through? Into black clay, and that black clay underlies the whole of this country. If you go down 150 feet you get into the same strata all through.

What is the rock above it? There is no rock; you may get a bit of ironstone, and in or through the black clay there is a sort of gray or blue rock in layers or in boulders, probably stratified.

What is the thickness of that strata? From an inch to 6 feet.

#### At Tankarooka.

Mr. E. J. Suttor examined:—

*Mr. Donkin.*] How long have you been in this district? Eight years.  
Have you lived here all the time? Here, and at Curranyalpa Station.

Mr.  
D. Brown.  
24 Sept., 1886.  
Feed in drought.  
Pumping.

Objection to  
irrigate.

Ensilage.

Low ridges on  
the Paroo.

Strata of wells.

Flow of well.

Black clay.

Mr.  
E. J. Suttor.  
Have  
24 Sept., 1886.

- Mr. E. J. Suttor. Have you had any experience in well-sinking? Yes, both on the river and out back.  
 Where did you sink the first well? About 10 feet from the bank of the river.  
 To what depth did you go? About 80 feet.  
 24 Sept., 1886. How much is that below the bed of the river? 40 feet. We did not obtain water, so we put a drive  
 Wells. into the river at the 40-foot level.  
 What is your experience here with regard to wells? The one at Tankarooka is about 40 feet deep, and has about 4 feet of water in it. It has no connection with the river. I have seen the river dry; but the same water has remained in the well.  
 Is there a rocky bar there? No.  
 What is your experience of the water out back? It is nearly all salt, hardly drinkable.  
 Is the water in this well near the river good? It is perfectly fresh, splendid water.  
 Is it discoloured in any way? Not in the least, except by the timber in the sides.  
 Flood. What is the difference between this flood and that of 1879? About 8 or 9 inches.  
 Judging from your experience, do you think a rise at Bourke corresponds with the rise here? I think so.  
 Does the river spread out here? It spreads out a good deal, but it is about the same level.  
 Has it been your experience that the wells have anything to do with the river? Yes.  
 Is this well about the same depth as the bed of the river? Yes.  
 How long do you think it will be before this flood goes down to summer level? Not before Christmas time.

WEDNESDAY, 29 SEPTEMBER, 1886.

At Wilcannia.

Present:—

Mr. DONKIN,

Mr. GIPPS.

Mr. Edward Quin, M.P., examined:—

- Mr. E. Quin, M.P. *Mr. Donkin.*] You are the Member of Parliament for the district? Yes.  
 How long have you been on the Darling? Twenty years.  
 29 Sept., 1886. Where was your first experience? Chiefly around Wilcannia and Menindie, and generally moving  
 Floods. about the Darling.  
 How many floods have you known in the Darling? The first flood I remember was in 1870. The flood of 1864-65 had just passed down before my arrival on the Darling. That was the largest flood ever known; but I did not see it.  
 After 1870, when was the next flood? I think the river was high from 1870 to 1873. After that we had the flood of 1879.  
 Was that flood higher than the 1870 flood? Not so high by several feet.  
 After the 1879 flood there comes the present one? Yes.  
 Highest flood. How do these floods compare one with another? The 1864-65 flood was the highest; then the 1870 and the present one. I recollect speaking to Mr. Green, of Menindie, in 1868; he had then been on the Darling nineteen years. He told me the 1864 flood was the largest he had seen, so that would be since 1849. He was a very observant man.  
 Do you know whether any record or permanent bench-mark has been kept showing the height of the 1864 flood? No; but I should imagine Mr. Woore would have more accurate information on that point. He was here then.  
 What height was the 1864 flood above the present? About 2 feet 6 inches. It was over the lower portion of the town of Wilcannia.  
 Had the flood entirely subsided in 1866 when you came? No. The river was in fair flood then, and the January rain of 1865 produced a local flood which rendered the river navigable to this place, but not beyond.  
 Cycle of floods. From your twenty years' experience here, have you come to any conclusion as to whether there is a cycle of floods? I cannot say that I have. I have heard men discussing the subject and speaking of a 3-years' cycle of floods, more or less large. In 1864 there was a fairly large flood; in 1867 there was a flood; in 1870, and in 1873, 1876, and 1879. It was predicted there would be a large flood in 1882, but it did not come, and so that theory was upset.  
 The Darling dry. Have you known the Darling to be dry for any length of time? I have camped in the bed of the Darling, in the Rocky Waterholes, about 45 miles from here.  
 What is the longest stretch of the river you have known to be dry? At that particular point it was dry for nearly half a mile, and then it would break into shallow waterholes, full of weeds.  
 Stoppage of navigation. Has this continued drought in the river impeded navigation to any great extent? Entirely so.  
 For what length of time have you known steamers to be laid up? Something like twenty months.  
 During that time, was it impossible to get produce away from here? Quite so. Twice during my experience here I have seen two clips of wool go down together. The 1868-69 clips went down together, and last year two clips went down.  
 In your knowledge, what has been the longest period that a clip of wool remained at Wilcannia? I should say about sixteen months.  
 Loss to producers. Has that caused loss to the producers? A very serious loss—the loss of a year's interest and deterioration in the character of the wool.  
 Rocky bars. Do you know many of the rocky bars in the river? I do not know very many, because I have not travelled up and down the bed of the river. I have generally travelled by road. I know one at Weinteriga, and one here, one at Murtee, and one at Curranyalpa. There may be others which I do not remember.  
 Is the one at Curranyalpa a natural one? Quite so.  
 Fall. Do you know what the fall is there? I cannot say positively. I should say something considerable.  
 It is reported to us as 3 feet? I should think it was fully that.  
 Are the rocky bars of the same character as the one at Brewarrina? Yes; but much more limited in size.  
 Weirs. From your knowledge of the river, do you think anything could be done in the way of a national undertaking towards locking the river or putting weirs across it? I think a great deal could be done. I think

think it would be very much better to erect weirs, so that they would throw the water back a limited distance. Mr. E. Quin,  
M.P.

What distance on an average would a weir 6 ft. in height throw the river back? I have heard the fall is 80 ft. between here and Menindie; if so, eight weirs would throw the river back to summer level at the extreme end. 29 Sept., 1886.

What is the distance from here to Menindie? 90 miles by land.

How does the river increase compared with the road? It is generally considered  $2\frac{1}{2}$  to 1.

That would make the distance from here to Menindie over 200 miles by river? Yes.

Do you think if a weir were erected on any of these rocky bars, and the water raised from 6 to 10 feet, that erosion of the banks would take place? I think so, unless you could form some artificial piers. I fear that the soil being so friable would completely wash away. Erosion of banks

Have the banks eroded at Curranyalpa and the other places? Not to any considerable extent, but that would not be likely, because they are so low that the river rises quickly.

As a national undertaking, what would you recommend at these places, locks or weirs? Locks, I should say. Locks.

Speaking from your knowledge of the producers on the river, do you think it would be sufficient for all purposes to give water communication between the railway termini, say Bourke and Wilcannia? I think if the people could get access to the termini of the railway that is all that would be required. Railway termini.

What would be the difference, approximately, between the carriage from here to South Australia down the Darling, and from here to Sydney in the event of the construction of a railway to Sydney? I think the difference would be very slight. The difference in the cost by rail would be more than counter-balanced by the great cost of insurance by river. Different rates of freight on wool.

Is there any certainty as to the despatch of wool from here? No certainty, except in a case like the present.

Would it be as expeditious as sending by rail? Not at all. Generally you have to wait until a steamer has 600 or 700 bales on board, but the railway would take away two drayloads in the trucks. There is another disadvantage in sending your wool by steamer. Adelaide is an open roadstead, and unless you put your wool in a small vessel you have to incur the expense of lightering it on board the "Orient" and such big steamers, which only remain in port a few hours. If you send to Sydney you have the best chance. I have known my wool to wait sixty days in Adelaide, and the ship to take 146 days to go home. If I had been able to send it by rail I could have shipped it on board at Sydney at once, and it would have been home in forty days. Advantages of Sydney as the port of shipment.

Do you know the large billabongs in the river? All of them, I think. Billabongs.

Would you enumerate those of the greatest magnitude in which you think any great body of water could be conserved? Of course the Great Ana-branch on the lower river is the largest, but I think the one coming in at Cultowa is almost equally important.

Do you know Lake Poopelloe? I have seen it, but I do not know it very intimately. I have never seen it with water in it.

Do you know the confluence of the Bogan and the Darling? I do, well.

Do you think it would be possible to divert the waters of the Bogan, and bring them down to Louth and the back country? I could not say that. I think it would be very desirable if water could be taken from the head-waters of the Darling and made to go with the Paroo and some of the other dry channels, but as to the cost I could not speak. Diversion into the Paroo.

Do you think the fall of the country would permit it? I think so. Fall of country

And would permit a canal from the Warrego to the Paroo? I think so. You may have a small range to cut through, but I think the water might be led right out into the back country.

Do you think there is any great amount of soakage in the river? Yes. I think there is soakage in all this country. The water percolates into the banks; and the climate has so great an effect on the soil that it opens it into great fissures. Soakage.

Is the Darling fed to any extent by local rains? I have never known an instance except in the 1865 flood. I have seen the Darling rise 17 feet at Menindie in one night from purely local rain. Local rains.

Has local rain had anything to do with the present flood? I do not think so.

Do you know of any large creeks from Brewarrina down running into the Darling? None except the Warrego.

You have had a good deal of experience, have you not, in constructing tanks and wells? Yes. Tanks and wells.

What do you consider the best form of construction for tanks, as to the depth and size? In this climate the larger the tank you can put down the better—say from 12,000 yards upwards. I do not think a tank below 10,000 yards is worth anything. You might have smaller tanks as auxiliaries, but not for supply.

What depth? As deep as you can go—say up to 18 feet. Depth.

Would a tank less than 10 feet last out a drought? It would not last six months with sheep drinking on it. They last longer if the water be pumped into troughing. The undulating character of the country at Tarella causes the water to rush down savagely. We have no source of supply such as a swamp for our tanks. The danger with us is the accumulation of silt. I have tanks 15 feet deep filled 12 feet with silt. The Bunker, which was a very good creek fifteen years ago, is now filled with silt in the larger holes level with the bank, and the water has not cut new holes to compensate for the ones silted up, but has spread over a large area, and formed three or four creeks. Silt.  
Bunker Creek.

From your experience, you consider the putting an embankment round a tank and pumping the water to be the most economical means? Certainly, because you get a very much larger body of water conserved within the banks.

Do you use troughing? I have found black iron troughing the most serviceable. Troughing.

How do you raise the water out of the tanks? I let stock drink direct from the tank, but many of my neighbours raise it by pumps, and in some cases by steam, but mostly by McComas' water-lifts. These are found to be the most serviceable, with the least expense.

What is the effect of evaporation on the tanks? I have observed it only in a rough way. I have noticed a tank go down 8 inches in a month without a sheep on it. Evaporation.

In depositing the spoil out of the tanks around the excavation, does that protect the water from the action of the wind? No doubt. I have seen tanks with an embankment raised 8 or 9 feet, and then a stub fence of 6 feet put on top of the embankment. You

- Mr. E. Quin, M.P. You have never tried the plan of covering in your tanks? No; I have thought of it seriously, but it would be too costly, the area is so large.
- 29 Sept., 1886. Since you have been a resident in this district, have you recorded the rainfall? Yes, most carefully. I think I have the record for fourteen years.
- Covering tanks. Was it generally recorded before that date? No; very little indeed. I have not all the details for the Rainfall. first three years.
- Average at Tarella. How many years is it since the rain-gauge came into general use here? About twelve or fourteen years. What do you make the average? I think ours is a little over 10 inches with last year's record. But last year's was an abnormally high one. It was 19 inches; 11 inches of it we had in three days, and of that 11 inches we had not a drop 30 miles beyond the station.
- Where are you speaking of now? Tarella, which is 50 miles from here.
- From which quarter do you look for the most beneficial rains? Generally east and north-east.
- Was that information you have just stated with regard to the 11 inches communicated to the Government Astronomer? Yes.
- Tropical rains. Do you not look for the southern tropical rains in Queensland to extend down? No. We occasionally get them, but it often rains 200 or 300 miles north of us and we do not get a drop. The general opinion is that we are too far north for the coast rains, and too far south for the tropical rains. We are in fact in the driest patch in Australia.
- Was it possible to occupy this back country before water was conserved? Perfectly impossible, except where there was permanent natural water.
- Extent of water-less country. Taking a line east from Wilcannia, what distance of country is there without natural water? I should say there was no permanent water till you got to the Lachlan, about 200 or 300 miles. What distance west? There are no rivers west until you get to the river Bulloo, in Queensland, over 300 miles. There are one or two very good holes, such as the Yancannia, and some springs on the Paroo and Peery Lake, which are always permanent. There are one or two waterholes which have never been actually dry, such as the Yancannia.
- With the exception of the Lachlan and the Bulloo and, I suppose, the Bogan, there is absolutely no actual water? None, except the Darling.
- Wells. What is your experience with regard to wells? Very peculiar and varied. I have a well 50 feet deep with a fairly good supply. I have another, 400 feet, with only water enough for eight or ten horses. Artesian supply? No.
- Do you know of any artesian water having been found? Nothing lower down than Kallara. I think from Kallara up there is more or less a large number of springs right into Queensland.
- Mud springs. Do you call them mud springs? Mud and other springs. Peery is not a mud spring. There are mud springs round it, but the main spring is not a mud spring. Do you prefer wells or tanks as to certainty? If there is the slightest chance of getting water sufficiently good to use I should prefer wells at a much greater cost.
- Government bores. Have the Government bored to any depth out here? They have a bore at Silverton and one 10 miles from here, down 260 feet. The Government party have removed through want of success. They have not bored to over a depth of 1,000 feet? Not to 500, that I know of. Do you think it would be advisable to test this part of the country with deep bores as to the possibility of an artesian supply? I think it would be very desirable. It would enhance the value of the country considerably.
- Deep borings. You know that in Queensland they are boring to 2,500 feet? Yes. I know that in South Australia they found an artesian supply at over 1,200 feet. I think advantage might be taken of what the squatters have done in this district in putting down bores 400 or 500 feet. Let the Government continue from that depth, and make a sort of open contract, the squatter to pay something towards the expenses if water be found, and if no water be found the Government to pay the cost. Do you think it would make it a greater certainty in carrying on pastoral industry if the Government discovered that artesian water could be found here? I think so.
- Cost of boring. What has been the average expense of boring your deep wells? I have paid up to £3 a foot for boring, and the men have knocked off work because they said it did not pay. Do you know the cost to the Government? I could not say. Something considerable, I should think.
- Diamond drill. The diamond drill is perfectly unworkable here unless you cart water for it. Have you noticed any great surface soakage from the overflow of the Darling? No.
- Underground supply. Do you think there is any body of water which escapes in these floods to supplement an underground supply? I have noticed a great soakage in some creeks, such as the Bunker, but not in the Darling. I have seen the stream half a mile wide empty itself on a plain, and all the water is lost almost immediately.
- Dams and tanks. I think you said that on the creek on your run you had constructed dams. I suppose you mean dams and tanks combined? In some cases. Have you any safeguard in constructing these? You can construct them to stop the water, but in all cases where I have constructed a dam the creek has run round the edge of the dam and formed a greater channel. But we have no safeguard against our neighbours. We are liable to action at any time. Do you know of any case in the district where water conservation has been objected to? Quite recently there was a case in Sydney. A Mr. Parker, of the Buckalow blocks, brought an action against a Mr. M'Gregor. Mr. M'Gregor had to pay the enormous law costs, which amounted to about £1,700, and was told he had no right to stop the water.
- Legal risks in conserving water. Was it a running stream? No; simply a depression which he created into a resting-place for water by making large drains for miles. No water had ever been known to go down this hollow. If he had not done this artificially, would the watercourse have supplied the water? It would not have been of the least benefit to the men below.
- Parker v. M'Gregor. His action did not absolutely deprive the lower run of water? I do not think it did in the least. I do not think water would have run through if he had not drained the country for miles around. I know many similar cases where water has not been known to run until drains were made. That is to be seen where there are roads. The roads have cut into deep ruts which cause a larger body of water to run, and the ruts form into small creeks.
- Surface flow increased. Mr. Gipps.] What is the position of your run as regards its direction and distance from Wilcannia? About 50 miles north-west. It

It is situated on the right bank of the Darling River? Yes.

What distance from the Darling? About 40 miles in a straight line.

And what distance from the left bank of the Paroo? About 40 miles.

What is the general character of the country? Sandstone, volcanic, and quartz.

Rolling country? Yes.

With plains? Yes.

Are there any large creeks on it? There is one creek, called the Bunker.

Any considerable watershed? Yes, a very considerable watershed. The water rises rapidly after rains. It may be dry now and rise quickly.

It has a great fall? Yes.

Where does it empty? Into Copago Lake.

Does it fill Copago Lake? I do not think it adds seriously to Copago Lake, except in high floods. It is much exhausted by soakage before reaching the lake.

What is the character of its bed? About 5 or 6 feet below the ordinary country.

And the depth of its banks? Varying from a foot to 10 feet.

Is it a wide creek? As wide as this room generally. In some cases it spreads a quarter of a mile in little bits of gutters.

Have you any dams on it? I have ten or twelve, and several were washed away.

Do these dams throw back the water to any distance? The dam that throws it the farthest is on the extreme boundary; it throws it back about  $1\frac{1}{2}$  miles, but the dam is useless, being completely silted up.

What is the height of that dam? I suppose 20 feet from the bed of the creek?

When was it constructed? It was commenced about ten years ago, but it has been more or less repaired since.

Was it an earthen bank? Yes, and the water was thrown over the plains.

What is the character of the soil? Almost pure sand.

The bed of the creek has entirely filled in ten years? Not entirely, but within 100 or 150 yards it is quite level with the creek.

Have the other dams been similarly affected? In some cases. One broke in the centre and washed away.

By having flood-gates in the dam you would be able to clear the creek? I think if they could be constructed economically and firmly you would be able to do so, but the soil is so porous there is a great danger of the embankment washing away.

What is the character of the watershed of that creek with regard to its rocks? Volcanic chiefly, I think, and old sandstone.

Are the volcanic rocks exposed? The ranges seem to be broken up into little conical hills of extraordinary and fantastic shapes.

Does each cone seem to be surrounded by volcanic tuff? There is no evidence.

What makes you think it is volcanic? Simply because men who profess to understand it say so. I see no sign of scoriae or lava. The only thing which resembles lava is found 5 or 6 inches under the surface, and we call it cement. It is a conglomerate, having little quartz pebbles in it. That might be lava perhaps.

You have not discovered any fossils? Not here. The nearest fossils I have known of have been at Dunlop. Some fossils were discovered in Peery Spring by Mr. Bonney, but he sent them home to Cambridge.

Do you know where the silurian or old rocks first make their appearance; do they intrude in that country? I could not say; I do not think so.

How many wells have you sunk on your run? Fifteen.

What natural features in the country induced you to sink these wells? What first induced me was my finding a shaft on Tarella, when I first went there, on the bank of the creek. It had been put down by the former proprietor. That is the shallowest well on the ground, water having been obtained at 53 feet. That induced me to sink other wells in the same valley. I sank a well 2 miles below that and got water at 80 feet. At 5 miles above it I sank 270 feet and got a limited supply in hard basalt.

What was the character of the strata in the 53-foot well? Soil for about 12 feet, then white sandstone.

The sand appeared to be like what is called baked sand. We found the water in the solid sandstone.

And the second well, at 80 feet? Not such pure sandstone; more of a rotten slate and sand mixed—very jointy. The water was obtained in a red sort of slate. It is very jointy, and has a gritty feel.

And the third well? It had slate, alluvial, baked sand, and stones for 200 feet, and then bluestone continued till we got to 270 feet. At this stage we found the work too costly to go on with it.

What was the character of the bluestone;—was it in veins? Quartz veins occasionally, from which we got water. That induced me to drive in a northerly and southerly direction, 100 feet each way. It increased our supply, but very slightly.

What is the character of the bluestone—is it slaty? Very hard indeed; very difficult to work except by dynamite or powder.

Did the hardness induce you to give up sinking? Yes, and the costliness. There is sufficient water at that depth to make it troublesome. The only means I have to get the water out is by whim.

Did the water in the creek seem to affect the level of the water in the wells? Not the slightest.

What was the character of the water in the first well? Slightly salt. So salt that if you carried it in a water-bag you would find the salt exuding from the bag.

You can drink it? I have lived on it, but it acts as a strong aperient.

Can you lower the water in the well? Yes; but the well fills again.

Drawing does not affect the character of the water? No; after the first water has been taken out the water is just as good the first day as in six months.

The second well? The water was better, but just a little hard.

Is there a large supply? Yes, but we can reduce it. We once exhausted it so much that we could not water any sheep. We put men in and extended the drive from 80 to 132 feet, and that increased the supply largely.

How do you keep the drives from falling in? We put in head timbers and uprights, but the stone is solid enough to stand without timbering. Where it is shook by the shooting we put in a head-piece of timber to sustain it.

Mr.  
E. Quin, M.P.  
29 Sept., 1886.  
Character of  
country.

Bunker Creek.

Dams.

Soil.

Dams washed  
away.

Flood-gates.

Volcanic rocks.

Cement.

Fossils.

Wells.

Strata.

Costliness of  
sinking.

Character of  
water.

Timbering the  
drives.

What

Mr. E. Quin, M.P. What was the character of the water in the third well? Fairly good. Quite good enough to drink, but very hard to wash with.

29 Sept., 1886. Could you give us a short report on these different wells, showing the position on the map of each well? I could. Mr. Orr has them all plotted out.

Rainfall. Does the rain fall as a general rule in heavy storms, or is it light and continuous? It is very erratic. One year the rainfall is very considerable, perhaps 4 or 5 inches in one month, but that year may not reach the average of the previous year. I recollect from June, 1883, to June, 1884, we had not a fall exceeding 40 points.

Winds. Then it falls lightly? Yes; and it is not of much benefit. In many cases we have 7 or 8 inches of rain, and perhaps not 1 inch in one fall. What are the prevailing winds? Southerly.

Windmills. Summer and winter? Yes. Are they sufficiently strong and continuous to allow of the use of windmills? I think so. Windmills do not seem to be much in favour in this country, because they are such a precarious means of raising the water. They might work for some time, and then perhaps fail you. I think they would be valuable as auxiliaries.

Evaporation. You say the evaporation in one of your tanks was equal to 8 inches a month? Yes. Do you not think that soakage accounted for some of it? Perhaps so, and the waves and the wash. The water went down 8 inches.

Paroo River. Does much silt come down the Paroo River? I could not say. Have you ever seen the Paroo River running through? I have not seen it running through, but I have seen the waters of the two rivers meet.

Silt. Is there any silt in the Darling? I should say there are large quantities of it. It would not be advisable to erect permanent dams? I should say not. My experience is that permanent dams are not advisable anywhere, on account of the silt.

Dews. Are there any dews in your part of the country? Very little indeed. I have seen some very good ones. Did you notice what winds the dews came with? I did not. Did they come at any regular time of the year? No; I have seen all winter pass almost without any dew. Do they appear to be in any way dependent on the rainfall on other parts of the country? I think so. Whenever the Darling is in high flood I have noticed our rains are better, and we are more liable to thunderstorms. This year we have had several thunderstorms; when the Darling was low we had none. Can you give us any information on the lakes on the Paroo? Of course I know these lakes, but there are other persons who could give you better information.

Soil. Is the soil, as a general rule, permeable or impermeable? I should say it is very porous in many cases. Over the whole run? No. Some of the lakes are hard clay-pans, very hard indeed, and glistening, but the outer edge of them becomes very dry and friable, with large cracks.

Irrigation. Have you any large depressions on your run? None on my run, except the ordinary valleys. *Mr. Donkin.*] Have you had any experience in irrigation or seen it carried out? I know an instance at Tapio, near Wentworth. What area is irrigated? They have about 40 acres, and they are supplying the water with a 12-horse-power engine and the usual scheme of canals. Is the lift great? About 25 to 30 feet when I saw it. What year? In 1885. Was that the first year they had it in work? I think they started it previously, but the crop looked very poor; but I think they have had a very good crop since. They would not have had any crop without irrigation, not a blade. Have you seen irrigation carried out at any other station on the river? I know it has been carried out at Winbar, but I have never seen it. They have made it so far a success that they will continue? I could not say that. Of course the lift was very great then? No; the pump would be under water now. You know from your experience that the natural irrigation by flood-waters is a very great boon to the district? Yes; water anywhere is a boon to the district. I think if the water in all the lakes were conserved it would soften the climate exceedingly.

Soil. *Mr. Gipps.*] In regard to the soil, do you think it is sufficiently rich to grow vegetation? I think so, if irrigated. I have seen gardens on all kinds of soil in different positions, and they all grow well if watered freely. I have seen all kinds of vegetables and fruit grown. At Albemarle and Tintinallong you will see a garden on black soil. At Moorara you will see a garden on a sand patch.

Advantages of reaping lakes nil. *Mr. Donkin.*] Speaking of the lakes which are close to the river, which plan, as a national undertaking, would produce the greatest benefit, to retain the water for stock and irrigation, or simply to allow it to run off for the sake of the grass and herbage in the bed? I should say to retain the water. If you do that it is possible for people to live on the banks of the lakes. The little feed that is now got off it is merely temporary. It would die off in three months, but the water might be kept for three years. The balance of the banks could be irrigated from the lake if the water were impounded.

River gauges. With regard to the floods in the Darling, which you have known for the last twenty years, is there any authenticated zero by which flood-level is read;—is it read from the bed of the river, or summer level or navigation level? I recollect a gauge was put up about ten years ago, but up to that time we had no authentic gauge.

Misleading records. You are aware there is a good deal of difference of opinion as to summer level—at Bourke they take it at 6 feet from the bed, and at Louth from the bed;—is not the information wired down the river therefore very misleading? Very misleading. I think the standard level should be the maximum height of the flood, and readings should be taken from below that. I should take the 1864 flood as the highest. Do you not think that the present flood would be better known, as there is a larger population now? I dare say. A great many who were here in 1864 are now away.

Mr.

## EVIDENCE TAKEN ON DARLING RIVER.

Mr. Charles Hebden examined:—

*Mr. Donkin.*] You are manager of Wanaaring Station, on the Paroo? Yes.

Is there a township on your run? Yes, Wanaaring township.

How many years have you been on the Paroo? Five and a half.

Will you enumerate the floods that have occurred in the river since you have been there? I think the river runs every year as a rule, and that there have been three big floods since I have been there. The first flood was in February, 1882.

Which was the highest flood? The beginning of 1882 and the beginning of 1886.

Has the water kept up in the river since the beginning of this year? Oh, no.

The present flood is another one? Yes; the present flood is 6 inches lower than the one in January.

Is the Paroo a defined channel? In some places it is a well-defined channel. It is always well defined between the banks, which are sandhills. As a rule it is a big flat with channels cut in it. Paroo River.Is the fall very slight in the river? I believe it is. Falls.

Is it equal to the Darling? I could not say, but I think it is more than the Darling.

Are there any large permanent deep waterholes on the Paroo? I only know of one by hearsay, and that is up in Queensland. There is one on Nocolleche which is said to be permanent. There are others which have been made permanent by dams. Waterholes.

Was the river considered permanent before dams were erected on it? No. The waterhole in Queensland was perhaps the only permanent waterhole. That is the Caiwarro. The one on Nocolleche might be reckoned permanent without a dam.

What method do they adopt for damming the river? They just look out for a spot where there are two banks, which is sometimes hard to find, and then put a clay bank across. Dams.

They do not use overshot dams? No.

Do the banks cut away in floods? As a rule there are very good by-washes, clay-pans. The Paroo itself is almost a very long clay-pan, and between the banks it will run out about a mile up. By-washes.

The river does not form another channel through the obstruction? Not as a rule.

Do you know the river right down to the Darling? No; I know it right down to where it is not a river.

Where does it run into? Into Lake Tongo, I think.

And one or two other lakes? After that, yes.

Do you think the water of the Paroo, since 1882, has ever joined the Darling? This is the first time it has ever joined, and it is only now running into a lake that the Darling is running into. It has gone into Lake Peery, but there is more Darling water there than Paroo water. Junction of Paroo and Darling waters.

How far is Lake Peery from the Darling? It is about 60 miles from Wilcannia.

From your experience, the flood-waters of the Paroo do not augment the Darling? No; I do not think so. This year a great deal of water has come down the Paroo which is not really Paroo water. A great deal of Warrego water came down it.

Which is the biggest flood on record on the Paroo? I do not know.

You were saying the waters of the Warrego ran into the Paroo;—by what channel was it? By the Cuttaburra. The Cuttaburra runs out from the Warrego in Queensland, and runs into the Paroo at Goorimpe, which is about 120 miles from here. The Cuttaburra is a very good creek where it runs out of the Warrego. The Cuttaburra.

By damming, would it be possible to divert the water right across the back country into the Paroo? Yes, it would.

Is there a large body of water coming down the Cuttaburra? There are a great many channels to it. I crossed it the other day, and it was from 4 to 6 feet deep, running in a slow stream. There is one channel about 200 yards wide, and another 150 yards wide.

What is the distance of the Cuttaburra water? From the time it leaves the Warrego till it goes into the Paroo is about 150 miles.

Do you know any parts of the river or any depressions where a large body of water could be conserved in the Paroo? Not besides those where there are the ordinary dams.

Is there any depth of water in the lakes you spoke of? No depth, but the water lasts a long time. Tongo Lake does not often get filled. Tongo Lake.

What depth of water is there now? 9 or 10 feet, I think.

What is the size of the largest lake, approximately? I think Peery is the largest. Peery Lake.

Have you seen that during the flood? I saw it in the distance. The coach road has been across it for fifteen years, I think. This year the coach had to go round.

Is it 3 or 4 miles across? Quite that, and a great deal longer than that. The coach used to go through it for about 6 miles. The length must be about 10 miles.

Would it be a difficult matter to dam the outlet: I suppose when the Darling falls the water would run out? If it were dammed the water would never go into it.

Would it be an undertaking of any magnitude? I think so.

Does the Paroo in flood extend to any distance over the river banks? Not far anywhere until you come to Nocolleche.

Do you derive any great benefit from the flooding of the country? No. The flood sometimes gets to be about a mile wide with us, but never more than that. We cannot grow anything on the clay-pans; it is not a grass country.

Do you think there is any great amount of soakage from the Paroo? I do not think so; it is very good bottom. Soakage from Paroo

With the exception of impounding water in those large lakes you spoke of, you think nothing more could be done with the Paroo? I do not think you could impound any water in them that does not stay. It only goes to Lake Peery once in ten or fifteen years.

Supposing a weir were put across the mouth of the Tongo Lake, how long would the present supply of water last? Three years very likely. It would only fill up once in five, six, seven, or eight years, because it does not run past Tongo. Weir on Tongo Lake.Have you recorded the rainfall? I have always kept a record of it. Rainfall.

What do you make the average? About 12 or 13 inches.

For pastoral purposes, is an average rainfall of 12 inches sufficient? It depends on how it falls; 12 inches is sufficient if it falls nicely.

- Mr. C. Hebden. What quantity of rain do you consider sufficient at any one time to be of service for the growth of grass and herbage? If the grass is growing half an inch is very good; but if half an inch comes by itself it is no good.
- 29 Sept., 1886. What in time of drought? From 2 to 3 inches.
- Loss of sheep. Any small fall such as 30 or 40 points is no good? It is almost thrown away.
- Have you had many losses in stock during the late drought? We lost about 10,000 sheep in 1883 and the beginning of 1884.
- Was that loss from want of water or want of grass? From both. If there had been plenty of water in the Paroo we would not have lost so many; we had twenty-one men cutting scrub for them.
- Feeding on scrub. With plenty of water, would the stock exist on scrub through a time of drought? If they get plenty of it cut for them they will. They would last six months on no grass at all.
- What sort of scrub? Mulga is the only one that is much good. We cut down emu-bush and white-wood.
- Dams. Have you constructed any dams on the Paroo? There are some on the run.
- What amount of earthwork? One little dam is 1,000 yards. From that they go up to 6,000 or 9,000 yards.
- Legality of dams. Has the legality of constructing these dams ever been questioned? We have had no difficulty.
- Is it generally recognised as a rule that there is sufficient security in constructing dams across the river? Well, I do not know. I have heard of one man down below saying it was a shame that the people up above should stop the water. I have known the water come on to the run above us without coming on to us.
- Has the want of legislation prevented you from carrying out any further improvements? The want of legalising these dams has not.
- Tanks. How do you provide water to the back country? By tanks. We put down one well, but we never completed it.
- What size of tanks do you consider sufficient to carry through droughts? I do not approve of very big tanks. I like them of 6,000 to 8,000 yards, with a depth of 12 feet.
- Will that size stand evaporation and draining by stock? I think so.
- Had you any tanks dry in the last drought of 1884? Yes. I do not mean to say that an 8,000-yard tank is as good as a 16,000-yard tank, but I would rather have two at 8,000 than one at 16,000.
- Wells. You spoke of wells—have you had any success in obtaining fresh water? No; we have one well which we sunk to 200 feet, and then bored for 170.
- Did you obtain water? We got water at about 40 or 50 feet.
- What do you rely upon, wells or tanks? Tanks.
- Advantage of tanks. That is, if you should carry out fresh improvements for water conservation you would prefer tanks? Certainly.
- Have you known any deep wells in the district whereby they obtain an artesian supply? Not an artesian supply.
- Artesian water. Do you think it is possible to obtain artesian water if you bore deep enough? I do not think it is, except where there are springs.
- Have you any mud springs on the run? No.
- Have you recorded the evaporation on the Paroo? No.
- Do you know what effect it has on the tanks? No. The water there being opaque is not affected so much by the sun's rays. The sun does not penetrate to any distance.
- Irrigation. Have you tried irrigation at all? We have only irrigated a cultivation paddock of 6 or 7 acres.
- When did you commence? About three years ago.
- What was the crop? Wheat for hay.
- Has it been successful? We got a crop, but not a very good one.
- Have you a crop this year? Yes. We have not irrigated this year, because we have had sufficient rain.
- From an economical point of view, do you think it is a success in producing feed for station purposes? I do not think it is.
- What was your crop? I have no idea; it was a poor crop.
- Without irrigation, would you have obtained any crop at all? We should not have had any at all; but we could have had the same amount of hay carried to us for less money than the cost of sowing, &c., unless the carriage were very expensive.
- Mr. Gipps.] What distance is your run from the junction of the Paroo and Darling? I do not think they join at all. If they join Peery Lake, we are about 110 miles from there—that is, Peery Lake.
- Nature of country. What are the natural features of the country? It is undulating, sandy country, very scrubby, with some stony high ground.
- What is the general character of the soil? Sand, decidedly.
- Red sand? Yes. There is some hard ground with a good deal of sand in it.
- Any rocks exposed? There are big stones exposed in some parts west of the Paroo.
- What is the nature of the stone? I do not know. A lot of the surface stones are quartz.
- Are there any rocky bars in the Paroo? No.
- Are there any steep banks—is there a confined channel? There is no confined channel anywhere.
- Tongo Lake. What lakes can you give any information on? Tongo is about the only one, and I cannot say much about that, as unfortunately I only saw it when travelling.
- What is the length of the Tongo Lake? I do not know that, it has so many arms to it. Perhaps you would get arms about 10 miles long.
- And the breadth? Two or three miles.
- The depth? Seven or eight feet when it is full.
- And how is it supplied? From the Paroo itself.
- Does the Paroo run in a channel into it? It runs in a channel close to it.
- Does the water run out from it in any direction? Yes, into Yantabangie Lake, and then into Lake Peery.
- Is it a direct channel? It covers a lot of flat ground, and then runs in.
- By a low embankment, could it be conserved in the lake? Yes, except that it is so very few years it can be conserved, because it gets quite filled so very seldom.

What

What is the character of the watershed of the lake—is it low sandhills? The sandhills are round it. Is that the only lake you can give us positive information on? I know Lake Peery from going through it. I have been across Lake Yantabangie in the coach.

Lake Peery is very similar to Tongo? Yes.

Supplied in the same way? Yes. It is supplied by the overflow of the Darling as well.

When the Darling falls, does the water in Peery Lake drain back into it? I do not know.

Are there any creeks on your run? None worthy of the name of creek except the Cuttaburra, which goes through part of the run. This is the first year it has run since I have been there.

Has the Cuttaburra any distinct channel? It has a great many distinct channels.

Does it expose rocks in any part of its channel? No. There are no stones about it at all.

Does the Paroo bring down much silt? No.

You mentioned having constructed dams, do they impound water on the Paroo? Yes, on the channel of the Paroo.

What is the height of the highest dam? The highest we have from the bed of the creek I suppose would be 12 feet.

How far back does that throw the water? When it is full it throws the water back about 2 miles in a straight direction.

What width? About 100 yards.

Does that show any signs of silting up? I do not think it does, but it is hard to tell. We cannot see that it is silting up. The 12-foot dam does not impound 12 feet of water. When the water comes down after flood and goes round the by-wash there is 6 feet of the dam exposed.

How long will the sheet of water last? About eighteen months.

Without any rain? Yes.

What is your rainfall? 12 inches.

Does the rain fall in heavy storms? Storms.

Have you any dews? This last winter we have had.

What do you think they depend on? I think the rain. If it is a wet winter we have plenty of dew; if there is no rain we have no dew.

Do the dews last any time? This time we had pretty heavy dews for about two months.

Are they sufficiently heavy to encourage the growth of grass? Yes. This year they have been very good.

What are the prevailing winds? South-west, I think.

Are they pretty constant summer and winter? I think spring and autumn are about the windiest times.

High winds in spring? Yes.

What waterhole did you pump from? From a billabong that runs out of the Paroo and into it again.

Does that provide a continuous supply? I have known it dry.

What is the character of the pump? A McComas, worked by horse-power.

What is the position of the well you spoke of? It is about 12 miles almost due west of Wanaaring township.

What is the character of the strata? The principal thing was a sort of soft blue slate.

Any veins in the slate? No, very little veins in it.

And the boring, was that the same? About the same. There were stones down below and a few pebbles.

At the bottom of the core, did you get stones? Not at the bottom, but about 200 feet down we got a few stones.

What kind of water? Very good water. The water came in at 40 or 50 feet down in a small supply, and we never got any more after it.

What made you stop boring? Because the machine got fast. There are some wells in the district which go down deep and get pretty good supplies, and some that go deep but do not get supplies. It would be cheaper to sink tanks.

What do the tanks cost you, as a general rule? From £300 to £400.

And they would be sufficient to last you through a drought? If we keep enough of them. As a rule, when there is a good rainfall we pump into them.

What is the ordinary capacity of those tanks? They are 6,000- or 8,000-yard tanks.

What area of ground would they suffice for? I reckon a tank requires about 2 yards to a sheep.

*Mr. Donkin.*] Did you give us the cost of boring per foot? I could not give it very well. We never made up the cost exactly.

Is there any information you could give us that we have omitted to question you on? No. I could tell you about the wells on some of the other stations.

Have they been a success? Some of them. There is one up to 620 feet.

What is the general experience, do the squatters prefer to depend on tanks? They like to have the wells. We suppose the Paroo to be permanent, but out back they have no permanent surface water. On Urisino they have two good wells, but the manager says he will not put down any more.

On Tinapagee Station, which adjoins you, did they not depend last drought on their wells for stock? They have only one well there, and they can only reckon on 4,000 gallons a day from that. I think they have some mud springs out back, but they are no good.

From your experience, could you suggest any scheme which could be carried out as a national undertaking to conserve water? Not on the Paroo. There is not enough water in the first place.

Do you think the Government should test that country for deep wells? They are doing so. They have been trying to get water for us on the road from Bourke to Wanaaring for four years, and have not succeeded.

What depth have they gone to? About 500 feet.

They have obtained no permanent supply? The only supply they have got is at Goonery, where there was a supply before.

Mr. J. W. Brougham examined:—

*Mr. Donkin.*] Your station is Outer Netallie? Yes.  
How far is it from Wilcannia? 9 miles.  
Have you been long in this district? Thirteen years. I have resided here the whole time.

Mr.  
C. Hebden.  
29 Sept., 1886.  
Lake Peery.

The Cuttaburra.

Water.

Cost of tanks.

Wells.

Preference for wells.

National scheme.

Mr. J. W.  
Brougham.  
29 Sept., 1886.

- Mr. J. W. Brougham. Is your country entirely dry? It was when we occupied it. There was no permanent natural water. Does the flood-water of the Darling find its way into Lake Woytchugga? Yes, that is on our run. Is there any outlet from Lake Woytchugga going further south-west? Not that I know of.
- 29 Sept., 1886. Lake Woytchugga. If the water in Lake Woytchugga, were impounded, could it be diverted and taken into the interior? Not south-west, I think. Have you known the lake to be filled in previous years? I think this is the fifth time it has been filled since I have been here.
- Dam. How long does the water last there? It will last there now about twelve months before it is quite dry. I have dammed it once or twice; then it has lasted a good bit longer. I have just put a temporary dam across.
- Cost. What did it cost you? At the outside, £10. What depth of water would that keep in? About 2 feet at the greatest depth. That would last how long? Once it lasted nearly two years. What is the depth in the centre of the lake now? I measured it a week ago and there were just 10 feet. Could that be easily impounded? Very easily.
- Flood-gates. Would it be sufficient to put flood-gates at the bridge to impound it? I think so. Suppose it were impounded now, how long would the water last? About four years if dammed at its present level. Of what use would be the water? For irrigation. You have not tried irrigation? No.
- Diversion to Culpaulin. You do not think it is possible to divert the water from Lake Woytchugga to Culpaulin? Yes; I do think it may be diverted south, but not south-west. Is there a channel there? There is a chain of lakes going down there. What do you think would be the approximate cost of impounding the water by putting flood-gates at the bridge? I could not estimate that, because I have never seen flood-gates.
- Cost of dam. Well, with earthwork? I consider £100 would make a really good dam. I would do it for £100. If the water were impounded, how far could it be taken to the back country down south? I think it would go right past Culpaulin to what they call the Basin.
- The Basin. How far is the Basin from here? It is called 10 miles below Culpaulin, and Culpaulin is 19 miles from here. How far is the Basin from the river? Between 6 and 7 miles. Have you known in any of the high floods the water to have found its way through the lignum channel? Once; that was in 1873. Then it would not be a very expensive work to form a channel? I do not think it would.
- Depth of lake. How much higher have you known the lake than it is at present? About a foot higher. In what flood was that? In 1879 or 1880. How many thousand acres in extent do you roughly gauge the present water in the lake? I could not tell you. We reckon it about  $1\frac{3}{4}$  miles across it. Are there 4,000 acres under water? Fully.
- Wells. How do you supply your stock with water? Chiefly by wells. Do you find them more permanent and economical than tanks? I do. What depth are they? Our shallowest is 80 feet, and the deepest 200. Of course they are bored deeper than that. We have bores in several of them. We have nine wells on Netallie (that is the back country), and four of them are successful.
- Cost of sinking. What does it cost you to sink? They are all alluvial on the frontage block. I should say about £2 5s. a foot on an average, timbering and sinking. Have you tried boring and tubing? Yes.
- Artesian supply. Does that answer? It has answered with me very well. We put a 5-inch bore in both of two wells. Have you discovered a flowing well, an artesian supply? No. How do you raise the water? By whims.
- Tanks. Have you any tanks? Some; the ground is too porous. When we get down about 8 or 9 feet we come to a fine drift. Is there any possibility of your irrigating any amount for cultivation? No; we have not enough water.
- Carting water. Did you suffer in the drought from want of water? No; but I had to cart fresh water from Wilcannia, the water on the station not being fit to drink. How many miles? Nine miles to the head station, and then it had to be carted out back.
- Loss of stock. Have you any idea as to your loss of stock in the drought? We had not much loss. The loss you had, was it from want of water or want of feed? Want of feed.
- Spelling the run. Is it possible to avert the loss by spelling the run? I think it is. If you can spell the run, and had area enough, no doubt it would recover again. In times of drought you have to place so many sheep in one paddock, or on one well, that all the feed is eaten down. If you had plenty of water, do you think you could make pastoral industry a certainty? I think so. What do you look to for pasture, herbage or grass? Herbage and scrub.
- Carting water. None of the water you have obtained has been fit for domestic purposes? None. 12653. What is the greatest distance you have had to cart water for domestic purposes? 25 miles. How often have you had to do that? Three summers. How often, once a week? Sometimes twice a week. Is there any means by which you could prevent that? If I could make my tanks sufficiently deep I could do so, but I cannot get down beyond a certain depth; I come to fine silt. What is the area of your run? 96,000 acres, the one close here. How many acres do you allow to a sheep? About 8 acres. How much would you have to keep in reserve to tide you over a drought? About a quarter of it.
- Herbage and scrub. In this climate, with such a temperature and wind, would the feed remain on the surface? No; it does not remain. If the herbage is not eaten off it will blow away, and then we have to go to the scrub again. If we were to spell the run it would only be as regards scrub. Since your experience of thirteen years, do you think the seasons are improving? This season has improved, but I have not seen any improvement in any of the others. Is the rainfall becoming more regular, or does it remain the same? I think it remains just about the same.

To

To what market do you send your produce from here? Sometimes to Adelaide, sometimes to Melbourne. Mr. J. W. Brougham.  
 That is by river communication? Yes. 29 Sept., 1886.  
 If the railway were constructed to here, and the river weired at different points so as to keep up navigation between the points of the railway, what market would the producers make use of? I think the Sydney Market for produce.

*Mr. Gipps.*] You said your station was situated 9 miles from the right bank of the river, how far does it extend inland? Sixteen miles.

What are the natural features of the country? Sandy, undulating country. Nature of country.  
 Any high ranges? No. There is a rocky hill in front of the house.  
 What is the character of the rocks? Sandstone and a little ironstone.  
 The same as these buildings are constructed of? I do not think it is. It is not such a white sandstone.  
 Have you noticed any volcanic rock? No.  
 Have you noticed those round mounds? No.  
 What is the character of the watershed round Lake Woytchugga? All sandy. Lake Woytchugga.  
 When the river falls, does the lake drain off? Yes, but not completely dry.  
 To what depth? To about a foot.  
 And the area is then reduced to about how many acres? I could not tell you.  
 Does the water soon evaporate? No, not even the foot in depth. The soil is very good for holding.  
 How long would it last when reduced to that depth without further rain? It would last about six months. The lignum protects the water.  
 What number of wells have you put down? We have nine on Netallie, and four of these are successful, Wells.  
 having good stock-water.  
 What character of boring machines have you? Just the ordinary hand-boring rods.  
 What does it cost you? It is very hard to say. I have generally done the boring by weekly work.  
 What kind of water do you get? Mostly salt water, but not too salt for stock. One water is sweet.  
 An unlimited supply? Not an unlimited supply. One well gives about 900 gallons an hour.  
 Do you notice any change in the river by drawing? No.  
 Does the well rise and fall with the river? No.  
 Have you any dams? One. Dam.  
 In what position? That is on the back country, on Booroorangie Creek.  
 What is the height of the dam? Originally it was 15 feet, but that dam was washed away, and now I have made an overshot dam.  
 What height? About 7 feet.  
 What is it constructed of? Loose earth, and stone put over the top—not cemented, but loose.  
 How far does it throw back the water? About three-quarters of a mile, with a breadth of 50 yards.  
 Is it continuously full? No; it has been dry several times. The creek is full of drift.  
 Is it silting up? Very much. It is within about 4 feet of the top of the excavation. I took out 22,000 silt yards, and that is nearly all silted up.  
 The creek has a considerable fall? A very great fall.  
 Where does it empty into? Into Nitre Lake. Nitre Lake.  
 What is the area of that lake? About a mile long, by about 300 yards wide.  
 How deep? When it was measured after the big rain of January, 1885, there were 20 feet in the middle of it. Now there are about 7 feet.  
 How do you account for the loss of water? It is very bad holding ground all around there.  
 What is the nature of the watershed of this creek? Stony country, with quartz and ironstone. Natural state of country.  
 Has that lake any outlet? No.  
*Mr. Donkin.*] Was it possible to have occupied this country before water was conserved on it? No, it was not. We carted out our first water in a cask. There was not a drop of water on the run.  
*Mr. Gipps.*] Is there much scrub on your run? Yes, wire-bush, apple-scrub, and mulga.  
 Have you noticed any dews? Only this winter that I can remember. Dews.  
 What do you attribute them to? To the rain, I think.  
 After these dews, do you get any thunderstorms? Yes.

Mr. M. J. C. Tully examined:—

*Mr. Donkin.*] What is your occupation? I am Inspector of Stock for the Wilcannia District. Mr. M. J. C. Tully.  
 How long have you been here? Nearly twenty years, within less than 100 miles of Wilcannia. 29 Sept., 1886.  
 You are one of the oldest residents here? I believe I am. Floods.  
 How many floods have you known in the river since you have been here? There was a considerable flood in 1867, another in 1870, one in 1873, which might almost be called a continuation of the 1870 flood. In 1879 I was not on the river. Then there is the present flood.  
 Which is the highest flood you have known? The 1870, which was about a foot higher than the present one.  
 Has any record of the floods been marked in the river? There has been no particular gauge kept until the last ten years.  
 Can you go by any marks on trees? We can judge by the distance the waters flow over the banks.  
 What do you think would be the best zero to adopt in order to record the floods? I am of opinion that this present flood would be the best because it is the best known, and more notice has been taken of it than of any previous flood. Zero of floods  
 To take the highest point of this flood would be the best zero? Undoubtedly.  
 And not to take the bed of the river, or summer level, or navigation level? No. The Talywalka.  
 Do you know the Talywalka running out from the river? I know a good portion of it.  
 What is its length approximately? About 200 miles.  
 How far from here does it run out of the river? About Cultowa, about 35 miles direct.  
 Does the Talywalka fill Lake Poopelloe? Yes.  
 Have you seen that lake filled? No.  
 What depth of water do you think there is in it? I could not say.  
 The Talywalka now is about 2 miles wide? Yes. Width of Talywalka.

Would

- Mr. M. J. C. Tully. Would that be for the whole length down? There are places where it would flood a great deal more country than that, and other places where it would come within its banks.
- 29 Sept., 1886. Do you think anything could be done to conserve any large body of water in the Talywalka? I do not know of anything that could be done.
- Does the Talywalka run into the river again? I am not well enough acquainted with the lower portion of the country to say whether it does or not.
- Dams. Are there any dams on the Talywalka? There are dams on it, but I cannot point them out. Without the dams, would the water be retained in the creek? Oh, yes; very much the same. You do not think that damming makes much difference to the body of water? I do not think so. The overflow of the Talywalka irrigates a large area of country? Yes.
- Natural irrigation. Is that of great benefit to the district? Undoubtedly it is, because all the frontage country requires irrigation to make it grow anything. The nature of the soil is such that it requires thoroughly saturating.
- Lake Woytchugga. Have you known Lake Woytchugga to be flooded? Yes; in most of the floods it has been flooded. Would you retain the water there, or allow it simply to flood the bed of the lake for the purpose of irrigation; which is the best as a national undertaking? I should think to let the water flood the bed of the lake as now.
- Benefit of flooding. After flooding, how would that area compare with the ordinary country around for feed? For a certain time after the flood dried up it would carry three times the number of stock that a similar area of outside country would carry. And for what time? The effects of the irrigation would be felt for about three years or more. Does that apply to all flooded land? I think so. It requires a flood in order to produce pasture? Yes.
- Rocky bars. Do you know any rocky bars in the river? I know the rocky bars at Weinteriga, and here and at Curranyalpa. Is there a fall at Curranyalpa? A considerable fall. The bar acts as a natural weir across the river? Yes. Have you noticed whether the banks have washed away at all? I did not notice it. I crossed the river twelve months ago on the bar.
- Erosion of banks. Do you think that an impediment in the river would have a tendency to cut away the banks? I should not think so. The bar at Weinteriga, would it be possible to raise that 3 or 4 feet? I think so. Do you think the banks would erode? A certain height above the rocky bed the banks would cut away. Has the bar there any local name? They call it the Christmas Rocks.
- Fall of river. Supposing the rocks there were raised 3 feet by a weir, what distance would the water be thrown back? I do not know the fall in the river, but it would send the water back an immense distance.
- Dry river. Have you known the river here to be dry for a lengthened period? Yes; early in 1867 it was dry for some months, and it was again dry in many places before the rain of 1885. What is the longest period you have known navigation to be stopped? About four years.
- Uncertain transit. Is there any certainty at present in being able to send produce away from Wilcannia? No certainty. Have you known wool to be detained here for any time? I have known two years' clip to be in the stores here waiting to get away, without any possibility of getting away. That was a loss to the district? An immense loss to the district.
- Railway. If the railway were constructed to Wilcannia, do you think it would be made use of in preference to the river? Undoubtedly it would.
- Locks. From your experience of the river, do you think it would be possible to lock it to any considerable height? I think it would be possible, but the expense would be very great, as the banks would be liable to wash away. Do you think it would be sufficient for all purposes of the residents and producers in this large extent of country if enough water were kept in the river to convey their produce to the points of the railway? I think that would be sufficient for the whole district. Do you know the country between here and Cobar, and here and Louth? I have known it between here and Cobar. Would there be any difficulty in running a railway on that road? There would be no difficulty. Is the country tolerably level? Yes.
- Lakes on lower Paroo. Can you mention any other depressions or ana-branches where a large body of water could be conserved, either on the Darling or the Paroo? There are a great many lakes on the lower Paroo where water can be conserved. What are the names? Peery Lake is the largest; not far distant is Olepoloko and Gulpopo. What would be the extent of water and the depth in this flood in the largest of those lakes? Peery Lake has the largest area; it is about 11 miles long, with an average width of 2 miles, although at the north-east end it is more than 2 miles. What depth of water was there in it before this flood ran into it? About 3 feet. This flood would raise it to about 5 feet. Have any of the other lakes a greater depth of water? Tongo has perhaps 8 feet of water in it. Do you know whether the Paroo water actually ran into the Darling? If sufficient water came down the Paroo it would undoubtedly run into the Darling. Have you ever known it to run in? No, except when the water of the Darling has backed out to meet it. From what you say the flood in the Darling is not affected by the flood in the Paroo? Not in the slightest degree. Would it be possible to divert the Paroo water through those lakes you spoke of, and run it down south-west into the back country towards Gnalta? Not from so low down as those lakes, but I am of opinion that it could be diverted higher up to go westward into some of the large swamps that are fed by the creeks from Yancannia. What distance is it possible it could be diverted? It could go right down to the South Australian border. Towards Silvertown? Yes, down through the country there.
- Diversion of Paroo water towards Silvertown. When you first came to this district, was there any large area unoccupied through want of water? The whole district almost was unoccupied. Was it possible to occupy it without conserving water? Quite impossible. Do

Do you know whether the waters of the Paroo River join the Darling? The water has only joined the Darling when the Darling has been in high flood. Mr.  
M. J. C. Tully.

The Paroo flood is of no service to the Darling? None whatever. 29 Sept., 1886.

Do you think from the trend of the country it would be possible to divert the Paroo down south-west? Only by diverting it from high up. It could not be diverted south-west from about Peery Lake. The Cuttaburra.

From where then do you think? It would have to be as far up as Wanaaring, and then I do not know whether it could be done. I think the country would be found too high to the west and south.

Do you know the Cuttaburra? Only at its junction with the Paroo, near Goorimpe.

Is there a defined junction there? It is not defined; it is known as the Cuttaburra. Peery Lake.

You do not know where it runs out of the Warrego in Queensland? I do not know.

Which is the largest of the Paroo lakes? Peery.

And that is filled by the Darling, Paroo, and Cuttaburra waters? Yes, by the water which leaves the Darling near Kallara, the Cuttaburra from the Warrego, and the Paroo water itself. The three waters have joined near Peery Lake, and are running into it.

Have you ever seen that lake dry? Frequently.

Is it full now? It is not full, but the rains of January, 1885, put a good deal of water in it, and it has not been dry since.

What depth of water is there now? It is a shallow lake. I do not think that at any time there would be more than 6 or 8 feet of water in it.

Are there any other deep depressions you know of where a large body of water could be conserved? I only know Copago Lake, and very little could be done to conserve water in that. Copago Lake.

What depth of water is there in it? When it was gauged last it had just ceased flowing, and there was about 30 feet in it.

How long would that water last? About six years. It was filled in the 1864 flood, and stock could water at it until early in 1870, and then it was not quite dry when, in the high flood of 1870, the river and Paroo water met and ran in for a short time.

Is that the largest depression you know of in the district? The deepest.

And likely to be the most permanent? Yes.

You say nothing could be done artificially to increase the supply in the lake? Not unless there could be some means of conveying the Paroo water through the rotten country at the lower end of the Paroo, so as to bring it into the lake without its being lost.

Could water from Lake Copago be taken down south at all? No; not anywhere from Copago, the sand-hills are too high.

Are there any other large depressions you know of west of the Darling? There are several very large lakes in the north-west, such as Cobham Lake and Yantara Lake. Cobham Lake.  
Yantara Lake.

The Bulloo runs into those lakes? I do not know that the Bulloo has ever been known to find those lakes, but no doubt that is the course the Bulloo would take.

Do you think it is possible to divert the Darling into the back country on the west side? It has already been diverted to a certain extent from Kallara.

But I am speaking of lower down the river, between Kallara and Menindie;—there is no large talywalka on the west side, is there? No.

On the east side of the river, are there any natural depressions where a large body of water could be conserved? Only those I have mentioned, such as Teryaweynya Lake, Pigeon Lake, and Bullabulka. Lakes east o  
Darling.

Have you kept a record of the rainfall since you have been here? I have not.

What is the general average rainfall calculated to be here? From 8 to 9 inches. But the very heavy rain of last year has raised the average considerably. Rainfall.

I think you gave us information, with regard to the flood-waters of the Darling filling up all the depressions and black-soil flats, that greater benefit was derived from irrigation by flooding the land than by conserving water? Yes. Natural  
irrigation.

What depth of water should there be in any of those depressions before means were adopted to impound water? I think that nothing under 15 feet would be of any benefit.

*Mr. Gipps.*] Have you seen the Paroo River itself in flood? Yes, several times. Flood-water  
of Paroo

Without the Darling being in flood? Yes.

What becomes of it? Peery Lake takes a great quantity of the water, and so do Tongo Lake and Yantabangie Lake and the Overflow. After this it loses itself in what is known as the Paroo Channel, which is a wide rotten flat about 2 miles wide, full of immense holes and ruts that you could not ride or drive across. They swallow up the overflow of the water.

And that might be called the sink of the Paroo? It might be so termed.

What becomes of this water;—does it seem to rush down the sink in a large stream? You can hear it running, and no one would attempt to cross the channel within half a mile of where you see the water, because the water might be running underground although the surface might appear dry.

Have any wells been sunk on this sink at all? Yes; several wells have been sunk near it, but at a depth of about 70 feet. Salt water has been struck in every instance, and the wells have had to be abandoned. Wells

There has been no attempt to trace the sink of this river beyond the plain? No.

What do you think becomes of the water? It must find its way down into the earth somehow.

And discharge into the Darling again? I would not advance that theory.

Have you noticed any large springs in the channel of the Darling? A number of them at low water. Springs.

Large springs? I could not say they are very large or discharge a great quantity of water.

Have you ever known the Darling River dry? On two or three occasions.

Was the water good? The water was not good at all; it becomes so bad that it is impossible to use it. Quality of water  
in river.

When the first of this flood came down the water could not be used for nearly a fortnight for domestic purposes, it was so salt and apparently full of mineral properties.

Then after the fortnight? After that the fresh water came on.

What do you think that is due to;—is it caused by the wool-washings being emptied into the river? I was under the impression it was due to the water running in from the springs in the bank.

Does the water produce any disease when the river is so low;—are fevers more prevalent? I have not noticed that, but I should fear it would interfere with the public health.

What are the natural features of the country between the Darling and the Barrier Ranges? Mostly undulating sandy country, and at a certain distance back you get into ranges. Ranges  
At

- Mr. M. J. C. Tully. At about what distance? A little to the north of west the ranges begin at about 50 miles. They are isolated ranges, more like hills. Further on you get into the rangy country right through.
- 29 Sept., 1886. Do these isolated ranges appear to run into the Barrier Range? I have not traced them along.
- Do they show any outcrop of rocks? Yes.
- Rocks. What is the character of the rock? Mostly red sandstone.
- Olepoloko Lake. How is Lake Olepoloko supplied? By the overflow of the Paroo after Tongo and Yantabangee are filled.
- Is it any size? About 2 miles by  $1\frac{1}{2}$  miles.
- What depth? It is only shallow, about 8 or 10 feet deep.
- Has it any outlet? I believe there is an outlet from it into Peery Lake, but I have not seen the water running from one lake into the other. There is a depression, apparently a watercourse, connecting the two lakes.
- I suppose it would be very easily dammed? I do not think so, because it is more like a wide watercourse than a creek.
- Lake Goolpooka. And Lake Goolpooka, how is that supplied? I think it is supplied in the same way.
- Lake Yantabangee. And Yantabangee? It is filled by the overflow of the Paroo after filling Tongo Lake. There is a channel between Tongo Lake and Yantabangee Lake.
- None of these have a watershed of their own? No; they have never been filled by local rains, although on one or two occasions some water has flowed into them.
- Dryer's Creek. Do you know of a creek called Dryer's Creek? Yes.
- Has that a watershed of its own? Yes.
- That creek rises where? On the ranges at the back of Momba Run.
- Has it any large watershed? Yes. The water comes in a considerable distance down that creek.
- Where does that creek empty? Into Tongo Lake.
- What is the length of the creek? About 15 miles.
- Is it a well-defined channel? Yes, when it nears the lake, but, like most of the back-country creeks, it is mostly a chain of waterholes, and then open flat country.
- Does it give the chief supply to Lake Tongo? No; the Paroo gives the chief supply.
- Dams. Are there any dams across Dryer's Creek? There was a very large one.
- What height? It contained over 20 feet of water.
- What was the length of the dam? The length across would be 250 yards.
- How far did it throw the water back? About a mile and a half.
- What width? From 2 chains to 1 chain.
- Did it conserve a permanent water supply? No; it dried up.
- And is the dam there now? The dam was carried away in the flood of 1885.
- Are there any other dams on that creek? None that I am aware of.
- Are there any large flats or depressions that could be fed from that creek? Not from that creek.
- Mr. Donkin.] Have you kept any return of the number of stock that have perished in this district? I have not kept a return.
- Loss of stock. Do you know about the percentage, taking the stations all round? In 1869 I should imagine that at any rate 33 per cent. of the stock in the district perished, and in 1884 about 20 per cent. The loss was not so great in the latter year, because better provision had been made for water storage.
- What would that represent in round numbers in sheep? It is a difficult matter to arrive at. Perhaps 400,000 sheep.
- That would be in your district? Yes, within a radius of 200 miles of Wilcannia.
- Do you know whether anything could have been done to prevent such a disaster? The only thing would have been to have water on the dry country. A great extent of country could not be used for want of water.
- Want of water. The loss of the 400,000 sheep, was it caused by want of water or want of grass? Chiefly by want of water, because stock had to be crowded on to the country that had enough water for a lesser number, but not sufficient for all. There was enough feed on the back country, but not enough water.
- If the country is not stocked, will the grass survive through a drought? The grass will survive through a drought, although it does not keep growing.
- Overstocking. Do you think some plan ought to be adopted of reserving a part of the holdings for time of drought? The pastoralist ought to be careful not to overstock the run, and not to allow the grass to be eaten down.
- Capacity of runs. What is the number of acres to a sheep that should be allowed? To be safe the average number should be not less than 8 acres to a sheep.
- Dam on Paroo. Mr. Gipps.] Do you know of any dams on the Paroo? None, except one at Warramurtie, on Goorimpe Run. It is about 8 or 10 feet high, and throws the water back about 2 miles.
- What width? The channel is rather narrow, not more than 15 yards wide.
- Are the banks exposed? Just near where the dam is erected the banks are defined.
- Is there any rocky bar? No rock showing anywhere.
- What length of dam is it? The dam is only short; the actual length across the creek is not more than 30 yards.

Mr. F. H. Bell examined:—

- Mr. F. H. Bell. Mr. Donkin.] What is your occupation? A licensed surveyor.
- 29 Sept., 1886. How long have you been in this district? Two years.
- Where have you been employed in this district? Within a radius of about 100 miles of Wilcannia, on the western side of the river.
- What work have you been principally engaged on? Surveying improvement purchase applications.
- Have you had experience in the Colony before coming here? Yes, in the Monaro country, and on the Murrumbidgee, and about Deniliquin.
- You have seen a good many water improvements during the time you have been here? Yes.
- What was the character of those improvements chiefly? Tanks and wells, and a few dams.
- Tanks. As a rule, have the tanks been a success for holding water? Yes, with very few exceptions.
- About what size has been the most advantageous? The larger the tank the better as a rule. The small tanks have not been a success.

What

What would you call a small tank? A thousand yards would be a small tank. Then within what range of cubic contents would you consider it advisable to make tanks to be of service in time of drought? I should think at least 6,000 yards.

And what depth? About 12 feet as a general rule, I think.

What is the usual method for stock to obtain water, by access to the tank or by pumping? By access to the tank.

What experience have you had with regard to wells? The wells throughout the district appear to be very useful and regular in their supply. They are better than tanks in the respect that they can always be relied on.

What is the average depth at which they have obtained water? The depths vary a great deal, from 150 to 300 feet.

As a means of permanent supply, then, which do you think is the most advantageous, the construction of tanks and dams, or the sinking of wells? Decidedly the wells if there were a certainty of getting a supply, but frequently wells are put down without getting a supply.

How does the cost of wells compare with that of tanks? The first cost of wells is greatly in excess of that of tanks. In constructing a tank you know what the cost will be, but with a well you do not know.

How are the wells put down? By sinking.

Have you seen any put down by boring? No.

Do you think there is any underground current? There is an underground supply, but no current that I know of. The water is generally found in drift.

Can you enumerate any large depressions where a large body of water could be conserved? There is Copago Lake and Lake Dick.

Have you seen Copago Lake since it has been filled? Yes.

What depth of water is in it? 28 feet when full.

How do you know it is 28 feet? It was measured at the time of the rains of January, 1885.

How is it filled? By an overflow from the Paroo.

What is the length of the lake? It is pear-shaped, and must be about 2 miles long.

What width? It varies in width. At the broadest part it is about  $\frac{3}{4}$  of a mile or a mile.

Do you think it would average 2 miles by 1? Barely that, I think; perhaps 2 miles by  $\frac{3}{4}$  of a mile?

What would be the average depth? Over a greater part of it it would be fairly deep, perhaps 23 feet.

Could that water be retained? Oh, yes.

Would it be a difficult or expensive undertaking? Not at all.

What do you think would be the cost; I suppose an earthen dam and a flood-gate would be sufficient?

It is below the bed of the Paroo. It would scarcely want retaining at all.

Then the water does not run out? No.

How long would the 28 feet of water last;—the lake is almost permanent, is it not? Yes; except for what it loses by evaporation and stock.

Do you know of any other lake in the Colony of that depth? Not about here.

Was that dry before the last flood? I believe so; but that was before my time.

Are there any other large depressions? There is one close to there, Lake Dick, on the opposite side of the Paroo.

Is that somewhat similar? That is a circular lake about a mile and a quarter in diameter.

What depth is there? I do not know. About 12 feet probably.

And that is filled in the same way? Yes, by an overflow of the Paroo.

Would it be possible to divert that water to run further south or south-west? I think not.

Towards the Dry Lake? No. I fancy there are very high hills round Lake Copago and Lake Dick, and in addition to that they are below the level of the river channel itself.

Is there any connection between Lake Copago and Lake Dick? Yes; they both come out of the Paroo.

Does the water run from the Paroo direct into each, or from one into the other? There is no direct channel; there is a depression. They run from the Paroo direct into each, not from each other.

Are there any other large depressions? There are several on Momba Station, but probably it would not be worth conserving water in them.

Do you know any other large depressions where water could be diverted or stored? There is a large depression on Culpaulin Station. It would take very little to run water into it. In fact there are natural channels which if they were deepened would connect it with the river.

Do you know whether it would be possible to divert the water from the Paroo down towards Dry Lake or out west? I do not know sufficient about that to say. I do not think it could be connected with the Dry Lake, as there is some high sandy country between.

Do you know Dry Lake? Yes.

Did you see it before it was filled? No; after it was filled.

Do you know what water there is there? The lake is pear-shaped, is about  $1\frac{1}{4}$  miles long, and about  $\frac{3}{4}$  of a mile wide in the upper part of it. It narrows up to the channel at the end.

What depth of water is there in it now? About 13 feet I should think.

Is it filled entirely from local drainage or overflow? I should think from local drainage.

The Dry Lake is where a house was submerged? Yes; the hotel was originally built in the bed of the lake.

How many years was it there before it was submerged? About thirteen years.

Then the filling of that lake is quite an unusual thing? Yes. It is twenty years since it happened before. In 1864 there was a little water in it, but not so much as now.

Could the water be taken from there and diverted down through the country at all? I think it might. There is a series of lakes connected with it; for example, it could be connected with Nitre Lake.

You do not know whether it is possible in any part of the district to divert the water of the river, and take it out back, except what is done by the ana-branches? No.

Would the fall of the country admit of it? Scarcely, because the Darling requires to be 30 feet high before the water backs up these channels. For instance, the water backs up Copago Lake when the river is 30 feet at Wilcannia.

Is Copago Lake filled partially by the Darling and partially by the Paroo? Yes.

Do you think the Paroo River affects the Darling at all? I think not. There is another lake near

Dry Lake, called Nitre Lake.

Is

- Mr. F. H. Bell. Is that full? Yes.  
 29 Sept., 1886. How far is Dry Lake from Wilcannia? 18 miles north-west.  
 Was it Dry Lake where a team of wool was submerged? I could not say.  
 Is Nitre Lake of any size? Yes; it is about 3 miles from Dry Lake, on the boundary between Netallie and Mena Murtee.  
 Is it full now? Yes. It is filled by Booroorangie Creek and the overflow.  
 What range does it rise in? It rises in the Mootwingie Hills, on the Daubeny Run.  
 Could the lake be made to store any large body of water? Yes.  
 In what way? There is no outlet from it that I know of. It is a natural holding lake.  
 Strata in wells. Mr. Gipps.] What is the character of the strata in the wells? They vary a great deal. In some of them you go down into blue slate. In the tertiary formation you go through copai and gypsum. Some of the wells contain almost pure gypsum.  
 What follows the gypsum? I have no sections of any of the wells, but it is generally limestone granules. I think they get into drift.  
 And then below the drift? Very often there is a second layer of that sort, which they go through if the water supply is not sufficient. They get a supply in some of the wells at 150 feet, very often salt. On going deeper they get a supply of fresh water.  
 Blue slate. Do you get a different top stratum in going through the blue rock? It is generally blue slate from the top.  
 At what distance from the river do the blue-slate wells commence? The first I know of is the Mount Daubeny well, which is about 60 miles from the right bank of the river.  
 Features of country. Is there any difference in the features of the country where you get the blue slate and where you get the alluvial and copai? Yes; where you get the blue slate you are rising up into stony hills; it is all rangy country; where you get the other the country is all level, tertiary flats.  
 Then the surface is of a sandy or gravelly nature over this blue slate? It is, but not for any great depth. When there has been alluvium washed down into the flats it is of that character, but on the side of the hills you go into slate at once.  
 Gopago Lake. Has Copago a watershed of its own? Yes.  
 Any creek? Only gathering ground.  
 Those are sandhills? Yes.  
 Gradually rising to any height? On the western side they rise pretty high, about 70 feet.  
 Have any wells been sunk near these lakes? Not that I am aware of.  
 Dry Lake. Could the flood-water of the river be thrown into Dry Lake? I do not know of any defined channel that would send it out there.  
 But could not a channel be cut to conduct it? I could not say that without knowing the difference of the levels. You can tell the level of Copago Lake by the height of the river water backing up.  
 Is there any outlet to Dry Lake? No.  
 12938. Is there any creek running into Dry Lake? There is a long depression, not a well-defined creek, but I do not know whether it goes over the gathering ground of the lake.  
 What is the character of the gathering ground? On the two sides it is sandhills. There is a marly clay soil, a broken flood-clay, which forms in the creeks.  
 What area do you suppose the watershed to be? I dare say it would be 3 miles by 2.  
 Nitre Lake. What is the area of Nitre Lake? Of the water itself about 4 square miles.  
 And what depth? I could not tell you the depth, but I should think it would be fully 20 feet.  
 How is that filled? It is filled by the Booroorangie Creek, the creek that comes from Mootwingie.  
 Is that a large creek? Yes, a large well-defined creek for about 20 miles.  
 Does that rise in any of the ranges? Yes; it is from the gathering ground of the ranges in storms.  
 Dams. Are there any dams on that creek? Yes; there was one very large dam constructed on Daubeny Run, which was washed away in the rains of January, 1885. It cost about £3,000.  
 Did that throw the water back? It threw the water back about 2½ miles.  
 What width? About 10 chains wide.  
 What was the height of the dam? About 15 feet.  
 What was the reason of its being carried away? Because the heavy downpour caused the water to rush round the end of the dam and gradually break it away.  
 What was the rainfall? About 10 or 11 inches.  
 Mr. Donkin.] In speaking of the Paroo, has its waters ever reached Kalyanka Creek? Not to my knowledge. If a dam were erected on the Kalyanka Creek the Darling water could be forced up to Copago Lake much more quickly than at present.

Mr. E. W. Donnelly examined:—

- Mr. E. W. Donnelly. Mr. Donkin.] How long have you been in this district? About eleven years.  
 29 Sept., 1886. Where do you reside? At Gnalta.  
 How far is that from Wilcannia? About 70 miles by the road, north-west.  
 Where have you also resided? At Langawirra.  
 Did you not reside at Cobham Lake? I go there sometimes; I am one of the partners.  
 You know Cobham Lake Station? I am one of the owners.  
 How far is Cobham Lake from here? 150 miles, a little west of north.  
 What is the nearest township? Tibbooburra.  
 Cobham Lake. What is the extent of Cobham Lake? It is about 8 miles long and 1½ miles wide at the widest part.  
 When it is full it floods about a mile wide.  
 What depth of water is there in it now? There is about 28 feet of water in it now.\*  
 How long will that last? It should last six years.  
 Is it the only large lake in the north-west? It is the deepest lake. Yantara Lake has a larger area, but is not so deep.  
 Could anything be done artificially to supplement the water there now? I do not think so.

What

\* NOTE (on revision):—I find only 22 feet now in Cobham Lake.—E. W. D.

What is Cobham Lake filled by? By several creeks.

Entirely by local rain? Yes. Mount Browne Creek is the principal creek.

How far is Cobham Lake from Mount Browne? About 36 miles.

Is the water good in Cobham Lake? Very good till it gets very low.

Do you depend upon it for water for the stock? It is not a permanent lake; it has been dry.

Could the water be diverted from the lake in any direction, if necessary? Not without making a very deep cutting. There are large sandhills all round it.

Do you know Yantara Lake? Yes.

What is that filled by? By several local creeks, entirely by local rain. I have heard that the Bulloo water has gone into it, but it is only hearsay.

Have you been on the Bulloo? Yes, where it runs out.

Where does it run out? Into swamps and clay-pans.

Can anything be done with Lake Yantara? No; it is very shallow. Nothing can be done to it, and the water cannot get away.

Do you think the Bulloo water or the Paroo water could be taken out into that large extent of dry country if it were possible to divert it? The Bulloo water might, but I have never been on the Paroo.

From Yantara, could it be taken on to Cobham Lake? I am afraid not. There is a salt lake on Yantara.

What is the name of the lake? Salt Lake.

Is it of large extent? About 6 miles square.

What depth? I have seen it full with about 5 feet.

It does not last a great time? Not more than eighteen months.

Is there a large body of water coming down the Bulloo? Yes, a great body of water.

How do you water your stock, by tanks or wells? By both.

Which do you find of the most service? Wells are the most serviceable, because tanks do not last.

At what depth have you obtained water? At different depths, from 150 to 420 feet.

Have you obtained a plentiful supply? In some cases. Many wells have been failures.

At 400 feet? Yes, I have some at 400 feet which failed.

What does it cost per foot to sink wells? About £2 per foot; that is in alluvial. Rock wells cost a good deal more.

Do you think if deep wells were sunk in your part of the country that a good supply could be obtained? Yes; I am in favour of deep wells.

You do not know whether any deep wells have been put down to 1,000 feet or more? I do not. I think the deepest well in our district is 400 feet.

Do you know of any plan by which water could be diverted or conserved to be of benefit to the district? There are some shallow lakes which would hold much more if they were excavated.

If tanks were made in the bed you think the water could be made almost permanent? I think so.

What depth of water do you consider would be permanent? I think tanks require to be at least 18 to 20 feet deep.

Do you know whether tanks have been put in any of the depressions? Yes.

Does the plan answer well? We have one on Pack-saddle, one of our stations.

Where is that from here? It is on Pimpara C block, about 140 miles north-west of Wilcannia.

Is it good holding ground? Very good.

*Mr. Gipps.*] What is the character of the country near these depressions? Principally sandy country, with cotton-bush and salt-bush plains between the hills.

What is the character of the gathering ground near Salt Lake? Principally cotton-bush and salt-bush country.

Any rocks? No.

Any rocks exposed anywhere on the run? No, none on Cobham and Yantara.

What is the depth of the deepest well? 420 feet.

Where is that situated? There are two—one on Cobham, and one on Gnalta.

Is it near a lake? No; it is on Mount Browne Creek, about 15 miles north of the station.

What is the nature of the soil? It is all alluvial.

From top to bottom? There is drift in places.

Coarse drift? No, very fine drift.

No rock at all? No.

What did you bottom on? Blue clay.

You have not gone through the blue clay? No; we got a small quantity of water in it, but we did not try to go through it.

What supply of water did you get? Not sufficient for stock.

You can easily draw it off? Yes.

What is the character of the water? Slightly brackish.

Does it improve by drawing? No.

Does it rise or fall with the rains? The rains have no effect on it.

How often does the Bulloo run? Sometimes it does not run for two years, sometimes it runs twice a year.

Is the channel well defined? Not very well defined. It runs through large cane-grass swamps and flats, which have the same depth right across.

Do you think if a channel were cut for it that these lakes could be supplied more often? I think so; but I am afraid it would be very expensive.

Could not the channels be cut on the surface? Yes.

Why would that be expensive? I think that on Yantara Lake a feeder for it would have to be cut through the sandhills.

Are the sandhills drift or rock? Drift.

Would you have to go through a large extent of these sandhills? I do not know the channel right round from Karyapundy Swamp.

Does the Bulloo ever run in a channel? Higher up.

Have you seen it higher up? No; I have only been 20 miles higher up.

What are the prevailing winds? West and north-west.

Mr. E. W.  
Donnelly.

29 Sept., 1886.

Yantara Lake.

Salt Lake.

Tanks and wells.

Cost of wells.

Permanent tanks.

Character of country.

Deep well

Bulloo River.

Sandhills.

Are Winds.

- Mr. E. W. Donnelly.** Are they pretty constant in summer and winter? Not very constant.  
Are they strong? Very strong, but very irregular. Sometimes we have them for several days, and then we are a month without them.  
**29 Sept., 1886.** Have you any windmills up there? No.  
**Windmills.** What is your average rainfall? Up to January, 1885, our average was a little over 7 inches.  
**Rainfall.** Do you get none of the tropical rains from Queensland? Very seldom.  
What is the character of the rainfall, does it come in heavy storms, or is it light? It is very light; it does not do much good.
- Billia Billia Lake.** Does Cobham Lake connect with any other lake? There is another lake called Billia Billia Lake. It is not quite connected with it, but there is only a sandhill between.  
How is that filled? From its own watershed; it is quite distinct from Cobham Lake.  
Is it good water? Yes.  
What is the length of that lake? It is about 2½ miles, and is nearly square.  
What depth? About 7 feet is the average.  
Have you ever seen it full? Yes; it is nearly full now.  
Does it last long? About two years.  
Do you think the loss of water in these lakes is due to evaporation or to soakage? To both a good deal, but soakage principally, I think.  
The soil is not retentive? No.
- Loss of stock.** *Mr. Donkin.*] Did you lose any quantity of stock in the drought? We lost about 6,000 cattle at Cobham Lake.  
In what year? 1883-1884.  
Within twelve months? About twelve months.
- Want of water.** What was the loss due to? Entirely want of water.  
Had you grass? We had plenty of bushes for feed.  
If you had had plenty of water you could have saved them? Yes, with a few exceptions.  
Did you lose all the cattle on the station? No; we saved about half.  
How many acres to a beast do you calculate on for safety? Eight acres to a sheep, and in proportion for cattle.  
It would take six times as much for cattle as for sheep? Yes; that would be about 50 acres per head for cattle.  
Do you think the great loss in stock has been due to overstocking? It has been due principally to want of water.  
What distance can cattle travel in to water? With safety they can travel 8 or 9 miles, in and out, to feed.  
Have you still cattle on the station? We have sheep on it now.  
Are there any cattle stations in the country? We have cattle at Boolka.  
As a rule, there is not so much loss in a drought with sheep as with cattle? No.
- Dews.** *Mr. Gipps.*] Have you had any dews? This year is an exception. We have had some heavy dews this year. I think they have been due to the heavy rains.
- Well.** What supply did you get in your best well? About 40,000 gallons in twenty-four hours. I think by sinking we would get more.  
Where is that well? At Gnalta, which is about 83 miles north-west from here.  
What depth is that well? 310 feet.  
Is it bored or sunk? 60 feet were bored.  
What is the character of the strata? Sandstone all through from 5 feet from the surface.  
What character of sandstone? White.  
What did you bottom on? Still in stone.  
What is the character of the water? Slightly sweet, but drinkable.

---

Mr. W. S. Downie examined:—

- Mr. W. S. Downie.** *Mr. Donkin.*] You reside at Tibbooburra? Yes.  
What distance is that from Wilcannia? 195 miles north-west.  
**29 Sept., 1886.** How long have you been there? About four and a half years.  
Have you been in the district before? No.  
Have you any permanent water there? None.  
What is the nearest permanent natural water? Cobham is the nearest. Wompah Waterhole is about 35 miles away on the Queensland boundary. Cobham is about 65 miles away, but it was dry for three years.  
Is there any permanent water nearer than the Darling? None that I know of.  
How have you managed for water during the drought? We depend principally on flying showers during the summer. Sometimes we have had to carry water 27 to 35 miles at great expense for domestic purposes.
- Carting water.** Where did you cart it from? From Wompah, and from a waterhole called Nockabinrah on the Wirra-binna Creek.  
None of those creeks are permanent there? None.
- Bulloo River.** Do you know the Bulloo River? Yes.  
Where does it empty itself? Into Karyapundy Swamp, about 40 miles from Tibbooburra.  
Is there a large body of water there? A large body of water flows down. The Bulloo is about 20 feet deep. Some of the swamps it runs into are 20 miles wide.  
These swamps are just below the Queensland boundary? Yes, on and below.
- Diversjon towards Yantar** Do you think it would be possible to divert the water towards Tibbooburra? Not towards Tibbooburra, as there is a range between; but I think you could do so towards Yantara at an enormous expense.  
Is it tolerably level country? Very level until you get into the vicinity of Yantara Lake.  
Do you think any scheme could be devised of bringing down the Bulloo to be of more service to the country? I have not travelled over that country enough to know, but I think it could be utilized.  
At present it is of very little service? Very little indeed.  
What do you depend on now for your water supply? On dams and small tanks made by the diggers and other persons living there.
- Government well.** Have you any deep bores there? No. The Government have started a well for us. They have got it down

down 200 feet, but there is only a small supply. It was started about eighteen months ago, and they have left off sinking to construct a whim. Mr. W. S. Downie.

Have you had any deep wells put down to test the water? Nothing over 200 feet. The quality of the water is very fair. 29 Sept., 1886.

Is it your opinion that if deep wells were sunk (say) 1,000 or 2,000 feet water could be obtained? I think so. Deep wells.

What has the rainfall been since you have been at Tibbooburra? Previous to January, 1885, it was about 6 inches. Rainfall.

Is that sufficient to make the herbage grow? Yes. The growth of herbage after rain is wonderful, but it soon parches up and blows away unless rain falls (say) every two or three months to keep it up.

Do they consider 6 inches sufficient for pasture? The country has not been very much stocked so far, and that quantity of rain would not be sufficient if the country were fully stocked.

What amount of rain at one time is sufficient to be of any service? An inch, if it falls rapidly, will cause the water to run into the waterholes, tanks, &c. The rains are very irregular; sometimes they are southerly and sometimes northerly. The heavy rains are from the north.

Are there any large depressions there in which deep tanks could be constructed? Yes. Tanks.

Would that ensure a permanent supply? I think so. The tanks would have to be very deep, say fully 25 feet deep.

*Mr. Gipps.*] Do you ever get the tropical rains from Queensland? About the tail end of them. Tropical rains.

At what season? From January to March. We have had them as late as May.

Do they come in heavy storms? Not at all times. Sometimes they commence with very light rain.

What are the general features of the country, rolling or plain? Some of it is a little hilly. The Grey Ranges run through there.

What is the height of the Grey Ranges? I am not very sure. Grey ranges.

400 or 500 feet? I suppose about that.

Are there any large creeks there? No. There are some small creeks. Small creeks.

Have you tried damming any of them? Some of them have been dammed, and have lasted very well.

What quantity of water do they throw back? Not for any distance—say  $\frac{1}{2}$  mile.

Have you many wells sunk? There are a good few wells in the district. Some are giving a good supply of water. Wells.

Any artesian? None.

What is the position of the principal well you know of? There is one about 4 miles from Tibbooburra, about 200 feet deep. The water in that is very good.

What supply of water do you get from it? About 20,000 gallons a day. It is a station well.

Would it give more? I think it would. The water was hardly more than tapped.

Is it sunk or bored? Sunk.

Did the water rise in the well? It rose 60 feet. There was a small soakage at 150 feet, then they went on and struck a further supply.

What is the character of the strata? Principally blue sediment and blue rock.

And the top stratum? Alluvial.

What did you bottom on? Blue slate.

Any veins in the slate? I think so.

Do you think the supply of water was due to a crevice in the rock or a slip in the rock? I could not say.

---

Mr. P. W. Tuxen examined:—

*Mr. Donkin.*] You are a staff licensed surveyor? Yes.

Have you been long in the district? Only twelve months.

What district have you been over since you have been here? Pretty well over the whole of the Wilcannia District. Mr. P. W. Tuxen.

Within what radius? About 200 miles north, 150 miles south, and to the South Australian border on the west. 29 Sept., 1886.

Do you know the Paroo? Part of it.

Have you seen it in flood? No.

Do you know whether the Paroo water joins the Darling? I do not. Paroo water.

Have you been on Lake Copago? I do not know it by that name; I do not think so.

Do you think the Paroo water could be diverted and taken down south-west towards Gnalta, and in that direction? No; there are very high ranges between. Diversion of Paroo.

Could it be diverted higher up from near Queensland? Probably.

And where could it be taken to? It would be from Tongo Station, I think, and would follow a creek that runs easterly into Tongo, close to Tongo Station.

How far could it be taken into the dry country? There is a dividing range about 60 miles from the Paroo. It could be taken into Cobham Lake by the Yancannia Creek.

You think it would be possible from the trend of the country to divert the Paroo into Lake Cobham? It would require a big cutting, but I think it is possible.

Have you any large depressions near the Paroo in which water could be conserved to be of advantage? I have seen so little of the Paroo.

Have you seen where the Bulloo runs out? Yes; into Karyapundy Swamp. Bulloo River.

The water there is not permanent? No.

Do you think the water could be taken down south? I do not know much of the country there and Cobham Lake.

Is there any feed on the clay-pans? There is no vegetation of any kind.

Then the water is absolutely useless? Absolutely. It is not permanent, and produces no feed. Water useless.

Is there soakage from the clay-pans, or does the water entirely disappear through evaporation? There is a channel leading out of the southern end, but I do not know where it runs.

The floods in the Bulloo are as large as those in the Paroo, are they not? Yes.

Then there must be an immense body of water which evaporates or gets away? Yes.

You

- Mr. You do not know of any large depressions coming south from there until you get to the lake on the river? There is the Yantara Lake somewhere between the big clay-pan and Cobham Lake.
- P. W. Tuxen. Can any large body of water be conserved there? It is shallow and perfectly useless.
- 29 Sept., 1886. You know the Darling River and the ana-branches? Yes.
- Yantara Lake. What depth of water is there now in Poopelloe Lake? I have not seen it full, but it must be very shallow.
- Poopelloe Lake. Would it be 12 feet? I should think not; it would be of no use.
- Wangalara Lake. Is there any depth of water in Wangalara Lake? Up to 12 feet.
- Would that be permanent? Yes, if dammed. It has two channels running into it, 15 feet in the centre, and 10 chains wide. I should think they could be dammed across at a cost of about a shilling a yard.
- What body of water would that conserve? The lake is about 6 or 7 miles by about 4.
- Is that the largest depression you know of? It is, there.
- Teryaweynya. Do you know the Teryaweynya? Yes; that is a branch off the Talyawalka.
- What depth of water is there in it now? I have not seen it full; there was only 5 feet of water in it when I saw it.
- Do you think it is possible to conserve a large body of water there? Not in the creek itself.
- Lakes east of Darling. Do you know the lakes on the other side of the river? The principal are Victoria, Teryaweynya, Dry, Eucalyptus, Waterloo, Denny's, Sawyer's, Gum, Bullabulka, and Ratcatcher's Lakes.
- How far are they from the Darling? About 40 miles inland.
- Can a large body of water be conserved there? They would be most suitable for irrigation purposes, as the water is so shallow and the ground round it so boggy that the stock cannot get near it.
- What depth of water is there now? The greatest depth is 10 feet.
- What depth of water do you think is sufficient to justify an expenditure to make the water permanent? I do not think it would keep good for any time. The water in Teryaweynya and Victoria would keep good. Victoria is 60 miles east of the Darling, is 6 miles by 3, and has about 10 feet of water in it when full in flood.
- Teryaweynya. And the Teryaweynya? That has not a great depth.
- What would require to be done to retain the water? It would have to be dammed close to the lake itself in some of the channels.
- Would it be expensive? I think it would be expensive because the country is very shallow on both sides. The upper part of the creek is deep and narrow.
- Could it be led towards the Willandra? Only by cutting through the Dividing Range, which is very high country.
- Suppose the Teryaweynya was not dammed, would the water run back to the river? Yes, the greater part of it.
- Lakes west of Darling. Do you know the lakes on the west side of the river? Yes.
- What are they? Menindie, Tandou, and Kangaroo Lakes.
- Menindie Lake. What is the size of Menindie Lake? It is 10 miles by 8.
- What depth of water? Only 4 feet in a high flood; but there is a lake to the south of it, the Cawndilla Lake, which in high floods would have 15 feet of water in it.
- Would there be 15 feet now? I do not know.
- Cawndilla Lake. Would it be worth while to do anything with Menindie Lake? Not as a reservoir. The Cawndilla would make a splendid reservoir.
- How far is that from the town of Menindie? The top end is about 12 miles south-west of Menindie.
- What are the dimensions of Cawndilla Lake? About 8 miles by 6, but it is egg-shaped.
- Is it lower than Menindie Lake? Yes.
- Could you take the water from Cawndilla Lake down south? No; there are very high banks and very hilly country.
- Natural depressions. As regards these natural depressions, which do you think would be of the greatest national benefit, the natural irrigation by flood-waters as carried on now, or the conservation of the water? Generally the natural irrigation; but I think a lake like Cawndilla could be made use of to irrigate Menindie Lake, and Victoria Lake could be used as a reservoir to flood the lower lakes for irrigation purposes.
- Mr. Gipps.] How is Cawndilla Lake filled? By the Menindie Creek, which runs through Menindie Lake.
- Where does Menindie Creek head? About 4 miles below Menindie.
- From the river? Yes. There is a large waterhole in the Darling just where the creek starts.
- Tandou Lake. This fills Lake Cawndilla first, and then goes into Lake Menindie? Yes.
- How is Lake Tandou filled? By a creek from the south end; by the river.
- What is the size of Tandou Lake? About 15 miles by 10.
- What is the depth? It is very shallow; it is low in the south end and high in the north end. It takes a great time to fill. It is about 4 or 5 feet deep.
- New Lake. What is the area of the New Lake? About half a mile in diameter.
- What is the depth? Of great depth.
- Is it full now? Yes.
- Stephen's Creek. How is it supplied? By Stephen's Creek.
- Where does that head? Near Silvertown.
- Is there any outlet? None at all.
- Are there any dams on that creek? I believe there are several.
- Is the level of New Lake higher than the level of Cawndilla Lake? I do not know.
- Are there any ranges between the two lakes? Only high sandhills.
- Do you think any irrigation could be carried on from New Lake? I believe from the appearance of the country that New Lake is high, but the quantity of water is very limited.
- Does New Lake dry up? Yes.
- Emu Lake. What size is Emu Lake? It is about 3 miles by  $1\frac{1}{2}$ .
- What is the average depth? I could not say, but I think it is of greater depth than the other.
- How is it filled? By a creek of its own from the river.
- Any outlet? It empties into the river when the river falls.
- Overflow from Lachlan. Does the overflow from the Lachlan River come down near this series of lakes supplied by the Talyawalka? No; the dividing range is very distinct and high.

What

What is the nearest point? I was told it was about 40 miles from Sawyer's Lake. There are some small lakes between the head of the Willandra and Victoria Lake, but they are not connected by any system.

What is the average depth of Ratcatcher's Lake? Two feet. The water lasts a long time.

What is the average depth of the Bullabulka Lake? The same as Ratcatcher's.

Does it dry up soon? It dries up at once.

Has Eucalyptus Lake any depth? No.

Waterloo Lake? Waterloo Lake and Victoria Lake are the most suitable for reservoirs.

What difficulty or expense would there be in throwing an embankment across the narrow inlet to Eucalyptus Lake? I do not know the creek there at all.

Would you allow this map to accompany your evidence? Certainly.

*Mr. Donkin.*] During drought the sand is very troublesome? Yes. I saw on the Albemarle Run old dray-tracks leading towards a sandhill 25 feet high, and disappearing under it. This sandhill, which was covered with scrub, had been formed by the wind since the track was made, or probably within the last twenty or thirty years.

Mr.  
P. W. Tuxen.

Eucalyptus Lake.  
Waterloo Lake.

Effect of sand  
drifts.

THURSDAY, 30 SEPTEMBER, 1886.

Present:—

MR. DONKIN.

MR. GIPPS.

Mr. Wm. Hogarth examined:—

*Mr. Donkin.*] You are manager of Momba and Mount Murchison stations? Yes.

What is the area of your property? 2,000,100 acres, I think.

How far is it situated from Wilcannia? The head station is about 50 miles distant.

The boundary adjoins Wilcannia? Yes.

How far up the Paroo do you run? About 80 miles from Wilcannia.

What number of sheep do you depasture? At present there are about 340,000, lambs included.

Have you been long in the district? Seven years.

Had you any experience of this part of the country before you came to Momba? Not on the New South Wales side, but in the interior of South Australia.

Is the country in South Australia similar to this? It is in parts, but I do not think the country is as good in South Australia as here.

What is the rainfall in South Australia? Where I was living for fifteen years it was something like 17 inches one year, and down as low as 3 another year, but I think the average would be 5 or 6 inches. That country is north-west of Momba.

Rainfall in South  
Australia.

Is an annual fall of 6 inches sufficient for pastoral purposes? It depends on how it falls. If it fell in two good falls it would be quite sufficient; but if it falls in dribbles of a quarter of an inch at a time it is not sufficient.

Since you have been here, what do you make the average rainfall? A little over 10 inches, I should imagine.

Average rainfall.

Is that ample? It is, provided it falls at the right time.

What fall do you consider sufficient to cause any benefit? In the winter anything less than an inch is of very little use; but in the summer, for the growth of feed, an inch will give a good crop of grass. The grass generally grows here with the summer rains; but of course you get slight herbage with the rains in winter. But the ground being so parched in summer, would not the rain be evaporated? Not if it is a steady rain. You think an inch for the purpose of grass is more valuable in the summer than in the winter? Yes.

Have you noticed the floods in the Darling during your residence here? Yes.

Have you had any experience of floods here before the present one? There was a flood in 1879 when I arrived on the station, but unfortunately I did not see any of the channels where it ran.

Floods.

What is the action of the back-water of the flood with regard to your run? It fills Peery Lake at the present time.

Peery Lake.

How far is that from the river? In a direct line about 35 or 40 miles, but the course the water follows is longer.

Is Peery Lake when full considered permanent? No; the water lasts good about eighteen months, and then it will kill stock that drink it.

What is the reason? The soda and salt and magnesia, or something of that nature. When the lake is dry the bed, which I suppose will cover 6 or 7 square miles, possibly more, is nothing but a white soda pan.

Poisonous  
nature of  
water.

Then the water there is absolutely of no use as a permanent supply for irrigation purposes? I should not think so.

Could anything be done to make the supply permanent? No; the surface is too great.

Paroo in flood.

Have you seen the Paroo in flood? This is the third time within the last seven years that it has entered the Momba Run, but it has not come far on it.

Is there a great body of water brought down the Paroo? In places it is 4 or 5 miles wide, but the depth is not great.

Loss of water.

What becomes of the water? It is all absorbed in the ground. The channel is rotten. After the water dries off there is an immense crop of grass; but three or four years afterwards, unless you have a big fall of rain, the grass dries off, and the ground cracks up.

Do you think any great body of water is lost by percolation? I am certain of it.

In your opinion, would that go to feed an underground supply? Yes.

Copago Lake.

Could anything be done with the Paroo in making any of these creeks permanent? The only lake which could be made permanent by the Paroo would be the Copago Lake, by the cutting of a channel.

It would be expensive, I think, to cut it so that the water would run direct to the lake instead of spreading over the flats.

What depth of water would it have? About 27 feet.

What would be the expense of cutting a channel? I could not say.

What is the depth of water there now? About 20 feet, I should imagine. That

- Mr. W. Hogarth. That will last for a number of years, will it not? I have no experience of my own as to the length of time it lasts, but judging from report it lasts about four years good, and the next year it is unfit for stock.
- 30 Sept., 1880. What depth is the water before it becomes unfit? About 4 feet.
- Lake Peery. When it lowers to that depth it is absolutely unfit for stock? Yes.
- In your own experience, do you know Lake Peery to have been unfit for stock? Yes; at the latter end of 1880.
- Which is the largest of those lakes? Peery Lake has the greatest surface by a long way.
- Diversion of Paroo south-west. Do you think the flood-water of the Paroo could be diverted, and taken down south-west into the dry country? I do not think it could be taken across to the west in any case.
- Have you had any experience in cutting channels to divert the water there? The last twelve months I had a little experience with Bunker's Creek, which runs through Tarella. There is a small lake on the creek, and the water never entered the lake but once, and that was only when we had 13 inches of rain last Christmas. A heavy flood came down the creek, and I took levels; and by cutting through a small sandhill I made a channel over a chain wide and 3 feet deep. Now I have 7 or 8 feet of water in the lake.
- Small cutting. What lake is that? Moorachee Lake. It covers about 2 square miles of country.
- Moorachee Lake. Bunker's Creek is entirely fed by local rains, and runs through Tarella? Yes.
- Before you cut the channel, how was the lake filled? To my knowledge it was only filled after the 13 inches of rain; but the creek ran many a time, and never a drop of water went into it.
- What was the expense of the cutting? £60.
- Advantage of cutting channels. Do you think that principle could be carried out with other lakes and watercourses? I think it could if proper levels were taken. There is a lake not shown on the map which has water in it at the present time, although it is over twenty months since this same creek was thrown back into the lake through a fall of rain. By cutting a channel I fancy the water could be thrown back there if proper levels were taken.
- Natural irrigation. Do you find much advantage from the natural overflow of the Darling or Paroo by the natural irrigation that takes place? For one year after the flood the country is benefited, but after the floods go down the local rains are not of much use.
- Do you think it would be possible to store any body of water in these lakes in order to flood the low lands? Not for irrigation purposes.
- Loss of Paroo water by soakage. Could you give any idea of the percentage, in your estimation, that is lost of the Paroo water by soakage? I could not give you the slightest idea, because the country is so covered that one could not form an estimate. But I have seen the Paroo running about 4 miles wide, and it did not make 200 yards headway in three or four days, and a horse would bog within 200 yards of the water.
- If it were not for soakage would not that great body of water coming down find its way to the Darling? It would have found its way three times within seven years if it were not for the soakage.
- At what rate does the Paroo water generally run? This present flood is travelling about a mile a day, but that is on country that has been heavily stocked. But on country not heavily stocked it took about a fortnight to go 4 miles.
- That slow speed is accounted for by the great soakage? Yes.
- Fissures in the ground. Are there any large cracks on your run? Any quantity of them.
- What depth are they? I have not the slightest idea of the depth, but on looking down some of them appear to be 6 or 7 feet. How much deeper they go I have no idea.
- Is that only in the clay-pans? No; it is on the channel. There is also a channel which runs out from Kallara, and which is about 5 or 6 miles wide. You cannot get on it. There is no solid land on it now. It is just a swamp. When the water dries off you have a splendid crop of grass, but since 1879 the grass has been as black as possible, and nothing green grew on the channel.
- Water lost in fissures. Before the water becomes stationary all these large cracks and crevices have to be filled? Yes.
- Have you remarked the body of water pouring down them? At times you can hear it a hundred yards before you come to it.
- Tanks and wells. What do you depend on principally for your water supply? Tanks and wells.
- How many tanks have you on the run? I think between seventy-five and eighty tanks.
- And what is the average size? They vary from about 5,000 yards to 20,000.
- And the depth? From 12 to 20 feet.
- Best sort of tank. What do you find the most convenient size for watering stock? For this country the larger the tank the better, I find. Not a long narrow tank, but a square tank.
- Do you allow the stock to water at the tank, or do you pump the water out? I allow the stock to water at the tank.
- Evaporation. Have you made any observations as to the evaporation? No.
- Could you state approximately what percentage is lost by evaporation? I should think, judging from tanks which I know hold well, that the evaporation would be about 4 feet in twelve months.
- Have you made any observations as to whether evaporation is greater from clear water than from opaque? I have not.
- You find the evaporation is not so great from the deep tanks as from the shallow tanks? That is so. The evaporation is greater from a long narrow tank than from a square tank. I imagine that is because of the greater amount of water round the shallow edge of the tank where the evaporation takes place.
- Speaking from your experience, you look upon tanks as the most reliable means of providing water? I depend upon wells for my permanent supply.
- Wells. How many wells have you on the run? Twelve. (*Appendix to Report on Darling River, No. 10*)
- What are the depths? They range from 30 feet to 305—that is, wells that have water. I have gone deeper on dry wells.
- Have you any wells flowing over the surface? Not over the surface. They rise very rapidly to within 100 feet of the surface. Some rise from 300 feet to within about 40 feet of the surface. Mount Damper well is 305 feet.
- How far is that from Wilcannia? 35 to 40 miles. The water rises to within 100 feet of the surface—a good supply of fair water for domestic purposes.
- How did you sink that well? With the ordinary slabs.

Did you strike any water before you got to 305 feet? Not in that well.

Or drift? No drift. After about 60 feet we got into a sort of a washed silt, little layers of blue clay and sand, the same as what the river will leave here when the water goes down. There was a boulder or two, but nothing of any importance. The water was got in this silt stuff. Occasionally there were small shells found in it.

Mr. W. Hogarth.  
30 Sept., 1886.  
Silt in well.  
Shells.

*Mr. Gipps.*] What kind of shells? Just small cockle-shells they had the appearance of being. I have a very good specimen of one.

*Mr. Donkin.*] Will you kindly send that to Sydney? Yes.

Was there nothing particular about the sand? It was a fine sand.

Fine sand.

No pebbles? None.

Is there an underground current in that well? I could not say. The water came up the shaft at the rate of over 30 feet an hour.

Does the well become silted up at the bottom? Not that one. There is a well situated about 8 miles south of the one I have just spoken of. It is 258 feet deep, and the water when it was struck rose in the shaft 150 feet in less than ten minutes. The shaft is 6 ft. x 3. The water was struck in sand.

Do you think the drift and the water were the same as in the other well? I think so. I have an idea it is the same water. It rises to within 100 feet of the surface, and I should think the levels are about the same.

If you had had that well tubed from the surface down to where you struck the water, do you think the water would have risen to the surface? I am of opinion it would.

Tubing wells.

The water may now escape through a drift? Yes. If I recollect rightly I believe that just where the water rises to, or perhaps a few feet below, salt water was struck (about 500 gallons in 12 hours), and if salt water was coming in fresh water could flow out.

You have not tried putting down tubing? No. The well at Mena Murtee was sunk before my time, but I have used it for stock-watering purposes. It is about 307 feet deep, and the water rises to within 40 feet of the surface.

From the experience obtained with these wells, have you come to the conclusion that you can obtain water within 200 or 300 feet? I can in this country on the fall south of the local ranges.

Depth to find water.

Is the water soakage from the Paroo River? It is difficult to say where the water comes from, but it is an underground supply; it is not local.

You have nothing to show it is from the Paroo? Nothing. There are artesian springs on Lake Peery, on both sides of the lake.

Artesian springs.

Are they always running? Yes. The water is good, but tastes slightly of soda. There is also another artesian spring here, which we call Peery Well. It is east of Lake Peery. I have put down a well 190 feet, and got stock water; one 460 feet, no water; one 316 feet, no water; and one 350 feet, no water.

*Mr. Gipps.*] In speaking of these wells, could you give us any idea as to the elevation of the surface? No, I could not.

*Mr. Donkin.*] Have your tanks ever failed in drought? As yet they have never failed.

If the tanks have never failed at their depths of from 6 to 20 feet, are they, from an economical point of view, more serviceable and profitable than wells? Yes. Any tanks 20 feet deep have never failed, and are more serviceable than wells; tanks under 20 feet have failed, and are not so serviceable.

Tanks as compared with wells.

But if you had a flowing well at a reasonable depth, would you look upon that as of greater benefit than a tank? Certainly.

Is there any country on your run which has been tried to any depth for artesian water? Not to my knowledge.

You know of no deep wells? 460 feet is the deepest I have gone to, and that was without success.

Do you think it would be advisable to have the country tested for artesian water? I would recommend the country to be tested on the south and west of the range. It would be a benefit to the country to know whether artesian water could be got at a distance away from the mud springs.

Testing of country by boring.

In the country of South Australia, north-west of here, where the climate is somewhat similar, what method do you adopt to obtain water? Wells, as a rule.

Water in South Australia.

Are they deep? No, very shallow. When I left there we had twenty-two wells at work. They were all shallow. The deepest was 150 feet, and some were 60 feet.

Were any of those flowing wells? Not at that time; but since I left my brother got one at 115 feet, the water of which is used for wool-scouring.

The natural feature in South Australia is that you can obtain any quantity of water by sinking? In that region known as Strangway's Springs, on the overland line.

What height were you above the sea? I fancy Lake Eyre is about 30 feet below sea-level, and judging from the flow of the creeks into the lake I should imagine that Strangway's Springs would be a few feet above sea-level. The creek that ran past Strangway's is a very sluggish running creek, and the distance was about 40 miles to the lake. Allowing a foot to the mile, that would bring you pretty nearly on a level with the sea. Not just the Springs, because they are on a mound which is perhaps 100 feet higher than the surrounding country.

Has the idea of bringing the sea in ever been mooted in South Australia? It has been. People have suggested a canal.

Canal from the sea.

Would it be an expensive work? I should think so; but there is a saddle of sand ridges, and I do not know exactly how they would take the water through them.

What extent of country could be submerged? In Lake Eyre, from one point north to south, I should say about 150 miles by 30.

Do you think the bringing in of a large body of water like that would improve the temperature and cause evaporation—would it affect the climate at all or the rainfall? I should not imagine it would. I am judging partly by the heavy rainfall we had in January, 1885. The whole country, you may say, was under water, yet we had a very dry time for six months after that.

Effect on climate.

It is a very dry country there, in South Australia? Yes.

No evaporation? Very little.

But a large inland sea would have some marked effect on the evaporation? Well, this Lake Eyre has generally a surface supply of water in it. I was there fifteen years and never saw it dry.

Lake Eyre.

- Mr. Does Cooper's Creek find its way down? It empties ultimately into Lake Eyre.  
W. Hogarth. Does it find its way to the sea? No.  
30 Sept., 1886. It is lost entirely? Not altogether, because there are chains of waterholes from 8 to 9 miles long. One is almost permanent.
- Loss of stock. During the last seven years, have you lost many stock through want of grass and want of water? I have lost stock through the want of grass more than the want of water.  
What have been your losses here in the drought? Speaking from memory I should imagine they were 24,000.  
In what year was that? The summer of 1883-84.  
You have lost less, proportionately, than anyone in the district? I believe so, from report.
- Want of grass. That was from want of grass? Yes.  
You supplied plenty of water? I had country out back on which I had improvements, but as they had never filled they were of no use for the time.  
In the drought, what did your stock exist upon principally? Mulga, cotton-bush, and salt-bush.
- Spelling country. You say you have lost stock through want of grass;—could any possible means be devised to prevent further losses by spelling portions of the country? I think so.  
Could you possibly have prevented the loss? Not at the time. Possibly I could carry more stock now than then, with the improvements that have been put down lately.  
Have you ever tried the plan of preserving a portion of the run by keeping it unstocked for times of drought? I always reserve the paddocks with the permanent wells in case of emergency. I do not reserve them altogether, but I stock them lightly, so that I could put on a big supply of stock.  
Do you think if that plan were generally adopted throughout the interior it would prevent to a great extent the fearful losses? I imagine so, or I would not do it myself.
- Irrigation. Have you had any experience with regard to irrigation? None whatever.  
Do you think irrigation could be carried on on the banks of those lakes where the water is permanent, or on the river? I believe it can be carried on on the river on a small scale, but even on the river I have seen it fruitless. We had a small garden at the Mount, and because we could not get enough water to irrigate it we had to do without vegetables.  
But if a half-river were kept up, or a navigable stream, you think it could be made use of? I think so, to a small extent. Not for sheep-feeding, but for the working stock.
- Deficient supply of water. Without feed of some sort I suppose the working stock could not have existed during this last drought;—how did you manage? I bought hay and chaff at £50 a ton. But I have been using camels for the dry times, as they can reach the tops of the mulga beyond anything else.
- Hay and chaff £50 a ton. How do the camels answer? Splendidly, in dry times.  
Camels. Have you any on the run now? Thirty odd.  
Are they adapted for this country? There is nothing better for a dry season, but they are no good in wet weather.  
Do they thrive on the scrubs? Yes, they get too fat.  
Do you use them for draught? That is how I use them.  
Do they breed here? Yes.
- National scheme of water conservation. From your long experience here and in South Australia, do you know of any national scheme that could be carried out for the conservation of water, either by the flood-waters or artesian wells? My opinion is that if anything is to be done with irrigation it will have to be done by artesian wells. That is my experience of the country.  
That is, where you could make use of gravitation? Yes.  
You think then that where you have to lift the water or conserve it it would not answer? I imagine that you would not be able to keep a supply for the ground here. The ground takes up so much moisture, and there is the clay subsoil.
- Artesian springs. You think if artesian water were discovered, as in the case of the well in South Australia, that it would be made use of for irrigation? That depends on the quality of it. All round these artesian springs nothing grows except saline plants.
- Saline plants. If that water is exposed to the atmosphere the mineral salts evaporate to a great extent, do they not? The water evaporates and leaves the salt. There is a certain smell in the water, but that goes away, and the sheep drink it better.  
The summary of your experience is that the great feature of the country here would be to discover an artesian supply? Yes.
- Paroo River. Mr. Gipps.] Have you ever seen the Paroo run direct into the Darling? No.  
Does the Paroo run into any sink? The whole bed you may say is a sink. Of course it runs into Peery Lake in a high flood, but I do not know that you could call it a sink.  
When you have no flood, where does it empty? It dies away in the channel, and soaks away.
- Soil. What is the character of the soil in the Paroo channel? It is loam for a certain distance, down about 2 feet, a loose loam. Below that it must be more inclined for clay, but it cracks up. It is similar to the frontage country, only the cracks are greater.
- Kalyanka Creek. What is the appearance of the Paroo channel as it enters the Darling? It enters the Darling through the Kalyanka Creek, the billabong which comes into the township here.  
Is it a shallow channel? About 15 feet deep in places. It is not very deep higher up, perhaps 8 or 9 feet. There is a sort of bar higher up.  
A rocky bar? A stony bar.
- Underground supply. Have you any direct evidence that the percolation from the Paroo River provides for a large underground supply? I have no direct knowledge of such a thing. I imagine it does.
- Bunker's Creek. What is the length of Bunker's Creek? I hardly know. I think it rises higher up than Mr. Quin's country. It runs over about 36 miles of country.  
What is the character of the watershed? The head of it is very hard stony country.  
Distinct ranges? No; they are broken ranges—rolling country.  
What is about the area of its watershed? I have no idea of that.  
Has it a distinct channel? It has a distinct channel before it enters the Momba country, then it spreads out perhaps 2 or 3 miles wide in places, and then forms a channel further on before it runs on to the Paroo channel.  
What is the width of its confined channel? I suppose about 50 feet in places. And

And the depth? From 10 to 12 feet. I am speaking of it off Momba country. It has hardly depth on the Momba country. Mr. W. Hogarth.

Has it a great velocity? After it passes through the Bunker block it goes about 2 or 3 miles an hour. 30 Sept., 1886.

Then it discharges on to plains? It discharges on to the Paroo channel. Velocity.

At present it fills the lake? Yes, at present.

Would it more than fill this lake? It would be more than sufficient to fill it. I only secured about half the supply in putting it into the lake, because I could not carry my drain across the road. Supply.

Do you think it could be thrown into any other depression, such as Lake Peery? It could not go into Lake Peery, but there is a lake at the back into which I think it might be thrown.

Is it a deep lake? Tolerably deep.

What is the name of that lake? We call it Pangora Lake. Pangora Lake.

What is about the length of it? I suppose it would cover about half a mile of country, possibly a little more.

About what depth? It must have been about 15 feet after the big rain. I have not seen the bottom of it. I have not been on it with a boat. There is a good quantity of water in it yet, although it is twenty years since it was filled.

Is Bunker Creek constantly running? Once or twice a year. Bunker Creek.

It runs every year? It has run every year within the last seven years.

For what length of time, as a general rule? About three or four days possibly; but this last winter rain ran continually for about four weeks, I think.

Do you think it would be more beneficial to allow the Paroo to spread out in its present natural condition than to drain it off by a narrow channel? For conserving water bring it into a narrow channel certainly, but whether the cost of doing so would justify it I do not know. Treatment of the Paroo.

Is the bed of Lake Peery good holding ground? Yes.

Do you not think that by taking the Paroo some distance back sufficient elevation might be had to bring it into Lake Peery, and that, by banking Lake Peery, you might have sufficient depth of water to form a permanent lake? Of course the outlet of Lake Peery is the inlet, and the other day the water was going in 4 miles wide. I do not see how the water could be taken in very well at a higher level if this were banked. It could be taken round the hills, perhaps. I do not think much could be done with Peery Lake for irrigation purposes.

Is it too shallow? Yes; and the water is so full of mineral qualities that it would not grow anything after standing a certain time in the lake.

What is the character of the ridges on the south of Lake Peery, about the centre of the run? Rough, broken, stony hills. Stony ridges.

Do they form the gathering ground of Lake Peery? This last 5 inches of rain put about 1 foot into the lake from its own gathering ground.

What is the average height of these hills? From the bed of the lake, I should say from about 200 to 250 feet.

Any rock exposed? Any quantity of rock.

What is the character of the rock? I do not know exactly the proper term. It is a rough, hard, flinty rock; there is very little sandstone. Character of rock.

Any ironstone? Very little. Sandstone is got south of Peery.

Could the waters of the Paroo be spread over a larger area than at present by small narrow channels? I do not think so. Not on the Momba country. The country seems perfectly level.

With regard to Mount Damper well, how far is that from Bunker's Creek? The Bunker channel when in flood comes within about 200 or 300 yards of it. The main channel is not within  $2\frac{1}{2}$  or 3 miles of it. Mount Damper well.

It is on the right bank of Bunker's Creek? Yes; on a sandhill.

What is the character of the water in the well? It is good stock-water; in fact, it is fit for domestic purposes.

Can you reduce the level by pumping? A little. You can take it down about 60 feet by pumping 3,000 gallons an hour.

In what length of time? In about eight or ten hours.

How far is Beefwood well from Bunker's Creek? About 8 miles. Beefwood well.

Can you reduce the level of the water there by pumping? You can reduce the water about 10 feet by pumping 3,000 gallons an hour. But if you let the water stand for two or three months without drawing any a sediment seems to settle on the inlet, and you can take the water down about 20 feet, and it rises up in half a minute, perhaps 20 feet, when the weight is taken off it. By some means or other the inlet seems to get closed.

That seems to be an artesian supply? That is my idea. I know when we put the pump down the well the man working in the shaft let some earth go down the shaft. They started the engine and pump going, and were taking the water out at a great rate. I was looking down the well at the time to see at what rate they were taking it out, and all at once I saw a movement in the water, and it rose 20 feet in a moment. Artesian supply.

Under ordinary conditions you can reduce the level of the well in what time? In about an hour and a half you can reduce it 10 feet.

You never get it lower than that? Not if you are working it regularly.

You have never tried by pumping more than 3,000 gallons an hour? The pump I have would not pump more.

Is the Mena Murtee well situated near Bunker's Creek? You may say it is on a sandhill in the bed of the creek. Mena Murtee well.

Does that give you an unlimited supply? Yes. You can reduce that well about 160 feet. Below that I have not been able to get.

What is the supply? 3,000 gallons an hour.

What are the prevailing winds in summer in that quarter? The wind often gets to the south-east. Winds.

And in winter? There is very little wind in winter.

Is there sufficient wind to keep windmills going? Not sufficient. You cannot rely on them.

Have you any dews at all? Very heavy dews at times. Dews.

In winter or summer? Always in winter.

Every year? Yes. The fore part of this winter there were less dews than I have seen the last seven years.

- Mr. W. Hogarth. years. After the rain started we had very heavy dews. Up to the middle of June there was very little dew.  
30 Sept., 1886. To what do you attribute the dew? I should imagine it is from evaporation after heavy rain.  
Levels of Paroo country. *Mr. Donkin.*] Do you think that any system of surveys to take the levels of the Paroo and the country out there would be of any benefit? I think it would be of service for the Government to know what the levels are if they intend to go in for water conservation, because a person riding over the country is deceived unless he takes levels.  
It is impossible to tell by the naked eye what the fall of the country is? Impossible.  
Have any surveys been made to ascertain the levels? Not that I know of.
- Rain-gauge. Do you keep a rain-gauge on the station? I do.  
Do you supply the Observatory in Sydney with records? Yes, every year.
- Diversion from the Darling. Do you think if legislation allowed for tapping the Darling, say at the Kallara boundary, would it be of any great advantage to the pastoral tenants to divert the water from the Darling right across the country? Provided it were taken into tanks on the solid ground where the stock could water, but stock cannot water in the channel as it is at present, unless it is just at the edge. When the river commences to fall the stock cannot get near it.  
What frontage have you to the river? About 40 miles.  
When the water is low, cannot the stock water? I am speaking of the channel coming in from Kallara—the rotten channel.
- Wool to Adelaide. How many bales of wool do you send off the station? This year we shall send off about 5,500 bales.  
Which port do you send to? Adelaide.
- Railway to Wilcannia. If a railway were constructed to Wilcannia, and the river kept up between the points of the railway, say Bourke and Wilcannia, would the pastoralists make use of Sydney as a port? It would depend on pounds, shillings, and pence, as far as we are concerned. Of course if there were no river down lower they would have to use the railway to Sydney.
- Dams on Paroo. *Mr. Gipps.*] Are there any dams on the Paroo? I believe so; higher up than we are.  
Do you know the height? I do not know. They are on Nocolche and Wanaaring, but I have not seen them.  
*Mr. Donkin.*] Would there not be a great advantage in shipping at Sydney on account of the greater convenience of the port there, as compared with Adelaide? I have had no experience as regards shipping at Sydney.
- Shipping wool from Adelaide. But are there not difficulties at Adelaide? I know we had 800 bales of wool landed at Morgan at 6 o'clock one evening, and the next day it had left Adelaide in the mail steamer at 6 o'clock in the evening. That shows there cannot be much difficulty in sending by Adelaide. The wool occupies twelve or thirteen days in reaching Adelaide from here.  
But it could be at the ship's side in Sydney in two days from here? By rail, I have no doubt.
- Conservation of water by Government. Have the Government done anything towards the conservation of water in this district;—is there sufficient water conserved? There is sufficient conserved by the Government through Momba. There is a dam on the leasehold which throws the water up the creek on to the Government reserve, and the public get the use of the water. With reference to the springs, the Government have done nothing with them.
- Folly in selecting Government tank sites. Have they opened them up? There has never been a spade put into them, but the Government have put a tank, at the cost of about £2,000, within a quarter of a mile of a running stream that would water about 20,000 sheep a day by a little trough. Then, at Copago Lake, which holds about 20 feet of water, there is a Government tank nearly completed, but the contract was stopped through the getting of salt water at 14 feet. A flood would wash the bank of the creek into that tank. A Government tank which cost £1,500 has now silted up.  
In putting a tank down close to the springs, could not information have been obtained from the manager? They could have obtained it if they had applied for it.  
Perhaps they were not aware the spring existed so near? They were well aware of it, because the spring has existed for years. I do not know of any travelling stock that water at the tank; they water at the springs.  
The conservation of water by the Government has not been altogether a success? Not in those cases I speak of. I believe they have a good tank in the 9-mile lake.  
Do you not think such errors would be avoided by a local Government? I certainly think so.  
The case you speak of meant actually £2,000 thrown away? Yes, wasted. Another tank is silted up at Copago Lake.  
Have you known Copago Lake to be dry? It was dry for five years after I arrived here.
- Tanks silted up. Then, without some expenditure by Government or private enterprise, it could not be considered permanent water? No. Still, at the same time, if they had looked for a proper site to put a tank down, their tank would not have silted up.

---

Mr. A. Munro examined:—

- Mr. A. Munro. *Mr. Donkin.*] Where do you reside? At Mount Murchison, on the Darling, about 18 miles by land above Wilcannia.  
30 Sept., 1886. You are manager of the station? Yes.  
Flood of 1885. How long have you been in this district? Nearly twenty years about Wilcannia.  
Is there any particular feature about this flood as compared with others? The flood caused by local rain in January, 1885, was different from the ordinary floods.  
Had you ever known a flood before from local rain? No; I have known it rise 2 or 3 feet.  
Did the Paroo run into the Darling? Not from the head of the Paroo.
- Darling and Paroo. You have never known the Paroo to run into the Darling? No; the Darling water came round into the Paroo.  
How did the local rain find its way into the Darling? By the lower Paroo channel.  
Did you say there was a flood in the Darling from local rain? The rain fell about Momba.
- Heavy rain. Did that cause a flood in the Darling? That made the river rise about 28 feet. We had 12.60 inches of rain at Copago Lake in four or five days. One of the effects of that flood was that there must have been millions of yards of silt washed into the Darling, forming banks and filling up holes that were free before. All the creeks cut away. Where

Where did that rain come from? I was not here the time the rain fell.

Where do you look for your heavy rains here? Nearly north-west.

Do you catch the tropical rains from Queensland? Very seldom. Thunderstorms are not as frequent as they were about sixteen or seventeen years ago.

Since your experience here, have you recorded the height of the floods in the river? I have not.

What do you generally gauge the height of the river by? Generally by the Wilcannia reading.

Does a rise of 2 or 3 feet in the river affect you at the station to any extent? When the river is dry it keeps the stock from crossing.

In high flood, is much of the run submerged? Most of the frontage.

What do you depend on to guide you as to the height of the river? The height as from up above.

What have you been accustomed to read by—the bed level, or summer level, or navigation level, or what? Summer level.

What do you call summer level? Say about 2 feet of water, when the river is not navigable.

That is rather misleading, is it not? Yes.

To adopt a zero right through, what would you recommend;—would you take some well-known flood-mark and read from that? I should say 3 feet of water, and call that summer level.

Three feet of water over the bars? Yes.

Are there any rocky bars at Mount Murchison? Two or three. Rocky bars.

Is there any fall in the river there? Very little.

Does it back the water at all? One bar, the Kennedy reef, backs the water up about 3 miles.

How far is that from Wilcannia? About 23 miles by land.

What proportion does the river bear to the road in length, taking in all the bends? About two and a half to one.

Do you think it would be difficult to raise Kennedy bar 2 or 3 more feet? I do not think there would be any difficulty at all.

Do you think any erosion would take place in the banks? I do not think so, because there are rocks to act as a by-wash.

It is only a matter of masonry and labour to raise the water 2 or 3 feet? That is all. Last year I Small dam. built a dam 4 feet high on the Darling, close to the house, and conducted the water over the rocks. It was an embankment about 3 feet wide on top and 4 feet high, and it backed the water up about 1½ miles.

How long did that stand? Until the big flood came—that is, for nearly two months.

Was the water running round? Running round on the rocks. A few sandbags were placed on the wing, and the water did not cut away.

You think there is no difficulty in raising the river where the natural bars are? I do not think so.

Do you know any large depressions where a great body of water could be conserved? On the run Copago Lake. the only place is Copago Lake.

That is filled from the Paroo? Yes, and from the Darling backed up. The present flood-water is backed up within 5 miles of Copago.

Have you known the water in the Darling, from being low, to be unfit for domestic use or for stock? I have known it to be very bad. Some of the waterholes have been quite salt from salt springs.

Have you seen any irrigation on the river? None.

*Mr. Gipps.*] Are there many rocky bars in the river? From Wilcannia to the Marra boundary I think Rocky bars. there are four or five.

What distance is that? Over 100 miles by river.

You think it would be advisable to construct a series of movable weirs on these rocky bars, so as Movable weirs. to provide for a kind of lock system to enable navigation to be carried on between Wilcannia and Menindie and Wilcannia and Bourke? I do not think there would be any difficulty at all, but I believe the river above would silt up. I do not think there is sufficient scour in the river to clear the silt away.

These movable weirs would be about 12 feet high;—what distance do you think they would throw the water back? Perhaps 40 or 50 miles.

Do the flood-waters of the Darling deposit much silt? No; the local rains send the silt into the silt river.

Have you known any large waterholes filled up by silt? Several, but not from flood-water of the Darling, only from local rain.

Do you know of any dams on the Paroo? I do not know the Paroo, except the lower part.

What is the average height of the banks of the Darling River? I think about 38 or 40 feet.

Is your country well timbered? No; some of it is badly timbered.

What is the kind of timber? Gum and box.

Is there much scrub on it? Not much on the frontage.

*Mr. Donkin.*] After your long experience here, is there any large national scheme you have thought of by which a large body of water could be conserved? There is a place about 9 miles from Wilcannia where, by means of a drain 2 or 3 feet deep, the present flood would give from 15 to 20 feet of water. That is on the Paroo Road.

Where would the water run to? It would fill the Nine-mile Lake. Nine-mile Lake

What distance would the cutting be? About 2½ miles at present, from the fall into the lake to the flood-water.

And what depth? About 3 feet.

What body of water would there be at the Nine-mile Lake? About 12 or 15 feet deep, and about 1½ miles across. After the rain of January, 1885, I measured the water in Copago; there was a depth of 27 ft. 6 in. in March.

What depth is there now? I think about 20 feet.

Is the water running in now? No.

That is much larger than the Nine-mile Lake? Much larger.

Could the supply in Copago be augmented? The present flood could not put over 8 or 9 feet more into it.

Does the water run out? A certain amount, as the flood-waters go down. It could be prevented by an embankment about 200 yards long, and about 8 or 9 feet more water would be sent in.

What depth would that give? Over 30 feet.

What would be the height of the embankment? About 8 feet. What

Mr.  
A. Munro.  
30 Sept., 1886.

River-gauge.

Rocky bars.

Small dam.

Copago Lake.

Rocky bars.

Movable weirs.

Nine-mile Lake

Mr. A. Munro. What is the length and breadth of Copago Lake? It is about  $2\frac{1}{4}$  miles by  $1\frac{1}{4}$ .  
 The supply would be absolutely permanent? I would consider it so.  
 What would it be used for? For stock only.  
 30 Sept., 1886. Mr. Gipps.] What is the general width of these rocky bars across the Darling? Some of them go Rocky bars. a long way back under water, from 20 to 100 feet, and some of them go a quarter of a mile from where the water flows over to where the rock disappears.  
 What is the character of the rock? A sort of rotten sandstone of a clayey description. Some of the rocks are very hard and close like ironstone.  
 Do you know this bar close to the township? Yes.  
 Is it right opposite the township? Yes.  
 What width is the bar? It must be about 20 or 30 feet I should say.  
 What is the character of the rock there? A hard sort of ironstone. Some of the bars are porous rock.  
 Mr. Donkin.] These bars run right into the banks? Right into the banks.

Mr. William Orr examined:—

Mr. W. Orr. Mr. Donkin.] You are the District Surveyor? Yes.  
 How long have you been in the district? Three years in all—eighteen months on one occasion, twenty-two years ago; and eighteen months during my second visit up to the present time.  
 Have you had any experience of country similar to this? I have had experience in Riverina. I have been there for the last twenty-two years, occasionally visiting the hills.  
 Where does your district extend to? Northerly to the Queensland border, westerly to the South Australian border, easterly about 120 miles from the Darling, southerly about 120 miles from Wilcannia.  
 Have you been over your district since you have been here? Not since I have been here this time.  
 Irrigation in Deniliquin District. During your experience in similar country, have you seen works carried on for water conservation? I have seen irrigation work carried on at Coonong; I have seen it in the Deniliquin District, and along the Murray; and I have tried a little irrigation myself.  
 Have you seen any irrigation in this district? There is none on a large scale.  
 Irrigation practicable. From your experience in Riverina, is it a success there? Yes.  
 Do you see any reason why it should not be carried on here? I see no reason. I am convinced it could be made a success along the river if water were supplied.  
 What do you mean by a supply of water? If it is possible to obtain water, irrigation is a matter of no difficulty whatever.  
 Would it be too expensive to pump it from the river when low? No; it would not be too expensive.  
 From my observation of what it costs the Municipal Council here to lift the water I am convinced irrigation could be carried on successfully.  
 Losses in stock. Are the losses from stock in this district in time of drought very great? I do not profess to say anything about that. I have seen at various places immense losses, but yet the people themselves have not acknowledged heavy losses. It seems to be the policy of each manager to state his losses are nothing, and that his neighbours' losses are very great. So when I want to find out what a man has lost I generally go to the man's neighbour, and he gives me a pretty good account. But this is simply a matter of curiosity on my part.  
 Would irrigation avert to any extent the great losses in stock? I think it would. I am sure if the question were set at rest as to whether water was obtainable it would save immense numbers of stock.  
 Artesian supply. Do you think it is possible to obtain artesian water for irrigation? I think artesian water could be supplied here much more cheaply than any other. I think artesian water is the water supplied by nature for the purpose. For instance, evaporation here is so fearful that water should be conserved under cover if possible, and of course that cannot be done. But nature has done that already by having the water in the bowels of the earth.  
 Underground supply. Do you think the great soakage which occurs in these rivers, the Paroo for instance, supplement an underground supply? I have an idea that such is the case from having seen the Paroo country, and having heard the evidence of Mr. Hogarth. It is my opinion that a great deal of water is absorbed by the soil. I think there must be some connection between the surface and the subterranean waters down the valley of the Paroo.  
 In speaking of irrigation from artesian wells, what crop would you recommend to raise? I think lucerne would pay here, for the reason that it could be cropped so frequently, but I have had some success myself with wheaten hay. I have watched others growing lucerne, but I have experimented with wheat myself, and have always had a very good crop.  
 Grasses. Are there any natural grasses or herbage here that it would pay to irrigate without cultivation? There is a grass, but I could not give you the scientific name. It is a long tussocky or bunchy grass which seems to stand the drought well.  
 Is this naturally a grass country or a herbage? Herbage.  
 Successful cultivation. Do you think, as a commercial enterprise, it would pay to irrigate to save stock? Not in the present state of the labour market. There is not sufficient population here, but I anticipate it would be successful in years to come, as it has been in the Deniliquin District. A man there with a large family of daughters cultivated land. He had 5,000 acres. He himself was a blacksmith by trade, and did not understand much about stock. He put in about 70 acres of crop, and got a very good return. That summer and the next he was enabled to carry his stock through the drought by giving them the crop in small quantities. He made ample provision for water for them in the shape of tanks.  
 What water did he use to irrigate? He did not irrigate at all. I mean to say, if he could have irrigated he could have carried double the number of sheep. The great want of stock in the summer is water. They can exist with comparatively little herbage if they have water.  
 We have been told by the Stock Inspector here that the losses in one drought were at least 400,000, ---do you think they could have been prevented? I think so, chiefly by conserving water. I think water would have reduced the losses. It is hard to kill stock if they have water.  
 Stock living on water alone. What do they live on? They seem to live on what is in the water.  
 You think that if water conservation is extended these frightful losses might be lessened? I am certain of it, from what I have seen of runs in the Urana and Deniliquin Districts,

was

Was it not impossible to occupy this country before private enterprise had conserved water? It was impossible to occupy it; this shows the necessity for water supply. Besides the Darling, is there any permanent water in your district? I look on Bencanya Lake as permanent. That is on the western boundary of the Colony. Mr. W. Orr.  
30 Sept., 1886.  
Bencanya Lake.

What is the position of it? It is on the direct line from Silverton to Cobham, and about north-west of here, approximately over 100 miles in a direct line from here.

What is it filled by? By local drainage. Apparently it has a system of its own. It was filled in January, 1885.

What depth of water is there in it now? That has not been ascertained. I am merely giving you the information I have gathered from others, but not from personal observation. I look upon all these lakes that are so deep, such as Copago, Cobham, and a small lake down at Menindie, as permanent. Have you ever known the water in the river to be unfit for domestic or stock purposes? Not in my experience. Permanent lakes.

In a time of prolonged drought this would be an utterly waterless district? Yes. I have reason to think that in a long drought the country would be quite untenable.

How long would stock exist without feed in these back runs if plenty of water were conserved? I think until the cold weather sets in. I think they would exist fully six weeks or two months with scarcely anything to eat, in fact three months. I have seen them pawing the ground up and eating the roots fully that period before they died. And some of them would exist through the drought and live until the weather turned, but they seemed to lose their wool, and were as bare as the palm of your hand. I think the best thing to do would be to conserve the water in every hollow throughout the country if possible. If the January rains were conserved in large bodies it might be to the injury of certain individuals who would be deprived of the use of the pasturage within the lakes, but I think it would be a benefit to the country as a whole, because, if the water were there to act upon, Providence would find means for raising it and letting it fall on the earth. Stock existing without feed.

If evaporation were increased in this country, you think it would moderate the climate? I think so. If we had the material to act upon, nature provides the engine in the shape of heat.

Do you think anything could be done on the runs by keeping in reserve a part of them for times of drought? I think very little can be done that way. I think the squatters here are quite alive to their own interest. They just want some assistance in legislation to back them up. For instance, if one squatter had a nice clay-pan, or a nice lake, and more than sufficient water in it, it would be to his interest to dry up the lake. And I think, for the benefit of his neighbours, he should be prevented from doing that. It would be to his interest to dry up the lake for the sake of the fodder, and such a course would not be desirable. Reserving runs.

Is there any national scheme you would recommend for the conservation of water? No. I have read your report, and I agree with it on the whole. But I think that no depression of any kind should be sold; that no frontages should be sold—that is to say, that no land should be sold within 2 chains of the frontage of any creek or river; and that all lands which hold water, such as lakes, should not be sold.

From your experience, the difficulty in occupying this country and the losses have originated through want of water? Entirely through want of water.

Have you had much experience in wells and tanks for conserving water? Only from observation, and in measuring and inspecting them, and so on during the course of my experience. I have seen and measured a good many. I have a well of my own, but it is only a small one. Wells.

Do you think the Government should be advised to test this country for an artesian supply? I strongly advocate that; I think it is well worthy of consideration. The Government should take advantage of some of the shafts already sunk by others. Test sinking for artesian water.

You have heard the evidence about the Paroo;—do you think that river augments an underground supply? I do.

Are you of opinion that the Paroo waters never join the Darling? No; I am not. I am of opinion that they do join them, from the fact that my predecessor was particular in pointing that out to me on my arrival. He mentioned the fact that the Paroo water flowed into the Darling, and he took me to the channels and pointed them out. That water came in in January, 1885. Mr. Munro, in his evidence, bore that out, I think. Paroo waters flowing into Darling.

Do you think the country as a whole has been overstocked? Judging from the appearance of it, I should say not. I think that so far as herbage is concerned they do not know what a drought is here yet. Overstocking.

How many acres do you allow to a sheep in this district? I think with the present water supply that eight is a fair thing.

There have been great complaints throughout the country generally about overstocking;—you think they are not justified? I think they are not. At Wanganella, in the Deniliquin District, where they grow some of the best sheep in the country, the sheep are obliged to eat roley-poley, but here they say the sheep will not eat it.

Will they eat roley-poley when it is dry? When it is not actually dry like sticks.

You think all the bushes that are grown here are edible? Not all, but there is a good deal of herbage here which is edible.

Do you know the lakes of South Australia? Not from personal observation, although I have been in South Australia.

You say you think that by filling up the depressions in this district evaporation would take place, and possibly an alteration in the climate; do you think it would have an effect on our territory if those lakes in South Australia were filled? I do. How far it would affect the rainfall of South Australia I could not say. I think if South Australia allowed the ocean to run into the lakes it would have a beneficial effect through the increase of evaporation. South Australian lakes.

Have you noticed that after heavy floods, when the country is submerged, the seasons continue fairly good;—is there a greater rainfall? There was a very heavy flood prior to my coming here in 1865, and that was succeeded by a very severe drought. The river fell very low, and was dry in places. The country was very bare, although there had been heavy floods the previous year.

What does the State derive the greatest benefit from, the flooding of these black-soil flats, as in the talywalkas, by which means natural irrigation takes place, or the conserving of the water? I think it would be better for the State to distribute the water, that is to say, by means of works to conserve it, and let it be distributed as required. Water distribution preferable to natural irrigation.

Are

- Mr. W. Orr.** Are there any places where that plan could be carried out? I think so, in the vicinity of Menindie.
- 30 Sept., 1886.** But does not a great benefit accrue to these black lands through the natural irrigation? No. By keeping the water a length of time on the land it is made useless. All the vegetation is killed on it. But after the water dries up, does not the land recover? Not quickly; the vegetation seems to be killed. With regard to Lake Woytchugga, we have evidence that after it is flooded, as it is now, the feed would be sufficient to keep all the stock on the town reserve here;—is that correct? I do not agree with that at all. I am sure the little feed there is on the bed of the lake is insignificant. It was quite dry at the end of last year, but I never saw any stock on it.
- Weirs on Darling.** You have heard the evidence with regard to the River Darling, and the possibility of erecting weirs across;—do you think it is feasible to erect weirs on these bars? I certainly do. What is the average fall of the river from Wilcannia to Wentworth? I have it here in a document, showing the fall in 20-mile stages. (*Appendix to Report on Darling River, No. 11.*)
- Locks and railways.** Which would you advise as a State scheme, to keep up a system of locks in the river, or to construct a railway to the metropolis? I think both should be carried out. By means of locks the river would act in unison with the railway, and be a source of great revenue. Do you not think that weirs in between points on the river would be sufficient? I think the lock system would be more desirable. Would not the construction of locks be expensive? I think it would be expensive to erect locks, and they would involve a great waste of water.
- Grey Range and Barrier Range.** *Mr. Gipps.*] Is there any connection between the Grey Range and the Barrier Range? I think not; there is no evidence of it. Is there a distinct gap between? Quite a distinct gap, and the trend of the country is quite different. The Barrier Ranges and the Grey Ranges have different axes altogether. What is the character of the natural features of the Grey Range? I have not seen the range, but from what I hear it is a sort of conglomerate, with nothing special to denote its character. And the character of the Barrier Ranges? Somewhat similar, showing they are probably a primary formation. And the height of the Grey Range? I have been told up to as high as 500 feet. And the Barrier Ranges? About the same. And what width is there between them? There are two gaps;—one is about 18 miles, and the other is nearly 18 also. Are these gaps crossed by any watercourses from Queensland? Yes. The Bulloo water passes between the first gap I spoke of and the ranges, and discharges into Cooper's Creek; or rather, it is supposed to discharge there; probably it did discharge in former times into Strzlecki Creek.
- Diversion of Bulloo River.** Would there be any means of diverting the Bulloo River before it crosses that range? I think it could be diverted with comparative ease, but I believe it serves its purpose better by following the course nature has given it. At the present time I believe it is continuous into Yantara, Yancannia, and Cobham Lakes. Have you examined this country yourself? Not personally. Can you give us any information as to the Wangalara Lake? Not from any personal knowledge at the present time, but probably a few months hence I may be able to give you some evidence, as I intend to see it. I have not had time to visit all such places.
- Artesian supply.** You say you consider nature has supplied a system of underground drainage which would provide an artesian supply;—what reason have you for such a supposition? The fact of seeing the water passing away. At what level? Passing away in the Paroo and other parts. I feel confident there must be an underground channel. How could it be an artesian supply if it passes away under the Paroo;—you could not get it up there? Not there, but at some lower point. What is the character of the rocks in the Paroo basin generally? I have not seen any. There are rocks in the vicinity of the town, but there are no organic relics or specimens of any kind in them. You have no actual reasons for supposing there will be a large artesian supply at any time? My only reason is that I have heard people state they have obtained it in other places, and I have heard of springs in other parts of the country. I also judge by the configuration of the country. Is there any proof whatever of what may be termed an artesian basin—that is to say, a basin flanked by a large deposit of tertiary rocks, which you can see at any time outcropping? You might compare the form of Australia to a saucer of which the border forms the edge or lip, and knowing that the tertiary strata is in the centre, I presume the other would find its way underneath.
- Soft sandstone.** Have you any reason to think there is a thick bed of permeable rocks anywhere within this basin of the Darling? I have not sufficient knowledge of that. I have not come across any permeable rocks here. There is a soft sandstone in the quarry here which I believe to be permeable. What is the character of that sandstone? Eolian, I think. Is it very hard? No; it is comparatively soft and water-worn grit. Is it close-grained? Very close. Is there a thick bed of it? That has not been tested. Has it any inclination? No; it is eolian. You do not know the extent of it? I cannot say. You say you know something of the Urana District? I do.
- Urana Lake.** What is the length and breadth of the Urana Lake? 8 miles by 6. What is the source of the supply? Coonong and Urangeline Creeks, but they never fill it. I have seen Coonong pouring into the lake and disappearing. Is there any outlet? There is one, but it acts sometimes as an outlet and sometimes as an inlet. It is called Cocketjedong Creek. What is the average depth of the pan? Roughly, it is about on an average 20 odd feet, but the cliffs on the bank of the creek are about 90 feet. They show a Devonian formation. Is that the character of the whole gathering grounds of the lake? I think so. You said the outlet of the creek was also at times an inlet of the creek? Yes; it is so flat that when the lake is full and there is no local rain the flood-waters pass away through the creek. I have seen the water flowing into the Cocketjedong Creek, and sometimes out of it.

We have had evidence that Lake Urana has filled from the Murray? Not from the Murray, but from the Murrumbidgee. Mr. W. Orr.

Do you know the Billabong Creek? I do.

Has it a well-defined channel? It has at the higher part, but lower down it bears the usual characteristic of creeks in Riverina. Where it is in the mountains it is well defined; but on the plains it becomes tortuous and ill-defined. 30 Sept., 1886.  
Billabong Creek.

Is it a permanent stream? I should say it was.

Does it bring down a large volume of water in flood-time? I have seen it well filled in flood-time.

Do you know of any sites on it that would make large impounding basins? There is one place which would be very good, I think, on the upper Billabong; but no doubt the basin has been alienated since my time.

Would you advise examination of the Billabong? I would strongly advise the examination of the head of the Billabong, and the head of Urangeline Creek, too.

Do you know anything of the Tumberumba Creeks? No.

What was the quality of the water supplied to Wilcannia during the late drought? It was very inferior. The water obtained from the river seemed to be full of salts of some kind.

Was it drinkable? I certainly thought it was not fit to use.

Do you think it would be advisable to back up the water for the purpose of water supply? I do. I think it would be an excellent thing to store a large body of water, if possible, for the sake of keeping the water pure.

Mr. Donkin.] You were a resident of Deniliquin? I was.

Do you know the Edward River well? I do, well. Edward River.

Is it an ana-branch of the Murray, or has it a separate drainage area of its own? I am certain it is an ana-branch of the Murray. I have known the Edward to be dry when the Murray was nearly dry also.

You think the flow of water in the Edward depends entirely on the Murray River? Entirely.

MONDAY, 4 OCTOBER, 1886.

At Menindie.

Present:—

MR. DONKIN,

MR. GIPPS.

Mr. Nicholas Sadleir examined:—

Mr. Donkin.] How long have you been in the district? Since 1858.

Have you been in this lower part of the Darling the whole time? Between here and Wilcannia, in fact from Wentworth to Wilcannia. We had a station at Tarcoola, near Pooncairie. Mr.  
N. Sadleir.

What is the name of your station here? Albemarle; and I am the manager. 4 Oct., 1886.

What is the extent of it? About 700,000 acres.

Will you please enumerate the floods you have seen in the Darling? They are described in this statement. Floods.

(Appendix to Report on Darling River, No. 12.)

What is the lowest rainfall you have known? It was in 1883, 5.74 inches. Rainfall.

And the greatest? 15 inches, in 1870.

Do you remember the first year the river was navigable? In March, 1858. When I came up the country was unoccupied from Tintinallong to Bourke, on the east bank, a distance of 200 odd miles. Early navigation.

Who is the oldest resident on the Darling—which is the first station formed here? I think Dr. Fletcher was the oldest.

Had the Darling been occupied many years when you came? About four years.

How far did navigation extend up the river in 1858? Some steamers went to Bourke.

From your experience since 1858, what is the average of years that the river has been open for navigation? It has been open for navigation for about thirteen or fourteen years in that time. For five years we have had wool in the shed for twelve months before sending it away.

What is the longest time you have known steamers to be stuck through a low river? Two years, I believe. Steamers stuck.

Is the river here affected by the flood-waters of the Murray? I do not think so, further than the Murray backs up some 60 or 70 miles. Without a flood in the Darling we could feel no direct influence from the backing up of the Murray. If there is a big flood in the Murray the Darling rises much higher, because it does not run off. Murray backing up.

Do you know of any rocky bars in the river? Yes; there is one at Weinteriga, one at the Rocky Waterholes, and there are the Christmas Rocks at Wilcannia. Rocky bars.

Are there any lower down the river from here? That I cannot tell you.

Do you know whether there is a fall at these bars? There is a fall at the bars, or a series of rapids, which must throw the water back.

Do you think it would be possible to raise the rocky bars 3 or 4 feet? Quite possible. I think captains of steamers dread these bars because they interfere with navigation. The river is perfectly safe between the bars, but unsafe over the bars.

If the bars were removed, would it not have the effect of levelling the bed of the river all through? If the bars were removed navigation would not last so long.

Has there not been some agitation to have them removed? I do not know; it would be a serious and foolish thing if it were done. The bars have the appearance of sluice-gates, the water rushes through so fast. This is particularly the case with the one at Weinteriga.

Is that the most noted instance you know of? That is about the only one I know of. It is a rapid there.

You know the ana-branches of the Darling, near Menindie, the Talywalka and the Lakes? Very well. Ana-branches.

Which is the principal ana-branch between here and Wilcannia? That is not a fair question to ask, because they come in above Wilcannia.

Well, up the river, there is no other ana-branch between here and Wilcannia? Many.

Which is the principal one? On the east bank of the river the first of any importance is Three-mile Creek. Three-mile  
Creek.

- Mr. N. Sadleir. Could any large storage of water be made there? The whole lot is a most valuable storage, if the land is any good to irrigate, but I question whether the land is any good. It runs through plain country, and could be easily irrigated.
- 4 Oct., 1886. You know the Talywalka? Yes.
- The Talywalka. Can you give us an idea of the total length of it? It is about 300 miles in length.
- Dam. Is there any large ana-branch running out from the Talywalka again? Yes; an artificial one.
- How is that formed? It is forced out on the east bank of the Talywalka by the erection of a dam across the Talywalka Creek about half a mile west of where the artificial channel leaves the Talywalka Creek.
- How far is that from Menindie? 54 miles.
- By whom was the dam erected? By Mr. Phelps, the owner of Albemarle.
- Do you know at what cost? The dam cost about £3,000.
- Was that work carried out entirely by Mr. Phelps? No. It was conceived by him, and the first work was done by him. Then the lessees of the adjoining stations, Tintinallogy, Teryaweynya, and Tolarno, joined with Albemarle, and paid their proportion.
- Success of dam. Was it carried out in any way under the authority of the Government, or were the Government consulted? After we showed the result of our labours we had it inspected by the Commissioner, Mr. Lockhart, and he considered the work of so much importance to the country, and thought the lessees deserved so much credit for having conceived and carried it out, that he recommended a mile to be reserved all round the system of water. This represented, I think, 444 miles.
- What was the object gained in carrying out this work of diverting the water? It increased the capacity of the country, and enabled it to be improved.
- Filling lakes. What was the object of diverting the water? To fill the lakes and send the water into the back country. There were a series of depressions, some of which showed indications of lakes, and some did not. There was timber—oak, for instance—in some of the depressions, which looked as if it had never been felled.
- In what year was the dam erected? In 1867.
- Had you ever known the depressions to be filled before? No.
- Was there any water in them? Only in those near the creek.
- Would they have been filled if you had not carried out the work? No. The 1864 flood forced out water there, but not a tenth part of it went out, and that flood was  $2\frac{1}{2}$  feet higher than any flood before or since.
- Was the 1864 flood the highest you have known on the Darling? Yes.
- Area of water. Can you tell us the area covered by water in those lakes? About 160,000 acres.
- The perimeter of the water is about 444 miles? That is what we paid for in surveying.
- How far into the south-east country did the water reach through the action of the dam? In a direct line from where it leaves the creek to its extreme southerly point it would be about 50 miles.
- When was the first flood after the erection of the dam in 1867? In 1870.
- And were all the lakes in this series filled? Yes; 10 feet higher than they had been before.
- How many lakes are there in the series? Twenty-two, I think.
- Which is the largest lake? Bullabulka, I think, or perhaps Ratcatcher's.
- How long is that? 9 miles long by  $2\frac{1}{2}$  broad.
- What is the size of the smallest of the series? Pinchgut is about the smallest, and it is about a mile by half a mile.
- Duration of water in lakes. Has the water from the 1870 flood been permanent? No. The 1870 water, which was supplemented by the 1873 flood, lasted till 1878. The lake was dry in the spring of 1878. The flood of 1864 lasted till 1867.
- When were these lakes dry last? They were dry a month ago, and have been dry since 1883.
- You cannot look upon any of them as being absolutely permanent? Not at all.
- In the ordinary course of seasons, how long will they last without being filled? They vary. They afford about three years good stock-water.
- Which do you consider the greatest benefit you derive from the flood: the water supply, or the irrigation of the country? The greatest benefit we derived from the flooding was that it enabled us to improve surrounding country. The increased capacity by irrigation is nil, scarcely worth calculating, because it is not flat country.
- Are the banks of the lakes steep? Rather steep; steeper than the banks of the river.
- Do you look upon the lakes as your water supply? Oh, no. We look upon them as nothing. We have a water system entirely independent of the lakes, but they supply the ground with fresh water underneath.
- Is there great soakage? It is the only place where we can get fresh water. It is within the flood-mark system.
- You say the lakes were dry a month ago;—how many of the series now are filled? I suppose about half the series.
- Do you consider this flood will be sufficient to fill the whole of them? I know it will not be sufficient. I understaud the series of lakes forms a sort of horseshoe, and that the flood enters at one end and gradually fills the lakes right round;—do you think anything could be done to bring the waters of the Darling into the other end of the horseshoe, that is, Ratcatcher's Lake? Nothing could be done.
- Ten-mile Creek. Could anything more be done than has been done by private enterprise to divert the water into these lakes? You could have a larger supply by making a cutting on the Ten-mile Creek, on Billilla Run 20 miles lower down than Wilcannia. By cutting a bar for about a mile in the Ten-mile Creek—the connection between the Darling and the Talywalka—you will get your supply of water in 2 miles into the Talywalka. We had a survey made of the bar, and found a 6-foot cutting would give us a 6-foot lower level, and we would get our supply 60 miles nearer from the river. Besides it would not come through rotten country. It would enable the people who hold the country up above to store water that they are not allowed to do now. Anything they do now cuts off our supply.
- Have any objections been made to the dam erected by the lessees on the Talywalka Creek? None whatever.
- Does it injure any interest? I have never heard of its doing so.
- Water supply into Murrumbidgee River from Darling River. Do you think it would be possible to carry water into the dry country below Bullabulka Lake? I do. I believe it is possible to have a water supply into the Murrumbidgee.
- Whereabouts

Whereabouts in the Murrumbidgee? I can only judge from the indications of the Gundagai flood. I think it is possible for the water to be carried on from the series of lakes down to Waldaira Lake, near Balranald.

Mr. N. Sadleir.  
4 Oct., 1886.

Is it very dry country between the lakes and Waldaira Lake? Very dry. It is very difficult country to get fresh water in. I do not know of any fresh water there fit for human beings.

Do you know whether levels have ever been taken of the Big Talywalka or these other depressions? The only levels taken that I know of were from the Teryaweynya Lake to White-water Lake.

What is the fall between those lakes? I can supply you with the papers. The fall is considerable between those two points. It is about 5 feet in a mile and a half.

You know the fall in the river is about  $3\frac{1}{2}$  inches to the mile? Yes.

Do you know the lakes on the west side of the Darling, near Menindie? Yes.

Which is the principal? I think Menindie and Cawndilla Lakes are; they are the same lake to all intents and purposes. Menindie and Cawndilla Lakes.

What distance is there between the two? There is no distance; they are continuous.

Really you could call it Menindie Lake? Yes. When they are dry they form two lakes, but they are within the same bank.

How does Menindie Lake compare with the lakes on the eastern side of the river for size and permanency? It is not so permanent as the lakes on the eastern side, but the size is infinitely greater.

What is the length, approximately? I could not say.

Do you know the distance round? Over 50 miles.

And about what depth of water? I am not sure, but there may perhaps be 15 feet.

What is the action of Menindie Lake with regard to the river? I believe it keeps the river navigable from Menindie to Wentworth for a year after it ceases to be navigable from Menindie up stream.

When the river goes down below navigation level above Menindie the action of Menindie Lake is to keep it up for another year? Yes.

That is, without Menindie Lake the river would be altogether unnavigable from here? I think so. Steamer captains have told me that the lake has kept the river navigable from here to Morgan, as the Murray was not navigable above the Wentworth Junction.

Do you think it is advisable to carry out any work to impound the water in Menindie Lake? I think it is very desirable to make scientific inquiry first, as the work would necessarily be very expensive.

Do you know Tandou Lake? I have no information about it.

Are there any other large depressions we have not referred to that you could give evidence upon? Not that I could give evidence on. I know there are others, but I am not sufficiently informed about them.

Have you recorded evaporation since you have been here? Yes, and the waste. Evaporation.

What do you consider it is from these depressions? Five feet a year.

Do you know what proportion would be lost in evaporation? I have no idea. The waste from wind is greater than the soakage. The wind blows the water on to the shallows, and the water never comes back again.

Does the dry surface on the banks of the lake crack to any great extent? Not very much so.

When the water is lost by waste, is there a good growth left behind? If followed by rain there is, otherwise there is not. The ground parches.

Would it be possible to irrigate the country surrounding these depressions? Not to any extent. The bank is too high, and the country is too lumpy. Irrigation around lakes.

Have you recorded the evaporation from tanks? Yes. Evaporation.

Is it about the same as from the depressions? Exactly the same—5 ft.

Do you find it makes any difference to have deep water? Yes.

What size of tanks do you consider the best to give a permanent supply? I do not think any tanks in this district will give a permanent supply. Tanks.

What size do you generally adopt? That depends on the catchment. Our largest tanks are from 12,000 to 17,000 yards, with a depth of from 15 to 17 ft. We find less waste when the water gets below the surface than when it is above the surface.

Have you had many losses through the drought? Very heavy losses. Losses in stock

Which was the most severe year? We lost most in 1883-84. We lost all our lambs in that year except 5,000. We ought to have had 80,000 lambs. We cut 50,000, and they all died.

What were your losses in grown sheep? Our actual losses were 156,000 in two years. And besides we got no lambing for one year.

Could anything have been done to prevent these fearful losses? Nothing whatever.

What were the losses due to? Utter starvation. We had sufficient water for the sheep everywhere on all our paddocks. Their loss was due entirely to want of vegetation. Cause of losses

Do you carry out any principle of spelling a portion of the run? Now we do; and I used to do it for the sixteen years from 1861 to 1876. When such was done there was no loss. We only occupied the country for six months in twelve. While we adopted that plan we had no losses, and our returns came in regularly. During those sixteen years we never stocked more than a sheep to 20 acres. Reserving portion of run.

What do you allow now? 10 acres to a sheep.

You have plenty of water now to meet any season? We have had for years.

Is it possible for you to lose again as you lost before? Of course. A small rainfall would bring on the same loss. We have had more than thirty-five men cutting scrub for our sheep during the drought.

Are you spelling any of the country now? Yes; we are spelling half of it.

You think that is the only plan to adopt? It is the only plan to adopt in this part of the country. We have had very severe seasons before. For instance, in 1858 there was only 8.50 inches of rain, which is equal to nothing.

What do you consider to be a sufficient fall at one time to be of any good during a drought? Any-thing less than 4 inches is no good. Rainfall.

And in ordinary seasons? 2 inches is a nice fall.

Have you tried irrigation at all? In a small way. Irrigation.

Have you tried it for crops? For lucerne it succeeds admirably. In fact I could not estimate the results of irrigation if you had the water.

But in the Talywalka and the big dam you spoke of, have you not plenty of water? Over a year after a flood. Results: flood

Mr.  
N. Sadleir.  
4 Oct., 1886.

flood you have. I have seen irrigation tried by nature on Billilla and Albermarle, and other stations, and it increases the capacity of the country a hundredfold.

One acre irrigated during the dry time would be equal to what area of dry country? It would be improved a hundredfold. I have landed 8,000 sheep on an irrigated patch of 3 miles square in the middle of summer, and had a good lambing; but the very same land, if it had not been irrigated, would not have carried 1,200 sheep.

Do you think anything could be done to assist private enterprise on the river in carrying out irrigation? I do.

What is wanted? To make the dams of a more permanent nature and higher. The wings are not sufficiently extended to keep the overflow from running back into the Darling. We have succeeded in keeping the outer Talywalka back, but quite as large supplies as that run into the river. All this lost water could be retained, and after every flood I think you could irrigate from the date of the arrival of the flood for a year and a half afterwards, and that would influence the growth of the country for at least two years.

Have you ever tried storing the food in good seasons by ensilage? Never by ensilage. Our food here is not of sufficient quantity to collect except in very exceptional cases.

What is the herbage generally grown by natural irrigation? There is grass and crow-foot, marsh-mallows, and the saline plants. Crow-foot is a grand thing.

Have you the blue grass or Mitchell grass here? No.

Which would be the most profitable to grow by irrigation to any extent, lucerne or the natural grass? Lucerne decidedly if it would grow. It is the most profitable grass I know of. We have lucerne on other properties, and it beats everything else.

Is there any great difficulty in preparing the soil for lucerne? I do not think so; but I do not think the soil is entirely applicable. I think it is too clayey. If I had plenty of water I would have no hesitation in planting it.

You think an extended system of irrigation is only held back on account of want of water? That is all.

And that could be obtained by making large reservoirs in the creeks? I do not think you could get a permanent supply by doing it, but you could increase the capacity of the country.

*Mr. Gipps.*] What is the character of the rock forming the bars in the river? Sandstone, I fancy.

Do these floods seem to wear the bars away? Not at all. They never touch the hard bars, but they sometimes scour the sand out. The sand accumulates at the bar while the river is high, and as the river becomes low the scour cleans it out.

Have you much wind in this part? I do not think we get an undue quantity of wind.

What is the prevailing wind in summer? West. Nine months in the year we have south-west wind.

What is the character of the timber? Stunted, useless box and eucalyptus.

Is there much scrub? It is not a scrubby country from here up the river.

Do you consider that timber influences the rain at all? I do, most decidedly. I have seen the result.

Where? Along the river. The summer rains always follow the river timber, and seldom extend more than half a mile back. Clumps of pines attract the rain in the back country. I have seen storms follow the pine ridges, and seem to gather there, where we would not have had rain in country in which the timber is not so well defined.

Would you advise planting of trees? I do not think they would grow without irrigation. Where possible I would consider it advisable.

What is the character of the banks of the Talywalka, are they steep? Very much like the river, but not so steep.

Is the bed as deep as the river? No. The Talywalka is 16 feet deep on an average.

Do you think a larger supply of water might be thrown into the lakes by straightening the Talywalka? I do, but I do not think it would be worth the labour and cost. A cutting at the Ten-mile Creek would improve the supply.

Would you advise the locking of the river at all? If possible. I think low weirs would be very valuable. I do not think it is possible to lock the river.

Movable weirs or fixed? Low-level weirs, that could be raised a few feet. I should think that anyone who would attempt to lock the river as it is at present would be mad. New channels would be formed, because the banks would scour away.

How much water a day do you consider is required for a sheep? A gallon a day.

And for every head of cattle? About 15, I think.

Were many stock lost here for want of water? I do not think many were lost through want of water, but chiefly through want of feed.

Have you constructed any dams across any of the creeks or talywalkas? Yes.

What is the character of the dams? All earthen dams. We like a clay heart and a sand conc.

Do you construct by-washes? In some cases.

Have you any gates to them? Yes.

What is the character of the gates? Sluice-gates. They are lifted up by screws.

Are the sluice-gates in the dam itself? The sluice is in the centre of the dam, on the lowest level of the creeks. So we allow the water to go on its natural level and fill all the creek below us. Then we put our sluice down. When the men below are not satisfied with the supply we lift the gates up. It takes about half an hour.

Do you think if that were done as a general rule that there would be any objection to damming the creek? There could be no objection, because you give everybody what nature would give them, and do not interfere with the supply at all.

Do the sluice-gates cost much? In some instances they do. Large works cost perhaps £2,000; you get a sluice-gate, a bridge, and the command of the water.

Do you use masonry? No, only timber and iron.

Have you any wings to the embankments? No. I can give you a sketch of the works if you like. In every case you increase the section of the creek and the approach to the dam? Yes.

What was the height of the 1879 flood? 39 feet.

According to that the floods of 1870 and 1873 were higher? The flood of 1864 was the highest, then those of 1870 and 1873. The present flood is about 36 feet.

Mr.

*Mr. Donkin.*] What is that read from? Bourke. We always record from there. And what do they record it from there? I do not know. I consider that a 34-foot flood at Bourke flows into the Talywalka.

*Mr. Gipps.*] Do you mean by that that the river has to be 34 feet high before it will flow into the Talywalka? Before the Talywalka will reach us.

*Mr. Donkin.*] What do you think would be the best zero to adopt to read the flood-levels from;— at Bourke they take 6 feet as summer level, at Louth the bed of the river, and somewhere else navigation level? We take summer level to be when the water is running over the bars.

Do you think it would be best to read from a well-known flood level, or from the bars? I should read from the bars, and call that summer level. I should propose the record should be taken as it has been taken this year. The effect of the rise as recorded at Bourke we can gauge.

You think they understand what the rise is at Bourke this year? I think so.

*Mr. Gipps.*] Do you know the Willandra? Yes.

Where does it cease running? I think it goes as far as Clare Run.

Does it ever run into Victoria Lake? No; it is impossible.

On what account? Because of a distinct ridge of high land in between.

If it does join any river, what river is it? The Murrumbidgee, about Waldaira Lake, I should think.

I consider it would be a public advantage if the Willandra were sent down into the back country.

*Mr. N. Sadleir.*  
4 Oct., 1886.

The Willandra

Mr. G. W. Moore examined:—

*Mr. Gipps.*] What is your occupation? I am one of the Inspectors of Runs for the Western Division. Have you been long in this district? I have been backwards and forwards in the Darling District for the last seven years, and in the country between the Darling and the Lachlan for five years longer.

Can you give any information as to the country on the right bank of the Darling? Yes.

Over what extent? From here to Netley Run, and Buckalow and Burta, on the South Australian border.

Do you know anything of Cawndilla Lake? No.

Tandou Lake? Yes.

How is it supplied? By an ana-branch of the river. It runs out of the river, and runs in at Polio, I think.

What is the length of the Tandou Lake? About 10 miles; and it is about 3 or 4 miles broad. The average depth is about 25 feet, I should think.

What is the character of the gathering grounds;—are they high? Very high banks. The red scrub country breaks off abruptly on the edge of the lake, almost in cliffs on the southern side.

And on the northern side? Not quite so abrupt.

What is the height of them? The actual banks are about 30 feet, and in some places higher. Behind them run high sandhills.

Has the lake any watershed of its own? No.

Are there no creeks supplying it? There are gutters, but they do not put water into it to any appreciable extent when it is dry. It is full of immense cracks when dry.

Are there any other depressions towards the Barrier Range? There is Nettlegoe Lake, but it is not very large. It is about 2 miles by 1, and of about the same depth as Tandou Lake.

And the overflow from Tandou supplies Nettlegoe? Yes.

Has Nettlegoe steep banks all round it? Yes.

Then it would be easy to prevent the water from going back again? Very easy.

Do you think it would be advisable to impound the water in Nettlegoe Lake? I do not think it would be of any use to that part of the country. It would be of use to the lessee of Netley Run, but not of public utility.

Do you know of any large depressions to the west of that again? There is Waneba Lake, on Wanebah block.

What is about the area of that lake? It is nearly circular, and a little over 3 miles in circumference.

What creek supplies it? Pine Creek.

Is that a permanent lake? No; it will hold water for about three years after being filled by Pine Creek.

It was dry about two years ago, I think.

What is its depth? About 15 feet.

Has it any outlet? None. Pine Creek ends there. The creek runs from Thakaringa Ranges.

What is the character of its watershed? Pine Creek is a narrow gutter through plains. It is about 4 or 5 feet deep, with a sandy bottom, and perhaps 60 yards wide. It gains no water from the country through which it passes. It is simply a gutter from the Thakaringa Ranges.

Is that a permanent creek? It very rarely runs; only once in two or three years.

Does it bring down any heavy floods? Yes; very heavy floods, and runs very fast.

Are there any dams on that creek? No; it is too sandy.

Are there any wells? All along its course water can be got by sinking at various depths, from 190 to 240 feet, I think.

Is it fresh water? Very good water.

What is the general character of the strata sunk through? Firstly alluvial, then they have great difficulty with very fine quicksand.

Is the water in the quicksand? They find it on a bottom below the quicksand. They call it chalk, but I think it is really pipeclay.

Does the water rise in the wells? Not to any great extent.

Is there an unlimited supply? As a rule, a 7ft. by 4ft. 6in. shaft would give a supply of from 20,000 to 24,000 gallons per diem. In one well on that creek they had very good fresh water at a depth of 240 feet, but not a very large supply. Then they bored to a further depth of 40 feet, and were flooded out by an immense rush of intensely salt water, but through the pipe becoming choked they were able to put a cap on the pipe and stop the salt water.

To what level did the salt water rise? The pipe became choked before the water filled the shaft, and the man at work had to run for his life. The water appeared to be artesian, but it was intensely salt.

Do you know of any other depressions? There is a swamp or lake on Buckalow Run, known as Ryan's Lake,

*Mr. G. W. Moore.*  
4 Oct., 1886.

Lakes.

Lakes near Darling.

Wells on Pine Creek.

Salt water.

- Mr. G. W. Moore. Lake, which also fills by a creek from the Barrier Ranges, and holds water for nearly twelve months. It is about a mile in diameter.
- 4 Oct., 1886. Are the gathering grounds of the same character? Very similar.  
 What is the general character of that country? Rolling downs, and very dry, as a rule.  
 And the character of the rock? On the ridge there are ironstone, sandstone, and large bodies of reefs of quartz generally running north and south. There is a large quartz-reef there.  
 Where is that? On West Dhoon. On the alluvial level plain I saw an outcrop of quartz, which in the distance I thought was a tent. It is an enormous outcrop. There is a main reef with thousands of tons of quartz in it.  
 Have there been any wells sunk in that country? I do not think there have been any on West Dhoon.
