D			
DISORDER :—			
Mr. A. G. Taylor, removed from Chamber by Sergeant-at-Arms, by direction of the Speaker, for refusing to obey the Chair, Mr. Speaker gave reasons for his action in removing Mr. Taylor; motion made, (<i>Mr. Garvan</i>), that House disapproves of action of Speaker and amendment proposed, (<i>Mr. Willis</i>), that Mr. Taylor be heard in his place, and negatived; Mr. Garvan's motion negatived, 395-6.			
The Chairman reported disorder from the Committee of Ways and Means; and also that he had directed the removal from the Chamber of the Member for West Macquarie (<i>Mr. Crick</i>); Mr. Crick admitted by direction of Mr. Speaker, and invited to explain; Mr. Crick addressed the House, and refusing to obey the Chair, was ordered to be removed from the Chamber; and having used certain disorderly words, was adjudged guilty of disorder, &c., and was expelled from the House, 430-1.			
ARISING WHILE THE HOUSE IS IN COMMITTEE :—			
Mr. Speaker, having observed grave disorder when the House was in Committee on the Broken Hill Water Supply Bill, resumed the Chair, and expressed astonishment that the Honorable Member for Burrows (<i>Mr. Slattery</i>) did not obey the ruling of the Chairman; and also stated that if the Honorable Member did not do so he would have to take an extreme course; Mr. Slattery explained, Speaker gave ruling, and Committee resumed, 419.			
Motion made (<i>Mr. Dibbs</i>) that when any Member refuses to obey the Chairman the case shall be reported without debate to the House, to be dealt with after explanation from the offending Member; and amendment moved (<i>Mr. Garrard</i>) to give the Chairman the right to make an explanation—amendment and original motion negatived, 436.			
DISTRESS FOR RENT BILL :—			
Motion made (<i>Mr. Walker</i>) for leave to bring in, presented and read 1 ^o , 26; Order of the Day postponed, 76, 195; Order of the Day discharged and Bill withdrawn, 553.

Report on, for 1889, laid on Table, 52	7	649
PRIVATE BILL (See also "BILLS"):—		
Referred back to Select Committee, 436.		
PRIVILEGE:—		
SEAT OF HONORABLE SYDNEY SMITH, SECRETARY FOR MINES:—		
Motion made (<i>Mr. Crick</i>) to refer to Elections and Qualifications Committee, 27.		
NEWSPAPER ARTICLE:—		
Motion made (<i>Mr. Copeland</i>) that article in the <i>Daily Telegraph</i> headed "The Vernon Boys" is a breach of privilege, 177.		
Mr. Hurley called attention to article in the <i>Maitland Mercury</i> , and stated his intention to move a motion of Privilege thereon; article read by the Clerk, and Mr. Hurley not being present to make the motion of Privilege Mr. Dibbs moved a motion censuring the Honorable Member, 352.		
NEWSPAPER ARTICLE:—		
Motion made (<i>Mr. Traill</i>) that House do to-morrow proceed to inquire into statement that bribes had been offered to and asked for by Members of Parliament, and that the editor of <i>Truth</i> be summoned to give evidence at Bar, 291-2; Order of the Day read and Question put, that House proceed to the consideration of the statements referred to, and agreed to—Speaker informed House of issue of summons to editor of <i>Truth</i> , and motion made (<i>Mr. Traill</i>) that the editor of <i>Truth</i> be now examined at the Bar and agreed to—Mr. Adolphus George Taylor conducted to Bar, sworn by the Clerk, and examined—Witness withdrew, and on motion of Mr. Bruce Smith was discharged from further attendance—Order of the Day discharged, 299.		
THE HON. J. H. YOUNG:—		
Mr. Dibbs referring to certain correspondence in reference to alleged Bankruptcy of Mr. Speaker, drew the attention of the House to section 26 of the Constitution Act and section 4 of the Bankruptcy Act under which he considered Mr. Speaker's seat was vacated. Sir Henry Parkes having stated that, in the opinion of the Attorney-General, Mr. Young had not become a bankrupt within the meaning of the 26th section of the Constitution Act, Mr. Dibbs laid the correspondence on the Table, 375		799
Motion made (<i>Mr. Crick</i>) that seat be referred to the Committee of Elections and Qualifications and negatived, 380.		
CHARGES AGAINST MEMBERS OF PARLIAMENT:—		
Motion made (<i>Sir Henry Parkes</i>), instructing Mr. Speaker to require Mr. Crick to state whether he had, at Lambton, denounced the Parliament as being "rotten and corrupt." Point of Order: That the matter not suddenly arising was not one of privilege, overruled; amendment proposed (<i>Mr. Crick</i>) for appointment of Royal Commission to inquire into charges of corruption and bribery in reference to the Broken Hill Water Supply Bill; amendment negatived; original motion passed. Mr. Crick denied having used the specific language as quoted in the resolution, 524, 525.		
PROBATE BILL:—		
Motion made (<i>Mr. Gould</i>) for Committee of the Whole, 58; Message from Governor, 68; House in Committee, Resolution agreed to, Bill presented and read 1 ^o , 142; read 2 ^o , committed, 170; House in Committee, 208; reported with amendments, report adopted, 314; read 3 ^o , passed, and sent to Council, 316; returned with amendments, 490; amendments agreed to, 498; assent reported, 527	3	863
PROBATE OF WILLS (See "GRANTING OF PROBATE OF WILLS AND LETTERS OF ADMINISTRATION FACILITATION BILL").

S		
SPEAKER (continued) :—		
Reports attendance of House in Council Chamber to hear Opening Speech, 2.		
Reports issue and return of writ, 1 (?), 171, 213, 239, 255, 395, 503.		
Reports presentation of Address in Reply to Governor, and Answer to Address in Reply, 15.		
Reports resignation of Member, 139, 157		
Gives casting vote, 164, 342.		
Reports receipt of Certificate notifying death of Member, 161, 223.		
Informed the House that Sir Henry Parkes would resume his duties on 27th August, and asked for the departure from certain rules for that purpose, 267.		
Clerk announces receipt of letter from James Henry Young, Esq., resigning Office of, 387.		
Joseph Palmer Abbott, Esq., elected, and presented to His Excellency the Governor, 387.		
Refers to an amendment made by the Legislative Council in the Board of Water Supply and Sewerage Offices Erection Bill, 294.		
Calls attention to nature of amendments made by the Legislative Council in the Marrickville to Burwood Road Railway Bill, 359.		
Clerk informs the House of the unavoidable absence of, 385.		
Commission to Administer the Oath, 388.		
Orders removal of Member from Chamber for disobeying Chair, 395, 430.		
Motion that House dissents from action of, and negatived, 396.		
Having observed grave disorder in Committee resumes Chair, 419.		
Authorised to present Appropriation and Loan Bills to Governor for Assent, 558.		
RULINGS OF :—		
That the Agricultural Society of New South Wales Lease Bill was not beyond the order of leave, 104.		
That he could not accept the Public Works Act as governing the proceedings or limiting the powers of the House, 125.		
That under section 13 of the Letters Patent, in the absence of His Excellency, Message signed by the Lieutenant-Governor by deputation from the Governor was in order, 154.		
That amendment was in order to substitute another name in a motion to appoint a member to the Parliamentary Standing Committee on Public Works, and against a demand for a ballot, 181.		
That special reference to provision in the Crown Lands Bill, in reference to the repeal of existing legislation, was not necessary in the Title, 208.		
That clause 9 of the Crown Rents Bill which interfered with actions pending or a judgment obtained should be mentioned in the Order of Leave, and that therefore the Bill was improperly before the House, 208.		
That since the adoption of the Additional Standing Orders, altering the character of the Motions for Adjournment, the practice of the House of Commons in respect to two motions of a similar character being moved consecutively, did not apply to these questions, 247.		
That Papers should not be laid upon the Table of the House which reflected upon the conduct of a Member of, or referred to a debate in, the House, 265.		
That Bills coming from the Council could not be ruled out of order in this House on the ground of informality in its initiation there, 265.		
That the Order of Leave to bring in the Imprisonment for Debt Abolition Bill was sufficiently comprehensive to cover the Bill, 227.		
That papers did not refer to the action of a Member in this House, and could be laid on Table, 272.		
That the Borough of Newcastle Electric Lighting Bill was beyond the Order of Leave, 288.		
That Sessional Order relative to New Business after 11 o'clock rescinded after that hour in the same sitting was not in force to end of sitting, 337.		
That motion for expulsion of Mr. Crick was in order, 431.		
That no dissent from, could be made without notice, 432.		
That Bank Holidays Act Amendment Bill was beyond the Order of Leave, 423.		
That Early Closing Bill did not involve expenditure, and did not require to be covered by a Message from the Governor, 436.		
That Boats Registration and Regulation Bill was beyond the Order of Leave, and was therefore out of order, 461.		
That question as to what was a matter of "public importance" under the Additional Standing Order in reference to Adjournments of the House was not a matter for him to decide, 465.		
That in future cases of swearing in new Members he would put in operation the Standing Orders of the House of Commons, passed on 30th April, 1886, which prevented the interruption of the business, 505.		
That provision in Marrickville to Burwood Road Railway Bill (No. 2) was covered by the order of leave, 511.		
That in Supply, during the discussion of a Minister's salary, reference could be made to subsequent items, as the Committee had a right to criticise the Minister's policy when voting his salary, 517.		
That Honorable Members should sit in the Chamber in a manner respectful to other Honorable Members and to the occupant of the Chair, and so that the passages would be left clear between the seats, but that it was a matter to be left to the good taste of Honorable Members, 517.		
That certain provisions in the Eight-hour Bill were beyond the order of leave, and also referred to rules in reference to preparation and drawing of Bills, 521.		
That the Net-fishing in Port Hacking Prohibition Act Amendment Bill was beyond the order of leave, 521.		
That motion was one of privilege dealing with language which denounced Parliament as "rotten and corrupt," 524.		
That motion in reference to charges of Bribery in connection with the passing of the Broken Hill Water Supply Bill was substantially the same as an amendment submitted the previous night, and, therefore, could not be put, 529.		
SPECIAL ADJOURNMENT :—		
Motion made for, and passed, 14, 373, 383, 393.		
SPECIAL AREAS (See "CROWN LANDS").

1890.

NEW SOUTH WALES.

DEPARTMENT OF MINES.

(ANNUAL REPORT OF THE STOCK AND BRANDS BRANCH.)

Presented to Parliament by Command.

TO THE HONORABLE SYDNEY SMITH, ESQ., M.P., MINISTER FOR MINES AND AGRICULTURE.

Sir,

I have the honor to submit herewith the Report of the Chief Inspector of Stock, which shows that the several Inspectors have performed a large amount of work during the year.

There has been a steady increase in the number of horses each year since 1882, and as regards the breed they appear to be improving in most of the districts.

Though there is a serious decrease in the number of cattle as compared with the number in 1879, it is satisfactory to note that there has been a steady increase since 1885, and in only three districts are the cattle said to be deteriorating. It is also satisfactory to find that inoculation where tried has proved successful.

The increase in the number of sheep is very satisfactory, the number having nearly doubled since 1878 notwithstanding the heavy losses from drought in the interior. In only two districts is the condition of the flocks said to be deteriorating. With regard to lambing the general averages are satisfactory, considering that the western portion of the Colony was suffering from drought during the early part of the year.

The clip of wool for the year shows a large increase, but a much larger proportion was shipped from Melbourne than in 1888, through the rivers being up.

Appendix G contains some valuable information concerning the chilled meat trade, and I venture to think great credit is due to the Chief Inspector for his persistent efforts in this direction. It is to be hoped they will eventually be crowned with success, as it will tend not only to increase our export of meat, but will greatly improve the meat supply of the metropolis, and will put an end to the cruelties inflicted upon the stock brought to market for killing.

The opening for increasing our exports of meat and dairy products with the aid of artificial cold are exceptionally good, and special efforts should, I think, be made to secure the full benefit of it.

I have, &c.,

HARRIE WOOD,

Under Secretary for Mines.

Department of Mines and Agriculture,
Sydney, 5th May, 1890.

The Chief Inspector of Stock to The Under Secretary for Mines.

Sir, Department of Mines, Stock Branch, Sydney, 1st April, 1890.
 On the 1st February last I submitted a Progress Report for the year ending 31st December, 1889, giving the approximate number of the horses, cattle, and sheep then in the Colony; and I have now the honor to submit for your consideration my complete Report for that year on the working of this Branch, which is as usual based very much upon Inspector's estimates—owners still showing very little inclination to furnish data. It will be seen that the actual number of horses, cattle, and sheep in this Report exceed those in the Progress Report.

I have, &c.,

ALEX. BRUCE,
 Chief Inspector of Stock.

I.—INSPECTORS AND THEIR WORK.

1. *The Inspectors.*

There are now forty-eight inspectors, having charge of sixty-two Sheep Districts.

2. *The Inspections made.*

The inspections made during the year were as follows:—

Of Stock	18,545
„ Reserves	4,329
„ Pounds	407
„ Noxious animals	5,521
„ Dogs	650
„ Pigs	100
Total	29,552

This would give an average of 616 inspections made by each of the forty-eight inspectors, and is exclusive of inspections made as overseer of Public Watering-Places.

3. *Horses, Cattle, and Sheep inspected.*

Horses.—The number of horses inspected during the year was 90,836, by forty-seven inspectors.

Cattle.—The number of cattle inspected during the year was 1,024,343.

Sheep.—The number of sheep inspected during the year was 28,203,337. This is an increase of 2,808,770 on last year's inspections.

4. *Inspections at Homebush Sale-yards.*

During the year bi-weekly visits to the Homebush yards have been made by the Sydney inspector, with the view to inspecting the stock yarded. The total number of stock submitted to auction was as follows:—Cattle, 89,845 head; sheep, 1,575,195, or a weekly average of 1,727 cattle and 30,292 sheep, being a decrease of 63 cattle and an increase of 5,080 sheep on the weekly average, as compared with previous year. These inspections are called for not only for the prevention of disease but also to check stock stealing, and with that view the inspector sees that the brands and marks of the stock correspond with those in the permits or travelling statements accompanying the stock, which are collected and filed in this office for future reference, should, as it at times happens, inquiry be made with respect to stock suspected of being stolen.

5. *Distance travelled by Inspectors during the year on duty.*

The total number of miles travelled by forty-eight inspectors was 190,037, or an average of 3,959 each per annum, being a decrease of 70 miles for each inspector as compared with last year.

6. *Prosecutions and Convictions.*

The prosecutions instituted during the past year were as follows:—

Under Sheep Act	144
„ Imported Stock Act	3
„ Brands Act	5
„ Pastures Act	173
„ Public Watering-places Act	27
„ Impounding Act	1
„ Slaughtering Act	1
Total	354

This shows a decrease in the number of prosecutions for the year. Under the Public Watering-places Act only have the prosecutions increased, they being for trespass on reserves.

The number of convictions were:—

Under Sheep Act	127
„ Imported Stock Act	3
„ Brands Act	3
„ Pastures Act	154
„ Public Watering-places Act	23
„ Impounding Act	1
„ Slaughtering Act	1
Total	312

II.—HORSES.

1. *The Number.*

The number of horses in the Colony during the twenty-nine years previous to and including 1889 was as follows:—

Year.	No.	Year.	No.	Year.	No.
1861	251,497	1871	337,597	1881	398,577
1862	233,220	1872	304,100	1882	328,026
1863	273,389	1873	328,408	1883	326,964
1864	262,554	1874	334,462	1884	337,172
1865	284,567	1875	357,697	1885	344,697
1866	282,587	1876	366,703	1886	361,663
1867	278,437	1877	328,150	1887	390,609
1868	280,201	1878	336,468	1888	411,368
1869	280,818	1879	360,038	1889	490,777
1870	280,304	1880	395,984		

This shows an increase of 19,409 during the year, and is due principally to an increase in the number of breeders and to the returns being more complete.

The number of horses in each Sheep District will be found in Appendix A.

2. *The different Breeds.*

Draught.—The numbers returned under this head are—Ordinary, 119,528; thoroughbred, 19,850; total, 139,378.

Light Harness.—The number returned as ordinary is 95,433; thoroughbred, 14,226; total, 109,659;

Saddle.—The numbers of ordinary are given as 156,683; thoroughbred, 25,057; total, 181,740.

3. *Horses introduced.*

From other districts.—The number of stud horses introduced were 369, and stud mares, 165; ordinary mares, 2,752; and horses, 3,215.

From other Colonies.—The number introduced by sea was—Stud horses and mares, 65; and ordinary horses and mares, 302.

The number introduced overland was 76 stud mares and 49 stud horses; and ordinary, 382 mares and 623 horses.

From England and other Countries.—The number introduced under this head was 24. For particulars see Appendix B1.

4. *Horses fit for sale.*

The numbers returned as being fit for market during the coming year are 22,517 draught; 22,096 light harness; and 32,478 saddle.

Of this number it is estimated that 18,220 are suited for the India and China markets.

There were sent from three districts 154 horses to be shipped from Sydney, and from three districts 514 horses to Melbourne for foreign countries.

5. *Improvement.*

In forty-two districts the horses are said to be improving. The principal reasons given are—Introduction of superior stud horses, breeding from good mares, more attention to the rules of breeding, and better prices obtainable; and in fifteen districts there is no improvement. In three districts they are deteriorating,—the reasons given being too much light blood introduced, breeding from weedy mares for racing purposes.

6. *Diseases in Horses.*

This year has been unusually free from epizootic diseases in horses.

Anthrax was reported in one district.

Horse Fever.—This disease appeared in a mild form in two teams of horses in the Balranald district; but it did not spread, as few horses were travelling at the time.

Australian Stringhalt occurred during January, February, and March in three districts. Some of the cases were investigated by Mr. Stanley, G.V.S., and he is confirmed in his opinion that the disease is due to intestinal parasites. A paper read by him at the Stock Conference on this subject is reprinted as Appendix C.

Rheumatism and Pneumonia.—Have not been reported.

Strangles.—Has during the year been of a mild character, and has been reported in only seven districts.

Prurigo.—Continues to give much trouble in the Clarence and Richmond River districts. Cleanliness of the horse's body and washing with caustic soda and water— $\frac{1}{2}$ oz. to a pint of water—are said to give good results. A full account of this disease appeared in last year's report. It is about to be further investigated by Mr. Government Veterinarian Stanley.

7. *Losses in Horses through Accidents, &c.*

The losses in horses from wire in chaff and other accidents, as reported, amount to 1,638.

8. *Wild Horses.*

The number of wild horses in the Colony is estimated at 4,230, which shows a decrease on the previous year of 1,251.

9. *Tax on Entire Horses.*

A large majority of owners are still in favour of a special tax being placed on entires.

III.—CATTLE.

1. *Number.*

The returns of cattle in the Colony during the twenty-nine years ending 31st December, 1889, stand as follows:—

Year.	No.	Year.	No.
1861	2,271,923	1876	3,131,013
1862	2,620,383	1877	2,716,385
1863	2,032,522	1878	2,771,583
1864	1,924,119	1879	2,914,210
1865	1,961,905	1880	2,580,040
1866	1,771,809	1881	2,597,318
1867	1,728,427	1882	1,859,985
1868	1,761,411	1883	1,640,753
1869	1,795,904	1884	1,425,130
1870	2,195,096	1885	1,317,315
1871	2,014,888	1886	1,367,844
1872	2,287,660	1887	1,575,487
1873	3,794,327	1888	1,622,907
1874	2,856,699	1889	1,741,592
1875	3,134,086		

This shows an increase during the year of 118,685, and a decrease as compared with the decennial year 1879 of 1,172,618.

The number of cattle in the several Sheep Districts will be found in Appendix A.

The number of cattle introduced from Queensland was 175,117, and the number sent from this Colony into that, 1,867.

2. *Different Breeds.*

Shorthorns.—The number of pure-bred and stud Shorthorns is estimated at 46,099; and ordinary, 642,375; total, 688,474.

Hereford.—Pure and stud, 25,713; ordinary, 206,270; total, 231,983.

Devon.—Pure and stud, 10,274; ordinary, 54,043; total, 64,317.

Black-polled.—Pure and stud, 671; ordinary, 972; total, 1,643.

Ayrshire.—Pure and stud, 2,620; ordinary, 6,613; total, 9,233.

Alderneys.—Pure and stud, 441; ordinary, 464; total, 905.

Jersey.—Pure and stud, 10.

Brittany.—Pure and stud, 100.

Crosses.—First crosses, 5,273; ordinary, 739,654; total, 744,927. The crosses are estimated as follows:—Shorthorn and Hereford, 248,121; Shorthorn and Devon, 86,476; Hereford and Devon, 48,610; Shorthorn and Black-polled, 4,662; Ayrshire and Shorthorn, 4,132; the balance, 352,926, being unrecognizable.

There is a comparatively large increase in the milking breeds of cattle. This arises through many of our cattle-owners in the coast districts having turned their attention to dairying instead of fattening for market; and it is believed that this change will continue and increase.

3. *Cattle introduced.*

From other Districts.—Stud bulls, 322; stud cows, 605; total, 927; ordinary cattle, 100,841.

From other Colonies by Sea.—Stud bulls, 49; stud cows, 13; total, 62; ordinary cattle, 189.

Overland.—Stud bulls, 242; stud cows, 851; ordinary cattle, 175,117; total, 176,210.

From Countries outside the Australian Colonies.—Bulls, 12; cows, 3; total, 15. Of these, 2 were Shorthorn; 2 Devon; and 11 Hereford. For particulars, see Appendix B2.

4. *Increase and decrease of Cattle.*

In fifty-one districts the cattle are reported to be increasing, for which the following reasons are given:—(1.) The good season and no losses from starvation and disease. (2.) Increase in number of owners. (3.) Considerable numbers of store cattle have been introduced from Queensland. (4.) More owners have taken to breeding cattle, and are stocking-up their runs, cattle having become good property of late. In the remaining districts they are decreasing on account of large sales, owners not breeding or stocking-up, and bad season.

5. *The "Cast" of Fat and Store Cattle.*

The estimated "cast" of fat cattle to be sent to market during the coming year is 298,153, and store cattle, 174,571. From twelve districts the fat cattle are principally sent to Melbourne; from two districts they are principally sent to Adelaide; and the remaining districts supply the markets of Sydney, Maitland, Mudgee, Bathurst, Orange, Goulburn, Tamworth, and Albury.

6. *How kept.*

The number of cattle kept wholly in paddocks is returned as 1,318,488; on open runs, 250,214; and the balance, 172,890, are depastured both ways.

7. *Improvement and deterioration.*

In forty districts the cattle are said to be improving; in seventeen districts they are stationary; and in three districts deteriorating. The principal reasons given for the improvement are—introduction of good stud stock; more attention and care in selection; also, in culling and keeping in paddocks. The reason given for deterioration is inattention to breeding, many owners breeding from all sorts without respect to breed or quality.

8. *Their diseases and Ailments.*

Pleuro-Pneumonia.—In twenty-six districts, on 195 runs, the cattle were reported as affected with pleuro-pneumonia; and in thirty-four districts the cattle are reported as being free from that disease.

In

In the whole of the infected districts the disease is attributed to introduction of cattle and contact with infected travelling-stock from Queensland.

Inoculation was tried on 165 holdings in twenty-five districts, and in every case but one with satisfactory results—the disease leaving the herds without further loss. The failure in the one case was caused by bad virus and an inexperienced operator.

The number of owners in favour of inoculation is given as 7,798; against, 517; undecided, 2,076; and 7,696 opinions not known.

The number of owners in favour of compulsory inoculation in the case of infected herds is given as 6,398; against it, 1,533; undecided, 1,993; and 9,709 opinions not known.

This shows a very large majority of owners in favour of the compulsory inoculation of all herds in which the disease appears; and it is hoped that legislation in this direction will soon be obtained.

Cultivation of Virus.—Following up the experiments made by M. Pasteur's representatives—Dr. Germont and M. Loir—in Brisbane, an attempt has been made by Mr. Government Veterinarian Stanley to cultivate the virus of pleuro-pneumonia by injecting the virus taken from the lung of a diseased beast beneath the skin of a healthy calf on the fore ribs and in the neck; but the cultivation was made on too small a scale to give satisfactory results. Only fourteen calves having been inoculated, it is therefore as yet in the experimental stage, and it is intended immediately a supply of reliable natural virus can be obtained, to take the matter up on a more extensive scale, and there is no doubt the results will be as successful here as it is reported they have been in Queensland.

Tuberculosis.—Although power is given under the Imported Stock Acts to deal with and destroy imported stock affected with this deadly and dangerous disease there is no law in force which empowers an inspector of stock to interfere with any of our own cattle so affected. It is true that the meat of such cattle can be seized and destroyed by inspectors of slaughter-houses, but to do this effectually all the slaughter-houses in the Colony would have to be regularly inspected, and this cannot be done.

It is also the case that under the Dairies Supervision Act tuberculous milch cows can be seized and destroyed, but notwithstanding this it is currently reported by persons competent to judge that there are tuberculous cows now in the dairies in Sydney and the suburbs.

Several cases of this disease have been detected at the Homebush and Maitland sale-yards during the year, and agents have notified sellers that they will not receive cattle affected in this way at the sale-yards.

Notwithstanding this, cattle affected with the disease are still met with at the public abattoirs. They are of course condemned and destroyed. It is to be hoped that in the interests of the public health local authorities will prohibit the slaughter for food of tuberculous cattle in the country townships.

Cumberland Disease.—From eight districts the number of cattle reported to have died from this form of anthrax is 682, being 534 less than last year.

Symptomatic Anthrax or Blackleg is reported to have carried off 782 head in eight districts, being an increase of 454 on last year, the principal outbreak being in a mob of cattle belonging to Mr. R. Hassall, of Braidwood, which were travelling from Mudgee. For Mr. Government Veterinarian Stanley's report on this case see Appendix D.

Cancer.—Cattle to the number of 1,997 are reported from twenty districts to have died of tubercular swellings in the throat, being an increase of 92 on last year.

Red Water.—From one district 20 deaths are recorded, but the disease is very prevalent in certain localities in the coast country.

Ophthalmia occasionally assumes an epidemic form, and the losses are often considerable. From ten districts 367 deaths are recorded from this cause.

Blaine has not been reported this year.

IV.—SHEEP.

1. *The number.*

The number of sheep in the Colony during the twenty-nine years ending 31st December, 1889, stands as follows:—

1861	6,119,169	1876	25,269,755
1862	6,558,896	1877	21,521,662
1863	7,169,126	1878	25,479,484
1864	9,082,463	1879	30,062,910
1865	9,650,106	1880	35,398,121
1866	11,644,593	1881	36,591,946
1867	15,066,377	1882	36,114,814
1868	16,000,090	1883	37,915,510
1869	16,848,217	1884	31,660,321
1870	16,218,825	1885	37,820,906
1871	16,766,012	1886	39,169,304
1872	17,873,696	1887	46,965,152
1873	18,990,595	1888	46,503,469
1874	22,797,416	1889	50,106,768
1875	25,353,924				

The number of sheep in the several Sheep Districts will be found in Appendix A.

Increase and Decrease.

This shows an increase for the whole Colony of 3,603,299. The increase in this instance was greatest in the north-eastern and eastern portions of the Colony and less in the central, with an actual decrease in the north-western and western districts, where the drought of 1888 was most severely felt, and it continued there to the month of March in 1889. The result was that not only were considerable numbers of sheep lost, and those that remained so reduced as to be in very low condition for breeding, but the owners in that dry country, with the sad experience of 1883-4, dreaded a continuance of the drought, and refrained in many cases from putting the rams to the ewes. During the year 223,369 sheep left this Colony for Queensland and 311,583 were brought from that Colony into this.

Sexes and Classes.

Rams	778,313
Ewes	23,647,106
Wethers	13,501,656
Lambs	12,179,693

50,106,768

3. Sheep introduced and imported.

- (1.) From other districts in this Colony—Stud, 8,598; ordinary, 3,826,299; total, 3,834,897.
- (2.) Overland from other Colonies—Stud, 6,390; ordinary, 356,912; total, 363,332.
- (3.) By sea from other Colonies—Stud, 3,988; ordinary, 89; total, 4,166.
- (4.) From England and Countries and Colonies other than Australian—143; of these 87 were American Merino, 5 German Merino, 4 English South Downs, 20 Shropshire Downs, and 27 Lincoln. See Appendix B 3.

During the year 4,077 sheep passed through quarantine, and the Inspectors into whose districts they went reported that in almost every case the sheep when inspected after arrival at destination did not appear to have suffered from the effects of the dressings, of these 3,054 were disposed of at the annual sales of stud sheep, and were from the flocks of the several breeders mentioned in appendix E.

4. Long-woolled and cross-bred Sheep.

Amongst the long-woolled sheep the Lincoln is said, in a large majority of the districts, to give the best returns in wool and in weight of mutton, the cross-bred sheep being second.

5. The "Cast" of Fat and Store Sheep.

The annual "cast" of fat sheep for the ensuing season is estimated at 5,926,434, and store sheep, 7,020,696.

6. How Sheep are kept.

Paddocked	48,617,818
Shepherded	918,362
Both ways	570,558
								50,106,768

7. Condition of the Flocks.

In forty-five districts the sheep are said to be improving; the principal reasons given being—more attention to breeding, paddocking, introduction of high-class rams and ewes, more careful classing and culling, and good seasons.

In thirteen districts they are said to be stationary, and in two districts they are deteriorating. The reasons given are—effects of bad seasons, breeding from inferior ewes, bad management, and bad selection of rams.

8. Lambing.

The general average for the whole of the Colony of the paddocked sheep is returned by inspectors at 64½ per cent., and shepherded sheep at 54 per cent. In twenty-two districts the lambing was high, in twenty-five districts medium to fair, and in thirteen districts very low. The reason given for the high percentage is the favourable season and runs not overstocked, while the fair and low percentages are attributable to unfavourable season, poverty of ewes, want of food and water, and bad season after lambing, numbers of lambs having perished through heavy rains, and flocks harrassed by dogs.

The paddocked sheep show a higher percentage than the shepherded sheep by 10½ per cent.

9. The Clip.

Average per sheep.

Lambs.—The number of lambs shorn in the grease was 6,790,889; the number washed, 74,693; total lambs shorn, 6,865,582.

Sheep.—The number of sheep shorn in the grease was 36,553,856; hot water and spout, 80,000; creek-washed, 475,254; and scoured, 1,446,105.

The average weights of the clip are estimated as follows:—

	Lambs.		Sheep.	
	lb.	oz.	lb.	oz.
Grease	1	11½	5	13½
Creek-washed	1	9	3	3
Hot water and spout washed	4	2
Scoured	2	14

Total Clip.

The total clip in the Colony for the year 1889, according to the number of sheep, would be 36,553,856 shorn in the grease, average clip, 5 lb. 13½ oz. per sheep = 213,611,596 lb.; 475,254 sheep, creek-washed, average clip, 3 lb. 3 oz. per sheep = 1,514,872 lb.; 80,000 sheep, hot water and spout, average clip, 4 lb. 2 oz. = 330,000 lb.; 1,446,105 sheep scoured, average clip, 2 lb. 14 oz. = 4,157,552 lb. Lambs—6,790,889 lambs shorn in the grease, average clip, 1 lb. 11½ oz. per lamb = 11,671,840 lb.; 74,693 lambs washed, average clip per lamb, 1 lb. 9 oz. = 116,707 lb.; total clip, 231,402,567 lb.; or an increase of 23,071,487 lb. on last years clip, and is accounted for by a greater number of sheep having been shorn in the grease this year than in 1888, and the heavier fleeces through the favourable season.

Condition of Clip.

In twenty-one districts the clip is reported as sound and containing a plentiful supply of yolk; in twenty-six districts, sound, and containing a fair amount of yolk; in eleven districts, sound, but light in yolk; and in the two remaining districts, light and unsound. On the whole the clip was clean, but in a few districts the value of the wool was affected by grass-seed and burrs.

Exportation of Clip.

The clip grown in the Colony of New South Wales is shipped principally to England, America, France, and Germany, from the ports of the three neighbouring Colonies, as well as from Sydney. The portion of our clip thus shipped from the other Colonies is often mistaken as the produce of those Colonies, more particularly for that of Victoria and South Australia.

The

The following is an estimate of the clip sent to Sydney, and also the proportion sent across the Borders and to Melbourne, Adelaide, and Brisbane, for the years 1888 and 1889:—

Port of Shipment.	1888.			1889.		
	Greasy.	Washed.	Total.	Greasy.	Washed.	Total.
	lb.	lb.	lb.	lb.	lb.	lb.
Sydney.....	148,681,473	3,410,500	152,091,973	161,240,577	3,101,814	164,342,391
Melbourne	38,421,221	163,327	38,584,548	54,265,699	1,519,199	55,784,898
Adelaide	14,369,559	14,369,559	9,470,909	1,481,528	10,952,437
Brisbane	269,352	15,648	285,000	306,251	16,590	322,841
	201,741,605	3,589,475	205,331,080	225,283,436	6,119,131	231,402,567

This shows an increase in the quantity of wool shipped during the year from the Port of Sydney, of 12,250,418 lb., as compared with that shipped in 1888.

Classing the Clip.

In thirty-five districts the clip is reported as having been well classed. In the other districts it is not considered to have been so; the reasons being, owners do not think it pays, want of convenience, sheds not large enough to warrant expense, and the difficulty of obtaining competent woolsorters.

Wool-presses.

A great number of different kinds of presses are used; those most in favour are Ferrier's Patent and Williams' and Robinsons'; rack screw and pinion presses are used. There is still room for improvement in the mode of pressing, especially by the owners of small clips.

Woolpacks.

The woolpacks used are mostly Calcutta and Dundee, of various sizes, from 4 ft. 6 in. x 2 ft. 2 in. to 5 ft. 3 in., and the weight from 10 to 12 lb.

On fifty-three stations the wool is dumped before leaving.

10. Sheep-brands and marks.

Ear-marking.

In most districts the system of ear-marking sheep is properly carried out, and may now be said to be approved by all the Boards.

Tattoo-marking.

This system of marking is mostly used by owners of stud-sheep, not as yet to any great extent in the case of ordinary flock sheep, but where tried, it has been found to be a good preventive to sheep-stealing.

V.—DISEASES IN SHEEP.

1. Scab.

The flocks in this Colony and in the Colonies of Queensland, Victoria, South Australia, and Tasmania are free from scab. It exists, but to a very slight extent, in New Zealand and Western Australia, and it is hoped that these Colonies will soon be declared clean. The importation of sheep into this Colony from New Zealand and Western Australia is prohibited.

2. Anthrax.

In November last a communication was received from M. Pasteur through his representatives, Dr. Germont and M. Joir, offering the use of M. Pasteur's Vaccine of Anthrax in all the Colonies for a lump sum of £38,000. This was submitted to the Intercolonial Stock Conference held in Melbourne in November last, but was not entertained, as the Conference considered it would be the better course to allow M. Pasteur to appoint agents in the Colonies, who would deal directly with the owners requiring the vaccine, the Governments of the several Colonies giving them every facility for establishing and working these agencies. Although M. Pasteur's offer of his vaccine for a lump sum was declined and the other course recommended by the Conference, it is believed that the delegates were largely induced to make this recommendation because they considered the amount asked too high, and if a more moderate sum were asked, it is probable the Colonies would agree to contribute to its payment.

3. Foot-rot.

In twenty-three districts the sheep have been more or less affected with foot-rot during the year; the reasons given being wet in the early part of the year, running on low rich pasture, and contagion. The principal remedies tried were careful paring, butyr of antimony and bluestone, bluestone and kerosene, arsenic, arsenic and lime, blue vitriol, sulphate of copper, carbolic acid, and nitric acid—with satisfactory results. Of these, bluestone and butyr of antimony have been most effective for hand-dressing, and arsenic in troughs.

4. Fluke.

In nine districts the sheep were affected with fluke, through depasturing on low swampy ground, unsound country, and rank pasture. The remedies used were—arsenic, salt, tar, and turps, sulphate of iron, and Liverpool salt and sulphur—with good results; but the best course where it can be followed is to remove the sheep to salt bush country.

5. Parasitic Worms.

In sixteen districts the sheep are reported as having been infested with worms, to an extent of (say) 7 per cent., attributed to,—rain in the early part of year,—to being affected from previous year,—to rankness in the grass,—and to unsound country.

Of these worms the most common and most injurious to the sheep have been the tœnia (the tape-worm), the anchylostomum (the thread-stomach worm), and the filaria (the lung worm).

Of the remedies used for the stomach and tape-worms, arsenic has been the most general, and with very satisfactory results. Turps and oil, sulphate of iron, and salt and tobacco have also been given with good results.

For the lung worms, a mixture of turpentine and oil is believed to be the best remedy. VI.—

VI.—PIGS.

The number of pigs in the Colony, as returned at 31st December, 1889, is 237,276 being a decrease of 11,407 as compared with the returns for the previous year.

From the other Colonies, 55 have been introduced by sea.

Foreign pigs are prohibited.

Diseases in Pigs.

No disease whatever has been reported amongst pigs.

VII.—DOGS.

Thirty-nine (39) foreign dogs, *i.e.*, dogs from England, America, France, Germany, and other places outside the Australasian Colonies, passed through quarantine during the year—exclusive of fifty-four ships' dogs which were quarantined during stay of vessels in port—and 615 Colonial dogs were introduced at the port of Sydney.

Diseases in Dogs.

Rabies is still reported as prevalent in Europe, and in London and in some other parts of England the regulations requiring dogs to be muzzled were, during the dangerous months of the year, strictly enforced.

Pasteur's method of treatment of hydrophobia continues in favour, and patients from almost every part of the world are sent to his Institute for treatment.

Rigorous quarantine regulations are absolutely necessary to prevent the introduction of this disease into these Colonies.

VIII.—TRAVELLING STOCK.

1. *Trespass on Reserves.*

In twenty-four districts the driftways and reserves for travelling stock are reported as having been trespassed upon, more or less, by neighbouring lessees' and selectors' stock. In some instances the stripping of the reserves of pasture arises through their not being withdrawn from lease, and being used by the lessees of the run. In thirty-six districts they are reported as being entirely free from trespass. Inspectors suggest, in order to enable them to exercise proper supervision over these reserves, that the boundaries should be properly marked.

2. *Grass on Reserves and Driftways.*

In seven districts the inspectors report that there is not sufficient grass on the reserves and driftways in their districts to enable fat stock to reach market in good condition; in twenty districts that there is only sufficient in fair to good seasons; and in thirty-three districts that, as a rule, there is sufficient grass on these reservations.

From sixteen districts it is reported that sheep to the number of 2,019,256 have passed through during the year in search of grass and water. From seven districts the number of loafing sheep is given at 182,651.

3. *New Roads for Travelling Stock.*

In fourteen districts new roads are required for travelling stock, and in forty-six districts no new droving roads are recommended.

4. *New Reserves for Travelling Stock.*

In seventeen districts new reserves and alterations of existing ones for travelling stock are required. In forty-three districts there are sufficient reserves; but in a good many cases these reserves are now being curtailed in a way that will, I fear, be injurious to the stock traffic.

5. *New Wells, Tanks, or Dams.*

In twenty-five districts the inspectors report that new wells, tanks, or dams should be constructed by the Government at places which they indicate.

6. *Travelling Charges for Stock.*

In twenty-four districts travelling charges for stock have been collected on 134 separate occasions, the total amount collected being £10,646 15s. 2d., most of which has been refunded to date on appeal to the Boards.

7. *Laws relating to Travelling.*

In all the districts the inspectors report that the provisions of the amended Sheep Acts relating to travelling stock are working fairly well, but are at times evaded, and should be amended.

IX.—REGISTRATION OF HORSE AND CATTLE BRANDS.

1. *Brands registered.*

The number of horse and cattle brands registered up to 31st December, 1889, was 61,790. The number of brands registered during the year 1889 was—horse brands (alone), 525; cattle brands (alone), 600; and horse and cattle brands, 1,296; making a total of 2,424, being an increase of 112 applications on the previous year.

This shows an increase of 112 in the total number of brands registered during the year as compared with 1888, and is accounted for by increased settlement. There is a decrease in the number of brands transferred and addresses changed, while there is a large increase in the number of brands cancelled.

2. *Brands transferred.*

The brands recorded during the year 1889 as transferred were—horse brands, 20; cattle brands, 24; horse and cattle brands, 94; total, 138.

3. *Brands cancelled.*

The brands cancelled (horse and cattle) in 1889 were 180.

4. *Addresses changed.*

The number of addresses of owners changed in 1889 was 97

5. *Compliance with the Act.*

In fifty-five districts the provisions relating to registration and the other requirements of the Act are reported as being duly carried out, and in the remaining five districts fairly so.

6. *Benefits of the Act.*

The inspectors, in alluding to the benefits of the Act, report that it prevents duffing, stock-stealing, facilitates identification, assists in recovering lost stock, and otherwise is a great convenience and protection to stock owners.

X.—POUNDS.

1. *Number and inspection.*

There are 410 pounds in the Colony, some of which are at present closed for want of pound-keepers. The whole of the pounds are inspected periodically by the various inspectors of stock.

2. *State of Yards.*

Forty-one of the pound-yards are reported to be old; several require renewing, being unfit for the safe custody of stock; and the remainder are said to be in a fair and good condition.

3. *Keeping and depasturing Pound Stock.*

The provision made for the proper sustenance of impounded stock, according to the reports received, is, with a single exception, satisfactory. As a rule, pound-keepers have now paddocks for the stock.

4. *Management of Pounds.*

The pound-keepers are reported to be performing their duties, upon the whole, in a satisfactory manner, and the appointment of inspectors of stock as inspectors of pounds has had a very beneficial effect.

XI.—NOXIOUS ANIMALS.

1. *The Districts in which the Pastures and Stock Protection Act is in force.*

The Act has been brought into operation in all the districts, and during the year work has been done to the extent shown in Appendices F 1 and F 2.

2. *Receipts and expenditure under the Act.*

The amount of assessment paid by stock-owners during the year 1888 was £24,938 4s. 6d., and the amount expended, £52,121 9s. 6d. The amount of assessment paid by stock-owners in 1889 was £33,257 0s. 3d., and the amount expended, £50,525 14s. 3d., the difference being accounted for by the subsidy granted by the Government to the Boards, and large amount to credit of some of the Boards at commencement of the year. Eleven districts are reported to be in debt to the amount of £1,834 2s. 3d.

In ten districts full rates were levied, in thirty-four districts less than full rates, while in sixteen districts no rates whatever were levied.

During the year the bonuses paid by the Boards for scalps ranged as follows:—For kangaroos, from 1d. to 1s.; wallaroo, 6d.; wallaby from 1d. to 1s.; paddymelon from 2d. to 1s.; Bandicoots, 2d. and 3d.; hares, from 2d. to 1s.; kangaroo rats, 2d. to 6d.; native dogs, from 10s. to 80s.; pups, 5s. to 10s.; bilbees, 2s. 6d.; opossum, 1d. and 2d.; wild pigs, 1s.; eagle-hawks, 2s. 6d. to 7s. 6d.; and emus, 6d. to 2s.

3. *Estimated number of Noxious Animals.*

The aggregate of the returns by inspectors of the estimated number of noxious animals in their districts shows that there are supposed to be 1,036,717 kangaroos, 3,064,961 wallabies, 25,333 native dogs, 2,744,810 hares, and 3,354 wild pigs in the Colony.

4. *Increase and Decrease.*

Kangaroos are reported to be increasing in fifteen districts, wallabies in twelve districts, native dogs in five districts, hares in twenty-two districts, and wild pigs in two districts. In twenty-seven districts kangaroos are reported to be decreasing, wallabies and native dogs in twenty districts, hares in six districts, while pigs in eight districts, and in the remaining districts they are said to be stationary.

5. *Number destroyed.*

The number of kangaroos destroyed during the past year was 495,673; of wallabies, 642,782; of kangaroo rats, 86,527; of paddymelons, 5,670; of wild pigs, 9,700; of hares, 329,683; of native dogs, 9,142; of eagle-hawks, 3,199.

6. *Steps taken for their destruction.*

In the majority of the districts, hunting with dogs, drives, shooting, and trapping have been adopted with satisfactory results. In thirty-six districts poison has been used with fair to best results, and only from one district has it been reported as not satisfactory.

7. *Amendments suggested in the Act.*

Owners are desirous that the Amended Stock and Pastures Bill speedily become law; and they suggest that all owners of stock, irrespective of number, should be liable to an assessment, as also owners of 5 acres of land and over; that hares be included in the list of noxious animals; that the Boards be empowered to cope with the rabbit nuisance; that the Government should grant larger subsidy; that uniform rates be levied; that the rate of bonus be the same throughout the Colony; that all returns of stock be made on the same day; that adjoining Boards assimilate bonuses; and that the provisions of the Act *re* defaulting Boards to be strictly enforced.

8. *Losses from Tame and Native Dogs.*

The losses in stock for the past year from the ravages of native dogs are estimated at 57,561 sheep, valued at £21,654; and from tame dogs, 41,067 sheep, valued at £17,252, making the loss from tame and native dogs together £38,906.

Appendix F 1 shows the work which has been done under the Pastures and Stock Protection Acts since they were passed, and how far the objects for which they were so have been attained.

A proposal has been made to discontinue the bonus for kangaroos; but if this is done the hunters will not kill the small kangaroos, and the number will increase.

XII.—COMMONS.

1. *Number and extent.*

The number of permanent Commons in the Colony is 94, with an average extent of about 1,300 acres each. The number of temporary Commons is 230, with an average extent of 2,300 acres each.

2. *Number of Commoners, Stock, &c.*

The average number of Commoners to each Common is estimated at 96, and the average number of stock kept on each Common at 140.

In twenty districts the Commons are reported to be used for other purposes than that of grazing Commoners' stock.

XIII.—MISCELLANEOUS.

1. *Artificial Grasses.*

In twenty-seven districts artificial grasses have been sown for pasture during the year to a small extent, in six districts to a large extent, and in remaining districts none; the most successful being lucerne, prairie, and rye.

2. *Number and Division of Runs.*

The number open or unenclosed runs in the Colony is 7,899; the number enclosed is 32,908; the number partially subdivided is 12,029; and the number properly subdivided is 20,784.

3. *Improvements, Fencing, Dams, Tanks, and Wells.*

The number of miles of fencing throughout the Colony is estimated at 1,462,511, at an average cost of (say) £40 2s. 6d. per mile, amounting to £58,650,054.

The number of dams used for stock purposes is estimated at 25,666, at an average cost of (say) £83 7s.; number of tanks, 27,345; average cost of each, £180 18s. 9d.; and the number of wells used is estimated at 3,338, at an average cost of £184 14s. 6d. each.

Cost of fencing, £58,650,054; cost of dams, £2,139,500; cost of tanks, £4,947,751; cost of wells, £616,624; making a total of £66,353,929, as representing the amount expended by way of improvements, &c.

4. *Plants and Weeds.*

In fourteen districts *trefoil burr* grows to a slight extent, in twenty-six districts to a large extent, and in twenty districts there is none reported.

In twenty-five districts *variegated thistle* is reported to a slight extent, in nineteen to a considerable extent, and sixteen districts are reported as free from it.

In twenty-four districts *black thistle* is reported to a slight extent, in twenty-three to a great extent, and thirteen districts are reported to be free from it.

In twenty-seven districts the land is reported as being slightly infested with *Bathurst burr*, in twenty-five to a large extent, and in eight the land is not infested.

In twenty districts other noxious weeds grow to a slight extent, in twenty-three districts to a large extent, and in seventeen districts there is none reported.

Darling-pea, Roley-poley, are reported to be growing in a few districts.

Euphorbia Drummondii.—Although this plant has been carefully experimented with, and shown so far to be non-poisonous, and put to a practical test by owners, reports still continue to be received of its causing the death of sheep.

5. *Cost of clearing Commons, Reserves, &c., of Weeds.*

The cost of clearing the permanent Commons of noxious weeds throughout the Colony is estimated by Inspectors at £44,595; the temporary commons, £29,484; the police paddocks, £3,538; the travelling stock reserves, £177,745; and the droving roads at £90,502; amounting in all to (say) £345,864.

6. *Examination of intending Applicants for appointment of Inspector.*

During the past year two examinations were held by the Stock Board of Examiners. The following table shows the result:—

Date of Examination.	Number of Candidates.	Names of successful Candidates.	Nature of Certificate issued.
1889.			
January 14th	5	{ A. A. Devlin	2nd class.
September 9th	4	{ D. C. Gordon	2nd „
		{ Geo. Day	2nd „
		Nil.	
Total	9		

It will thus be seen that nine candidates were examined, three of whom received 2nd class certificates.

7. *The Stock and Pastures Bill.*

It is hoped that the Government business will, in the coming Session of Parliament, admit of this measure being passed.

8. *The Chilled Meat Trade.*

As there is seemingly considerable disinclination on the part of many of our stock owners, and those connected with the pastoral interest, to give the establishment of this trade the practical assistance and support which are necessary for its successful initiation, I have thought it necessary to deal with the question at considerable length, and to restate a good many of the arguments which I have already adduced in its favour. [See Appendix G.]

9. *Intercolonial Stock Conference.*

The Conference, which met at Melbourne on the 1st November, was convened at the instance of the Premier of Tasmania, in accordance with the resolution passed at the Intercolonial Stock Conference held at Sydney in 1886, that a similar meeting should be held triennially in one or other of the Colonies.

On

On this occasion, the regulations in force in the several Colonies relating to the introduction of foreign stock, *i.e.*, stock from places outside the Australian Colonies and New Zealand, were first considered by the Conference, together with the infectious and contagious diseases affecting such stock.

These regulations were revised and amended, and where they could safely be so were so far relaxed.

The same course was followed with respect to the regulations relating to the interchange of Australian stock by sea and land between the Colonies, and to the diseases to which these stock are subject.

The nature, cause, and best mode of treating the different diseases in stock prevalent in the Australasian Colonies were then discussed, with the view to their prevention and eradication; and the tenor and form of the regulations best adapted for securing these objects were to a large extent settled by the Conference.

Besides dealing with these matters, the Conference, at the instance of some of its members, took up and discussed several subjects having a general but very important bearing on the pastoral interests in the Colonies, such as the establishment of an Australian Stock Institute, the encouragement of a chill or fresh meat trade, the erection of rabbit-proof fencing, an annual convention of stock owners, and a uniform code of regulations for all the Colonies. The resolutions of the Conference, will be found under Appendix H.

APPENDIX A.
RETURN of Stock in the several Sheep Districts.

Districts.	Year 1888.					Year 1889.				
	Acrcage.	Horses.	Cattle.	Sheep.	Pigs.	Acrcage.	Horses.	Cattle.	Sheep.	Pigs.
Albury	865,284	6,888	15,037	606,486	869,833	6,903	16,452	746,859

APPENDIX C.
STRINGHALT IN HORSES.

Paper read by Mr. E. Stanley, F.R.C.V.S. (New South Wales), at the Australasian Stock Conference, Melbourne, 1889.

Mr. Chairman and Gentlemen,

Having been asked to prepare a short paper on this subject, I shall confine my remarks to the consideration of some theories promulgated as to the cause of this affection; and finally support my theory of Helminthiasis. First, as to the noxious plant theory, the common British flat weed or cat's ear, *Hypochoeris Radica*, often erroneously called dandelion because it has a yellow flower, has the most supporters, who believe it causes stringhalt; for what reason I cannot understand. I know this weed is good and wholesome food, it covers immense geographical areas in New South Wales and in the other colonies, it has been eaten by thousands of horses year by year, and continues to be eaten where the stringhalt never existed; again, I have seen many cases of stringhalt where this weed has never been seen. How is it that the weed theorists during all the years the disease has been about have not made an extract or decoction of their plant? and so proved their case by producing the disease at will, simply by administering a concentrated dose of the plant; nothing could be more easy or convincing; the late Mr. Graham Mitchell, V.S., tried to do so, but he failed. Some New Zealanders attribute the disease either to the dandelion or to the Cape weed—African marigold (it has a yellow flower with a black centre); if so, why do they not make a decoction of the plant and prove it? These weeds are very common, and are valuable as food. Fungus on plants has been suggested, but has not been demonstrated in any way;

as a matter of fact, the symptoms and pathology do not accord with the toxic effects produced by fungi, or indeed any other weeds or plants. The medicinal ingredients of plants are well known to be expelled from the animal body in a very few hours, and when medicines capable of producing toxic effects are repeated time after time disastrous results must follow, and would be seen in the excreting organs; nothing of the kind is found in this disease, on the contrary affected horses actually recover while living on these weeds all through the various stages of the disease; therefore it appears that the plant theory is untenable and entirely without foundation.

I therefore still maintain that the disease is Helminthiasis, that is, caused by worms. It will be remembered that I reported at some length on this disease in July, 1886; since then I have seen the same affection at Moana, on the Murray River, in 1887, and again at Moss Vale this year, therefore I am able to confirm my opinion as to the parasitic origin of the disease. It is caused by worms infesting the mucous membrane of the horses' digestive organs, especially the intestinal canal, where, by setting up irritation of the bowels, they disturb the nervous system, thereby affecting the nutrition and action of certain sets of muscles, producing inordinate contraction whenever the animal moves; this I attribute to perverted nervous action, which is possibly aggravated by deterioration of the blood, produced by the ever increasing myriads of parasites; they are biting, perforating, and bleeding like leeches the highly sensitive mucous membrane during the whole time they are the tenants in possession; they not only deteriorate the blood by altering its constituents, but I believe they also *by virtue of their excretions and debris, eliminate toxic material*, which being absorbed into the circulation may assist in producing the disastrous effects on the nervous and nutritive systems which are so characteristic of this affection.

That toxic elements are manufactured in the blood by parasitic organisms is well known to scientists who are engaged investigating bacteria and other microbes in their relation to diseases.

In stringhalt parasitic worms are found in countless numbers, and of several distinct varieties, in the large and small intestines, invading their tunics, making innumerable sores, ulcers, and abscesses, accompanied by the products attending chronic inflammation, thus paralysing peristaltic action, they interrupt the natural nutritive functions of these important digestive organs; they are so overcrowded and voracious that they actually bore right through the bowels, and some are found as wanderers in the muscular walls of the abdomen; they stray about to become finally encysted in various places, and die; their debris creates still further trouble.

In passing I wish to note that I consider many of the larger and common worms found frequently in all animals that live on mucous or epithelial cells and food in the stomach and bowels are unimportant in this disease, therefore I exclude them. The arteries are free from stronguli, and I have never seen hæmatozoa in the blood in stringhalt; neither do I find disease in the cerebro-spinal organs; there is discoloration in the blood vessels, which is due to impure blood; the cerebro-spinal system is only temporarily deranged.

Having given the basis of my opinion, I am further confirmed by the symptoms, peculiarities, progress, and terminations of this affection.

I am in a position to state that Veterinary Surgeons Archibald Park, of Tasmania, William Scott, of Sydney, and Frederick William Day, of Randwick, confirmed my views; each of these gentlemen formed their own opinion after investigation and observations extending over three years, during which they have noted the various opinions brought forward in the Press and expressed by horsemen they have questioned. [*Opinions of these gentlemen read to the Conference.*]

The opinions of such well-known veterinarians carries much weight, and I feel satisfied that the treatment of the disease will never prove successful unless carried out in detail by those who understand its pathology and deal with it accordingly.

The test of diagnosis is that the line of treatment I advise proves successful, and effects a cure.

The impatient public, who do not understand the structure, use, or importance of the organs attacked, cannot grasp the direful effects produced by chronic disease, therefore fail to understand the great difficulty there is in expelling the parasites without injury to the animal, or the length of time that must elapse before nature can effect repairs; weeks and even months are required for nature to re-establish her sway, before a complete recovery can be proclaimed.

Veterinarians find this disease intractable and difficult to contend with, because the cases are too far advanced before their advice is sought.

The objects of treatment should be to expel the worms, purify the blood, then to assist nature in the restoration of the deranged organs, and avoid contamination.

Hence the line of treatment will consist of purgatives and anthelmintics and tonics, with change of locality, water, and food.

Horse-owners beyond the reach of veterinary skill I advise to trust nature and assist her by simple means, such as change of pasture and water (infested water should be boiled), provide good and wholesome food, and keep out of infected paddocks. Common salt, one ounce daily, alternated with a drachm of sulphate of iron, may be given with advantage; also give two or three times in a month a purgative of spirits of turpentine, three or four ounces, mixed with a pint of olive or other oil.

Further information may be obtained from my report to the New South Wales Government, July, 1886.

EDWARD STANLEY, F.R.C.V.S., London,
Government Veterinary Surgeon, N.S.W.

APPENDIX D.

Department of Mines, Stock Branch, Sydney, 24 July, 1889.

Sir,

ANTHRAX IN CATTLE.

I have the honor to report having examined the diseased cattle in the district of Young, just across Cowra bridge, on the travelling stock reserve; they were the property of Mr. R. Hassall, store cattle, composed of cows and heifers, in good condition.

He started 355 from Mudgee, *via* Wellington and Molong; when about 10 miles on the road to Canowindra sickness broke out and cattle began to die, this continued to Cowra, where I saw several ill and dead; forty-three deaths had then occurred.

Riding

Riding through the cattle the following symptoms were observed:—Erect hair, empty stomachs, wild expression of eyes; in several cases well marked swollen patches could be seen, in one a thigh or shoulder, in others on the neck, rump, or on the back or ribs; they walk stiffly, often lame; traces of blood stains were on the tail and buttocks, blood was mixed with the black liquid dung.

The urine was seldom altered in colour; now and then blood trickled from the nostrils. These symptoms precede death for two or three days.

This is anthrax, the form known to Veterinarians as blackleg or charbon symptomatique.

A dozen or so lay dead on the Cowra reserve. I selected for examination three animals, recently dead, and found in each the typical pathological lesions of the disease, namely: Extensive patches of black bloody and yellow gelatinous effusions in various parts of the body, and also black bloody discolourations on some of the viscera, chiefly the rectum and colon; the serous membranes of the heart and liver were extensively infiltrated with black blood; the peritoneum had numerous patches of congested vessels, and the mesenteric membrane was thickened by a gelatinous fluid. The spleens were pale and small, in one the covering was distinctly congested, the lungs and kidneys were healthy in each case.

This is identically the same disease that killed so many cattle near Dubbo, in 1887.

In consequence of its fatal character curative treatment is almost useless, therefore preventive measures are advised.

In Europe this is done by inoculation, with a cultured or prepared virus from a diseased animal, but such virus is not obtainable in this Colony. Move the cattle from contaminated places on to fresh pasture, and rigorously enforce cremation of every carcass (it is dangerous to remove the skins). This is all that can be done with travelling stock. For cattle that are exposed to the disease and can be handled, I advise a few doses of saline medicine with the insertion of a medicated seton in the dew-lap.

I have, &c.,

EDWARD STANLEY, F.R.C.V.S.,
Government Veterinarian.

A. Bruce, Esq.,
Chief Inspector of Stock.

N.B.—The whole of the accounts of expenditure for 1889 are not yet to hand.

APPENDIX G.

THE CHILLED MEAT TRADE.

It is now some sixteen or eighteen years since the late Mr. T. S. Mort, to whom the Australian Colonies and New Zealand are indebted for the establishment of the frozen meat trade, endeavoured to form a fresh meat depot at Lithgow, and although like a great many other public benefactors, he was himself unsuccessful in that enterprise, the trade in chilled meat has, in America, not only become firmly established, but is there fast supplanting the live stock trade, as there cannot be a shadow of a doubt it will before long do in Australia and throughout the civilized world.

So much for the late Mr. Mort's foresight, enterprise, and patriotism. His theory was that with the aid of artificial cold properly applied there need be no more waste, and although we have to lament that he has not lived to see the success of his proposals, their correctness and practicability are fully exemplified in the success of the chilled meat trade, but more especially in that of the frozen meat export from the Australian Colonies, New Zealand, and South America.

It did not take very much consideration after all that Mr. Mort did and said on this subject to see that the principles which he advocated were thoroughly sound, and adopting his views I have for the last ten or twelve years constantly advocated the establishment of a fresh or chilled meat trade, both on account of the numerous evils which attend the existing live stock trade and the advantages which must accrue from the change. These I have previously stated, but I think it will be of service to recapitulate them again.

I.—THE EVILS OF THE LIVE STOCK TRADE.

1. *The suffering and cruelty inflicted on the Stock.*

Leaving entirely out of view the hardship which stock frequently undergo, even in the outlying districts (where as a rule the feed is comparatively good), in travelling to the nearest railway station, and following them from the time they are yarded there till they are killed at the abattoirs, the treatment to which they are now subjected in reaching Sydney from an outlying station like Bourke is cruel and wasteful in the extreme, for they are between seven and eight days without any food whatever, made up as follows:—

In yarding, trucking, and despatching, say, from Bourke, 10 hours; on the train to Homebush, unloading there and yarding, say, 40 hours; lotting, selling, and removal to paddock at Leichhardt, 15 hours; in waiting paddocks there (as a rule the cattle purchased at one sale remain in these paddocks until after next sale day and a fresh lot have been purchased before they are sent to the abattoirs), say, 84 hours; at the abattoirs waiting slaughter, say, 24 hours. Total, 173 hours.

That is 173 hours, or 7 days 5 hours without any food whatever, and sometimes without any water.

From this it will be seen that a considerable portion of some 1,500 head of cattle and 15,000 sheep are week after week subjected to the terrible torture of five, six, seven, and even sometimes more days starvation till the cattle are to be seen at the abattoirs with their heads hanging down, their bellies tucked up to their backs, and looking utterly miserable and wretched.

Nor is this all, the poor animals in trucking are terrified, beaten, and bruised, and when in the truck they push and horn each other, the stopping and shunting often throw them down, and some of them are not unfrequently trampled to death. The losses of cattle on the train, and the bruises on the ribs, hips, and rumps (so noticeable on their bodies when killed), show conclusively the cruelty now inflicted on the animals under the live stock trade, and with the terrible starvation which that system entails, cries aloud for a thorough change.

II.—THE WASTE AND DETERIORATION OF THE MEAT.

1. *The shrinkage in weight.*

This alone is a very serious matter, for if quiet, fat cattle in England carefully driven short distances, and fed two or three times a day, waste, as it has been proved they do, on an average over 8 lbs. in twenty-four hours, it is certain that the loss in weight on our comparatively wild fat bush cattle must, in trucking

trucking on the train, and till they reach the killing pen—subjected as they are to the barbarous treatment and starvation from which they now suffer—waste nearly double that amount, and that the shrinkage in their case will amount to 12 or 14 lb. a day, which again for seven or eight days would on an average be at least 100 lb. per bullock, *i.e.*, one-eighth of the whole weight, and the very best of the meat.

III.—THE DETERIORATION IN THE QUALITY OF THE MEAT.

It is notorious that the meat supplied in Sydney is, as a rule, inferior; no doubt a good deal of it may in favourable seasons like the present look well, and in some cases where the cattle have not had far to come to market, may possess a good deal of the flavour and nutrition so noticeable in first class country killed meat. But a large portion of the supply is comparatively tough, and void of flavour, and in bad and even only hard seasons, the beef supplied to the people of Sydney and suburbs is inferior, tough, and flavourless. It is, in fact, after the cruelty and starvation to which the stock are subjected, simply hard well-trained muscle with all the primest and most nutritious part of the meat gone, which not only renders it dear and innutritious to the consumer, but so far at least as the beef is concerned, utterly unfit for export to London; while as regards the frozen mutton now sent from Sydney to London—it on an average brings $\frac{1}{4}$ d. per lb. less than the New Zealand.

IV.—THE REMEDY IS THE ESTABLISHMENT OF A FRESH OR CHILLED MEAT TRADE.

1. *How conducted.*

The remedy for this unsatisfactory state of things is now exceedingly simple. It lies in the improvement, or more correctly speaking, the preservation of the quality of our meat by artificial cold, which can be obtained at a comparatively trifling cost. On or near its own pastures, our meat is as good as any in the world; and we have only to convey it from the pastures to market without deterioration to have an article which is in every way fit for local consumption, and which we can with confidence offer in any market, either in a fresh, frozen, chilled, tinned, or salted state, and obtain a paying price for it. To effect this we would have—

- (1.) To kill the stock at the main centres of the stock traffic on the railways, as near the pastures on which they are fattened as possible; or, if they have travelled any distance, to keep them in paddocks near these centres where they can get plenty of good grass and water for six, eight, or even more days, till they are well rested and cooled down, and thoroughly free from fever.
- (2.) To send the meat, with as little handling as possible, to a chilling-room cooled down to 36 degs. *fab.* in winter and moderately cool weather; and in the Summer time down to 33 degs. (just above freezing), in order to have a good surplus of cold to meet the loss which takes place in the transit when the weather is warm, and thus do away as far as possible, with the necessity for providing ice by the way. The meat for consumption in Sydney could in this way afford to lose, say 30 degs. (the truck would then only be 53 degs.), and arrive perfectly safe. The cost of chilling would in the height of Summer be, say, 2s. 6d. per body of beef from Bourke or Hay, with the temperature at 100 degs. in the shade.
- (3.) To put it late in the day into non-conducting meat trucks (which would also be cooled down to the temperature of the meat, and send it by train at a speed of at least 20 miles an hour to market; and
- (4.) To run the truck, on its reaching Melbourne or Sydney, into a meat market provided with the necessary appliances for cooling and keeping the meat, and there, according to the state of the market, either dispose of it to the retail butchers, send it to the chill-room (where it can be kept perfectly sound for a fortnight) to wait a better market, or prepare it for exportation as frozen, chilled, tinned, or salted meat.

A proper chilled room to protect the meat should it not be sold on arrival is a *sine qua non*. It was the want of this that was one of the principal causes of the failure of the Orange Company to establish a fresh meat trade, for as the company had no means of protecting the meat when not sold, they had to take the price offered by the retail butchers, or allow it to stink. They were, in fact, largely at the mercy of the trade; whereas with a proper chill-room the salesman could put the meat in and wait a fortnight if necessary for better prices, to say nothing of the other outlets secured by a proper system of artificial cold.

2. *The Advantages of a Fresh Meat Trade.*

Advantages which can be claimed for this trade—

- (1.) The great suffering and terrible starvation to which our fat stock are now subjected would cease.
- (2.) The risk and inconvenience from which the people in the suburbs now suffer, through the driving of the stock, would be at an end.
- (3.) There would then be very little slaughtering near Melbourne or Sydney, and the nuisance which abattoirs near these cities now occasion would cease.
- (4.) The owner would receive full value for stock, as he would be paid for every pound the carcass weighs, for the loose fat, for the hide or skin, and other saleable offal; and as his returns would in this way be far better, he would be able to supply the retail butcher with meat of a very superior quality at considerably less cost than the wholesale butcher now does.
- (5.) The appearance and quality, as well as the flavour and nutriment, of the meat will be thoroughly preserved; and after it is taken to the shops in the city, it will keep from thirty-six to forty-eight hours longer than abattoir-killed meat now will.
- (6.) The conveyance of the fat stock to market in the carcass will cost their owner considerably less than sending them alive; for a great deal of space is, so to speak, wasted in a truck in which live stock are conveyed; and thirteen bodies of cooled well-set beef could be put into the same space as nine live cattle, while the charge for the truck should in each case cost the same; or rather the meat ought to cost considerably less, as the truck in which it is carried can be loaded back with general merchandise, which the live stock truck cannot be.

(7.)

- (7.) The making the trade a fresh meat one would tend to prevent the spread of contagious and infectious diseases among stock, as it would do away with the necessity for bringing large numbers of stock (as the live trade does) together, and on the same ground, and thus save our stock-owners from the recurrence of the heavy losses they now sustain, from the diseases which are spread by fat stock going to market, and at the same time give the consumer cheaper, better, and healthier meat.
- (8.) Companies would be formed, at the different centres of the stock traffic, to kill the stock, chill the meat, put it in the refrigerating cars, and charge them when necessary with ice, on reasonable terms, while the meat would be consigned to the owners' agents, who would have stalls in the meat market; and in this way the producer would be able to offer his meat in an open well-regulated market, which would be within easy reach of the retail butchers as a class; and they again would be able to get an ample supply of prime well-set meat day by day as required.
- (9.) The meat would be thoroughly fit for export, which it now really is not; for our beef, and the greater part of our mutton, now, through wasting and deterioration, only rank as inferior in the London market, which practically prevents our sending it there; and unless we have this outlet, we will have glutted markets, low prices, depreciation in pastoral property, and hard times for owners. This advantage is, therefore, the most important of all, so far as owners are concerned.
- (10.) With a steady supply of artificial cold at a moderate cost (which will then be available) a salt beef trade will be established, and the extraordinary anomaly will no longer exist—that British and other shipping visiting the Australian ports should bring a sufficient supply of American salt beef to take them back again—while the beef in Australia on its own pastures is far better and cheaper than in America; the explanation being, that the use of cold and care in salting have enabled the Americans to obtain a monopoly of this most extensive and profitable business.

Nor would these be all the advantages which would be attained by the change. With the completion of the spacious meat market on the railway line at Darling Harbour, now being fitted up with salesmen's stalls and chill-room, we will very shortly see extensive Freezing, Tinning, and Salting Works erected in the vicinity of the market (they would create no nuisance whatever), and in this way the whole of the meat, and every part of it, will be turned to the best possible account, and the heavy losses which have been entailed on owners in by-past years through glutted markets will, to a very large extent, be avoided; for the meat thus killed up country will, as a rule, be of the primest quality and fit for any market in the world, and when the requirements of the Sydney trade are met the balance will, as the case may be, either be sold for freezing and shipment to London, or for tinning or salting, and the market cleared. If our fat stock trade were conducted this way, and due care exercised in its management, Sydney, with its large ocean-going steamers, cheap coal, and the railways running to Hay, Bourke, and Tenterfield, ought to do by far the largest meat export trade of any port in the Australian Colonies.

V.—SUCCESS OF THE FRESH MEAT TRADE.

1. In America.

Mr. Gilderoy W. Griffin, Consul for the United States, who has done so much to make our resources known there, and to promote trade between the Colonies and America, kindly obtained from the Commissioner of Agriculture, Washington, an exhaustive and very valuable report on the fresh meat trade in the United States, which showed that the fat stock trade in America, in spite of the powerful vested interests which exist there, was fast becoming a fresh meat one. In the short space of six years the volume of the fresh meat trade from the Western to the Eastern States of America, which only began in 1880, had increased with great rapidity, and has by this time overtaken and passed that of the live stock trade; and the Commissioner of Agriculture in reply to the question whether the fresh meat trade is likely to increase, very tersely observed that, "It must continue to increase unless there should be a revolution in trade affairs, and in the desire of the people to obtain the best meat for the smallest outlay,"—a contingency which it would be simply absurd to suppose would ever arise.

During the five years, from 1881 to 1885, the growth of the trade in dressed meat was as follows:—From 1881 to 1882 the increase was 42·5 per cent. over the trade of 1880; in 1882 the gain was 52·3 per cent.; in 1883 it was 127·5 per cent.; in 1884 it was only 23·6 per cent.; and in 1885 it was only 25·2 per cent.

In 1888-9, under the heading of Dead Meat Imports, and Live Stock Imports, a writer in the *Mark Lane Express*, of the 6th January last, in alluding to the chilled meat trade, says:—"The dressed beef business has driven the (carcass) butcher out, and is the coming method of handling beef in America."

The chief centres from which dressed beef is distributed there, are—Chicago, Omaha, Kansas City, and St. Louis; and none of these centres are less than 1,000 miles from Boston and New York, while some of them are as much as 1,500 miles; yet this writer tells us that chilled meat kept at an average temperature of 36° Fah. is regularly sent by train from these places to Boston or New York, and from there across the Atlantic to London, Liverpool, and Glasgow, where it is sold to the retail butchers, to be sent out by them to their customers who cannot tell it from Scotch or English beef.

On this point a writer in the *Daily News* (London), of the 21st December last, says:—"From the main slaughter-houses in America the carcasses are run off by tramways into the coolers, where the temperature stands at 36 degrees, and from these coolers they are run out to the loading platforms, cut into quarters, and sent off in refrigerating cars and vessels. In about a fortnight's time the meat thus hurried off from Chicago may rattle into the Smithfield market looking as fresh and appetizing as the best Scotch beef, and all the tenderer and nicer it is said for the keeping."

Further on again this writer says:—"There are enormous numbers of us able to regale ourselves on the roast beef of old England brought straight from Chicago."

In support of the statement that the chilled meat trade is fast driving out the live stock, the writer already referred to in the *Mark Lane Express*, gives the returns of the export of fresh meat from America for the year 1887-8, and for eleven months of the year 1888-9 (the December returns not being received), and they completely confirm this assertion.

They are as follows :—

						lb.
In the year 1887-8 the export was	90,816,426
„ „ 1888-9 „ „	149,793,485
<i>or</i>						bodies.
In the year 1887-8 the export was	106,280
„ „ 1888-9 „ „	187,241
<i>or weekly,</i>						
In the year 1887-8 the export was	2,042
„ „ 1888-9 „ „	3,677

Showing the American fresh meat trade had in one year increased 65 per cent., and that there were now an average of 3,677 bodies of chilled meat sent from America to Europe every week, none of which had been conveyed in refrigerating trucks on its way to the seaboard a less distance than 1,000 miles, and some of it 1,500 miles; and in no case could the time, counting from the time the cattle were slaughtered in America till the meat was offered by the retail butcher to his customers be less than ten days, and more frequently twelve or fourteen.

How utterly ridiculous, therefore, it is to assert, as some of those connected with the live stock trade here do, that we cannot kill our fat stock at Bourke, or Hay, and send the meat down safely for sale in Sydney, a journey occupying only some twenty-two to twenty-six hours.

2. *In Australia, 1889-90.*

Notwithstanding that the evidence which is here adduced of the success of the fresh meat trade in America is overwhelming, and ought to convince the most sceptical, it is still asserted by some in the trade that, although that system has proved to be a success in America, it may not answer in Australia. Fortunately, we are not dependent on American experience; for, through the praiseworthy energy and enterprise of Mr. Robert Hudson, of the firm of Messrs. Hudson Brothers, of Sydney and Melbourne, the reports of the success of the fresh meat trade in America have been fully confirmed by the experimental trips which he has made with his refrigerating car from Narrandera and Narrabri to Sydney, both of which were thoroughly successful, not only as regards the condition of the meat on its arrival in Sydney, but also as regards the expense and the owner's net returns. These, however, are not all the advantages. Through the excellent quality of the meat, with all the flavour and nutriment in it, it would, when these come to be more generally known, fetch top prices both in the Sydney market as well as in London, when frozen and exported there.

VI.—LIVE STOCK AND FRESH MEAT TRADE CONTRASTED.

1. *As regards the Stock.*

The live stock trade.—If the stock have to be conveyed any distance to market the trade entails great cruelty and seven or eight days starvation.

Under the fresh meat trade.—All this cruelty and barbarity is avoided. A great deal of the stock would have only short distances to travel to the killing and chilling depôts, and where they had to come from any distance they could be put in some of the paddocks which would be provided in the neighbourhood of the depôts till the fever induced by the journey had left them.

Every feeling of humanity cries aloud for the change from live stock to a fresh meat trade.

2. *As regards the Stock-owners.*

This is a matter of pounds, shillings, and pence, and as such the contrast will be best shown in figures.

With that view I have prepared a statement of a suppose case, where two fat bullocks of the same weight at Bourke are sent to Sydney; one of them is sent alive and sold at Homebush, and the other killed and chilled at Bourke, and the carcass sent with the profitable offal by refrigerating car to the Meat Market Sydney; and it will be seen that the advantages are very much in favour of the chilled meat trade,—the statement showing that there is a saving under the system of at least 10s. per bullock to the owner, while the indirect advantages to the stock-owner through the superior quality of the meat and the price it will bring in the London Market if frozen and shipped are of great moment to him.

As regards the Railway Commissioners.

The direct advantages which would accrue to the Railway Department from the change by the adoption of a fresh meat trade would be a considerable saving in the loss now sustained in having to haul the sheep and a good many of the cattle trucks up country empty. This saving is estimated in the statement referred to at from 3s. to 4s. per bullock or say 30s. per truck per trip.

Then the change would be of considerable benefit to the Department in getting rid of the responsibility and trouble which the live stock trade entails.

Item 10.—The price of ice which depends on the cost of coal is calculated at 20s. a ton, at Dubbo, and 30s. at Bourke, or at an average of say 26s., which would make the cost of keeping each body cool by the way—something less than 2s. each; and when it is considered that in the Winter time, and running at night when little or no ice will be required,—it will be seen that the allowance for the cost of this item is a very ample if not an excessive one.

Item 11.—It may be that the estimates and calculations in the contrast here submitted are in some respect incorrect, and that the change from a live stock to a chilled meat trade may not be so advantageous as I suppose to the Railway Department; but I would in the interest of stock-owners and of the Colony at large, urge, for the many potent reasons I have advanced, that the Railway Commissioners should assist in the establishment of this new trade, and that they should not at first at least, until the trade is on a firm footing, ask to make it pay better than the live stock trade now does, seeing that the chilled meat trade will have many powerful vested interests to contend with, while there is no doubt but when it is established the export of frozen, tinned, and salted meat from Sydney will far exceed that from any other Australian port, and it must all be conveyed to Sydney by rail.

VII.—KILLING AND CHILLING DEPÔTS.

1. *Who should erect Killing and Chilling Depôts.*

These depôts will as a rule be, it is believed, constructed by joint stock companies formed to a considerable extent by trades people in the towns near which the depôts are to be established, but principally, by the stock-owners in the areas from which the stock would be brought to the depôts for slaughter and chilling.

These companies again would act as agents for the stock-owners and dealers—would take delivery of the stock and kill and chill them,—and forward the carcasses on owners account to market in the refrigerating cars, for which they would supply the ice when required, charging a reasonable amount for their services, which would to some extent at least be paid for in offal.

2. *Cost of Killing and Chilling Depôt and Plant.*

After consulting one of the leading mechanical engineers in Sydney, who has given this matter special study both here and in America, I understand that the cost of the necessary buildings and of a complete chilling and ice making plant, together with yards, slaughter-houses, appurtenances, land, &c., for an establishment capable of dealing with, say, 120 cattle, or 1,200 sheep a day, and supply the necessary ice for transit, would be from £11,000 to £12,000.

3. *Working Expenses of Depôt.*

The working expenses again of such a depôt, including interest on cost of plant, wages, coal (at from 30s. to 40s. per ton), water, ammonia, sundries, &c., would, I understand, bring the cost of chilling a body of beef, weighing, say, 800 lb., to 2s., or about $\frac{1}{3}$ of a farthing per lb.

VIII.—WHO SHOULD PROVIDE THE REFRIGERATING CARS.

While, again, it is taken for granted that the tradespeople in the more important towns will co-operate with stock-owners in the surrounding country in the formation of companies for the erection of killing and chilling depôts—it is here supposed that the Railway Commissioners will find the necessary refrigerating cars and carry the meat at a reasonable rate—the killing and chilling companies not only providing the cold for chilling the meat as slaughtered, but also the ice for keeping the cars cool by the way.

An endeavour was made to form a Metropolitan Company for the purpose of renting the meat market and chill-room at Darling Harbour from the Railway Commissioners, and, where necessary, assisting the up-country killing and chilling companies in the construction and working of their depôts; and the promoters of the Metropolitan Company proposed that they should find the refrigerating cars, that the cars should be hauled by the railway at a stated rate per ton, and that the Commissioners should have the use of the cars for back loading.

It will, I think, however, be seen that there are several serious objections to this arrangement, and among others the following may be mentioned:—

- (1.) It would take a great deal of capital to provide the necessary cars; and shortness of funds is one of the principal drawbacks to the formation of the proposed Metropolitan Company.
- (2.) The question of who should make the repairs to the cars would be a difficult one to settle, and it would, I am afraid, be at times impossible to say who should do so.
- (3.) The Commissioners would be able, besides conveying the fresh meat, to make much more use of the refrigerating cars than the company in carrying milk, dairy produce, fruit, and game to Sydney, and fish and other perishable articles up country.

It would seem, therefore, that the best arrangement would be for the Commissioners to find the refrigerating cars; and if a killing and chilling depôt were erected, say, at Narrandera, by a company, there would be little or no risk in the Commissioners providing the necessary cars for the traffic; for, in the first place, the experience of America and other parts of the world all goes to show that the fresh meat trade, if carried out with ordinary care and energy, must be a success; and in the second place, supposing the fresh meat trade proved a failure, all the cars which would be required for the traffic from this centre, and even from a good many other centres, could be utilized by the Department, without ice, in carrying meat, milk, game, fish, and other perishable articles, to and from such railway stations as Orange, Bathurst, Cooma, and Goulburn. Or even if that course were necessary (which it is not reasonable to suppose it ever could be), it would not cost the Department very much to alter the refrigerating into ordinary cars.

At any rate, the risk to the Railway Department (supposing the Commissioners provide the cars) in changing from a live stock to a fresh meat trade, would be infinitely less than that of the companies which erected killing and chilling depôts; while it is plain that, until this trade is established, the meat market at Darling Harbour, which is said to have cost the Department some £80,000, cannot be utilized, and the Commissioners will have to submit to the inconvenience and scanty net returns which they complain the existing live stock traffic entails on the Department.

APPENDIX H.

AUSTRALIAN STOCK CONFERENCE.

Conference of Chief Inspectors of Stock, Veterinary Surgeons, and Stock Breeders of the Australasian Colonies, held in Melbourne in November, 1889.

REPORT.

The Conference commenced its sittings on the 1st November, and concluded its labours on the 14th November.

It was called together at Melbourne by the Hon. the Premier of Tasmania, with the concurrence of the Victorian Government, with the view of assimilating the regulations in force in the colonies for the prevention of diseases in stock.

The following were the representatives of the several colonies :—

<i>New South Wales</i>	...	{ Mr. J. De V. Lamb, Stock Breeder. Mr. A. Bruce, Chief Inspector of Stock. Mr. E. Stanley, F.R.C.V.S., Government Veterinarian.
<i>Victoria</i>	{ Mr. C. M. Officer, M.L.A., Stock Breeder. Hon. J. Buchanan, M.L.C., Stock Breeder. Mr. R. Stirling, Chief Inspector of Stock.
<i>Queensland</i>	{ Mr. J. Tolson, Stock Breeder.
<i>Tasmania</i>	{ Mr. W. H. Bennett, M.H.A., Stock Breeder. Mr. T. A. Tabart, Chief Inspector of Stock. Mr. A. Park, M.R.C.V.S., Government Veterinarian.
<i>New Zealand</i>	{ Mr. C. Cowan, M.H.R., Stock Breeder. Mr. R. C. Pasley, Inspector of Sheep.
<i>South Australia</i>	{ Mr. A. D. Handyside, M.P., Stock Breeder. Mr. C. J. Valentine, Chief Inspector of Sheep.

Western Australia was unrepresented, but a letter was handed in by Mr. Valentine, which had been received by the Government of South Australia from the Government of Western Australia, saying that they would adopt any additional regulations suggested by the Conference.

The following is a copy of the circular letter, dated 3rd August, 1889, by which the Conference was called together :—

“ Sir,

Premier's Office, Hobart, 3rd August, 1889.

I have the honor to transmit herewith, for the consideration of your Government, copy of a letter addressed to me by the Chief Inspector of Stock in this Colony, suggesting that, in accordance with the terms of a resolution passed at the Australasian Stock Conference, held at Sydney in September and October, 1886, recommending triennial conferences, steps be now taken to arrange a meeting of delegates, to comprise Chief Inspectors of Stock, Government Veterinary Surgeons, and representatives of flock-owners, in Melbourne, at an early date.

I shall be glad to learn that your Government acquiesce in the proposed arrangement.

I have, &c.,

P. O. FYSH.”

All the delegates were present, with the exception of Mr. Tolson (Queensland), who, it was announced, would arrive in time for the next meeting.

The delegates were introduced to the Honorable J. L. Dow, Minister for Agriculture, by Mr. David Martin, Secretary for Agriculture.

Mr. Dow, in opening the Conference, welcomed the delegates, and expressed his conviction that the result of their deliberations would be of great importance and benefit to all the colonies.

The Minister having declared the Conference opened, both he and Mr. Martin withdrew, and Mr. C. M. Officer, M.L.A., was unanimously elected Chairman.

RESOLUTIONS PASSED BY THE CONFERENCE.

Preliminary.

1. That each Colony represented have three votes.
2. That where a Colony is represented by the Chief Inspector of Stock and another delegate, the former shall have two votes.
3. That a notice of motion must be in the hands of the Chairman not later than the day preceding the proposed discussion thereof, unless the matter is considered urgent by the Conference.
4. That no member of the Conference be allowed to speak on any subject under discussion for more than 10 minutes, but that such time may be extended 5 minutes or a still further period by the indulgence of the Conference; but the mover of any motion shall have the right to reply.
5. That the Conference meet each day (Saturdays and holidays excepted) at 10 a.m., and sit until 12.30 p.m.; re-assemble at 2.30 p.m. and sit until 4.30 p.m.
6. That eight members shall constitute a quorum.
7. That the following be the subjects for discussion :—
 1. Regulations regarding the introduction of foreign animals. Foreign diseases, *i.e.*, diseases not known in Australia.
 2. Regulations regarding the introduction of Australian animals—
 - (a) By sea.
 - (b) By land.

3. Regulations regarding disease—
- | | |
|---------------|----------------------------------|
| (a) Scab, | (g) Pleuro-pneumonia, |
| (b) Catarrh, | (h) Tuberculosis, |
| (c) Fluke, | (i) Stringhalt, |
| (d) Worms, | (k) Coccidium and Actinomycosis, |
| (e) Foot-rot, | (l) Horse-mange (Queensland). |
| (f) Anthrax, | |
4. The rabbit pest.
 5. Chilled-meat trade.
 6. Stud-sheep book for Australasia.
 7. And any other subject which may be suggested and agreed to by members of the Conference.
 8. That the term Australasian Colonies comprises the Colonies on the continent of Australia; also Tasmania and New Zealand; and that the term Foreign includes all other parts of the world.

Animals and things prohibited.

9. That the following foreign animals and things be prohibited :—
- (i.) Cattle and sheep from all foreign countries and colonies other than Great Britain and Ireland, unless they have been fourteen days in Great Britain or Ireland.
 - (ii.) Swine from all foreign colonies and countries.
 - (iii.) Goats, deer, antelopes, llamas, buffalo, and any other ruminants from all foreign colonies and countries, unless for a zoological society.
 - (iv.) All fodder and litter with which foreign animals have been in contact from any foreign colony or country, or from any foreign vessel.

Introduction of foreign animals.

10. That the following foreign animals be admitted subject to regulations framed on the resolutions of the Conference.
- (i.) Horses from any colony or country.
 - (ii.) Camels from any colony or country.
 - (iii.) Cattle and sheep from Great Britain or Ireland.
 - (iv.) Goats, deer, llamas, antelopes, buffalo, and any other ruminants from any colony or country, if intended for a zoological society.
 - (v.) Dogs from any colony or country.
11. That the following be included among the regulations under which foreign animals and things not prohibited may be admitted into any Australasian Colony :—
- (i.) That twenty-four hours' notice be given by the owner of the animals of his intention to land them.
 - (ii.) That the animals be accompanied by a declaration by the owner and certificate by the inspector or by a qualified veterinary surgeon in the district from which they start.
 - (iii.) That no animals, nor any fodder, fittings, or effects with which foreign stock have been in contact, be landed without the written permission of the inspector.
 - (iv.) That notice be given to the owner when any stock are ailing or about to be destroyed.
 - (v.) That notices be given personally, or left at the person's residence or place of business, or sent by registered letter.
 - (vi.) That four weeks' notice be given to the Chief Inspector of Stock of an owner's intention to introduce foreign stock.
 - (vii.) That all cattle and sheep exported to Australasia be shipped from the ports of London or Glasgow.
 - (viii.) That the Agents-General for the several colonies be asked to appoint one (*i.e.*, the same) registered veterinary surgeon at each port of shipment, to examine all stock intended to be exported to any of the colonies; such veterinary surgeon to give a certificate of health to accompany the animals.
 - (ix.) That animals intended to be introduced into any of the colonies, and all other animals on board the same vessel, be examined by the veterinary surgeon appointed by the colonies, and with respect to which he shall certify that they are all free from infection, and that in their case these regulations have been complied with.
 - (x.) That the skins of all animals which may have died or been slaughtered on board any foreign vessel during the voyage, and not destroyed or thrown overboard, be salted and securely packed in cases or casks, and not landed.
 - (xi.) That a declaration be obtained from the captain of the vessel as to the health of foreign stock on board on arrival in port.
 - (xii.) That all foreign animals while in any port in the colonies be securely confined and fastened up to the satisfaction of the inspector, and shall not without his sanction be touched or handled except by their attendants.
 - (xiii.) That foreign animals intended to be landed in the colonies be examined by a veterinary surgeon and an inspector of stock, who shall report to the Chief Inspector of Stock whether or not such or any other animals on board such vessels are infected.
 - (xiv.) That if foreign animals (except camels) are infected they be destroyed or disposed of, as the Minister directs.
 - (xv.) That camels found on arrival to be infected with scab shall be dressed as the Chief Inspector directs.
 - (xvi.) That if foreign animals are not prohibited, and are reported free from infection, and if the Chief Inspector be satisfied that they are not infected, they may, after being washed and disinfected when necessary, as he shall direct, be landed for quarantine on sufficient bond and guarantee.

(xvii.)

(xvii.) That all foreign animals be conveyed by water, at the owner's risk and expense, to quarantine, and remain for the terms respectively prescribed for the different kinds of animals, at their owners' risk and expense, and that they be washed, dipped, or disinfected, as the Chief Inspector of Stock shall direct.

(xviii.) That the quarantine for the several animals shall date from day of landing, and shall be as follows:—

- (a) For horses, 14 days.
- (b) For cattle (including buffalo), 60 days.
- (c) For sheep, 90 days.
- (d) For camels, 90 days.
- (e) For goats, deer, antelopes, llamas, and any other ruminants, 60 days.
- (f) For dogs, 6 months.

(xix.) That all foreign sheep landed in the colonies forthwith receive two or more dressings with tobacco and sulphur, or with lime and sulphur.

(xx.) That on the expiry of the term of quarantine prescribed for foreign animals, they be examined by a duly qualified veterinary surgeon and an inspector of stock, and released on the order of the Chief Inspector.

12. That dogs on board a vessel in any Australasian port not intended to be placed in quarantine be kept securely confined and fastened to the satisfaction of the inspector, and the owner shall give a bond that the dogs shall be so kept; but the inspector, if he deem it necessary, may place them in quarantine.

13. That dogs be quarantined in the Government quarantine grounds only.

14. That foreign stock be not transhipped without the permission in writing of an inspector, and that no foreign stock be put on board any Australasian vessel unless they have undergone quarantine and otherwise complied with the regulations referring to foreign stock.

15. That foreign stock, and the stalls and pens used by them, and the attendants' clothes and effects on board a foreign vessel in any Australasian port be disinfected as the Chief Inspector may direct.

16. That Australasian stock coming into direct or indirect contact with foreign stock, or with infected stock, be deemed infected stock.

17. That if the inspector is doubtful as to the freedom of any stock from infection, he may temporarily detain them on board ship, or in some convenient place, at the owner's expense, where they may be dressed or disinfected as the inspector directs.

Interchange of Australian Animals.

18. That no colony be deemed to be a clean colony in which scab exists or has existed within the next preceding two years, and no sheep nor sheep-skins shall be introduced except from a clean colony.

19. That no sheep shall be imported except by vessels that have not traded to any but a clean Australasian colony within the next preceding six months, nor by any vessel which shall within that period have had any sheep on board from any colony or country other than a clean Australasian colony, and the captain of the vessel shall when required make a declaration to that effect.

20. That all stock intended to be landed shall be accompanied by a declaration from the owner and a certificate by the inspector or a qualified veterinary surgeon at the port from which such stock were shipped that they are not infected, and had not during the next preceding twelve months been infected, and that they are from a clean colony.

21. That if the inspector be doubtful as to the freedom of any stock from infection, he may temporarily detain them on board ship or in some convenient place at the owners' expense, and they may be dressed or disinfected as the inspector may direct.

22. That if on examination by the inspector or a qualified veterinary surgeon and the production of the necessary declaration and certificate, the inspector considers the stock free from infection, he may allow them to land.

23. That if the stock be found to be infected they may be destroyed or otherwise disposed of, as the Minister directs, without compensation.

24. That where an outbreak of disease occurs in any colony the neighbouring colonies may, pending the expense and risk of the outbreak being definitely ascertained, at once issue a prohibition against the introduction of stock from such colony; and that the duration of the prohibition depend upon the amount of risk arising from such outbreak.

25. That sheep imported into any colony, and certified by an inspector of that colony as free from infection, may be introduced into any other colony if found to be so by the inspector of the colony into which the sheep are being imported.

26. That Australasian dogs, accompanied by a declaration by the owner and a certificate from the inspector or veterinary surgeon, be allowed to land on the permit of a Customs officer.

27. That no Australasian stock be transhipped in any Australasian port without the permission of the inspector.

Diseases in Animals.

28. That this Conference considers that M. Pasteur's vaccine of anthrax is effective, and recommends that assistance be given him in establishing agencies in all the colonies, with a view to those owners who require the vaccine obtaining and using it.

29. That the travelling, selling, or offering for sale, or slaughtering for food, of any animals affected by the diseases known as tuberculosis and actinomycosis, or the using of cows affected by tuberculosis and actinomycosis for dairy purposes, be punishable by law; and that there be a more thorough inspection of dairy cattle in use in populous districts.

30. That the Conference expresses its belief in the efficacy of inoculation as preventive of pleuro-pneumonia.

31. That the Conference affirms the principle of compulsory inoculation for pleuro-pneumonia where the disease appears.

32. That there be no restrictions against the free interchange of inoculated cattle, bearing the inoculation ear-mark, but that a declaration by the owner that the cattle have been duly inoculated accompany them.

33. That all sheep infected with catarrh be destroyed; that the owners be recompensed to the extent of two-thirds the value of sound sheep at the date of destruction; and that the run or place on which the sheep were pasturing be strictly quarantined for six months.

34. That, as the conditions are so various in the different colonies, each colony should legislate for itself, where practicable, on the subjects of fluke, worms, and foot-rot in sheep.

35. That the Governments of Western Australia and New Zealand be urged by the Governments of the colonies represented at the Conference to take more energetic steps than those at present adopted for the speedy eradication of scab.

36. That steps be taken by the several Australasian colonies to thoroughly eradicate ticks and lice in sheep.

37. That any animals found to be infected with glanders, farcy, foot-and-mouth disease, rinderpest, sheep-pox, swine fever, rabies, trichinosis, or any other infectious or contagious disease not existing within the colonies be at once destroyed.

38. That it is desirable that an efficient and competent staff of inspectors of stock be maintained in each colony, to prevent the introduction and to arrest the spread of scab or any other contagious or infectious disease; and that the Governments of Queensland, South Australia, and Western Australia, exercise the greatest possible vigilance with respect to their northern ports to prevent the introduction of diseases from Eastern, Indian, or Chinese ports.

The symptoms, nature, and cause of the diseases, Stringhalt in horses and Horse-mange, were discussed by the Conference, but no decision was arrived at with respect to their proper treatment.

It was decided not to recommend legislation for Horse-mange.

Additional.

39. That regulations in regard to the travelling, movements, or conveyance of animals be left to be dealt with by each colony within its own boundaries.

40. That all drafts of laws or regulations dealing with the diseases of animals be, as far as practicable, submitted by the Government framing them to the Governments of the other colonies for remark before they become law; and that proofs of any papers or reports relating to pastoral matters, which would be likely to be of benefit or interest to stock-owners generally, be also forwarded, in order that the other Governments may, should they see fit, order a supply of copies for distribution.

41. That this Conference affirms—(a) The desirability of establishing a laboratory or institution for the purpose of investigating and experimenting upon any diseases to which stock are or may become liable, particularly, in the first instances, pleuro-pneumonia, anthrax, and tuberculosis. (b) That the institution be a permanent one, and to be supported by the respective colonies becoming parties to the arrangement *pro rata*, according to the number of stock, sheep, cattle, and horses returned for the year preceding the assessment. (c) That a permanent board of direction be formed, to be composed of members to be appointed by the Government of each contributing colony. (d) That a competent European scientist be engaged as director, who shall deliver an annual course of lectures to students, and who shall be allowed to charge fees for so doing. (e) That the laboratory or institution shall be called the Australasian Stock Institute, and that it be located in the Colony of New South Wales.

42. That the inspectors of the various slaughter-houses and dairies shall, as far as possible, be qualified veterinary surgeons.

43. That in the opinion of this Conference a commission of experts should be appointed to investigate and report on all specific diseases known to exist throughout the Continent of Australia, New Zealand, and Tasmania, viz.:—Tuberculosis, actinomycosis, coccidium, Australian stringhalt, ophthalmia, pleuro-pneumonia, anthrax, and coast disease.

44. That the Conference recommends that the several Australasian Governments be asked to assist in giving encouragement to the fresh-meat trade by erecting suitable market buildings and chilled chambers, establishing killing and chilling depôts at the principal centres of stock traffic, putting on the necessary refrigerating cars, carrying the meat at a reasonable rate, and adopting a uniform railway gauge.

45. That it is most desirable that a stud-book for horses, cattle, and sheep be kept in each colony as a register; and as the best means to accomplish this end the different representatives present be requested to communicate with their principal agricultural societies, and endeavour to prevail upon them to keep such register.

46. That the means hitherto in use in the different colonies that are infested with rabbits have not had the effect of materially reducing the number of those animals, and that, in consequence, the period of being relieved from the pest is still uncertain, thereby entailing continued loss to the pastoral and agricultural industries of the Australasian colonies; and that joint action should be taken by the Governments of the different colonies to offer a bonus for a scheme that will lead to the more rapid extermination of the pest than at present in use holds out the prospect of.

47. That the resolutions, 1 to 8, hereunder, passed by the Royal Commission and reported to the Government of New South Wales, be the measures recommended as altered for adoption by this Conference for dealing with the rabbit pest.

- (1) That the responsibility for the destruction of rabbits, whether on freehold or on leasehold land, must rest on the landholder. That with respect to unoccupied Crown lands, the State must accept similar responsibility.
- (2) That the rabbit pest has made the continuance of the system of annual leases of Crown lands impossible.
- (3) That no finality in rabbit destruction will be obtained without making the erection of rabbit-proof fences compulsory.
- (4) That there are very large areas of land so poor that the erection of rabbit-proof fences around individual holdings might cause financial failure. That the department administering the Rabbit Destruction Acts should be empowered to permit the fencing of such poor holdings in groups. That in dealing with land of very poor carrying capacity, the State should show special consideration to the lessees in respect of tenure.
- (5) That in all infested country, but especially in such poor districts, simultaneous operations for the destruction of rabbits should be made compulsory.

- (6) That netting 42 inches wide (3 feet above and 6 inches in the ground), with a mesh of $1\frac{1}{2}$ inch, forms a practically efficient barrier against the incursions of rabbits.
- (7) That the system of compulsory trapping, with professional trappers and State bonuses, is radically bad.
- (8) That legislative measures should be taken compelling landowners or lessees in districts infested by rabbits to join, subject to the above provisions, in payment of the cost of rabbit-proof netting fences or in the addition of such netting to existing fences.

48. That the Conference, taking into consideration the importance of the subjects that have come before them for discussion and decision, are of opinion that an Australasian Stock Conference should be held triennially at the chief city of one of the colonies, and they respectfully offer this recommendation to the several Governments.

49. That the Conference desire to call the attention of stock-owners to the fact that the cattle-owners in the United States of America hold an Annual Convention of Delegates from all the States in the Union, to discuss matters of general interest to them as a class, with very great benefit; and would suggest that a similar convention of delegates, chosen by the stock-owners in the several colonies, be held annually in one of our chief cities, each colony to send, say, three delegates, as may be agreed upon.

50. That a uniform code of regulations, embodying the resolutions passed by this Conference, be adopted by all the colonies, and that the framing of such regulations be placed in the hands of the Victorian Government.

51. That a copy of the proceedings of this Conference be forwarded to the Government of Western Australia, and that they be asked to adopt and act upon the resolutions agreed to.

C. M. OFFICER,
Chairman of the Conference.

14th November, 1889.

1890.

LEGISLATIVE ASSEMBLY.
NEW SOUTH WALES.

STOCK BOARD.

(RETURN OF EXAMINERS OF, AND STOCK INSPECTORS.)

Ordered by the Legislative Assembly to be printed, 17 July, 1890.

[*Laid upon the Table in reply to Question No. 12, on 17 July, 1890.*]

Questions.

DR. ROSS asked THE SECRETARY FOR MINES AND AGRICULTURE,—

- (1.) Will he give the names of the members composing the Stock Board of Examiners?
- (2.) Have any of the members composing the Stock Board of Examiners at any time undergone the necessary examination to qualify them for such a position; if so, will he state when and where they passed such examination, or if any of them possess credentials from any Examining Board, showing that they are competent to hold such a position?
- (3.) What are the subjects intending applicants for the appointment of Inspectors of Stock are supposed to possess before submitting themselves for examination before this Board; and where and how do such applicants obtain the necessary information to enable them to go up for examination?
- (4.) The names and number of Inspectors of Stock now employed in the Government service who have passed this alleged necessary examination; also, the names and number of those who have passed but are not employed; also, the salary each receives respectively?
- (5.) Have the respective candidates to pay any fee for such examination; and will he state the nature of such examination, and what it consists of?
- (6.) Will he give a list of the names of those who have passed this necessary examination, and who are waiting for an appointment in the Government service?
- (7.) Does the passing of such examinations by candidates and Inspectors of Stock entitle them to rank as veterinary surgeons, or to give advice on diseases and distempers belonging to stock?

Answers.

- (1.) John de V. Lamb, Esq., Chairman of the Board of Sheep Directors, Sydney.
Alexander Bruce, Esq., Chief Inspector of Stock.
Edward Stanley, Esq., Government Veterinarian, F.R.C.V.S., London.
- (2.) The Government Veterinarian, Mr. Stanley, holds the Diploma as a Fellow of the Royal College of Veterinary Surgeons, London. The other members of the Board have been selected because of their very large experience.
- (3.) The subjects are:—
 1. A practical knowledge of horses, cattle, sheep, and pigs, and their care and management.
 2. A thorough knowledge of the Acts and Regulations which an Inspector of Stock is appointed to see carried out.
 3. A thorough theoretical and practical knowledge of the diseases in stock known to exist in any of the Australian Colonies or New Zealand.
 4. A general knowledge of the principal infectious and contagious diseases in stock existing in other colonies or countries not known in these colonies.
 Besides this, testimonials are required from applicants as to character.
It is not considered a matter for the Board to inquire as to where or how applicants are to obtain the necessary information.

(4.) There are twenty-one Inspectors now employed, who have passed the required examination, and their names and salaries are as follows:—

Name.	Salary.	Name.	Salary.	Name.	Salary.
A. James £285	W. G. Dowling ...	£285	E. Stanley £335
G. S. Smith ...	285	J. L. Henderson ...	285	(Also £270 as Government Veterinarian.)	
R. W. Dawson ...	285	T. Cadell ...	275	G. Day 15s. per day
P. L. Smith ...	285	E. W. Procter ...	275	C. Lyne £285
J. W. Chanter } ...	300	H. J. Sealy ...	285	E. May-Steers 275
(Acting) }		J. Wilks ...	385	M. J. C. Tully 385
T. W. Medley ...	285	E. G. Finch ...	285	C. W. Dargin 285
T. Watson... ...	385	J. Yeo ...	275		

There are fifteen gentlemen who have passed, but are not employed as Inspectors, viz. :—

B. O. Meek, V.S.,	D. C. Gordon,
Alfred Welman,	J. W. Boulton,
John Fraser,	C. J. Vyner,
H. A. Gethings,	J. W. McKellar,
N. Silverthorne, V.S.,	G. W. Lee,
Sydney T. Cox,	H. E. Palmer,
A. H. Farrand,	J. A. T. Rochfort.
A. A. Devlin,	

(5.) There is no fee. The latter part of this question is answered by the reply to Number 3.

(6.) The names are given in the reply to Number 4.

(7.) Certainly not. The passing of the examination merely renders them eligible to apply for the office of Inspector of Stock in terms of the Regulations issued under the Diseases in Sheep Acts.

1890.

LEGISLATIVE ASSEMBLY.
NEW SOUTH WALES.

SHEEP TRUST FUND.

(RETURN OF MONEYS RECEIVED AND DISBURSED SINCE INCEPTION.)

Ordered by the Legislative Assembly to be printed, 8 October, 1890.

RETURN to an *Order* of the Honorable the Legislative Assembly of New South Wales, dated 17th September, 1890, That there be laid upon the Table of this House,—

“ A Return of all moneys received and disbursed in connection with the
“ Sheep Trust Fund since its inception.”

(Mr. Lyne.)

RETURN of all moneys received and disbursed in connection with the Sheep Trust Fund since its inception, under Act 30 Victoria No. 16.

LEGISLATIVE ASSEMBLY.
NEW SOUTH WALES.

IMPORTED STOCK ACTS OF 1871 AND 1884.
(REGULATIONS UNDER.)

Presented to Parliament, Pursuant to Act 35 Vic. No. 6.

IMPORTED STOCK ACT OF 1871 AND THE IMPORTED STOCK ACT AMENDMENT ACT
OF 1884.
QUARANTINE AND DRESSING OF AUSTRALIAN IMPORTED SHEEP.

Department of Mines, Stock Branch, Sydney, 18 February, 1890.

His Excellency the Governor, with the advice of the Executive Council, has been pleased to cancel so much of the Regulations of 22nd May, 1888, issued under the abovenamed Acts, relating to the Quarantine and Dressing of Australian Sheep imported from a clean Colony, as will admit of sheep from Tasmania, and intended to be offered at the sales of Stud Sheep in Sydney, arriving by special steamer in the charge of their owners or their servants, being introduced into this Colony, if found on inspection to be free from disease, without being subject to quarantine or dressing.

SYDNEY SMITH.

1890.

NEW SOUTH WALES.

IMPORTED STOCK ACTS.

(REGULATIONS UNDER THE.)

Presented to Parliament, pursuant to Act 48 Vic. No. 12, sec. 4.

NEW SOUTH WALES, } Proclamation by His Excellency The
to wit. } Right Honourable CHARLES ROBERT,
BARON CARRINGTON, a Member of Her
Majesty's Most Honourable Privy
(L.S.) Council, Knight Grand Cross of the
CARRINGTON, Most Distinguished Order of Saint
Governor. Michael and Saint George, Governor and
Commander-in-Chief of the Colony of
New South Wales and its Dependencies.

WHEREAS by section 10 of the "Imported Stock Act of 1871," the Governor is empowered, by Proclamation in the Government Gazette, to restrict or absolutely prohibit for any specified time the importation or introduction of any stock, fodder, or fittings from any other colony or country in which there is reason to believe any infectious or contagious disease in stock exists; and whereas there is reason to believe that certain infectious and contagious diseases exist in some of the countries in Europe, Asia, Africa, America, and in colonies other than the Australian Colonies: Now, therefore, I, CHARLES ROBERT, BARON CARRINGTON, the Governor aforesaid, do, by this my Proclamation, hereby absolutely prohibit for a period of two years from the date hereof the importation or introduction into this Colony of the stock, articles, or things mentioned in Schedule A hereto, except from the countries and colonies therein named, and under the conditions therein specified, and subject to the Regulations issued under the abovenamed Act, and the "Imported Stock Act Amendment Act of 1884."

SCHEDULE A.

IMPORTED STOCK ACT OF 1871 AND THE IMPORTED STOCK ACT AMENDMENT ACT OF 1884.

Foreign Stock and Things Prohibited from being Imported or Introduced.

Stock.	From what colony or country.
Cattle and Sheep	From all foreign countries and colonies, except from Great Britain and Ireland, unless such cattle or sheep shall have been 14 days in Great Britain or Ireland.

SCHEDULE A—continued.

Stock.	From what colony or country.
Swine	From all foreign colonies and countries.
Goats and Deer, Antelopes, Llamas, Buffaloes, and other Ruminants.	From all foreign colonies and countries, unless they are imported for a Zoological Society, when they may be landed and quarantined as provided by regulation.
Fodder and Litter	From any foreign colony or country, or from any foreign vessel, with which foreign animals have been in contact.

Given under my Hand and Seal, at Government House, Sydney, this thirtieth day of July, in the year of our Lord one thousand eight hundred and ninety, and in the fifty-fourth year of Her Majesty's Reign.

By His Excellency's Command,

SYDNEY SMITH.

GOD SAVE THE QUEEN!

Note.—The foreign stock undermentioned are not within the terms of the above prohibition.

Foreign Stock not Prohibited.

Stock.	From what colony or country.
Horses	Any colony or country.
Camels	Any colony or country.
Cattle	From Great Britain and Ireland.
Sheep	From Great Britain and Ireland.
Goats and Deer, Antelopes, Llamas, Buffaloes, and other Ruminants.	From any colony or country, if they are intended for a Zoological Society; otherwise they are inadmissible.
Dogs	From any colony or country.

Department of Mines,
Stock Branch,
Sydney, 31st July, 1890.

IMPORTED STOCK ACT OF 1871, AND THE IMPORTED STOCK ACT AMENDMENT ACT OF 1884.

It is hereby notified for general information that Nos. 3, 4, 9, 12, 14, 15, 21, 22, 23, 24, 27, 29, 30, 31, 35, 39, 40, 43, 48, 51, and 52, and also sub-sections (1), (5), and (7), of Regulation 59, and sub-sections (2) and (3) of 61 of the Regulations of 22nd May, 1888, issued under the abovenamed Acts are hereby cancelled, together with the Regulation of 18th February last, issued under the said Acts; and that the following Regulations under the abovenamed Acts have been made by His Excellency the Governor, with the advice of the Executive Council, and are now published, for general information, in lieu of the Regulations hereby cancelled, and shall be read and construed with the unrescinded Regulations of 22nd May, 1888.

SYDNEY SMITH.

PART A.—GENERAL.

Owners to give notice of arrival of stock.

1. If any stock are brought by sea to a port or place in this Colony, the owner thereof shall, within twenty-four hours of their arrival, give the inspector at or near such port or place notice to the effect of Form 1 hereto: Provided that the notice hereby required may be dispensed with, if the Master of the vessel by which such stock are brought make and deliver to the Customs Officer first boarding his vessel a declaration to the effect of Form 4 or 9 hereto, according as such stock are either Foreign or Australian stock.

PART B.—FOREIGN STOCK.

2. If an owner intend to introduce any foreign stock into this Colony other than dogs, he shall give the Chief Inspector of Stock at least four weeks' notice of his intention, to the effect of Form 2 hereto.

I.—Foreign stock prior to leaving port of shipment.

Foreign horses, camels, cattle, sheep, swine, and goats to be accompanied by certificate from Inspector for District from which they come.

3. All foreign horses, camels, cattle, sheep, swine, and goats intended and permitted to be introduced into this Colony, shall be accompanied by a declaration from the breeder or owner, and by a certificate to the effect of Form 3 hereto, from the Inspector or Veterinary Surgeon for the District from which they start for the port of shipment, that they are not, nor have within the next preceding six months been, infected with any infectious or contagious disease.

II.—Foreign stock on arrival, and while in the waters of this Colony.

Stock while in New South Wales waters to be properly confined.

4. It shall be the duty of the Master of the vessel, on board of which there are any foreign stock, as well as of the actual owner thereof, to cause all such stock to be kept securely confined, penned, chained, or fastened up, as soon as such vessel is in the waters of this Colony; and no person except the attendant on such stock shall touch or approach or handle the same without the permission of the Inspector; and while the vessel remains therein all such stock shall be kept and treated, to the satisfaction of the Inspector, so as that they shall not be able to stray from such vessel nor to come in contact with any person other than their attendant, nor if the stock be dogs to come in contact with other dogs which may come on board such vessel, and the Inspector may, if he deem necessary, place any dogs whether intended to be landed or not in quarantine at their owner's risk and expense.

Master on arrival to make declaration.

5. On the arrival of a foreign vessel the Master and the attendant on the stock on board such vessel shall make and deliver to the Customs Officer, first boarding such vessel, a declaration to the effect of Form 4 hereto.

Master to give bond to keep ship's stock, &c., securely.

6. If there be on board a vessel any foreign stock for ship's use or any other stock which are not intended to be landed in this Colony, the Master of such vessel shall execute and deliver to the Inspector a bond by himself, and two sureties to be approved by the Chief Inspector of Stock, to the effect of Form 5 hereto, that he will keep such stock securely confined, penned, or fastened up as prescribed by these Regulations, and the Inspector shall direct.

Foreign stock not infected, if intended to be landed, to be sent to quarantine.

7. If foreign stock intended to be landed, and not prohibited, are reported to be free from infection, and if the Chief Inspector is satisfied that they are not infected, and that the requirements of the abovenamed Acts and these Regulations have been complied with, he shall, on obtaining from the owner or consignee of such stock a bond and guarantee, duly executed by the owner or consignee and two approved sureties, in the terms of Form 6 hereto, grant the prescribed order for the removal of such stock to quarantine, without which no stock shall leave the vessel by which they arrived.

Stock to be taken by water to quarantine, and kept at owner's risk and expense.

8. All such foreign stock, including dogs, found on inspection to be free from infection shall, where necessary, before leaving the vessel, be washed and disinfected as the Chief Inspector shall direct, and shall be conveyed by water, at the owner's risk and expense, to the quarantine set apart for such foreign stock, and shall remain in quarantine for the terms respectively prescribed hereunder for the different kinds of such stock, during which they shall be kept at their owner's risk and expense, and shall be washed, dipped, and disinfected as prescribed by these Regulations, and as the Chief Inspector of Stock shall direct.

III.—Landing, quarantine, disinfecting, and dressing of foreign stock.

Quarantine of foreign stock.

9. Foreign stock, including dogs, permitted to be introduced shall be conveyed to and remain in the quarantine set apart for foreign stock, for the periods specified in Form 7 hereto.

As to foreign sheep in quarantine.

10. All foreign sheep landed in this Colony shall forthwith receive three dressings with tobacco and sulphur or with lime and sulphur, at intervals of from ten to fifteen days between each dressing; and the medicaments shall be of the strength and the bath at the temperature and for the duration herein-after prescribed in regard to imported Australian sheep required to be quarantined and dipped under the abovenamed Acts and Regulations thereunder.

IV.—Charges for inspection and risk of transport and quarantine of foreign stock.

Charges and expenses in relation to foreign stock to be borne by owner.

11. All charges and expenses connected with the veterinary inspection or treatment, and the landing, conveying, detaining, feeding, dressing, disinfecting, and reconveying of any stock, or with the destruction, or other dealing with any stock or fodder under the said Acts or any regulations thereunder, through or in relation to any owner's stock, shall be borne by the owner of such stock, and such charges and expenses shall be at the rates stated respectively in Form 8 hereto, in so far as therein specified, and shall be payable on demand; and such charges and expenses shall be calculated on the whole number of stock inspected, disinfected, conveyed, or dressed at the one time, whether they belong to the same owner or not.

V.—Foreign stock for ships' use and for transhipment.

No foreign stock to be transhipped without permit and not on to Australian vessels.

12. No foreign stock shall be transhipped in the waters of this Colony without the permission, in writing, of the Inspector: And no stock, other than stock from a clean Australian Colony, brought by any vessels into the waters of this Colony, shall be transhipped from such vessel to any of the vessels usually or occasionally trading between any of the Australian Colonies until such stock, if allowed to be landed, shall have performed the quarantine, and otherwise complied with the provisions of the abovementioned Acts and these Regulations.

PART C.—AUSTRALIAN IMPORTED STOCK AND THINGS.

VI.—General, as regards Australian imported stock and things. Declaration and certificate to be produced to Inspector examining stock.

13. If an owner intends to introduce any Australian imported stock other than sheep into this Colony, he shall produce to the Inspector examining the same a declaration duly certified by the Inspector or veterinary surgeon of the port or place from which such stock were shipped to the effect of Form 3 hereto.

Master's declaration that vessel is a clean vessel.

14. On the arrival of an Australian vessel the Master shall make and deliver to the Customs Officer first boarding his vessel a declaration to the effect of Form 9 hereto.

VII.—Special as regards Australian horses and dogs.

Imported Australian horses and dogs to be admitted by Customs Officer on declaration and certificate from Inspector.

15. All Australian horses or dogs imported from any of the Australian Colonies, if they are apparently free from disease and are accompanied by a declaration, duly certified by the Inspector or Veterinary Surgeon of the port from which such horses or dogs were shipped, to the effect of Form 3 hereto—may be landed on the permit of the Officer of Customs in charge of the vessel by which such horses or dogs are so imported.

Horses and dogs not accompanied by certificate, how admitted.

16. If any Australian horses or dogs imported from any of the Australian Colonies are not accompanied by a declaration and certificate, as provided by the next preceding Regulation, such horses or dogs shall not be landed until the owner thereof shall have made a declaration to the effect of Form 3 hereto, and paid to the Inspector, a fee of five shillings for inspecting such horses, and two shillings and sixpence for inspecting such dogs.

VIII.—*Australian sheep.*

What is to be deemed a clean vessel.

17. No sheep shall be imported except by a clean vessel; and no vessel shall be deemed a clean vessel which shall, within the next preceding six months, have traded to a place not in a clean Australian Colony, nor any vessel which shall within the period hereinbefore mentioned have had any sheep or sheep skins on board from any place not in a clean Australian Colony.

Quarantine and dressing of Australian imported sheep.

18. Sheep from any clean Australian Colony which are accompanied by a declaration and certificate, to the effect of Form 3 hereto, and a declaration by the master of the vessel by which such sheep are imported, to the effect of Form 9 hereto, may, if found on inspection to be not infected, be landed, and, if other than those arriving from Tasmania by special steamers and in the charge of their owners or their servants,—shall be taken by a conveyance to the quarantine station for such sheep, where they shall be quarantined and dipped under the supervision and direction of the Inspector; and the length of such quarantine, the medicaments to be used in dipping, the temperature and duration of the bath, the dipping, and the fees to be charged for the keeping and dipping of the sheep, shall be as follows, viz. :—

Quarantine.

- (1.) The sheep shall remain in quarantine until they shall have been dipped as herein prescribed.

Medicaments.

- (2.) The medicaments to be used in dipping shall be good sound tobacco, or tobacco leaves and flowers of sulphur, at the rate of 1 lb. of each to every 5 gallons of water, the tobacco to be put into boiling water and infused for five hours at least, and the sulphur to be added to the infusion in the dip.

Temperature.

- (3.) The temperature shall not be less than 100 nor more than 110 degrees Fahrenheit.

Bath and duration.

- (4.) The sheep shall swim and be completely immersed while in the bath, and the bath shall last from one to two minutes, according to its temperature, and as the case may require.

Number of dippings.

- (5.) The sheep shall receive one dipping.

Charges.

- (6.) The rates to be charged for the keeping and dressing of sheep in quarantine shall be as set forth in Form 8 hereto.

Admission of Tasmanian sheep without dipping, in certain cases.

19. Sheep from Tasmania arriving by special steamers in the charge of their owners or their servants, which are accompanied by a Declaration by their owner and certificate by an Inspector in that Colony to the effect of Form 3 hereto, and with respect to which the Master of such vessel shall have made a Declaration to the effect of Form 9 hereto, may be introduced into this Colony, if found on inspection to be free from infection, without being subject to quarantine or dressing.

How imported Australian sheep are to be admitted overland from other Colonies.

20. Sheep imported from any clean Australian Colony into any other clean Colony, and intended to be introduced overland into this Colony, may be admitted if their owner produce to the Inspector for this Colony at the border, a certificate under the hand of an Inspector for the Colony from which they are intended to be introduced to the effect, that when such sheep were introduced into that Colony they were certified to be free from infection by an inspector of the Colony from which they were imported, and that such sheep have been once dipped as required by No. 18 of these Regulations, unless they shall have been brought from Tasmania by special steamer, and thereby exempt from dipping; but all such sheep, unless they have been imported, and, where prescribed, quarantined and dressed as herein provided, shall, on crossing the border, be placed in quarantine, and kept and dipped in the same manner in every respect as prescribed with regard to Australian imported sheep required to be dipped at Sydney.

How Australian imported sheep which have not complied with all the Regulations are to be admitted.

21. Should any Australian sheep be imported into this Colony by a vessel other than a clean vessel, and such vessel is an Australian vessel, or should any such sheep not have been examined in the Colony from which they were exported, as prescribed by these Regulations, then such sheep may, with the sanction of the Minister, be admitted and shall remain in quarantine for twenty-one days, and shall in every such case receive three dippings at intervals of not less than ten days.

22. If any person fail to comply with or offend against any of the foregoing Regulations, for which a penalty is not already specially provided, he shall, on conviction for every such offence, be liable to a penalty not exceeding £20.

1890.

LEGISLATIVE ASSEMBLY.

NEW SOUTH WALES.

BOVINE TUBERCULOSIS IN THE SOUTH COAST DISTRICT.

(REPORT OF THE BOARD OF HEALTH ON).

Ordered by the Legislative Assembly to be printed, 9 October, 1890.

The Secretary, Board of Health, to The Principal Under Secretary.

Sir, Board of Health Office, 127, Macquarie-street, Sydney, 19 September, 1890.

I have the honor, by direction of the Board of Health, to inform you that the enclosed papers on the above subject were considered at a meeting of the Board, held on the 17th instant, when the following resolution was adopted:—

The Board adopts the memorandum of the President, and directs that it be forwarded, with all papers, for the information of the Colonial Secretary. The Board considers the matter of very great public importance, and is of opinion that it is desirable that the papers be published.

I have, &c.,

EDMUND SAGER,

Secretary.

[Enclosures.]

MEMO. BY PRESIDENT.

THE Government Veterinarian, in a letter dated 21st March, 1890, directed the attention of the Board of Health to the prevalence of bovine tuberculosis in the South Coast District, and stated that this disease was locally known as "coast cough," and was treated as being of little importance.

The Board deemed an inquiry into this matter necessary, and Mr. Stanley was directed to visit the Coast District, examine into the general condition of the dairy cattle, and with a view of establishing the fact that "coast cough" is due to tuberculosis, to obtain possession of animals producing milk and suffering from "coast cough," and having caused them to be slaughtered to make *post mortem* examinations and forward the pathological specimens to the Health Office for detailed examination.

Mr. Stanley was unable to carry out the instructions of the Board immediately, but on the 19th of May and four subsequent days he visited a number of the dairies in the Municipal District of Kiama, and received assistance from the officers of police stationed in the district in carrying out the instructions of the Board. The Kiama District was selected because the local authority under the Dairies Act objected at that time to carry out the provisions of that Act, but there was reason to believe that the condition of the cattle in this district was in no wise exceptional, but that "coast cough" existed among dairy and other cattle in all the districts along the Southern Coast being, however, more prevalent in the flat and swampy places than in the more elevated districts. The dairies were found generally in a highly unsatisfactory condition as to cleanliness and sanitary regulation. Mr. Stanley states that "with three exceptions there was no attempt at sanitary arrangements, and even at these three improvements are necessary, the others were all in a neglected state and filthy, the milkers have to wade in mud to fetch each animal up to milk. Cleanliness in milking, such as washing the udders or hands, is not practised. Few premises include a store, and when they do, many objectionable articles are kept in it." Out of 776 cows, in eighteen dairies, twenty-five were found seriously diseased, some being found in almost every herd.

Five cows were selected for *post mortem* examination, four of these being typical cases of "coast cough" disease, and one of "diseased jaw," resembling actinomycosis, and specimens were obtained from all. A specimen from a cancerous growth, of which three other instances in dairy cattle were seen, was obtained, and, as at a slaughtering-place and at two of the butter factories, swine were found to be suffering from a disease also suspected to be tubercular in character, and known locally as "the pants." Three of these animals were secured *post mortem* examination, and specimens obtained. In all these cases the owners willingly gave the cattle for slaughter, and were anxious to ascertain the exact nature of the disease from which they were suffering and the best means of dealing with them. All the specimens, eighteen in number, were forwarded to the Health Office, carefully labelled and identified, and they were distributed thence to the Hon. H. N. MacLaurin, M.D., Professor Wilson, of the University of Sydney, and Dr. Gibson, of Windsor, for detailed and microscopic examination.

From the reports of these gentlemen it appears that the specimens taken from four dairy cattle showed unmistakable examples of tubercular disease, that of the specimens from swine, one showed a condition of "caseous broncho-pneumonia, probably tubercular in character," and in the others, clusters

of bacilli were found, believed to be those of tubercle, that four specimens from one dairy cow showed actinomycosis, and one specimen, also from a dairy cow, epithelial cancer. The detailed reports on these specimens are appended. It appears, then,

- 1st. That the disease known as "coast cough" is really bovine tuberculosis, and that animals suffering from it are the subjects of tubercular disease, although there are no swellings or other external manifestations of the malady.
- 2nd. That bovine tuberculosis, manifesting itself by "coast cough, or by other symptoms, is extensively prevalent among dairy cattle in the South Coast District.
- 3rd. That actinomycosis and cancer are also to be found among dairy cattle in this district.
- 4th. That infective disease, probably tuberculosis, is to be found among swine fed on skim milk from butter factories, and is not improbably due to the use of milk from tuberculous cattle.
- 5th. That all these diseases are identical with diseases occurring in human beings, and are, so far as is at present known, incurable.

It has been established beyond all doubt, by observation and experiment, both in Europe and America, that milk from cows affected with tuberculosis in any part of the body, contains, in a large proportion of cases, the tubercle bacillus, this being present whether there is disease of the udder or not, and that tuberculosis is conveyed to calves, pigs, and other animals by means of milk from tuberculous cattle.

The communicability of bovine tuberculosis to animals by means of the milk of tuberculous cows was conclusively demonstrated by Herr Gerlach, Director of the Veterinary School of Hanover, who induced tuberculosis in calves, lambs, and pigs, by feeding them on milk from tuberculous cows, and Mr. George Fleming and other observers have made numerous experiments to the same or an allied purpose. ("The Transmissibility of Tuberculosis." Med. Chir. Review. Vol. 54, p. 461).

It is more difficult to establish absolute proof of a communication of bovine disease to man since the experimental test is out of the question, but Dr. Creighton, Demonstrator of Anatomy in the University of Cambridge,* traces twelve cases in man to infection from the cow, and relies on the evidence of identity of the diseased products, whilst evidence from other sources renders it as certain as anything can be without absolute scientific demonstration that the disease is communicable, and is communicated from cows to man, milk being the infective medium.

In view of these facts, and with the knowledge that a large part of the milk produced in the South Coast District finds its way to Sydney, and is distributed by large milk companies, the Board of Health is strongly of opinion that the provisions of the Dairies Supervision Act should be strictly enforced in this district. Under existing conditions the milk supply from the South Coast District is, apart from the question of typhoid fever, likely to be more dangerous to health, especially in the case of children, than that produced in suburban dairies in districts where the Dairies Supervision Act is properly administered.

The extensive prevalence of tuberculosis in the South Coast District is also important, in view of the absence of any Act or regulations, except those in force at the Sydney Abattoirs, prohibiting the slaughtering of diseased cattle and the sale of the flesh for food. Tuberculosis is by no means confined to dairy cattle, and even in the case of these, when they cease to give milk, and are not in bad condition, they are slaughtered for food.

The attention of the Board of Health is frequently called to cases of tuberculosis and cancer in cattle sold at the Homebush Sale-yard, and in the majority of cases these cattle are traced by the police to suburban districts, where the owners, if not interfered with, slaughter and sell them for food.

F. NORTON MANNING,
President.

16/9/90.

(* "Bovine Tuberculosis in Man." London, 1890.)

Re Tuberculosis in dairy cattle, Kiama District.

To the Secretary, Board of Health,—

Sydney, 21 March, 1890.

Sir,

I have the honor of bringing under the notice of the Board of Health the extensive prevalence of the bovine disease tuberculosis in the Kiama dairying districts.

The disease is locally known as "coast cough," and it is ignorantly treated, as being of little importance.

I would suggest that the local authorities responsible for carrying out the Dairies Supervision Act might have instructions to enforce clause 10, *re* "the supply of milk which shall have been produced from any diseased animal."

They might be informed that the disease known as "coast cough," and which is very often clearly indicated by lumpy, that is, tubercular enlargements of the throat glands, &c., is the disease under the Dairies Act, Tuberculosis.

That the disease is infectious, contagious, hereditary, and incurable; therefore, it is the duty of all local authorities to use their influence to exterminate the disease, which can only be done by destroying the animals, both flesh and milk being unfit for food either for man, pigs, or poultry.

I have, &c.,

EDWARD STANLEY, G.V.S.

Board of Health Office, 127, Macquarie-street, Sydney, 31 March, 1890.

I SHALL be glad if Mr. Stanley will take an early opportunity of visiting the Coast (Kiama) District, and examining into the general condition of the dairy-cattle. He should also select an animal, or animals, producing milk, suffering from "coast cough," and having obtained possession, by purchase or otherwise, make a *post mortem* examination, and forward the pathological specimens found to this office for examination.

The Government Veterinarian.

F. NORTON MANNING.

The Secretary, Board of Health,—
MEMO from the President duly received.
instructions.

I will visit Kiama at an early date and carry out the

EDWARD STANLEY, G.V.S.

Police

Police Station, Kiama, 22 May, 1890.

SERGEANT BRAYNE respectfully reports *re* attached, that Mr. Stanley has been here since Monday last, at noon, inspecting dairies every day; the sergeant has accompanied him and given all the assistance he could. Diseased cattle have been found at almost every dairy visited, and some very bad cases of tuberculosis and cancer. He has made five *post mortems*, and takes about twenty specimens with him to Sydney to-morrow. Dairy premises generally were very dirty.

Mr. Stanley appears very well pleased with the assistance rendered by the police.

Mr. Stanley has also visited some of the butter factories and piggeries, and has made three *post mortems* on pigs which have a disease among them.

C. BRAYNE,

Sergeant.

James Ryeland, Esq., Superintendent of Police, Sydney. Forwarded to the President of the Board of Health.—EDM. FOSBERY, B.C., 27/5/90.

Re Kiama Dairies, &c.

To the President, Board of Health,—

Sir,

Sydney, 25 May, 1890.

Acting on your instructions, dated March 31st, I proceeded to Kiama on the 19th instant, and inspected cattle and dairies on that and the following days, viz., 20th, 21st, 22nd and 23rd, riding about the district principally on the Gerringong Road, and hilly parts round Kiama, as time only permitted my visiting Jamberoo one day. I was accompanied by Police Sergeant Brayne or a constable, their assistance as pilots, showing me the nearest routes from place to place saved me time, and their knowledge of the owners and their cattle paddocks was very necessary, as I had no volunteer willing to show me about. Owing to the hilly character of the country and the cows being dispersed throughout the paddocks, I could only inspect them on horseback during the morning, but every afternoon from 3 to 5 I always arranged to meet them herded at the dairies. I inspected eighteen dairies and 776 cows belonging to them; twenty-five of these animals were seriously diseased, some being detected in almost every herd.

I selected five cows for *post mortem* examination, four of them being typical cases of "coast cough" disease, and one with diseased jaw resembling actinomycosis.

A detailed account I give with the pathological specimens sent herewith for microscopic examination.

The cows in the elevated places were in splendid condition, those on the flats and swamps were in good store order, but will fall away as winter progresses, then the tuberculous ones can be more readily observed.

At a slaughtering place, and also at two of the butter factories, I noticed that the swine were suffering from an analagous disease locally known as "the pants," from their difficult respiration due to lung disease. They also suffer from putrid sores on various parts of their bodies.

I secured three for *post mortem* examination, and have preserved specimens for further investigation.

I have to thank the owners for having provided subjects for dissection, and I promised to inform them of the exact nature of the diseases, with the best means of dealing with them. With regard to the dairy premises, with three exceptions there was no attempt at sanitary arrangements, and even these three require improvements; the others were all in a neglected state, and filthy. Where the cattle are accommodated, very few had more than five or six bails, so that the milkers have to wade in mud to fetch each animal up to milk. Cleanliness in milking, such as washing the udders or hands, is not practised. The cans and buckets usually stand in the open air; very few premises include a store, and even where they do, many objectionable articles are kept in them. It is necessary that isolated stores for milk and dairy utensils should be provided, as the milk is frequently stored all night and in many cases all day on Sunday.

I append a detailed list of the dairies inspected, but there are many more in the district that I had not time to visit.

I may, perhaps, be permitted to suggest that registration should not be granted so long as diseased cows or pigs are kept, nor until suitable premises are provided. Water is abundant in creeks and wells, and stone suitable for flooring is widely distributed throughout the district. The surface of the ground is favourable for drainage, and further, the business is a lucrative one: the dairymen are wealthy, so that I see no excuse for the present neglect, which only shows the necessity for the 'Dairies' Supervision Act.

I have, &c.,

EDWARD STANLEY, F.R.C.V.S.,

Government Veterinarian.

P.S.—The local name for tuberculous cattle is "coast cough" disease; some call it "lumpy-jaw," others "cancers in the throat."—E.S.

Read meeting of the Board of Health held this day. Consideration postponed until reports on specimens of diseased animals obtained by Mr. Stanley had been received from Hon. Dr. MacLaurin, Dr. Gibson, and Professor Wilson.—E.S., Secretary, 4/6/90.

Pathological Specimens.

K.'s cow:—No. 1 A, lymphatic glands (thoracic); 1 B, liver.

W.'s cow:—No. 2 A, lungs; 2 B, uterus.

F.'s cow:—No. 3 A, tubercles from costal pleura; 3 B, lymphatic gland (bronchial); 3 C, parotid salivary gland; 3 D, tubercle (deposit on the heart).

H.'s cow:—No. 4 A, lung; 4 B, kidney (slightly affected); 4 C, liver.

E.'s heifer:—No. 5 A, intestinal lymphatic glands, and piece of small intestine; 5 B, slice of tumour (deep-seated) taken from near the bone (chronic); 5 C, a mass of the same growth from the external surface (recent); 5 D, section of diseased jaw-bone.

No. 6, lungs of swine.

No. 7, intestinal lymphatic glands and one tumour (swine).

No. 8, cuticular cancerous growth on a fire-brand.

Post mortem

Post mortem Examinations No. 1.

Mr. K.'s—5 years old, dairy cow, been milking, now drying off. Evidence of disease—a frequent cough, hide-bound, rough dry hair, and losing condition. No external tumours were visible.

The lungs had patches of tubercles in all stages, many being broken down, in the interlobular tissue, the pleura and peritoneal membranes were thickly studded with tubercles, and the thoracic and intestinal mesenteric glands were generally diseased. The liver, kidneys, and throat glands were not affected. See specimens No. 1.

Post mortem No. 2.

Mr. W.'s—10 years old cow, bred in the locality, at present in full milk and fair condition. Evidences of disease are several tumors, involving the glands of the throat, some of which have suppurated and healed. She coughs on moving hurriedly. The parotid glands, also the sublingual thoracic and mesenteric lymphatic glands, the lungs, liver, uterus, and intestines were studded with tubercular growths. As the butcher expressed it, she was rotten with the disease. See specimens No. 2.

Post mortem No. 3.

Mr. F.'s—3 years old cow, in full milk, bred by owner, with first calf, she was in good condition. Evidence of disease was tumefied enlargements of the throat glands, cicatrices from healed abscesses, and tumours near the shoulder-point, there being diseased bronchial glands. Extensive disease was found in the parotid submaxillary and thoracic lymphatic glands, patches of tubercles in the lungs, costal pleura, and liver, with traces on the bowels. Several of the mesenteric and other lymphatic glands were healthy. See specimens No. 3.

Post mortem No. 4.

Mr. H.'s—3 years old, now being milked, with second calf, is in fair condition, and bred in the locality. Evidence of the disease—Very large tumours on the throat and coughing on exertion; extensive chronic disease in the parotid, submaxillary, bronchial, and thoracic glands; many patches of disease in the liver and lungs. The mesenteric glands were healthy, but the intestines were studded with tubercles, also traces in the kidneys, and large growths were on the heart; the femoral lymphatic glands were both a mass of broken-down tubercles, and one mammary gland had lost its function of secreting milk, but I could not detect tubercular growths in its structure. See specimens No. 4.

Post mortem No. 5.

Mr. E.'s.—3 years old, barren Alderney heifer, bred locally:—Is healthy looking, fat, and ripe for the butcher. Evidence of disease was an immense enlargement of the right ramus of inferior maxillary, with tumors attached; some cicatrices after suppuration, and a large, cancerous-looking bunch of tumours, engorged with blood, and from which a purous discharge escaped. On examination I found the disease involved the whole of the right molar sockets, having ulcerous sores on the buccal membrane, which had communicated with abscesses. The tongue and fauces were free from the disease, also the large lymphatic glands and the parotid: the internal organs were healthy, excepting only one deposit, as large as a horse bean in the lung tissue, and traces in the small intestines, and in one or two of the intestinal lymphatic glands. To the naked eye this case closely resembles actinomycosis. The carcass was very fat, and splendid looking beef, and the owner secured it for his own family use. See specimen No. 5.

Post mortems Nos. 6, 7.

ON three swine—two at Mr. W.'s slaughter-house, fed on offal; one at Mr. H.'s, joining the Pioneer Factory, fed on milk. They were half-grown store pigs; had fœtid ulcerous sores, that seem to originate from subcutaneous abscesses; their respiration was panting, and when moved coughed severely; all were in fair store condition, which indicated chronic disease. In each case the lungs, parotid, and lymphatic glands appeared to be in a tuberculous condition, also the intestines. The mouths and fauces appeared healthy. See specimens Nos. 6 and 7.

Pathological specimen No. 8.

FROM a cancerous growth on a milking cow's rump, the site of a fire-brand mark. Specimen No. 8. The other cases of cancers in the orbital regions I left for another investigation.

Kiama District.—21st May, 1890.

G. E.

Cows—Twenty-five milking, in fair condition. Premises—Poor sheds, and very dirty yards and surroundings. Site—Hill-side. Drainage—None attempted. Water—Spring well. Store—None. Business—Milk sent to Sydney. Utensils—Clean. Remarks—Intends to see if sick cow will make up for beef.

Diseased—One red cow apparently suffering from general tuberculosis.

W. E.

Cows—Forty milking. Premises—Shed, six bails, yards and all filthy. Site—Between hills. Drainage—None made. Water—Spring well. Store—None. Utensils—Very old, fairly clean. Business—Milk all sent to Sydney. Remarks—Great want of cleanliness.

Diseased—Light roan cow, tubercles in throat.

J. P.

Cows—Twenty-five milking, in fair condition. Premises—Filthy yards and sheds for three bails. Site—Sloping ground. Drains—None made. Water—Spring well, badly situated below the yards. Store—None. Business—Milk delivered at factory. Remarks—No attempt is made to clean cows' bags or milkers' hands.

Diseased—Roan cow, tubercle off side face and throat. Red and white, lump on front of nose (nasal bone), probably an injury. Light roan, cancer growth on rump.

T. L.

Cows—Twenty-seven milking, in very good condition. Premises—Good sheds, three bails, stone floor, wants cleaning out. Site—Hilly, good drainage. Water—Spring well, good situation. Store—Good building, the best in the district (sheet-iron and timber). Utensils—Clean. Business—Butter maker. Remarks—This place shows what can easily be done in the shape of buildings; they might be kept cleaner and sweetened by whitewash.

Diseased—One big red cow, lost three-quarters. Suspected to be tubercled.

10th May, 1890.

Mr. E.

Cows—Thirty milking, ten dry. Premises—Shed with four bails, yards rough and dirty. Situation—Hill top. Drainage—Surface. Water—Spring well. Business—Butter factory, churn, and rear calves. Utensils—Clean. Remarks—Healthy-looking, stock in good condition.

Diseased—One dry heifer, actinomycosis in lower jaw.

Mrs. G.

Cows—Twelve milking, in fair condition. Premises—Poor cottages, very neglected, wretched hovel, filthy yards. Site—Hill-top. Drainage—None attempted. Water—Tanks, roof catchment. Store—None; verandah used. Utensils—Clean; sheeting used for strainer. Business—Retail milk in the town. Remarks—At present quite unfit for registration.

Diseased—None seen.

22nd May, 1890.

Mr. C.

Cows—Seventy, milking, in good condition. Premises—Shed for six bails, yards and surroundings were very filthy. Site—Top of Hill. Store—None. Utensils—Clean; under a tree. Water—In tanks and from creek. Business—All milk goes to factory. Remarks—Untidy and neglected place; cleanliness is not thought of.

Diseased—Brindle cow, very bad tubercle throat (in the yard milking); others hinted at, as being left in paddock; I had not time to visit them.

H. F. N.

Cows—Fifty milking. Premises—Shed for five bails being filthy hovels; yard rocky, and could be easily cleaned. Site—Hill-side. Water—Carted from creek. Store—None. Utensils—Clean in open shed. Business—All milk goes to factory. Remarks—Proper and clean premises very much needed, and cleanliness of milkers also.

Diseased—I saw none diseased, as my visit was expected; they were left away in paddock.

Jamberoo.—22nd May, 1890.

S. V.

Cows—Twenty-seven cattle, in poor condition. Premises—Shed five bails, and yards all very dirty. Site—Bad on flat low ground. Water—From creek by carting. Store—None. Utensils—Set about in the open. Business—All milk to factory. Remarks—Undesirable situation and water supply; very dirty and neglected surroundings.

Disease—Red cow with black muzzle has a very suspicious cough.

T. F.

Cows—Seventy milking, in fair condition. Premises—Shed for seven bails; yards and surroundings filthy dirty. Site—Hill-side. Utensils—Clean in a dirty open store. Business—All milk to factory. Remarks—A large business, and well-to-do man; place neglected; drains and altogether very dirty.

Disease—Old roan cow; bad tubercles in throat; another very much wasted chronic tuberculosis.

22nd May, 1890.

T. H.

Cows—Forty-six milking. Premises—Shed, five bails; surroundings neglected and dirty. Site—Hill-side. Drainage—None made. Water—Spring well, and by gravitation through pipes. Store—End of building open. Utensils—Old galvanized, and worn thin. Business—Milk to factory. Remarks—Pigs here, and at the Pioneer Factory adjoining, have the same disease.

Disease—White cow bleeding cancers in orbit; white cow with red head tubercles in throat; roan cow very bad; tubercle throat; killed; pigs ill; one killed.

Mr. C.

Cows—About 100 milking in poor condition. Premises—Good shed for thirty cows; cement floors; wants cleaning out and lime washing; yards and surroundings filthy. Site—Low; sloping to the swamps. Drainage—Neglected. Water—From creek by hydraulic lift. Store—Unclean, and containing much rubbish, machinery, &c. Utensils—Clean. Business—All milk goes to factory. Remarks—Neglected premises, and very unclean, and lots of diseased cattle.

Disease—White-spotted cow, tubercle throat; brindle cow, old; same disease; young white cow, same disease; yellow and white cow, same disease; red cow very bad with same disease; old red cow with same disease.

R. F.

Cows—Forty-seven milking, in fair condition. Premises—Shed, with five bails, all very dirty. Site—Hill-side. Drainage—None formed. Water—Well spring. Store—Open shed used for vessels milk-room a dirty place, with man's sleeping-room in it. Utensils—Unwashed and dirty. Business—Milk goes to factory, but is often stored at night and on Sundays. N.B.—This is the usual district practice.

Disease—Red cow, ulcerating tubercles; very bad throat; killed.

G. W., JUN.

Cows—Fifty milking, in good condition. Premises—Shed, with five bails; good stoned yard, but all very dirty. Site—Hill-side. Drainage—None formed. Water—Well spring. Store—In-house, with copper, saddlery, &c. Utensils—Clean. Business—Milk goes to factory.

Disease—Red cow, bad case tubercle throat; white cow, bleeding cancer in orbit.

21st May, 1890.

E. M'C.

Cows—Fifty-two milking, in good condition and healthy. Premises—Large shed, seven bails, yard, &c., dirty. Water—Tanks and spring well. Store—Clean. Utensils—Clean; use a separator. Business—Butter-maker.

Disease—None.

P.

P. S.

Cows—Thirty milking, in fair condition. Premises—Poor shed, four bails, very dirty; also yards and general surroundings unclean. Store—None. Utensils—Lying about the place. Water—Spring well. Drainage—None attempted. Business—Half milk to Sydney, half to factory. Remarks—A troublesome and unclean place.

Disease—Red cow, second calf very bad case tuberculosis; would not kill—said it was injury.

D. W.

Cows—Fifty-five milking, in fair condition. Premises—Shed, seven bails, yards, stores fairly clean. Site—Hill-side. Drainage—None formed. Water—Spring well. Store—Partly open end of shed used. Utensils—Clean. Business—Half milk to Sydney, and half to factory.

Disease—Yellow cow tubercle face and throat (killed); red and white cow, off side jaw and sub-maxillary glands tubercle; white cow, bleeding cancers in orbit.

I. K.

Cows—Twenty milking, in good condition. Premises—Low situation, three bail sheds, very dirty surroundings. Drainage—Surface into creek. Water—Spring well. Store—Large; smells unwholesome, lined with bags, wants air, light, and lime-washing. Utensils—Zinc and tin; clean. Business—Butter factory. Remarks—Cleanliness required.

Disease—None seen.

Sir.

Board of Health Office, 127, Macquarie-street, Sydney, 3 June, 1890.

I have the honor to acknowledge receipt of yours of the 31st ultimo, and have this day forwarded you samples of diseased animals, as per other side. You will see that there are—Firstly, four specimens from one cow; secondly, two specimens from another; and, thirdly, one specimen from a pig.

These specimens were collected by the Government Veterinarian (Mr. Edward Stanley) in the Kiama District (the first and second from dairy cattle, and the third from a pig fed on milk at a butter factory), and they are labelled in accordance with the views of Mr. Stanley from casual observation.

If you should find tubercle in one or two of the specimens from the first case, it may be unnecessary to examine the whole four from the same case.

I have, &c.,

EDMUND SAGER,
Secretary.

Dr. John Gibson, Windsor.

NOTE.—Similar letters were addressed to the Hon. Dr. MacLaurin and Professor Wilson.

Report on specimens received from the Board of Health, Sydney, on Tuesday, 3rd June, 1890:—

Specimens received.

- First*:—No. 3a—Tubercle, costal pleura, bovine.
 „ 3b „ bronchial glands, bovine.
 „ 3c „ parotid gland, „
 „ 3d „ heart, bovine.
Second:—No. 1a—Tubercle, lymphatic glands, bovine.
 „ 1b „ liver, bovine.
Third:—No. 6—Tubercle, lung, swine.

In accordance with your instructions, on discovering tubercle bacilli in three of the specimens from the first case, I did not examine the fourth specimen from the same case. All the other specimens I have examined most carefully, microscopically, omitting any detailed description of the naked-eye appearances, as these had, to a very large extent, become altered by the methylated spirit in which they had been preserved. Sections of the different specimens were stained in picro-carminic to demonstrate the ordinary structure, and Liehl-Neelsen's method was followed for the detection of tubercle bacilli, as this method is now looked upon as being the most satisfactory. According to this method the sections are allowed to stain for twenty-four hours in the following stain:—Fuchsin, 1 grm.; Acid Carbolic, 5 C.C.; Alcohol, 10 C.C.; Aq. Dist., 100 C.C. They are then decolourised in 25 per cent. aqueous solution of sulphuric acid, and washed in absolute alcohol until no more colour comes away, then washed in a large basin of water to remove any trace of acid still remaining, and afterwards mounted through oil of cloves in the usual way. If deemed necessary, a contrast stain, such as methylene blue, may be used. The tubercle bacilli, stained in this way, appear at first of a brilliant red colour, but after a time they assume a brownish tinge, which remains for some considerable time until after the lapse of some days or months all colour fades from them and they cannot be seen.

The following is my result of my examination of the various specimens:—

First:—No. 3a.—Tubercle, Costal Pleura, Bovine.

Picro-carminic stained sections:—Pleura much thickened, and caseous in some parts of the sections, with calcareous change here and there. Small cell proliferation and tubercle follicle formation outside the caseous portions. Giant cells were seen here and there in the small cell area.

Liehl-Neelsen stained sections:—Examined by a $\frac{1}{2}$ -inch oil immersion lens these sections contained great numbers of tubercle bacilli scattered all over the section. Dense masses of bacilli were seen occupying the interior of giant cells, and groups of them in rosette form in many of the lymphoid cells.

No. 3b.—Tubercle, Bronchial Gland, Bovine.

Picro-carminic stained sections:—In the sections examined there were two caseous-looking masses, each about the size of a small pea. A third smaller mass was also seen. The larger masses were sharply defined, and appeared to the naked eye to have a well developed fibrous capsule. In cutting them the knife encountered gritty, calcareous particles. The caseous-looking nodules presented all the appearances of tubercular structure somewhat advanced, centre caseous, partly calcareous, surrounded by an area of small cell proliferation, containing tubercle follicles and giant cells. Scattered over the section a few smaller tubercular nodules were seen.

Liehl-Neelsen stained sections:—By the $\frac{1}{2}$ -inch oil immersion lens enormous numbers of tubercle bacilli were seen in the caseous portions, between the lymphoid cells of the tubercle follicles and in the giant cells.

No.

No. 3d.—Tubercle, Heart, Bovine.

Picro-carminic stained sections:—Beautiful tubercular structure, numbers of tubercular nodules, composed of several tubercle follicles and giant cells. The tubercular process in the sections examined was evidently of a somewhat chronic nature, as most of the nodules were found to be surrounded by dense fully-formed fibrous tissues. Some nodules were caseous in the centre, whilst several had become calcareous. No trace of cardiac muscle was observed.

Liehl-Neelsen stained sections:—The chronic nature of the tubercular process noted in the examination of the picro-carminic sections led me to infer that I should not be able to discover very many tubercle bacilli in the specially stained sections, and such proved to be the case. With the $\frac{1}{2}$ -inch oil immersion lens tubercle bacilli were found, but in very small numbers. I had to examine very carefully indeed before I succeeded in finding any. In one giant cell I counted as many as five tubercle bacilli; but that was in one instance only. All the tubercle bacilli observed in this specimen were in the giant cells, and as a rule only one bacillus was to be seen after examining numbers of giant cells.

Second:—No. 1a.—Tubercle, Lymphatic Gland, Bovine.

Picro-carminic stained sections:—The greater part of the section was caseous in the specimens under examination. The centre of many of the caseous nodules was calcareous. The so-called hyaline-fibroid degeneration, which is so often seen in tubercle nodules, was present in some parts of the section. Outside the caseous portions there were several typical tubercle follicles. There were well marked small cell proliferation and beautiful giant cells.

Liehl-Neelsen's Sections:—Tubercle bacilli present in the sections examined, but very few in number. Great care and patience were required, in examining for bacilli, to find any. In one section, after the most careful examination, only four tubercle bacilli were seen—one each in two giant cells, and two in the caseous portions.

No. 1b.—Tubercle, Liver, Bovine.

Picro-carminic sections:—To the naked eye, a well-defined caseous mass was seen at one margin of the section examined, surrounded by what appeared to be a firm capsule. Under the microscope this mass was found to consist of several tubercle follicles, which had coalesced and become caseous, and in parts, calcareous. There was a capsule composed of fully formed fibrous tissue. Within the capsule and external to the caseous parts were numerous typical tubercle follicles with giant cells and small cell proliferation. In close proximity to the outer aspect of the fibrous capsule, and in part appearing as a prolongation from it, a few tubercle follicles were seen occupying some of the portal spaces. Here and there throughout the section one found collections of small round cells—evidently tubercle follicle formation in quite an early stage—situated within certain of the hepatic lobules. The liver cells otherwise appeared normal.

Liehl-Neelsen stained sections:—Very few tubercle bacilli found. There were one or two in the lymphatic spaces between the lymph cells, and one or two in giant cells, some with well developed spores. In this, as in the case of No. 1a. very considerable difficulty was experienced in finding tubercle bacilli.

Third:—No. 6.—Tubercle, Lung Swine.

Picro-carminic sections:—One or two caseous nodules visible to the naked eye. At one extremity of the sections examined a rounded mass was seen. The centre was caseous, and outside this there was a zone of small cell proliferation. From this area small cells extended outwards for a short distance along the walls of the pulmonary alveoli. Several of the alveoli in the immediate neighbourhood contained catarrhal cells. This nodule appeared to be in relation to one of the smaller bronchioles. A second nodule was seen at the other extremity of the section, the caseous centre of which had dropped out during the process of cutting and mounting. There were also a few smaller nodules apparently in relation to some of the smaller bronchioles. These smaller nodules consisted of small round cells. Broncho or catarrhal pneumonia was present to a limited extent in the pulmonary tissue in the neighbourhood of these nodules. In addition, there was some degree of small cell proliferation around many of the bronchioles and smaller branches of the pulmonary vessels, pointing to lymphatic irritation. There was considerable œdema of the inter-lobular connective tissue. No giant cells nor tubercle follicle formation were observed.

Liehl-Neelsen stained sections:—After the most careful staining and examination no tubercle bacilli were found. But it must not be inferred from this that the condition of caseous broncho-pneumonia which was present in the specimen under consideration was non-tubercular, because of course it is well known that in many cases of undoubted tuberculosis even the best observers fail to detect any tubercle bacilli in some specimens they examine. In these cases pathologists do not rest satisfied with a mere microscopic examination; but proceed to inoculate certain of the lower animals (rabbits, guinea pigs, mice, &c.), with some of the suspected tissue, and note whether, in these animals, tuberculosis develops after the inoculation. I well remember a somewhat similar instance to the one now under consideration coming under my notice whilst I was acting as assistant to Professor Greenfield of the Edinburgh University. A piece of pleura from a pig with the ribs attached was brought to us to be examined for tubercle. There were numbers of caseous nodules in the specimen, but neither Professor Greenfield nor myself could detect any tubercle bacilli. Being satisfied in our own minds that the specimen was tubercular, I was requested to inoculate some of the caseous material into some rabbits, &c., with the result that rapid acute tuberculosis supervened, thus confirming our opinion.

In the specimen No. 6, I did not rest satisfied with staining and examining sections of the lung tissue, but I got some of the caseous material, spread it out, on cover glasses, and stained for tubercle bacilli, but could not detect any.

Should the Board deem it necessary, and should they grant me the requisite permission, I have still some of the caseous material with which I could inoculate some animals, and thus prove conclusively the tubercular or non-tubercular nature of this case. At present all that I can affirm regarding it is that there is a condition of caseous broncho-pneumonia, probably tubercular in its nature.

In conclusion, I must express my regret that the unusually heavy calls, of a rather busy practice, together with the care required in the examination of specimens No. 1a and No. 1b, and especially No. 6, have prevented my sending this report sooner.

I have, &c.,

JOHN GIBSON, M.D.

Dear

Dear Dr. Manning,

University of Sydney, 14 June, 1890.

I enclose a short report on the specimens sent. There can be no doubt from the histological characters of the specimens "2a" and "2b," that they are tubercular, as I found very numerous and typical giant cells, surrounded by tubercular small-celled exudations and caseating areas in the centres of the cellular exudations. The giant-cells are quite pathognomonic.

I think it right to state also that I went through the more tedious process of staining for tubercle bacilli, but from some cause or other the results were negative, though I have not the slightest doubt that there were plenty of bacilli present. I may say that it is a common enough occurrence to have such an apparent failure as reagents have a way of being inconstant in their activity.

Although I unhesitatingly pronounce on the tubercular character of the specimens referred to, I shall be glad to repeat the tests for the bacilli (as I have plenty of material left), if you, for any reason, wish me to do so.

Yours, &c.,

J. T. WILSON.

Dr. F. Norton Manning.

90-3,266.

University of Sydney, 16 June, 1890.

REPORT on specimens sent from office of Board of Health, along with letter from Dr. F. Norton Manning, dated 2/6/90.

Specimen labelled "No. 2a. Tubercle, lung, bovine," in spirits of wine. Sections cut and stained some with picro-carmin, and others with hæmatoxylin. Microscopic examination shows in some places fairly normal lung structure; in other places are large areas of caseating inflammatory material, surrounded by a fibro-cellular structure, exhibiting typical tubercular structure centred round giant cells as foci.

Specimen labelled "No. 2b. Tubercle, uterus, bovine," also in spirits of wine. Sections of the tissue treated as above. Here also were rounded caseous areas, surrounded by zones of tubercular inflammatory exudations, as in lung, and containing typical giant cells. The sites of these tubercular caseous nodules were chiefly in the submucous tissue of the uterine wall.

Specimen labelled "No. 8. Cancer, cuticular, bovine," also in spirits of wine. Sections cut and stained as above showed the structure of typical squamous epithelioma. The main mass of the tumour consisted of a fibrous strand, enclosing in its meshes large areas of epithelial cells, sometimes simply packed together, but in very many places arranged concentrically around a centre of corneous epithelial material, giving the typical "cell nest" or "epithelial globe" appearance.

J. T. WILSON.

Sir,

Macquarie-street, Sydney, 25 June, 1890.

I have the honor to inform you that of the specimens you sent me I have as yet been able to examine only No. 5 A, marked bowel and gland.

The sections obtained from this show numerous unmistakable specimens of the actinomycosis fungus, and the animal from which it was taken would seem to have been in an advanced stage of the disease.

The method of demonstration adopted is a modification of Plant's, staining with Neelsen's fluid, and contrast staining with picric acid.

I took an opportunity of showing the specimens to Dr. W. H. Goode, who happened to visit me while I was at work.

Actinomycosis, or ray fungus, is a very important disease of cattle which has attracted a great deal of attention of late years. I believe its existence has not been recognised in Australia till the other day, when I demonstrated the presence of the ray fungus in a specimen belonging to Mr. Stanley which he was good enough to give me for examination.

Actinomycosis has been for the most part confounded with tuberculosis, until of late years, but those forms of the disease which attack the jawbones and tongue have been very commonly described as cancer.

Like tubercle, actinomycosis is also found in the human subject, affecting the viscera, and occasionally being associated with empyema; it bears a great likeness to consumption.

The importance of this disease among cattle cannot be overrated. I think the Board might add it to the list of diseases already gazetted, and I think it would not be unreasonable for the Board to direct or to undertake an inquiry into the prevalence of the disease throughout the Colony.

I have, &c.,

H. N. MACLAURIN.

The Secretary, Board of Health.

Dear Sir,

Macquarie-street, 10 September, 1890.

Of the remaining specimens I have to report as follows:—

4 A., bovine lung, contains tubercle bacilli; 4 C., Kidney, gave negative results; 5 A., 5 B., bovine glands, maxilla, &c., contain actinomyces.

Yours, &c.,

H. N. MACLAURIN.

E. Sager, Esq.

Macquarie-street, 16 September, 1890.

No. 7.—Swine glands.

Dear Sir,

This has required a long and tedious examination by various modes of staining before definite results could be obtained.

At last I have succeeded, by Gramm's method, in demonstrating several clusters of bacilli which I believe to be those of tubercle; but I have only found them in one of the very numerous sections which I have stained: this explains the delay and difficulty in discovering them.

I am, &c.,

H. N. MACLAURIN.

E. Sager, Esq.

LEGISLATIVE ASSEMBLY.
NEW SOUTH WALES.

DISEASES IN STOCK.

(PETITION FROM MAYOR AND OTHERS OF NEW LAMBTON, PRAYING FOR INTRODUCTION OF A BILL TO DEAL WITH.)

Received by the Legislative Assembly, 10 July, 1890.

To the Honorable the Speaker and Members of the Legislative Assembly of New South Wales, in Parliament assembled.

The Petition of the undersigned, Mayor, Aldermen, and Council Clerk of the Borough Council of New Lambton, New South Wales,—

HUMBLY SHOWETH:—

1. That at present there are a number of Acts in force dealing with diseases in stock in various ways, but they are not effectual in the object desired, and some stringent and comprehensive measure that would place the power in the hands of the local authorities would, it is considered, be a boon to the general community.

2. Your Petitioners, in consideration of this fact, therefore, pray that your Honorable House will be pleased to have a comprehensive Bill brought in during the present Session of Parliament, dealing with the subject of contagious diseases in animals throughout the Colony, so as to prevent stock so infected being sold in the public saleyards, and to stamp out such disease wherever found.

And your Petitioners, as in duty bound, will ever pray, &c.

[Here follow 10 signatures.]

LEGISLATIVE ASSEMBLY,
NEW SOUTH WALES.

AGRICULTURAL COLLEGES.

(INFORMATION RESPECTING.)

Ordered by the Legislative Assembly to be printed, 5 June, 1890.

[Laid upon the Table in accordance with a promise made in answer to Question No. 2, Votes 18, 5 June, 1890.]

Questions.

- (2.) MR. FULLER *asked* THE SECRETARY FOR MINES AND AGRICULTURE, -
 (1.) Has the Government received any recommendation from Mr. Pudney in regard to the purchase of sites for the purpose of establishing agricultural colleges?
 (2.) If so, what sites have been recommended?
 (3.) How many appointments have been made under the Department of Agriculture (if any) who have been appointed; and what salaries are being paid?

Answers.

- (1.) Mr. Pudney reported on several sites for experimental farms offered to the Government on purchase.
 (2.) He has not recommended any of these sites.
 (3.) Director, H. C. L. Anderson, £800; Inspector (temporary), R. L. Pudney, £350; Statistical Clerk, A. P. Reynolds, £200; Clerk, W. Preedy, £180; Clerk (temporary), A. A. Dunningcliff, £130; Clerk (temporary), G. Valder, £130. Probationer, W. H. Clarke, £50. Professional Staff:— Chemist, Dr. Helms, consulting, £150; Vegetable Pathologist, Dr. Cobb, consulting, £100; Entomologist, A. S. Olliff, consulting, £100; Economic Botanist, F. Turner, consulting, £50.

LEGISLATIVE ASSEMBLY.

NEW SOUTH WALES.

ITALIAN SETTLEMENT AT THE RICHMOND RIVER, KNOWN AS "NEW ITALY."

(REPORT BY THE DIRECTOR-GENERAL OF FORESTS ON.)

Ordered by the Legislative Assembly to be printed, 26 November, 1890.

The Director-General of Forests to The Colonial Secretary.

Sir,

Forest Department, 28 October, 1890.

In accordance with instructions received from you, I recently visited the settlement known as "New Italy," and which is situated some 7 or 8 miles from Woodburn, in the Richmond River District, and have now the honor to report my impressions of the settlement, and to make such suggestions in regard to it as have arisen therefrom.

I interviewed several of the leading members of the community, and to them explained the object of my visit, and of your earnest desire for their welfare and prosperity; and they desired me to convey to you their appreciation of your kindness and sympathy.

I find that there is a population of something like 250 Italians in the settlement, of which, perhaps, about 100 are adults, and that the several selections have been taken up contiguous to each other, thus making the community united, and the members of it within easy reach of each other.

From information received, and also from what came under my own observation, there is no doubt but that these Italians are a hard-working, sober, industrious, law-abiding people, and are proving themselves excellent colonists in every respect. They are thoroughly united in themselves, and give no trouble to the neighbouring settlers.

With regard, however, to the site of the settlement itself, I regret that it is not within my power to speak so favourably. The soil in places is of a somewhat cold and apparently uninviting nature, and requires a considerable amount of labour to subject it to profitable cultivation. Only a few miles further away, and nearer the Richmond River, a character of soil of a more suitable nature for *general tropical agriculture* could easily have been obtained. For the cultivation of various products, however, the site is all that could be desired, but the variety of these is limited in consequence of the special character of the soil and its want of *humus*.

The soil is excellently well adapted for the cultivation of the vine for the purpose of wine-making, and this fact has been recognised and acted on by most of the settlers at New Italy. On all the selections visited by me, from one to two and three acres of land had been carefully cultivated, and showed very fine crops of various kinds of vines. A considerable amount of wine is made by the settlers annually, but, as yet, principally only for their own consumption. There are great possibilities in connection with the making of light wines on the soil of New Italy, but systematic action is necessary for the production of a good article. This will no doubt come about in due time.

The land is heavily timbered, and requires a very considerable amount of labour to clear it, and hence the area of land at present under cultivation in the settlement is not very great, as the whole of the work has to be done by the Italians themselves, in consequence of their being unable to employ outside labour.

There is a State Public School in connection with this settlement. A Mr. Morgan is the teacher, and he informed me that the attendance of Italian children was good, very regular, and averaged about thirty-five pupils per day of various ages. All the children who had been born in the Colony and attended school were capable of speaking the English language very well indeed, and in several cases acted as interpreters between their parents and myself.

From my conversations with these Italians, and also judging from the excellent manner in which they have carried out the improvements already carried out upon their selections, it is evident to me that they have, as a body, decided to permanently settle upon the land.

According to your instructions, I entered carefully into the subject of the probability of establishing the industry of sericulture in this settlement, and have much pleasure in reporting that, in my opinion, it is one of the most important which could be undertaken in connection with it. I find that all the original settlers (*i.e.*, those who came from Italy proper) are well acquainted with the various ramifications of the industry; and it is therefore only a matter of application in order to make it the staple

production of this people. The soil, climate, and situation are all well adapted to the successful production and culture of the white mulberry, the leaves of which tree form the principal food of the silk-worm. Therefore, from the fact that the people themselves are well acquainted with the industry, and also from the fact that the work is one in which both women and children are peculiarly fitted to take part, it appears to me that sericulture should become the main support of these people. I may say that they one and all expressed the opinion that they would prefer the work of sericulture to any other.

Taking all these matters into consideration then, I have respectfully to recommend that every encouragement should be given by the Government to the settlers of New Italy to establish a thorough system of reproductive sericulture in their midst; and in connection with this I have much pleasure in herewith forwarding a full report upon the subject from Mr. Champ. who, in accordance with your desire, accompanied me on my visit to the settlement. I will not at present go into details as to how this might be done, as these can be fully gone into later on, should you approve of the suggestion. I may say that there would be little or no difficulty in raising 300,000 mulberry plants in our nurseries next season for distribution amongst the Italians.

I have, &c.,

J. EDNIE BROWN,
Director-General of Forests.

(Enclosure.)

To the Director-General of Forests,
Forest Department, Sydney,—

72, Newtown Road, Sydney, 24 October, 1890.

Sir,

Having, as requested, visited the Italian settlement in the county of Richmond, N.S.W., known as New Italy, for the purpose of ascertaining its suitability to the introduction of sericulture, I beg to report as follows:—

The Mulberry-tree.

I find that the soil, though poor compared with that of some of the surrounding country, is suitable for the cultivation of the mulberry-tree, and that in the one or two instances where these trees have already been planted they have thrived well.

These few trees planted by the Italians, though not of the best sort for sericulture (they being one of a Chinese species of black mulberry), showed a very good growth and abundance of leaves, besides a quantity of fruit, and it can therefore be taken for granted that the white mulberry, which is much more prolific in leaves, less nourishment being taken up in the fruit, would give a still better return of leaves. The climate, as is well known, is exceptionally suited for the growth of this tree.

From trees pointed out to me amongst these few referred to as being only two years old, I should judge there could be plucked some 3 or 4 lb. of leaves, whereas in most other countries, and in the more southern portions of this continent, it would probably take four years before such a return could be obtained.

I would here point out that too rich a soil is not always the best for the production of good silk, or rearing worms, though of course the tree itself grows more luxuriantly. This same luxuriant growth, however, is inclined to produce a too succulent leaf, and, if great care be not taken, to endanger the health of the worms in their latter stages, when they eat voraciously.

I therefore think that the soil of New Italy, combined with the splendid climate the country possesses, would grow a mulberry-tree well suited to silk-culture.

The Silk-worm.

The climate would be very suitable indeed for the rearing of the silk-worm, I should say even more so than it is in other parts of Australia, where worms have already been most successfully raised, experimentally.

The cool nights, absence of hot winds and drought, and the general even temperature of the summer would be most conducive to the general health of the worm.

The trees too, are long in leaf, and would enable many "crops" or hatchings to be obtained; a most important item in the pecuniary success of the undertaking, as of course the more times in a year the magnaneries and trees, can be utilised the greater the proportionate return.

Labour.

As regards the obtaining of a sufficient quantity of concentrated labour, that would be at the same time suitable and efficient, to enable the industry to be started on such a scale as would show its worth, I consider that under no circumstances could a more favourable spot be found in these Colonies than New Italy, for I find on interviewing these Italians that the whole of the adults have had, more or less, some experience in their own country of this culture, one man informing me that his wife had had twenty years, experience in an Italian "filature."

As can be easily understood, this would be a great help in successfully introducing the industry.

Having put the question to them, they seem to be united in opinion that the industry would do well, and all appear to be most anxious to take the matter up if they are enabled to do so, expressing the opinion that more money could be made and quicker returns obtained from sericulture than from viticulture, in which latter they are already doing some little cultivation.

There are about forty Italian families in this settlement, all bound close together by national ties and co-operating in every way for their general advancement, and, as I have already mentioned, all with some knowledge of sericulture, but they are so far without the means of utilising this knowledge.

They are an industrious, thrifty community, judging from what they have already done, in a small way, on their selections in other cultures, with the limited means at their command, and were they in a position to carry on the culture of silk, would be capable, as a body, of producing some comparatively handsome results.

Quantity

Quantity and value of Cocoons that might be produced.

Approximately, I should say these people would be capable, as far as their labour is concerned, of producing the following quantity and value of silk-cocoons:—

There are (say) forty families, and most of these are composed of eight or ten individuals, but, supposing an average be taken of only four per family that could attend to the industry. A 10-oz. silk-worm-house or "magnanerie" would take four people, if needs be, juveniles, to attend to it during the education of the worms. Forty families of four each would, therefore, be capable of taking charge of forty 10-oz. "magnaneries," or, in other words, of rearing 400 oz. of eggs or "grain."

These forty "magnaneries" should give about $\frac{1}{2}$ ton of cocoons per "magnanerie," valued at the present time at from £100 to £150 per ton.

Taking an average (say) £125 per ton, the produce of the forty "magnaneries" or 400 oz. eggs would be, therefore, £2,500. This would be for one crop only, or for work extending over a period of about six weeks.

But supposing, to take a small estimate, three crops are produced, and that two months are taken to rear each one, which allows a good margin for operations connected with the fresh hatchings, and getting previous crops ready for export, &c., there would be a production of cocoons, in six months, value about £7,500. Compared with what these men are now earning and producing, I am sure this would be to them a fortune.

Quantity of Trees requisite to produce above results.

In order to obtain the above results there would have to be some considerable quantity of mulberry-trees grown and silk-worm grain obtained, far more, I am confident, than these people are in a position to secure, however hard they may work.

I should estimate that to produce the above quantity of cocoons, and rear the necessary number of worms, viz., 400 oz. grain, some 250,000 young trees would be required, and might be planted in (say) 300 or 400 acres of land, though every year that is added to the age of these trees would mean a much larger silk-productive capacity.

In this district, from what I have seen and referred to above, a two-year-old tree would produce at least 3 lb. of leaves per picking.

This would give a total of 750,000 lb. for the above number of trees.

It takes about 20 lb. leaves to produce 1 lb. cocoons, giving about 37,500 lb. cocoons, or about the equivalent of the above product of 400 oz. grain, viz., 40,000 lb. = 20 tons—1 oz. grain producing about 100 lb. cocoons.

Assistance that might be given.

I think this might be divided into three heads—

1. Tree-planting.
2. Distribution of silk-worm grain.
3. The building, or assisting the building, of "magnaneries."

1. I should strongly recommend that such a plantation as I mention above be made by the Government and at the same time as many trees given to the Italians as they are able to plant on their own selections.

A nominal sum might be charged for the leaves plucked from the main plantation.

I may add that mulberry-farming is carried on upon a large scale in other countries as a distinct business, the leaves being sold, somewhat as I suggest above, to the cocoon-producers.

2. Good healthy silk-worm grain might be secured and distributed in proper quantities as soon as the trees are ready.

Such grain could, I believe, be obtained by arrangement from Dr. Cleland, of Adelaide, South Australia, and Mr. George Thorne, of Castle Hill, New South Wales.

Both of these gentlemen have very fine races of worms, quite free from any disease, and thoroughly acclimatised.

They have only small quantities at present, but with proper notice I have no doubt arrangements could be made with them for multiplying the grain, instead of their "choking" the bulk of their cocoons, as they are in the habit of doing.

This would be infinitely preferable to importing grain, as you can never be certain of what you are getting.

3. "Magnaneries" might be erected and let to the rearers at a small rental, or, according to circumstances, they might be assisted to erect them on their own selections.

But in any case it would be advisable to avoid, if practicable, the rearing of worms by individuals in small quantities, in improperly-constructed rooms, as these people would undoubtedly be tempted to do without assistance, owing to their pecuniary inability to procure better accommodation, and in order to get a quick return, thus producing an inferior article, and possibly discouraging others from attempting the industry.

These "magnaneries" might be constructed at small expense of "dab wattle" or mud walls, with thatched or bark roofs and gauze openings. This would be, independently of the cheapness, better, in my opinion, than possibly more expensive material, for keeping the interior at a suitable temperature. I observed a very good building (residence) built by one of the Italians (Antoniolli), of similar material.

It is impossible to say now what the exact cost of such buildings would be, but they need be only of the simplest structure and roughest material; in fact, a simple shed, care always being taken, however, to have proper ventilation and light—two important items. The fittings also, although they need be only of rough material, must be constructed in a proper way, and great care taken to avoid the attacks of any kind of vermin.

The outside measurement of a 10-oz. "magnanerie" should be about 60 feet by 20 feet.

It would be very advantageous to have a "magnanerie" in connection with the above plantation, belonging to the Government, devoted to the production of sound "grain" for distribution, which could at the same time be used for giving instruction to those who needed it.

General Remarks.

I may add that there is little doubt that, were once the industry proved to be a success in this district, and the people shown the basis upon which to work, sericulture in its various branches would spread further afield by private enterprise.

I have here only dealt with the production of cocoons, which, however, would find a ready sale on European markets, or even in India, and can, after proper desiccation, be press-packed and exported in bales, as is other produce.

Reeling the cocoons into silk, however, should, of course, undoubtedly be ultimately undertaken, but would require proper "plant" and more or less skilled labour, some of which latter, I am convinced, could be obtained amongst these Italian women. It would, however, be better to first prove the cocoon-raising a success.

In concluding, I beg to again allude to the one or two points that make New Italy almost a unique place in these Colonies for the successful introduction of sericulture:—

A perfect climate.

A suitable soil.

A small but concentrated population of Italians all more or less cognisant of the culture, and willing to work at it.

Large families of children, which would be only too glad to work and supply the juvenile labour, so requisite for sericulture.

I am, &c.,

REGINALD CHAMP.

Reginald Champ, Esq., to The Director-General of Forests.

Sir,

Sydney, 4 November, 1890.

Referring to my report concerning the introduction into this Colony of sericulture, I would point out that if the Government intends taking any steps in the matter, it would be well to do so *at once*, as regards one important item, viz., the multiplying of the available "grain" in the Colonies, as the worms are even now about to spin, and will in the ordinary course be "choked" or killed, if other arrangements be not made.

The two gentlemen I alluded to in my report, viz., Dr. Cleland, of South Australia, and Mr. Thorne, of this Colony, would be, I am sure, quite willing to make any reasonable arrangement with a view to the above, and thus a season would be saved.

I am, &c.,

REGINALD CHAMP.

Forwarded to the Hon. the Colonial Secretary respectfully requesting that this letter be read in connection with my report upon the subject.—J.E.B., D.-G. Fts., 8/11/90. The Principal Under Secretary, B.C., 9/11/90.

1890.

LEGISLATIVE ASSEMBLY.
NEW SOUTH WALES.

VINE DISEASES ACTS FURTHER CONTINUATION BILL
(MESSAGE No. 71.)

Ordered by the Legislative Assembly to be printed, 5 December, 1890.

ALFRED STEPHEN,

Message No. 71.

Lieutenant-Governor.

In accordance with the provisions contained in the 54th section of the Constitution Act, the Governor recommends for the consideration of the Legislative Assembly the expediency of making provision to meet the requisite expenses in connection with a Bill to continue the "Vine Diseases Act of 1886" and the "Vine Diseases Act Amendment Act of 1888" for a further period of one year.

Government House,

Sydney, 5th December, 1890.

NEW SOUTH WALES.

ROYAL COMMISSION OF INQUIRY INTO SCHEMES FOR
EXTERMINATION OF RABBITS IN AUSTRALASIA.

PROGRESS REPORT,
MINUTES OF PROCEEDINGS,
MINUTES OF EVIDENCE,

AND

APPENDICES.

Presented to Parliament by Command.

SYDNEY: CHARLES POTTER, GOVERNMENT PRINTER

1890.

38 (7)—a

[10s.]

Commission.

VICTORIA, by the Grace of God, of the United Kingdom of Great Britain and Ireland, Queen,
Defender of the Faith, and so forth,—

To our trusty and well-beloved—

HENRY NORMAN MACLAURIN, Esquire, M.D.,	}	New South Wales.
WILLIAM CAMAC WILKINSON, Esquire, M.D., M.P.; and		
EDWARD QUIN, Esquire,		
HARRY BROOKES ALLEN, Esquire, M.D.,	}	Victoria.
EDWARD HAREWOOD LASCELLES, Esquire,		
ALFRED NAYLOR PEARSON, Esquire, F.R.Met.Soc., F.C.S., A.I.C.,		
ALFRED DILLON BELL, Esquire, New Zealand.		
EDWARD CHARLES STIRLING, Esquire, M.D.,	}	South Australia.
ALEXANDER STUART PATERSON, Esquire, M.D.,		
JOSEPH BANCROFT, Esquire, M.D., Queensland.*		
THOMAS ALFRED TABART, Esquire, Tasmania.		

Greeting:

WHEREAS the Government of our Colony of New South Wales has invited the Governments of our Colonies of Victoria, New Zealand, South Australia, Queensland, Tasmania, and Western Australia to nominate skilled and experienced persons to make, in association with the above-mentioned representatives of our first-named Colony, an inquiry and a report on the matters hereinafter specified: And whereas the Governments of our said Colonies of Victoria, New Zealand, South Australia, Queensland, and Tasmania have respectively made such nominations accordingly: And whereas the Government of our said Colony of Western Australia has declined to make a nomination to such Commission: Now know ye, that we, reposing great trust and confidence in your ability, zeal, industry, discretion, and integrity, do by these presents authorize and appoint you or any three or more of you, as hereinafter mentioned, to make a full and diligent inquiry as to whether or not the introduction of contagious diseases amongst Rabbits by inoculation or otherwise, or the propagation of diseases natural to Rabbits, for the purpose of destroying them, or promoting their destruction, will be accompanied or followed by danger to human health or life, or to animal life other than Rabbits, or to interfere injuriously with the profitable carrying on of the agricultural or pastoral pursuits followed by the tillers or occupants of public or private lands in our Australian Colonies; if either or any of the above means are dangerous—to what extent; if not so dangerous as to justify absolute prohibition, under what conditions and restrictions should such inoculation or propagation be permitted to be introduced and carried on, and generally to inquire into and report to us upon the several methods or means proposed or that may be proposed to the Governments of our several Colonies concerned for the purpose of checking or suppressing the Rabbit pest in the said Colonies, and which may be referred to you by us for the purpose of inquiring into and reporting upon by you: And we do by these presents grant to you, or any three or more of you, at any meeting or meetings to which all of you shall have been duly summoned, full power and authority by all lawful ways or means to call before you all such persons as you may judge necessary, by whom you may be the better informed of the truth in the premises, and to require the production of all such books, papers, writings, and all other documents as you may deem expedient, and to visit and inspect the same at the offices or places where the same or any of them may be deposited, and, generally, to inquire of the premises: And you will be provided with such clerical and other assistance as may be deemed necessary for enabling you duly to execute this our Commission: And our further will and pleasure is, that you do within one month after the date of this our Commission, or as soon as the same can be done, using all diligence, certify to us, in the office of our Colonial Secretary of our said Colony of New South Wales, under your or any three or more of your hands and seals, what you shall find touching the premises: And we hereby command all Government Officers and other persons whomsoever within our said Colony of New South Wales, that they be assistant to you and each of you in the execution of these presents: And we do hereby empower you to elect one of your number to be President of this our Commission, which said Commission we declare to be a Commission for all purposes of the Act 44 Victoria No. 1, intituled "*An Act to regulate the taking of Evidence by Commissioners under the Great Seal*."

In testimony whereof, we have caused these our Letters to be made Patent, and the Great Seal of our Colony to be hereunto affixed.

Witness our right trusty and well-beloved Councillor, CHARLES ROBERT BARON CARRINGTON, Knight Grand Cross of our Most Distinguished Order of Saint Michael and Saint George, our Governor and Commander-in-Chief of our Colony of New South Wales and its Dependencies, at Government House, Sydney, in New South Wales aforesaid, this sixteenth day of April, in the fifty-first year of our Reign, and in the year of our Lord one thousand eight hundred and eighty-eight.

(L.S.) CARRINGTON.

By His Excellency's Command,
HENRY PARKES.

Entered on record by me, in Register of Patents, No. 13, pages 175-G, this sixteenth day of April, one thousand eight hundred and eighty-eight.

For the Colonial Secretary and Registrar of Records,
CRITCHETT WALKER,
Principal Under Secretary.

* At a meeting of the Royal Commission, held in Melbourne on 13th October, Henry Tryon, Esq., presented a document under the great seal of the Colony of New South Wales appointing him an additional member of the Commission, representing the Colony of Queensland,

Commission.

VICTORIA, by the Grace of God, of the United Kingdom of Great Britain and Ireland, Queen,
Defender of the Faith, and so forth,—

To our trusty and well-beloved—

HENRY TRYON, Esquire.

Greeting:

WHEREAS by an instrument under the Great Seal of our Colony of New South Wales, bearing date the sixteenth day of April last, we did appoint certain gentlemen therein named to make a full and diligent inquiry as to whether or not the introduction of contagious diseases amongst Rabbits by inoculation or otherwise, or the propagation of diseases natural to Rabbits, for the purpose of destroying them, or promoting their destruction, will be accompanied or followed by danger to human health or life, or to animal life other than Rabbits, or to interfere injuriously with the profitable carrying on of the agricultural or pastoral pursuits followed by the tillers or occupants of public or private lands in our Australian Colonies; if either or any of the above means are dangerous—to what extent; if not so dangerous as to justify absolute prohibition, under what conditions and restrictions should such inoculation or propagation be permitted to be introduced and carried on, and generally to inquire into and report to us upon the several methods or means proposed or that may be proposed to the Governments of our several Colonies concerned for the purpose of checking or suppressing the Rabbit pest in the said Colonies, and which may be referred to our said Commission by us for the purpose of inquiry and report: And whereas the Government of our Colony of Queensland has represented the advisability of appointing an additional member of such Commission: Now, therefore, know you, that we, of our especial grace, have thought fit to appoint, and do hereby appoint you to be such additional Commissioner accordingly.

In testimony whereof, we have caused these our Letters to be made Patent, and the Great Seal of our Colony to be hereunto affixed.

Witness our right trusty and well-beloved Councillor, CHARLES ROBERT BARON CARRINGTON, Knight Grand Cross of our Most Distinguished Order of Saint Michael and Saint George, our Governor and Commander-in-Chief of our Colony of New South Wales and its Dependencies, at Government House, Sydney, in New South Wales aforesaid, this twenty-fourth day of August, in the fifty-second year of our Reign, and in the year of our Lord one thousand eight hundred and eighty-eight.

(L.S.)

CARRINGTON.

By His Excellency's Command,

HENRY PARKES.

Entered on record by me, in Register of Patents, No. 13, pages 5,239-240, this twenty-fifth day of August, one thousand eight hundred and eighty-eight.

For the Colonial Secretary and Registrar of Records,

CRITCHETT WALKER,

Principal Under Secretary.

PROCLAMATION BY THE GOVERNMENT OF NEW SOUTH WALES.

EXTERMINATION OF RABBITS.

Department of Mines, Sydney, 31st August, 1887.

It is hereby notified that the Government of New South Wales will pay the sum of £25,000 to any person or persons who will make known and demonstrate at his or their own expense any method or process not previously known in the Colony for the effectual extermination of rabbits, subject to the following conditions, viz. :—

1. That such method or process shall, after experiment for a period of twelve months, receive the approval of a Board appointed for that purpose by the Governor with the advice of the Executive Council.
2. That such method or process shall, in the opinion of the said Board, not be injurious, and shall not involve the use of any matter, animal or thing, which may be noxious to horses, cattle, sheep, camels, goats, swine, or dogs.
3. The Board shall be bound not to disclose the particulars of any method or process, unless such Board shall decide to give such method or process a trial.

FRANCIS ABIGAIL.

INDEX TO SECTIONS OF REPORT.

	PAGES.
Section I.—Report of Proceedings of Commission	1 to 36
Section II.—Minutes of Evidence given before the Commission	37 to 107
Section III.—Evidence given before the Executive Committee, at Tintinallogy and elsewhere	107 to 114
Section IV.—Evidence concerning Rabbit Mortality in New Zealand, by Mr. Coleman Phillips	115 to 123
Section V.—Statement made in lieu of evidence by Mr. E. H. Lascelles, a Member of the Commission	123 to 125
Section VI.—Minutes of Proceedings of the Experiment Committee	125 to 133
Section VII.—Report of the Experiment Committee	133 to 136
Section VIII.—Description of the Laboratory Buildings at Rodd Island	136 to 137
Section IX.—Report on Rabbit with bladder-worm disease	137
Section X.—Report on the Experiments carried out by M. Pasteur's representatives ...	138 to 143
Section XI.—Experiments with Microbes of Chicken-cholera conducted by Dr. Katz, chief expert to the Commission	143 to 182
Section XII.—Investigation into fowl diseases, with a view to ascertain whether Fowl-cholera exists in the Australasian Colonies or not	182 to 188
Section XIII.—Description of the symptoms and <i>post-mortem</i> appearances in Fowl-cholera	188 to 189

INDEX TO APPENDICES TO REPORT.

	PAGES.
1. Schemes for the extermination of Rabbits by disease, as classified and reported on by the Correspondence Committee*	190
2. Expenditure by the Governments of the several Colonies in connection with Rabbit Destruction	190 to 192
3. Letters from M. Pasteur, extracted from papers on Rabbit Destruction, submitted to the Legislative Assembly of New South Wales, and ordered to be printed (March, 1888)	192 to 198
4. M. Pasteur's Letter to the Chief Inspector of Stock	198
5. Report by Dr. Bancroft of the visit of the Commission to Dr. Ellis' house, and of examination of diseased Rabbits from Tintinallogy	198 to 199
6. Abstract of Life History of <i>Coccidium oviforme</i> , by Professor Allen	199 to 200
7. Reports by Dr. Bancroft and Dr. Wilkinson concerning their visits to Tintinallogy ...	200 to 202
8. Professor Thomas' Report on diseases affecting Rabbits in the Wairarapa District, New Zealand... ..	202 to 214
9. Letter from Mr. Hawkins, of North Wairarapa (N.Z.), concerning bladder-worm disease	214
10. Nasal catarrh in Rabbits	215
11. Communications from Witnesses relative to Statements made in Evidence	215 to 216

* Omitted by direction of the Honorable the Colonial Secretary.

PROGRESS REPORT.

To His Excellency the Right Honorable CHARLES ROBERT, BARON CARRINGTON, Knight Grand Cross of the Most Distinguished Order of Saint Michael and Saint George, a Member of Her Majesty's Most Honorable Privy Council, Governor and Commander-in-Chief of the Colony of New South Wales and its Dependencies.

MAY IT PLEASE YOUR EXCELLENCY,—

We, the undersigned Members of the Royal Commission appointed "To make a full and diligent inquiry as to whether or not the introduction of Contagious Diseases amongst Rabbits, by inoculation or otherwise, or the propagation of Diseases natural to Rabbits, for the purpose of destroying them, or promoting their destruction, will be accompanied or followed by danger to human health or life, or to animal life other than Rabbits, or to interfere injuriously with the profitable carrying on of the agricultural or pastoral pursuits followed by the tillers or occupants of public or private lands in our Australian Colonies; if either or any of the above means are dangerous, to what extent? if not so dangerous as to justify absolute prohibition, under what conditions and restrictions should such inoculation or propagation be permitted to be introduced and carried on, and generally to inquire into and report to us upon the several methods or means proposed or that may be proposed to the Governments of our several Colonies concerned for the purpose of checking or suppressing the Rabbit Pest in the said Colonies, and which may be referred to you by us for the purpose of inquiring into and reporting upon by you," beg to submit the following Progress Report:—

PRELIMINARY WORK.

The Commission assembled for the first time on the 16th day of April, 1888, at Sydney, representatives of the Colonies of New South Wales, Victoria, South Australia, Queensland, and Tasmania being present. Dr. MacLaurin, one of the representatives of the Colony of New South Wales, was unanimously elected President of the Commission. A general discussion ensued in which all the members took part. The Commission then met daily, with the exception of one short adjournment, until the preliminary business was completed. At the fourth meeting the representative of the Colony of New Zealand associated himself with the Commission. At the request of the Commission the representatives of M. Pasteur received permission to introduce into the Colony of New South Wales cultivations of the microbes of chicken-cholera, on condition that they would undertake to conduct no experiments therewith without the sanction of the Commission. In order to test fully and safely the various schemes proposed for the destruction of rabbits by disease, the Commission immediately took steps to obtain a suitable laboratory in which small experiments might be conducted; and also an island infested with rabbits, and an inland area similarly infested and surrounded by rabbit-proof fencing, in which experiments could be conducted on a larger scale and under normal conditions. The evidence of Henry Augustus Ellis, Esquire, M.B., was taken concerning the great mortality which had prevailed among rabbits on Tintinallogy Station, bordering on the Darling River in New South Wales, and concerning the experiments which had been conducted by Herbert Pickering Butcher, Esquire, M.R.C.S., Eng., and himself in connection with the so-called Tintinallogy disease. The Commission then proceeded to the residence of Dr. Ellis, and examined certain rabbits suffering from the so-called disease.

At the request of Drs. Butcher and Ellis it was resolved that all particulars submitted by them concerning this disease would be considered confidential.

In consequence of a letter from M. Pasteur's representatives, it was resolved that in accordance with the terms of the Proclamation of the Government of New South Wales, the Commission would treat as confidential the details of any method that might be examined, but not adopted for trial by the Government.

The representatives of M. Pasteur were subsequently examined concerning the condition of the cultures of the microbes of chicken-cholera, which they were about to introduce into New South Wales, and the method which they proposed to pursue in order to exterminate rabbits. They were requested to prepare a written statement in connection with the scheme of M. Pasteur, and it was arranged that facilities be granted to them for the conduct of preliminary experiments at the laboratory of the Board of Health under such precautions as Dr. MacLaurin, the President of the Commission and of the Board of Health, might prescribe. It was ordered that a supply of rabbits be obtained for purposes of experiment. A schedule of experiments was adopted by which to test the utility of chicken-cholera and of the so-called Tintinology disease for the destruction of rabbits. Dr. Katz, Ph.D., was appointed chief expert officer for the conduct of experiments under the direction of the Commission, and a Committee, hereinafter called the Experiment Committee, was appointed to watch the experiments on behalf of the Commission. The representatives of M. Pasteur, on April 24th, submitted their written statement, including a list of the experiments of demonstration which they proposed to make. They were then examined concerning the existing evidence in favour of M. Pasteur's scheme. On April 25th a second general discussion was held, at the close of which the order of experiments was defined, and it was resolved that the Experiment Committee should have full discretion in all matters concerning the conduct of experiments within the terms of the Commission, and in all matters regarding the progress of the inquiry, subject to the limitations already determined by the Commission. Statistics concerning the cost of rabbit destruction in New South Wales and Victoria were received, and steps were taken to obtain like information from other Colonies. On April 26th the last meeting of the first session of the Commission was held, when a memorandum was received from the Rabbit Branch of the Lands Department of New South Wales, and a minute from the Under Secretary for Lands, forwarding for consideration by the Commission all the mechanical devices, &c., which had been submitted to the Government of New South Wales in connection with rabbit destruction. It was resolved that these appliances should be placed in some suitable store where they might be inspected by members, and the further consideration of their merits was postponed. The Experiment Committee was requested to scrutinize the correspondence concerning these appliances which was then in the possession of the Hon. the Minister of Mines. It was resolved that two members of the Committee should form a quorum and the Committee was requested to elect a chairman, who should have general control over the experiments about to be adopted. The Hon. the Secretary for Lands invited the Commission to take into consideration the question of the proper width and mesh of rabbit-proof netting fencing. It was accordingly resolved that a Committee, consisting of the members representing the Colony of Victoria, with such other members as were able to attend, should take evidence in Victoria from witnesses who had practical experience in the use of rabbit-proof fencing; and this Committee was authorised to make public advertisement inviting such evidence. The Commission advised that licenses to prosecute their experiments with the so-called Tintinology disease might be granted to Doctors Butcher and Ellis with safety to the public health. It was then resolved that on or about May 23rd the Commission should meet in Adelaide, and investigate the action of the disease known as rabbit scab, and subsequently proceed to Silverton, and if necessary to Tintinology or elsewhere, to take evidence concerning the so-called Tintinology disease. Steps were taken to secure the presence at Silverton of Dr. Butcher, and of rabbit inspectors and others who could give evidence concerning the mortality among rabbits

rabbits at Tintinallong, and the Government of South Australia was invited to provide facilities for the work of the Commission in South Australia. The first session of the Commission then closed.

APPOINTMENT OF EXPERIMENT COMMITTEE AND EQUIPMENT OF LABORATORY.

On the following day, April 27th, the first meeting of the Experiment Committee was held, and Dr. W. Camac Wilkinson was elected chairman. The minutes of the proceedings of this Committee are set forth in Section VI of the detailed report. At the outset great difficulty was experienced in obtaining a suitable site for a laboratory, in which the schedule of experiments adopted by the Commission could be executed. Many places were visited, which were in some respects capable of adaptation to the purpose, but some serious difficulty presented itself in every instance. It became evident that no suitable building could be obtained in any inhabited neighbourhood, without risking interruption of the experiments, on the ground of danger to the public health. Ultimately, on May 4th, after communication with the Hon. the Secretary for Lands, Rodd Island was set apart for the use of the Committee as an experimental station. The necessary plans were speedily prepared, and the works were executed with admirable expedition by the Department of the Colonial Architect of New South Wales. Mr. A. N. Pearson, one of the representatives of the Colony of Victoria, rendered most important service in connection with the designing of the station, and with the supervision of all the work. A description of the station is given in Section VIII of the detailed report, so that here it need only be said that the island is surrounded by a broad belt of water; that the general enclosure, in which animals are kept, measures nearly a quarter of an acre, with stalls and pens, an aviary, artificial burrows, &c., the whole enclosure, with every outlet from it, being protected by fly-proof gauze, the drainage being conducted into disinfecting tanks, and a furnace being provided in which dead carcasses and all infected matters may be burnt. A well-equipped laboratory is provided, with quarters for the experts and servants. All these works were completed in less than two months, and thus, at a comparatively small cost, provision was made for the experiments to be performed under the direction of the Commission; and when its work is ended, a permanent bacteriological station will remain, in which, from time to time, the communicable diseases of animals can be studied with facility.

DIFFICULTIES WITH M. PASTEUR'S REPRESENTATIVES.

Meanwhile, on May 8th, the Committee received a letter from Dr. Hinds, one of the representatives of M. Pasteur, stating that their preliminary experiments were completed. The list of experiments with microbes of chicken-cholera, which had been adopted by the Commission, was sent to Dr. Hinds, and he was asked to suggest any other experiments. At the meeting of the Committee on May 14th, a letter dated May 10th was read, signed by Dr. Hinds, Dr. Germont, and M. Loir, in which they stated that they were unable to accept any participation in these experiments. This letter and the correspondence which ensued will be found in the Report of the Experiment Committee forming Section VII of the detailed report. As considerable delay in the progress of experimental work was caused by this correspondence, it is necessary to show clearly the positions taken by the Commission and its Experiment Committee on the one hand, and by M. Pasteur's representatives on the other.

The Commission, at its meeting on April 24th, had adopted a definite schedule of experiments concerning chicken-cholera, which would test— (1) whether chicken-cholera would spread from infected rabbits to healthy rabbits in hutches, cages, and artificial burrows; (2) whether domestic animals could be injured by the microbes of chicken-cholera; (3) what birds are liable to chicken-cholera; (4) whether the virulence of chicken-cholera is altered when it is repeatedly communicated from rabbit to rabbit. Incidentally, it was to be tested whether birds at liberty in a large enclosure would contract chicken-cholera when rabbits were dying from that disease in the enclosure. At the same meeting, at which this schedule was adopted, the representatives
of

of M. Pasteur proposed to make experiments as follows:—(1) to show in the laboratory that they could kill rabbits by adding microbes to their food; (2) to show similarly that domestic animals are not affected by the addition of microbes to their food; (3) to make an experiment on an inland area of (say) 500 acres, enclosed with rabbit-proof fencing, but otherwise under natural conditions. In this experiment food containing microbes would from day to day be placed in different parts of the area. On behalf of the Commission it was explained that a laboratory would soon be ready, and that any experiments which M. Pasteur's representatives might desire would certainly be done; and it was proposed that they should associate themselves with Dr. Katz, the Chief Expert Officer of the Commission, in the conduct of their own experiments. The experiments proposed by the Commission were carefully explained, and M. Pasteur's representatives were informed that if they desired any modification of these experiments, their wishes would receive careful consideration, and also that Dr. Katz had been instructed that all work concerning chicken-cholera was to be performed in association with them. Dr. Hinds, on behalf of M. Pasteur's representatives, at once assented to these proposals. The Chairman asked if M. Pasteur's representatives would not take time to consult. They conversed shortly among themselves, and Dr. Hinds said, "We accept your proposals at once." In the course of their examination which followed, great stress was laid by members of the Commission on the necessity for proving, not merely that rabbits could be killed by administering infected food, but also that chicken-cholera would spread from infected rabbits to healthy rabbits independently of the administration of infected food.

When the Commission closed its first session, on April 26th, it was apparently understood by all parties that the laboratory experiments with chicken-cholera, including those proscribed by M. Pasteur and those directed by the Commission, would be performed as soon as the laboratory was completed. But the subsequent refusal of M. Pasteur's representatives to take any part in the tests proscribed by the Commission necessitated a tedious and disappointing correspondence. This refusal was considered by the Experiment Committee, as before stated, on May 14th.

VISIT OF COMMISSION TO MELBOURNE, ADELAIDE, SILVERTON, AND TINTINALLOGY.

Four days later the Commission met informally, in Melbourne, to hear the statements of Dr. R. F. Hudson and Mr. A. L. Gilbert, concerning their observations during a recent visit to Tintinallogy. As it proved possible to obtain a full attendance of the Commission in Melbourne, the intended committee meeting was replaced by a one day's Session of Commission, which was held on May 21st. Ten witnesses, who held land in various parts of Victoria and New South Wales, were then examined, chiefly concerning the proper height and mesh of rabbit-proof fencing. Two of the rabbit inspectors of Victoria were also examined.

The Commission then passed into South Australia, and on May 23rd, at Adelaide, the evidence was taken of seven witnesses, including owners, lessees, and managers of large station properties, and Professor Watson, who introduced the *Sarcoptes cuniculi*, or rabbit scab. Rabbits and sheep, which had been made the subjects of experiments with this disease, were examined by the Commission. It was then resolved that with a view to economise the time of the Commission, an Executive Committee, consisting of Dr. Bancroft, Dr. Wilkinson, Mr. Dillon Bell, and Mr. Tabart, should proceed forthwith to Tintinallogy, make investigations there, and submit a written report to the Commission.

On May 26th and 28th the Commission met at Silverton and examined Dr. Butcher, of Tintinallogy, and Mr. C. W. Reid, who assisted him in his experiments; also the managers of several large station properties in the Western District of New South Wales; Mr. H. E. Vindin, the Superintending Inspector of the Rabbit Branch of the Lands Department of New South Wales, and several of his staff, and Mr. M. J. C. Tully, the Inspector of Stock for the Sheep District of Wilcannia.

During

During the return journey the Commission examined, at Adelaide, on May 29, Mr. C. J. Valentine, Chief Inspector of Stock, and Mr. S. G. Hübbe, the Chief Inspector under the Vermin Destruction Acts of South Australia; and also one of the members of the Pastoral Board of that Colony. At Melbourne, on June 6th, the evidence was taken of Mr. E. M. Curr, Chief Inspector of Stock for the Colony of Victoria.

Meantime the Executive Committee had visited Tintinallongy, had personally examined the infested country on that and neighbouring runs, and had taken evidence there, and at Albemarle Station and at Adelaide.

FURTHER NEGOTIATIONS WITH M. PASTEUR'S REPRESENTATIVES.

On June 11th the Experiment Committee again assembled at Sydney, and gave orders for the completion of the necessary works at Rodd Island. Negotiations with the representatives of M. Pasteur were actively resumed. Finally, these representatives definitely declined to conduct any experiments to test the communicability of chicken-cholera from rabbit to rabbit, or to supply microbes of the disease for experiments under the direction of the Committee, until all the experiments of demonstration prescribed by M. Pasteur had been completed, including an experiment on a large scale on some inland area, protected only by a rabbit-proof fence. At last a cablegram was despatched to M. Pasteur, asking him (1) to consent to an experiment testing the contagiousness of chicken-cholera from rabbit to rabbit; (2) to permit infected rabbits to be given to the Commission for special experiments. M. Pasteur consented to an experiment, but directed that five infected rabbits should be kept for six days with twenty healthy rabbits in an enclosure of one square metre (*i.e.*, less than $1\frac{1}{4}$ square yards), and that his representatives should wait before giving microbes of dead rabbits.

On June 16th M. Pasteur's representatives were asked whether, if this experiment was successful, they would permit further experiments under less favourable conditions, say in artificial burrows, or in a larger space, or with fewer rabbits. They said they could not. They were asked again whether they would make the experiment several times over, placing two infected rabbits with five healthy rabbits in each of six enclosures of two square metres each. They refused.

The Commission was therefore called together, and met on June 19th, 21st, and 22nd. A report was submitted by the Experiment Committee, and the correspondence and minutes of the Committee were read. It was thereupon unanimously resolved:—

“That the representatives of M. Pasteur be informed that the experiment which they propose to perform is not satisfactory to the Commission—that even if it be attended with positive results the Commission will not be able to infer that the disease will spread from rabbit to rabbit under natural conditions; that the Commission refuse to permit any broadcast dissemination of chicken-cholera microbes on any inland area until satisfactory proof shall have been given by experiments approved by the Commission—(1) that the disease is capable of spreading freely from rabbit to rabbit; (2) that the disease is innocuous to domestic animals; and that the Commission express its surprise that as M. Pasteur is seeking to obtain a reward of £25,000 for his scheme, his representatives should have absolutely declined to permit the fullest testing of its merits. The Commission will not object to the conduct of an experiment on the lines laid down by M. Pasteur, but it requests a final answer without delay—whether M. Pasteur's representatives will allow the experiments prescribed by the Commission to be conducted, and whether they will furnish rabbits suffering from chicken-cholera for the purpose of experiments under the direction of the Commission. If M. Pasteur's representatives do not assent to these conditions the Commission will report accordingly to the Government of New South Wales, and will recommend—(1) that correspondence with M. Pasteur and his representatives be suspended; (2) that the permission granted to M. Pasteur's representatives to introduce into

New South Wales and keep in New South Wales the microbes of chicken-cholera, and to perform experiments on rabbits with a view to maintain a supply of the microbes in active state, be withdrawn; (3) that steps be taken to obtain the microbes of chicken-cholera from other sources, so that the utility of this disease for the extermination of rabbits may be tested in a satisfactory manner."

A copy of this ultimatum was sent to the representatives of M. Pasteur.

OTHER SCHEMES FOR THE DESTRUCTION OF RABBITS.

Papers by Mr. Coleman Phillips, concerning the bladder-worm in the Wairarapa district of New Zealand, were received from the Government of South Australia. This subject was afterwards made the subject of close study, as will be shown in another part of this Report.

As fears were expressed that Drs. Butcher and Ellis would lose control of the so-called Tintinallogy disease, the Commission advised that they be granted permission to employ the so-called disease among rabbits in such districts as they may desire, provided that the places in which the disease is being employed be notified to the Commission. Dr. Ellis was requested to forward to Dr. Katz, as soon as possible, fifty rabbits suffering from the so-called disease, or any less number which might be available.

A Committee appointed to examine the correspondence relating to the introduction of disease for the extermination of rabbits presented its report, which was adopted. In conformity with a recommendation in that report, it was resolved that letters be addressed to Mr. F. A. Bishop, of Sydney; M. Lanféron, of Nevers, France; M. A. Laplanche, of Fismes, France; Mr. E. D. Graham, of Cairns, North Queensland; and Mr. J. H. Richardson, of Colorado, asking for additional particulars in support of their statements. At an earlier stage the Committee had caused a message to be sent by cable to Messrs. West and Raphael, of London, through the Agent-General of New South Wales, requesting them to forward the microbe cultures which were mentioned in their letter. (*See Appendix I.*) Letters were also addressed to Professor Ribbert, of Bonn, and to Professor Loeffler, of Greifswald, asking for information concerning the diseases of rabbits recently discovered by them.

It was further resolved,—

- (1.) That the Commission recommend the Governments of the respective Colonies to issue licenses to responsible persons who may desire to keep rabbits in confinement for the purpose of poison experiments.
- (2.) That the Commission recommend that licenses to keep rabbits in confinement be granted by the Governments of each Colony to any competent persons who may desire to conduct pathological inquiries concerning the destruction of rabbits.
- (3.) That these resolutions be transmitted to the Honorable the Secretary for Lands, and that he be requested to forward copies of them to the Governments of the other Colonies.

The Experiment Committee was authorised to subject to experiment, on the general experimental lines already laid down, any disease that might be submitted to them for examination, and that might seem worthy of investigation.

SUMMARY OF EVIDENCE.

The chief diseases which were submitted for consideration by the Commission were—

- (1.) Chicken-cholera.
- (2.) The so-called Tintinallogy disease.
- (3.) Bladder-worm (*cœnurus*).
- (4.) *Sarcoptes cuniculi* or Rabbit Scab.

The evidence concerning the usefulness of these diseases for the destruction of rabbits will now be stated as briefly as possible.

EVIDENCE

EVIDENCE CONCERNING CHICKEN CHOLERA.

The case in favour of the employment of the microbes of chicken-cholera as submitted by M. Pasteur and his representatives was very imperfect. It will be found stated in Appendix III, and in Section II of the detailed report, pp. 43-49. It may be summarized shortly as follows:—

M. Pasteur states that, though he had made no special study of rodents, he had often seen rabbits die in cages which had not been disinfected after fowls had succumbed to chicken-cholera in them; that he soon convinced himself that the least meal given to rabbits, after the food has been tainted with the microbes of chicken-cholera, will speedily entail the death of the rodents. At his instigation M. Loir put five rabbits in a box and fed them with infected food, and six hours later introduced three healthy rabbits into the same box. The five rabbits fed with infected food died, and also one of the three rabbits placed with them. On another occasion four rabbits were fed with infected food, and four healthy rabbits were placed with them. Within twenty-four hours the four infected rabbits were dead. Their carcasses were left in the box with the healthy rabbits. Of the healthy rabbits one was found dead on the third day, one on the fourth, one on the fifth, and one on the seventh. Tame rabbits were used in both these experiments. In all these instances it was verified, according to M. Pasteur, that death was due to the microbes of chicken-cholera. Swine, dogs, goats, sheep, rats, horses, and donkeys were fed with infected food, and not one of them became indisposed. The microbes can be grown easily in broth made of flesh, *e.g.*, the flesh of rabbits. They lose their virulence and perish at 51° Centigrade (124° Fah.); but when not exposed to the atmosphere they may be kept for years. In addition, M. Pasteur gave a short sketch of the experiment on the Pommery Estate. Here a large number of rabbits, penned up for purposes of sport in an enclosure measuring eight hectares*, were absolutely dependent for food on eight large trusses of hay† that were daily scattered about their burrows. On one day (Friday) this food was sprinkled with a fresh growth of the microbes of chicken-cholera. The food was consumed in a few minutes. On the day following the exposure of the infected food (Saturday), nineteen dead rabbits were seen outside the burrows. On Sunday no one visited the paddock. On Monday thirteen other dead rabbits were counted. The rest died in the burrows. Not a single live rabbit was seen after the day on which the fatal meal was given.

This was the sum of the evidence available prior to the arrival of M. Pasteur's representatives. These gentlemen stated before the Commission (1) that the virus was not weakened by transmission from one rabbit to another; (2) that there was no instance on record in France, within their knowledge, in which a natural epidemic of the disease among fowls had spread to rabbits; (3) that they had never heard of the epidemics among domestic fowls spreading to wild fowls; (4) that several diseases may kill rabbits, with very similar symptoms and *post-mortem* appearances; (5) that it was doubtful whether all the rabbits at Mme Pommery's Estate partook of the poisoned food, but that it was thought that the quantity exposed was not sufficient for all of them, and that therefore some must have communicated the disease to others.

The plan of spreading the disease, as proposed by the representatives of M. Pasteur, will be found on pages 45 and 46 of the detailed report.

M. PASTEUR'S EXPERIMENTS OF DEMONSTRATION.

The experimental station at Rodd Island being in readiness, and the negotiations with the representatives of M. Pasteur having advanced a stage, the experiments of demonstration prescribed by M. Pasteur were performed by M. Loir, Dr. Germont, and Dr. Hinds, between July 7th and August 4th, under the supervision of the Experiment Committee, and of Dr. Katz, the Chief Expert Officer of the Commission. It was shown that, as a rule, rabbits died speedily after eating food to which the broth-cultures of the microbes of chicken-cholera had

* A hectare is equivalent to 2 acres 1 rood 35 perches.

† See Appendix No. III.

had been added, or after inoculation with such cultures; when several rabbits were fed, in some instances all died, in others some survived; but the survivors invariably succumbed after a second or third feeding. The proof that the rabbits died from chicken-cholera was not as complete as was desirable, but a strong presumptive case was established. The next experiment was that dealing with the contagiousness of the disease. Five rabbits were inoculated with about two drops each of a broth-culture of the microbe, and thereafter placed with twenty healthy rabbits in an enclosure of one square metre area (*i.e.*, 3 feet 3 inches square). They were kept under observation for a period of seven days. The five inoculated rabbits died within fourteen and a half hours; of the twenty not inoculated five died within seventy-one hours, and from that time until the conclusion of the experiment no more died. The dead rabbits were left in the little enclosure to the end, but none of them were examined so as to obtain certainty as to the cause of death. The rabbits which survived ate food from off the bodies of the dead. Of twenty-five healthy rabbits kept in a similar enclosure for the same time three died without any introduction of infection.

Subsequently, the experiment was repeated with slight variation in another enclosure of the same size. Five rabbits fed on infected food were placed among twenty healthy rabbits. One of the five, through inadvertence, was not specially marked. The rabbits were kept under observation for ten days. Within this period eleven died. Among them were three of the five to which infected food had been given. One of the five survived. The fate of the fifth could not be decided owing to the omission to mark it. So that either seven or eight of the twenty healthy rabbits died. Blood from three of the eight unmarked rabbits which died was examined microscopically, and organisms agreeing in form with those of chicken-cholera were found. In two cases out of the three so examined, blood from the dead rabbits was inoculated into living rabbits; death followed, and similar organisms were found in the blood. A control experiment on twenty-five healthy rabbits was not made.

It was next shown that a horse, a cow, a sheep, a goat, a pig, and a dog did not suffer after many meals containing large doses of broth-cultures of the microbes of chicken-cholera.

When these experiments prescribed by M. Pasteur ended on August 4th, Dr. Katz, with the permission of M. Loir, took some blood from the heart of one of the rabbits which had died after eating infected food, and from this blood successive cultures of microbes were grown, which were used in the experiments conducted on behalf of the Commission. The experiments of demonstration, carried out according to the instructions of M. Pasteur, were regarded by the Commission as unsatisfactory. But it was now possible to institute a new series of tests which would fully try the real issue.

EXPERIMENTS WITH CHICKEN-CHOLERA MICROBES, CONDUCTED BY DR. KATZ, ON BEHALF OF THE COMMISSION.

These experiments are fully described in Section XI of the detailed report, so that only a brief summary need be given in this place. They were carried out chiefly in order to ascertain whether chicken-cholera will spread freely from infected to healthy rabbits. In some of the experiments, infected rabbits were allowed to be with healthy rabbits in artificial burrows, or in hutches, either with wooden bottoms or wire-netting bottoms; in other experiments healthy rabbits were put in hutches or boxes in which other rabbits had died of chicken-cholera. The artificial burrows varied from 16 to 70 feet in total length of the branching passages, and were so made that they could be easily opened. According to the size of the burrows, infected and healthy rabbits were let go into them in the respective numbers of one to two, two to four, three to six. In all, eight infected rabbits were placed with sixteen healthy ones. Within twenty-five minutes all the rabbits had found their way inside the burrows. A transmission of the disease from the sick to the healthy did not occur in any instance. Of the eight infected rabbits six died outside the burrows, and two inside. In the hutch experiments, ten infected rabbits were placed with twenty uninfected in eight wooden hutches, in six of

of which one infected rabbit was placed with two uninfected, while in two hutches two infected rabbits were associated with four uninfected. Four of the twenty uninfected rabbits contracted chicken-cholera in the hutches, and died in consequence. In five separate experiments single rabbits were placed in hutches or boxes in which other rabbits had died of chicken-cholera; all of these hutches or boxes contained droppings of infected animals, but the rabbits placed in them did not in any instance contract the disease. In the course of these experiments several facts were established:—

- (1.) Australian rabbits are killed in a very short time by the addition of small quantities of the microbes of chicken-cholera to their food, most of them dying in between twenty and twenty-four hours. Inoculation of cultures causes death in from seven and three-quarters to about fifteen hours. But on the other hand Dr. Katz stated in a summary report, dated November 21st, that "food material polluted with small portions of the contents of the rectum or cæcum of rabbits which succumbed to chicken-cholera (feeding) did not prove dangerous to healthy rabbits which ate it."
- (2.) The stage of incubation, or latency, occupies most of the time before death, the symptoms lasting but a short time.
- (3.) While chicken-cholera in fowls is a form of blood-poisoning attended with severe diarrhœa, the excreta being virulently infective, in rabbits the disease presents the characters of pure blood-poisoning, without diarrhœa or intestinal hæmorrhage. With few exceptions, the rectum or lowest portion of the bowel of rabbits dead from chicken-cholera contained ordinary faecal balls. In one rabbit, however, the contents of the rectum were soft; a rabbit, inoculated with a small quantity of this soft matter, died from chicken-cholera; but another rabbit, fed with a larger quantity, survived. In another series of experiments, two rabbits were fed with cabbage leaves, to which had been added part of the contents of the cæcum (or the first portion of the large intestine) of a rabbit dead from chicken-cholera; in neither case was chicken-cholera developed.
- (4.) So far as may be judged from one experiment, the urine of rabbits suffering from chicken-cholera is not infective.
- (5.) Dr. Katz frequently observed that blood-stained liquid exuded from the nostrils of rabbits which had been lying dead for some days from chicken-cholera.
- (6.) The virus of chicken-cholera preserves its infecting power for some time in putrid or putrefying matter; thus blood taken from a rabbit dead from this disease, kept for nineteen days and allowed to putrefy, caused a vigorous rabbit to die from chicken-cholera in less than seventeen hours; but after being kept for twenty-three days it failed to cause death when inoculated.
- (7.) In the course of putrefaction, moisture is necessarily present. But a series of experiments were performed to ascertain whether the process of drying at ordinary temperatures would prove fatal to the microbes. Sterilized silk threads were steeped in the blood of rabbits dead from chicken-cholera or in broth-cultures of the microbes of this disease. They were then dried in a desiccator at temperatures between 64.4° and 71.15° Fahr. From time to time these threads were placed under the skins of rabbits. Those steeped in blood lost their power of inducing chicken-cholera within four days; those steeped in broth-cultures even earlier. Similar threads were placed on sandy soil in baskets protected from rain and sun, and were successively inoculated into rabbits; the thermometer ranged from 68.9° to 84.65° Fahr.; threads soaked in blood lost their virulence in twenty-four hours; those steeped in broth-cultures in less than eight hours. In a subsequent series of experiments the basket and its contents were exposed to direct sunlight on a warm December day with southerly breeze; the threads steeped in broth-cultures failed to cause chicken-cholera after two hours exposure; but those soaked in blood retained their virulence longer, one of them inducing the disease after eight hours exposure. The general conclusion is that the process of drying even at comparatively low temperatures soon destroys the virulence of the microbes.

(8.)

XVIII

- (8.) The virulence of chicken-cholera did not vary in any important degree when the disease was transmitted from one rabbit to another, from this to yet another, and so onwards for twenty removes from the first rabbit.
- (9.) In rabbits newly dead from chicken-cholera, the blood in the heart contained comparatively few microbes, contrasting strongly in this respect with blood taken from rabbits which had been left untouched where they died for twelve, twenty-four, thirty-six or more hours. The relative abundance of the organisms some time after death impressed itself upon Dr. Katz in every instance in which a comparison was made.
- (10.) No wild rabbit has manifested immunity from the disease, but one of the tame rabbits experimented upon survived after repeated feedings and inoculations with virulent matter.
- (11.) The virus of chicken-cholera, administered through the digestive organs, proved fatal to two magpies, two butcher birds, and a blue jay (which are principally animal feeders), and to two wonga pigeons, one bronze wing pigeon, one rose breasted cockatoo, and two swamp quail (all of them vegetable feeders). One cockatoo, which resisted two feedings, died of chicken-cholera after inoculation. Of two laughing jackasses, one died after feeding with infected matter, but not from chicken-cholera; the other resisted two feedings, but died from the disease after inoculation. Two Maori hens (wekas) remained alive after one had been twice fed and once inoculated, and the other once fed and twice inoculated. Of six crows variously inoculated and fed with infected matter, three died of chicken-cholera and three survived. Five infected rabbits were allowed to die in an aviary containing nine fowls and twelve pigeons; their bodies remained there for periods varying from two to five weeks, and were much pecked, those which lay longest being torn into fragments, while the others were pecked open and largely devoured. One of the pigeons died of chicken-cholera within the five weeks occupied by the experiment and one fowl died of that disease shortly after the experiment terminated. Apparently the tendency of birds to contract chicken-cholera in this way is not great.
- (12.) Hares are very liable to take chicken-cholera, after feeding or inoculation.
- (13.) Ferrets are not liable to the disease, after either feeding or inoculation.

In the various experiments so conducted concerning chicken-cholera, it is all important to establish the fact that the microbes used were in reality those of chicken-cholera. It may, therefore, be stated (1) that the cultures were developed from the blood of a rabbit which died of chicken-cholera in the course of the experiments conducted by M. Pasteur's representatives; (2) that the course, symptoms and post-mortem appearances of the disease produced by the microbes agreed with those which characterize chicken-cholera; (3) that the blood of animals experimented upon contained microbes of characteristic form and reactions; (4) that cultures of these microbes presented typical appearances; and (5) that introduction of these cultures or of the blood of infected animals into healthy rabbits succeeded invariably in reproducing the disease.

DOES CHICKEN-CHOLERA EXIST IN AUSTRALASIA?

Section XII of the detailed report contains the results of inquiries made into the question, whether chicken-cholera exists in the Australasian colonies or not. A large number of suspicious outbreaks were reported to the Commission from New South Wales, Victoria, and New Zealand. When possible, specimens of the affected fowls were obtained. Dr. Katz was able to make an examination in nine cases; in none of these could the disease be identified as fowl-cholera. So far, therefore, there is no proof that the disease exists in these colonies.

XIX

colonies, but more extended observations and experiments are necessary to determine this question. Dr. Gamaleïa, of Odessa, recently stated that he had obtained bacteria of chicken-cholera from the intestines of normal pigeons; that these bacteria had only slight virulent power, but that they acquired virulent power as against pigeons and fowls after being transmitted through susceptible animals, such as rabbits and other rodents. Several experiments made by Dr. Katz lent no confirmation to these statements.

LARGE EXPERIMENT WITH CHICKEN-CHOLERA.

At this stage the Commission resolved that a larger experiment should be performed, so as to test fully, under conditions as natural as possible, whether chicken-cholera would spread from infected to healthy rabbits to such a degree as to warrant the dissemination of a disease which does spread naturally among domestic fowls, which has not been known to spread naturally among rabbits, and which has not been proved to exist among domestic fowls in these colonies.

The details of this large experiment are given in the progress report (No. III) furnished by Dr. Katz, which will be found in section XI of the detailed report, pp. 168-171. Shortly stated, the experiment was as follow:—On November 7th, a hundred rabbits were turned loose in an enclosure measuring 100 feet by 80 feet, and containing artificial burrows in all 185 feet long. These rabbits were in very poor condition. They had been caught in the dry country around Hay, N.S.W., and had suffered from partial starvation. Other rabbits from the same source were fed with cultures of the microbes of chicken-cholera and placed in the same enclosure, as follow:—Ten on November 7th, six on November 14th, and six on November 22nd. Of the twenty-two rabbits so introduced, twenty-one died before the 29th November, when the experiment terminated. Three of the twenty-one were removed after death; of these, one died from chicken-cholera, whilst two died from other causes. The remaining eighteen rabbits, according to Dr. Katz, died of chicken-cholera, and their bodies were left in the enclosure until the completion of the experiment. Of the hundred rabbits not specially fed, five died very quickly, and five other rabbits were put in their places. Between November 8th and 14th, fifty-two died; between November 15th and 22nd, seventeen died; and between November 23rd and 29th, ten died. Of the seventy-nine rabbits which so died, not one perished from chicken-cholera. All died, apparently, in consequence of the primary starvation.

The result of this experiment was unsatisfactory, owing to the great mortality which occurred among the rabbits from causes independent of chicken-cholera. The Commission therefore ordered that another experiment on a large scale should be conducted so soon as a sufficient number of strong healthy rabbits had been obtained, the experiment to be conducted strictly on the lines laid down by the Commission on October 15th.

This order was made on December 19th, 1888. Delay followed, owing to the difficulty experienced in obtaining a sufficient stock of healthy rabbits. Subsequently on January 2nd, a fire broke out at the experimental station on Rodd Island, the kitchen being destroyed, the shed and passages and main enclosure being damaged. The injury to the enclosure was not repaired till February 4th, and the kitchen was not rebuilt till an even later date. Meantime, between January 7th and 30th, one hundred and sixty-one live rabbits had been sent to the station in different consignments; but, in spite of attention to feeding and accommodation, large numbers died, only eighty-six surviving on February 4th. The second large experiment was commenced on February 12th, though the full number of rabbits required was not available till the 14th.

SECOND LARGE EXPERIMENT.

The main enclosure on the island was divided into two nearly equal divisions, separated from each other by a double fence of rabbit-netting, the space between the two fences being one yard wide. In each division there were
artificial

artificial burrows and special feeding places (see diagram 9). One division, called the disease division, was stocked on February 12th with fifty rabbits, most of which looked healthy; among these five well-conditioned rabbits were at once introduced, which had been fed on cabbage leaves, sprinkled for each rabbit with two cubic centimetres of a virulent broth-culture of the microbes of chicken-cholera. At the end of a week other five rabbits, infected in the same manner, were turned loose in the enclosure, and at the end of the second week five others, similarly fed. At the end of the third week, on March 5th, the experiment terminated. All the infected rabbits died speedily. Their bodies were allowed to remain in the enclosure, with one exception. In that instance, the rabbit had been much bruised, but the microbes of chicken-cholera were found in its blood. A control rabbit which died of chicken-cholera was put in its place in the enclosure. It may be inferred with confidence that the fourteen other infected rabbits died of chicken-cholera, because other rabbits fed at the same times, in the same manner, were proved to have died of this disease, and because many of the fourteen died with characteristic symptoms, and their bodies after death showed distinctive characters. Dr. Katz has now acquired such experience that he is able to recognize the symptoms during life, and the appearance of the carcass soon after death with some degree of certainty. Though the fifteen infected rabbits so introduced died of chicken-cholera, and though their bodies were allowed to remain to the close of the experiment, only four of the fifty rabbits originally placed in the disease division died of chicken-cholera. But no less than thirty-two rabbits died during the experiment from causes independent of chicken-cholera.

At the outset of the experiment, on February 12th, thirty-eight rabbits, mostly full-grown, were placed in the other half of the enclosure, called the control division. The majority of these rabbits were not in such good condition as those in the disease division. Two died almost immediately; and, when a fresh supply of rabbits arrived two days later, the number in the control enclosure was raised to fifty. No infected rabbits were introduced. Of the fifty, twenty-nine died during the course of the experiment. Dr. Katz satisfied himself in every case that death was not due to chicken-cholera.

The great mortality among the rabbits in both enclosures from causes other than chicken-cholera is attributed by Dr. Katz, in part at least, to the oppressive state of the atmosphere and the excessive heat prevailing at intervals during the course of the experiment. Injuries sustained by the rabbits in capture and during transit from the interior must also be taken into consideration. In examining the bodies of rabbits which died during this experiment from causes other than chicken-cholera, Dr. Katz found in quite a number of cases an appearance of the entrails resembling that found by Dr. Wilkinson in rabbits examined at Albemarle (*see* Appendix VII). Such rabbits, therefore, were in anything but a healthy state. In other rabbits the lungs were distinctly pneumonic. Before the experiment was commenced on February 12th ninety-one rabbits had died out of one hundred and ninety-one sent to the station. Even in the contagion experiments conducted by the representatives of M. Pasteur, which lasted only one week, and in which comparatively few rabbits were used, several deaths occurred from causes independent of chicken-cholera.

The details of this large experiment will be found in the Progress Report (No. V), submitted by Dr. Katz.

GENERAL CONCLUSION CONCERNING THE UTILITY OF CHICKEN-CHOLERA FOR THE DESTRUCTION OF RABBITS.

The Commission therefore finds that while rabbits are easily killed by the addition of the microbes of chicken-cholera to their food, the disease does not spread freely from infected to healthy rabbits. The disease in rabbits differs widely in this respect from chicken-cholera as seen among fowls. In poultry-yards it is virulently infective. The inquiries conducted on behalf of the Commission furnish a satisfactory explanation of the difference. Fowls infected with chicken-cholera suffer not only from blood poisoning but also from severe diarrhoea, and the droppings have power to spread the disease. On the contrary, infected rabbits, with

with few exceptions, remain free from diarrhoea, and die of pure blood poisoning. The microbes are chiefly in their blood. If these microbes are to infect other rabbits in any number the bodies of rabbits dead from the disease must be broken up by decomposition, or by the agency of carrion birds, &c., and the microbes so set free must contaminate the food of other rabbits. If the dead bodies lie in the burrows it will be remembered that rabbits do not feed there. If they lie in the open and the microbes are set free, a temperature of 124° Fah., or the mere process of drying at a much lower temperature, will suffice to destroy their virulence. Moreover, the experiments of Dr. Katz indicated that while the microbes retain their virulence for a time when mixed with putrefying matter, there is a limit to their power of survival. Generally, therefore, it appears that the destruction of rabbits on a large scale by chicken-cholera can be obtained only by feeding the rabbits with the microbes of the disease; and, as other poisons, such as arsenic and phosphorus, to the use of which no objection can be taken, will kill rabbits to which they are administered, the Commission cannot recommend that permission be given to disseminate broadcast through Australasia a disease which has not been shown to exist in these Colonies, which in other countries prevails in disastrous epidemics among fowls, but which has never been known to prevail naturally among rabbits.

EXPERIMENT WITH CHICKEN-CHOLERA UNDER NATURAL CONDITIONS.

It has already been made manifest that the Commission has arrived at an unfavourable conclusion concerning the practical utility of chicken-cholera for the destruction of rabbits. The Commission, in fact, does not feel justified in recommending any further expenditure by Government in testing the efficacy of this disease; but as M. Pasteur and his representatives desire that the microbes should be tried in an infested country under natural conditions, the question arises whether such experiments should be permitted. The investigations and experiments conducted by the Commission tend to prove that exaggerated notions have prevailed concerning both the probable spread of the disease from rabbit to rabbit and the contingent danger of spread from infected rabbits to birds. It has been made certain that chicken-cholera will not affect domestic animals other than birds. Even with the most susceptible animals the spread of the disease will be far less free in open country than among fowls in poultry yards. Certain wild birds, such as jackasses, crows, and cockatoos, are not so susceptible to infection as fowls or rabbits. Birds kept in an enclosure in which rabbits are dying or lying dead from chicken-cholera do not contract the disease in great numbers, though they peck freely at the carcasses. It may be urged that the experiments conducted at the station at Rodd Island, though very severe as regards the number of infected rabbits turned loose among healthy rabbits, and as regards the limited space within which diseased and healthy rabbits were penned together, do not furnish an absolute test of what would be the degree of contagion in an experiment conducted under natural conditions with natural food. The Commission, therefore, is not prepared to advise the Government of New South Wales to forbid the performance by M. Pasteur's representatives of an experiment in infested country under natural conditions, provided that such experiment be conducted on certain lines and subject to adequate precautions.

M. Pasteur's representatives, at their interview with the Commission on April 24th, 1888, spoke as follows: "We propose . . . to make an experiment on a larger scale in a space in the country, enclosed with rabbit-proof fencing, but otherwise under natural conditions. For this purpose we would go to a station, prepare there the broth, and make a cultivation; and this we would spread on food (natural, if available; if not, an artificial food—the cheapest to be procured in the neighbourhood) where the rabbits are thickest. From day to day we would go to the different parts of the area to spread the disease. We ask for this purpose an area of not greater extent than about 500 acres, for if we are able to prove that rabbits can be poisoned under natural conditions, the only question for future consideration will be the distribution of the poison. We consider that if we practically clear the area given to us for experiments it will be a fair and good test of the efficacy and practicability of the method advocated by M. Pasteur." Such

Such an experiment would, in the opinion of the Commission, be utterly unsatisfactory, whatever might be its result.

It has already been demonstrated that the microbes of chicken-cholera are deadly to rabbits, but do not injure domestic animals, excluding birds.

If M. Pasteur is to claim a reward of £25,000 simply on killing the rabbits in an area of 500 acres, his task is an easy one. No one doubts that such an area could be cleared with ease by means of chicken-cholera. But in such a case most, if not all, of the rabbits would be poisoned with infected food. No experiment can possess any value unless it is performed under such conditions that the main agent in the destruction of the rabbits shall be the spread of infection from diseased to healthy rabbits. One or other or both of the following experiments would be satisfactory:—(1) On an area of 500 acres of infested land, enclosed by netting-fencing, to catch from time to time a number of rabbits, infect them with chicken-cholera and turn them loose in their old haunts; (2) On a generally infested area of not less than 25,000 acres similarly enclosed, to lay food infected with microbe cultures at the discretion of the experimenters. In the former case all consequent mortality would be due to contagion; and in the latter case any approach to extermination would imply either a very extensive operation of contagion, or the use of such large quantities of infected food as to reduce the entire experiment to a mere competition between the present methods of poisoning, on the one hand, and the use of infected food (considered as a direct poison), on the other. In either experiment the enclosures should contain sufficient natural food to eliminate any possibility of death from starvation. There is obvious necessity for supervision by competent inspectors, and for the observance of all possible precautions.

The Commission, however, considers that the possibility of any useful results from such experiments is so remote, that its definite judgment on M. Pasteur's scheme, as above recorded, need not longer be withheld.

M. PASTEUR'S LETTER TO THE CHIEF INSPECTOR OF STOCK.

On the 1st October, 1888, M. Pasteur addressed a letter to Mr. Bruce, the Chief-Inspector of Stock in New South Wales. A free translation was published in the *Sydney Morning Herald*, and a copy of the published translation was forwarded to the Commission by the Under Secretary for Lands. Certain inaccuracies in the translation were calculated to cause misconception of M. Pasteur's position. The part of M. Pasteur's letter on which the Commission desires to comment, when literally translated, reads as follows* :—

"With regard to the rabbit plague, I have not confided further to any one the secret of the use on large scale of the means which I have proposed for the partial or total extermination of these rodents by the adoption of chicken cholera. It is to the Government of Sydney that I will make it known, if there be occasion. My representatives have only one thing to do, and I have sent them to do it, at the request of that Government: they have to show that I have proposed a means harmless to domestic animals, a means which kills the rabbits in twenty-four hours, after a single meal sprinkled with the microbes, and that this means is contagious, that is to say, that the rabbits which have taken the fatal meal communicate the disease and death in a notable manner to healthy rabbits, with which they are mixed, as they are in the burrows.

"How to arrange for the manufacture of the fatal ingredient, how to mix and use at a distance this ingredient with all its properties, that is my secret, about which the Commission is to see and know nothing for the present, and which I will only make known if the prize proposed on the 31st August, 1887, is awarded to me."

The

* "Quant au fléau des lapins, je n'ai pas davantage confié à personne le secret de l'application en grand du moyen que j'ai proposé pour l'extermination partielle ou totale de ces rongeurs, par l'emploi du choléra des poules. C'est au Gouvernement de Sydney que je le ferai connaître, s'il y a lieu.

"Mes représentants n'ont qu'une chose à faire, et je les ai envoyés la faire, à la demande de ce Gouvernement: ils ont à démontrer que j'ai proposé un moyen inoffensif pour les animaux domestiques, moyen qui tue les lapins en vingt-quatre heures à la suite d'un seul repas souillé par le microbe, et que ce moyen est contagieux; c'est-à-dire, que les lapins qui ont pris le repas mortel, communiquent d'une manière notable la maladie et la mort à des lapins sains auxquels ils sont mêlés, comme ils le sont dans les terriers.

"Comment disposer une fabrique de l'ingrédient mortel, comment ingrédier et utiliser au loin cet ingrédient avec toutes ses propriétés, là est mon secret, sur lequel la Commission n'a rien à voir ni à savoir pour le moment, et que je ne ferai connaître que si le prix, proposé le 31 août 1887, m'est attribué."

XXIII

The translation previously published implied that there was some essential secret concerning M. Pasteur's method kept back by him. From the original letter it is clear that M. Pasteur instructed his representatives to make, on a small scale, a demonstration of the efficacy and safety of his scheme; but that he retains the method of applying it on a large scale as his own secret, which he will make known only if the prize of £25,000 is awarded to him. M. Pasteur, however, seems not to understand the terms of the proclamation concerning the reward, which was offered to "any person or persons who *will make known and demonstrate* at his, or their own expense, any method or process, not previously known in the Colony, for the effectual extermination of rabbits."

According to M. Pasteur's letter, he sent his representatives to show, *inter alia*, that chicken-cholera was contagious; whereas, in point of fact, the Commission had the utmost difficulty in inducing his representatives to perform any experiment testing the contagiousness of the disease among rabbits. M. Pasteur's letter implies that he expects the reward to be adjudged him for his scheme on such proofs of its efficacy as he may determine, and before the mode of carrying it out on a large scale shall have been revealed.

MORTALITY AMONG RABBITS IN CERTAIN DISTRICTS.

From time to time great mortality has prevailed among rabbits in different parts of the Australasian Colonies. Thus, on the Ellenthorp property in Tasmania, about five years ago, a disease prevailed among rabbits, but not to such a degree as to exterminate them. On two other occasions disease appeared among the rabbits on two other estates in that Colony, 60 miles distant from each other, and destroyed all the rabbits. Two very recent instances of great mortality among rabbits have engaged the close attention of the Commission—namely, the so-called outbreak of disease at Tintinallogy Station, on the Darling River (N.S.W.), and the disappearance of rabbits from the Wairarapa district, in the North Island of New Zealand. Much information concerning the former will be found in this report, but no absolute conclusions can be arrived at in the absence of further experimental tests. The Commission is able to reprint an exhaustive report by Professor Thomas, of Auckland, on the causes of the mortality in the Wairarapa district.

THE SO-CALLED TINTINALLOGY DISEASE.

Tintinallogy is a station on the eastern bank of the Darling River, between Menindie and Wilcannia. It includes about 380 square miles of country appraised at one sheep to 7 acres, but more heavily stocked. Rabbits were present in 1884 when the present manager went to reside there; but they increased vastly in numbers in the following years. In 1885, 5,000 rabbits were killed on this station; in 1886, 32,000; in 1887, 291,000. The maximum was in the month of September, 1887, when twenty-two men killed 56,510 rabbits. Dr. Butcher, who was resident at the station, and Dr. Ellis, of Sydney, had discussed the probability of an outbreak of disease among the swarms of rabbits, and agreed to investigate any disease which might present itself. The so-called Tintinallogy disease appeared about $1\frac{1}{2}$ mile above the home station, and Dr. Butcher obtained a rabbit suffering from it at the beginning of September, 1887. He at once commenced a series of experiments to test the contagiousness of the disease, and reported the matter to the Minister of Mines. In consequence, orders came to destroy his rabbits. Proceeding to Sydney, he obtained permission to fence off with rabbit-proof netting a bend of the Darling, including about 500 acres, and to continue his experiments in this enclosure. He claims to have spread the disease through the bend, and subsequently through the Tintinallogy station by turning loose rabbits which he had infected artificially. His first attempt to infect the bend, early in November, 1887, failed, in his opinion, because he used rabbits from the back country which would not mingle with the bend rabbits. He then caught rabbits in the bend, infected them, and turned them loose in their old haunts. From that time, he says, the rabbits died in the bend. From the original centre of the outbreak,
the

the disease spread in all directions, and with great fatality. Dr. Butcher turned loose infected rabbits in various parts of the run, especially in places where the natural spread seemed to be checked. In five or six months from the first appearance of the mortality among the rabbits, Tintinallogy, which was so heavily infested before, became a thinly infested country. Mr. Tully, Inspector of Stock for the sheep district of Wilcaunia, was sent to Tintinallogy to report on the experiments made by Dr. Butcher concerning the transmission of the disease to stock. At his first visit early in January 1888, he saw little evidence of general mortality among the rabbits in the country which he passed through on his way to Tintinallogy. He saw no evidence of disease till his arrival within two or three miles of the home station; within this limit the rabbits were in very low condition, and he noticed carcasses lying about. In the bend he saw evidence of general mortality. At his second visit, early in February, he noticed a falling off in condition of the rabbits, which were apparently ill from some cause a much greater distance up the river, more than 9 miles from the station. There did not seem to be anything like the same number of live rabbits in the bend. Carcasses were lying about. There was still green feed along the river frontage. On his third visit, in the middle of March, there were very few rabbits left in the bend. Many dead rabbits were lying about, and the live rabbits were very weak. The river frontage was still in good condition, though dry and a little bare. The rabbits along the frontage outside the bend enclosure appeared more or less sickly, and their number had decreased amazingly. The rabbits were sickly for 20 miles up the river. He was quite satisfied that at the time of his first and second visits, the mortality could not have been due to starvation; and even at his third visit, the condition of the feed was not such that he could conclude that the mortality was due to starvation. Mr. Clarke, the Rabbit Inspector of the district, which includes Tintinallogy, Murtie, Billilla, Teraweynia and adjoining stations, stated that Tintinallogy was very heavily infested with rabbits; that the rabbits began to die in large numbers in November, 1887; that the feed was then good, and the condition of the stock good; that he had reported the decrease in the number of rabbits as 95 per cent. At Billilla and Teraweynia, on the Tintinallogy boundary, the mortality was also great. On Murtie, nearly 60 miles from Tintinallogy, the mortality was startling in its intensity and suddenness, as great an effect being produced in one month as in six months at Tintinallogy. The manager of Murtie is reported to have said that in one month (February) 80 per cent. of the rabbits died.

According to Dr. Butcher, the course of the disease is as follows:—The fur on the head stands up, the eyes are prominent, and there is a very slight discharge from the eyes and nose, lasting only three or four days. By the end of a week, emaciation is perceptible, the fur stands up all over the body, power is lost in the hind legs, so that when the rabbit tries to sit up, it falls over. Weakness and emaciation become more and more marked, and the animal dies in a kind of convulsion in about twenty or twenty-one days.

In the course of a large number of post-mortem examinations, Dr. Butcher found slight increase of serous fluid in the abdominal cavity; the liver blackish and friable, but not increased in size; the mesenteric glands swollen, and infiltrated with jelly-like fluid; and the glands above the kidneys (supra-renal glands) enlarged and altered in colour from dull white, the natural colour, to blood-red or black. He had found little nodules containing pulp in the liver in many cases, but these were absent in a large number of affected rabbits.

Dr. Ellis, in his evidence given at Sydney, said he had not noticed enlargement of the mesenteric glands, that the supra-renal bodies were red instead of white, and that points like tubercular abscesses were scattered over the surface and in the substance of the liver.

In examining diseased rabbits at Dr. Ellis' residence, the Commission noted chiefly the great emaciation, and the presence in the liver of lines and nodules of yellow pulpy matter, due to the growth in the bile ducts of a gregarinoid animal parasite, called *coccidium oviforme*.

During

During their visit to Tintinallogy, Dr. Bancroft and Dr. Wilkinson made examinations (post-mortem) of several rabbits suffering from the disease. The chief appearances were general emaciation of the body and darkening in colour of the liver. Dr. Wilkinson examined a number of rabbits suffering from the same disease at Albemarle station. He found emaciation, excess of fluid in the abdominal cavity, the liver dark-blue or black, and very friable, the supra-renal capsules, spleen and kidneys healthy; but there was invariable evidence of catarrhal inflammation of the stomach, with small patches of hæmorrhage in the lining membrane, and in many cases erosions, or even ulcerations of the surface. Signs of chronic inflammation were present in other parts of the alimentary canal.

Dr. Butcher found a scabby skin disease prevalent among the rabbits, and also, in constant association with this skin disease, cheesy deposits in the muscles. But in the great majority of the rabbits suffering from the so-called Tintinallogy disease the skin was healthy. The skin disease had been known in the district for some considerable time.

Dr. Butcher's experiments concerning the transmission of the disease from affected rabbits to healthy rabbits are described with great fulness in the detailed report (pp. 73 to 79). Blood-clot, blood serum, and the substance of the liver or the supra-renal glands mashed up in water, were used to communicate the disease. The infective matter was introduced into other rabbits by injection beneath the skin with a hypodermic syringe, by inoculation into a vein, and by the passage of a seton steeped in infective matter beneath the skin. In all these ways the disease was reproduced. A few animals operated on died from septic poisoning in a few days, others from various accidents, but in the great majority of cases the disease was produced and ran its regular course, death ensuing usually on or about the 16th or 17th day. Control rabbits, kept under similar conditions, but not inoculated, did not die. The rabbits experimented on were well cared for in every way. Infected rabbits having been kept in a certain crate, other rabbits placed in the empty crate contracted the disease. A rabbit suffering from the natural disease was put with sixteen rabbits in a yard measuring 10 ft. x 12 ft.; all the rabbits died between the 18th and 23rd day. One inoculated rabbit was placed in a crate with six other rabbits; after 24 hours the inoculated rabbit was removed; the six rabbits died on the 19th and 20th days. A diseased rabbit caught in the bend was placed in a yard 20 ft. x 24 ft. with thirty-eight other rabbits; the bend rabbit died in 9 days, all the other rabbits died between the 19th and 24th days, the one remaining rabbit was lost sight of. In each case, some kind of control experiment was conducted. Thus, in the last instance, ten rabbits were kept in a similar yard under similar conditions, and these all remained alive. Diseased rabbits caught in the bend were nursed and fed; but they died in the usual way. A number of sheep, a horse and a calf, variously inoculated, remained healthy. The carcasses of rabbits lying dead from the disease in various parts of the run were eaten by dogs, cats, pigs, fowls, crows and hawks. None of these animals died except cats. The cats died in great numbers. When the Executive Committee visited Tintinallogy, the bodies of eighteen cats were seen on the bank of the river. Two of these cats were examined by Dr. Bancroft and Dr. Wilkinson. They died fat; inflammation with exudation was present in part of the small intestine.

The witnesses examined before the Commission at Silverton, and by the Executive Committee, varied greatly in their views concerning the cause of the great mortality among the rabbits at Tintinallogy. Thus, Mr. Sadler, the general manager of the Albemarle station, on which, also, the disease made its appearance, believed that it was produced by the food. He remarked that "A very similar disease to the present one—in fact, identical, so far as I can observe—has displayed itself on this station during the summer in previous years; but as these seasons were unusually good, and the feed abundant, it did not last long, and the rabbits seemed to get quite healthy again. . . . At the present time, since the rain a fortnight ago, the rabbits are becoming quite active, and getting quite strong." Mr. Vindin, Superintending Inspector of the Rabbit Department of New South Wales, was at Tintinallogy from the 5th to the 9th March. He came to the

conclusion that the rabbits were dying of some disease, and that the disease was caused by the dryness and poverty of the feed. Over a large part of his district, since the beginning of March, there had been great mortality among the rabbits, which he ascribed to the condition of the feed. His general conclusion was, that the rabbits at Tintinallogy died through eating dry feed and astringent barks, and through want of nourishing food; and that, as the feed improved, the disease would disappear to a great extent, and the rabbits would recover. Mr. Brown, manager and part-owner of Kallara Station, visited Tintinallogy on behalf of the Wilcannia Pastoral Association. He held that the disease was Nature's remedy for the plethora of rabbits; but he thought that it was closely connected with the condition of the feed—"Where the rabbits are very thick, and feed very scarce, there this disease appears." The theory that the mortality was directly due to the rabbits eating bark, through want of other succulent food, was not supported by the general tenor of the evidence given before the Commission. It was stated, on the contrary, that the rabbits died in the open country as well as where scrub was abundant, and that the rabbits were not dying in some parts where the barking of the shrubs had been extreme.

Amidst these diversities of opinion, it was all-important that the experimental results should be placed beyond question. But the experiments conducted by Dr. Butcher cannot be regarded as conclusive. They were not watched by any competent independent observer. The rabbits used in them were obtained from the run, on which vast numbers of rabbits were dying naturally from the so-called disease. Hence, comparatively little weight can be attached to Dr. Butcher's results unless they be confirmed by a disinterested expert, working with rabbits obtained from a district where no unusual mortality prevails. Why, then, were such experiments not performed under the direction of the Commission? For the simple reason that Drs. Butcher and Ellis would not, or, at all events, did not, furnish diseased rabbits to the Commission, though repeatedly requested to supply them.

The history of the correspondence between the Commission and Drs. Butcher and Ellis may be shortly stated as follows:—The Commission, having heard the evidence of Dr. Ellis on April 17th, resolved on the 23rd that experiments be at once made on behalf of the Commission with the disease suggested by Drs. Butcher and Ellis. On April 24th, a schedule of experiments was adopted for the testing of the so-called Tintinallogy disease. On April 26th, the Commission advised that licenses to prosecute their experiments with the said disease might be granted to Drs. Butcher and Ellis, with safety to the public health. It was then clearly understood that Dr. Ellis would forward to the Commission rabbits suffering from the so-called disease. On May 28th, the evidence of Dr. Butcher was taken at Silvertown. On June 21st, as fears were expressed that the control of the disease would be lost, owing to the limited number of rabbits obtainable at Tintinallogy, the Commission advised that Drs. Butcher and Ellis be granted permission to employ the so-called Tintinallogy disease among rabbits in such districts as they may desire, provided that the places in which the disease is being employed be notified to the Commission. It was further resolved, that Dr. Ellis be requested to forward to Dr. Katz as soon as possible fifty rabbits suffering from the so-called disease; or if fifty were not quickly available, to send, in the first instance, such number as might be forthcoming. On August 18th, the Chairman of the Experiment Committee reported that no further communication had been received from Drs. Butcher and Ellis; that no experiments with the Tintinallogy disease had been conducted, owing to rabbits not having been supplied; and that he was unable to say when rabbits affected with the disease would be forthcoming. It was resolved that a communication be addressed both to Dr. Butcher and to Dr. Ellis, asking whether their experiments were being conducted in new country in accordance with the permission granted on 21st June, and enquiring when they would be able to provide twenty rabbits, suffering from the said disease, for the purpose of experiments under the direction of the Commission; that Messrs. Butcher and Ellis be also reminded that the permission granted to them to establish this so-called disease in fresh country was merely intended to prevent the disease from being lost, and did

did not involve approval of their scheme by the Commission. On October 13th, a letter from Dr. Butcher was read, complaining that his account for expenses for his attendance at Silverton had not been attended to, and intimating that no infected rabbits would be forwarded until such account was paid, and a guarantee given to refund the cost of the carriage of such rabbits to Sydney. A scale of payment for the expenses of witnesses was adopted; provision was made for the payment of Dr. Butcher's expenses according to this scale; and it was resolved that Drs. Butcher and Ellis be again requested as speedily as possible to forward to Sydney fifty rabbits suffering from the so-called Tintinallong disease, or such less number as may be forthcoming—the Commission undertaking to defray the expenses of conveying such rabbits to Sydney. Dr. Butcher intimated that, being at considerable expense through his experiments, he had closed his camp at the bend and could not provide rabbits, but that, on receipt of his expenses as already applied for, he would re-open the camp. The Commission regards the neglect by Drs. Butcher and Ellis to supply rabbits suffering from the disease as highly unsatisfactory. The failure to supply such rabbits was of long standing, before any difficulty arose concerning expenses.

The Commission finds it hard to believe that the abandonment of this scheme by its promoters was due to the alleged illiberality of the official scale of expenses. The Commission is not in a position to state whether, independently of conditions arising directly from starvation, any disease, and especially any communicable disease, existed at Tintinallong. The balance of the very imperfect evidence at present available appears to incline to the negative.

BLADDER WORM AND COCCIDIAL DISEASES IN NEW ZEALAND.

Section IV of the detailed report, pages 115 to 123, consists of the evidence of Mr. Coleman Phillips, concerning the disappearance of rabbits from the South Wairarapa district of the North Island of New Zealand. This district contains over a million acres, and the rabbits, which a few years ago were swarming in the country, have almost entirely disappeared. According to Mr. Phillips, the poisoning operations conducted in 1883-4 were not successful; and in the South Island, where millions of rabbits have been destroyed by poison, the plague is as severe as ever. He attributes the success in the Wairarapa district to the ravages of the bladder worm, which is an encysted parasite, forming a bladder-like tumour in the muscles of rabbits. The mature form of the parasite is a tape worm, found in the intestines of dogs. Segments of these tape worms, or the eggs thereof, pass from the intestines of the dogs, and, when eaten by rabbits with their food, produce the bladder worm; just as the little echinococcus tape worm in the dog leads to the hydatid cyst in man. In this bladder worm, heads of new worms develop in large numbers. Dogs in turn feed on the flesh of rabbits containing bladders, and the heads thus swallowed form new tape worms in the intestines of the dogs. This cycle is constantly being repeated. Mr. Coleman Phillips therefore recommends that all dogs at stations where rabbits abound be fed on rabbit flesh till they get thoroughly infested with these worms, so as to become thin and mangy in appearance; that they then receive doses of areca nut, so that the worms may be expelled. The segments with their myriads of contained eggs will then infect the grass. Rabbits will eat the grass and develop the bladder worm. Mr. Phillips thinks that other natural enemies of rabbits, such as ferrets, stoats, weasels, cats, and hawks may also harbour the parasite in its tape worm stage, and thus assist in propagating the bladder worm among rabbits. He maintains that these natural enemies of rabbits slay by the parasites contained in their excreta, and not by directly killing the rabbits; that the process is slow, but effectual.

Professor Thomas, of University College, Auckland, made an inquiry into the causation of the disappearance of rabbits from the Wairarapa district, and his Report to the Honorable the Minister of Lands of New Zealand will be found reprinted in full in Appendix VIII. The Commission regards this Report by Professor Thomas as most valuable. He concludes that the decrease
of

of rabbits in the Wairarapa has, in the first place, been due to the measures adopted by man, especially the winter poisoning; but that certain parasitic diseases have appeared in the district, have been widely but unequally prevalent, and have assisted, to a small extent, in keeping down the rabbits. These parasitic diseases include—(1) the bladder worm (*cœnurus*) of which Professor Thomas gives an excellent history, and the smaller bladder worm (*Cysticercus pisiformis*); (2) the *coccidia** or gregarinoid animals which have already been referred to in connection with the so-called Tintinallody disease; (3) the rabbit mange, itch, or scab; and (4) the rabbit louse. The little mite which causes the scab disease is distinct from the *Sarcoptes cuniculi* experimented upon by Professor Watson; it lives on the surface of the skin and is comparatively harmless. In the opinion of Professor Thomas, the effects of this mite, and of the larger louse, are seldom so serious as to lead to the death of a rabbit infested with them. Professor Thomas found comparatively few rabbits affected with the bladder worm, but rabbiters told him that 20 per cent. were not uncommonly infested. Infested rabbits usually contained only one bladder, some had two, and in one instance of the natural disease Professor Thomas found three bladders. The bladder-like cyst is usually situated among the muscles in one of the limbs, the trunk, or the head, but may be in the internal parts of the body. It may reach the size of an orange, and consists of a gelatinous membranous sac full of clear fluid, and supported externally by the thickened tissues of the part in which it lies. The inner surface is dotted with minute heads of future worms.

“Avoiding unnecessary details,” (writes Professor Thomas) “we may say that the effect of a single bladder-worm will, as a rule, hardly be shown during the first three or four months, but that afterwards, as it continues to increase in size, it may be a source of weakness to the rabbit; but I have not been able to find any evidence that a rabbit affected with a single bladder-worm only might not live till death came to it from some other natural cause. But with the increase of the number of parasites the tax on the strength of the rabbit becomes greater than it can bear, and it succumbs to the burden, sometimes directly, sometimes indirectly, being brought into a low and weak condition, in which it readily falls a victim to other adverse influences, such as weather, scarcity of food, or enemies.”

The presence of one, or at most two, bladder-cysts indicates that as a rule the rabbit swallows isolated eggs of the tape-worm; but Professor Thomas' experiments showed that when whole segments were swallowed, little bladder-cysts grew in multitudes in the tissues, and death followed from the disturbance so caused. It is difficult to estimate how often such an event occurs in the natural process of infection.

The researches of Professor Thomas prove that the bladder worm of rabbits and the tape worm of the dog from which it is derived are perfectly distinct from the *cœnurus* which sometimes proves fatal to sheep. Stock of all kinds that fed on the same ground with the diseased rabbits remained in good condition. A few experiments on ferrets and cats gave Professor Thomas no reason to think that any animals except dogs could be the bearers or hosts of the adult tape-worm.

The smaller bladder-worm of the rabbit (*Cysticercus pisiformis*) was found by Professor Thomas in only two of the rabbits from the Wairarapa district, but it was present almost constantly in rabbits caught in the Waikato, each rabbit usually containing one to ten specimens. This bladder-worm is round, about the size of a pea, and is found free in the abdominal cavity, or, at a later stage of development, adherent to the lining membrane, usually in that part forming the great omentum or that covering the rectum. “When present in small numbers it causes very little injury to the rabbit It must be seldom, however, that this parasite can, under conditions obtaining in nature, cause the death of a rabbit.”

Professor

* Further information concerning *coccidia*, with magnified representations of the lesions caused by them, will be found in Appendices V and VI.

Professor Thomas found *coccidia* in the liver more prevalent than the bladder worm, and apparently productive of more serious mischief. *Coccidia* spread from infested rabbits to healthy rabbits through the droppings of the former falling on to the food which is eaten, or being carried into water which is drunk by the latter.

Immediately before summarizing his general results, Professor Thomas writes as follows on parasitic diseases generally:—

“One of the most prominent characteristics of parasitic diseases is their unequal development in different localities and in different seasons. So, with reference to the diseases due to the bladder-worm and liver coccidia, we may expect in some localities a more extensive development and useful results, whilst in other localities the diseases may not meet with the necessary conditions, and little or no good may result. Further, we have seen that moisture is favourable to the spread of these diseases; we may expect them therefore to be more prevalent in moist or ill-drained localities, and to be more useful in wet seasons and climates than in dry ones. Hence, over a great part of Australia the diseases would be less effective than in New Zealand.

“When animals of the same kind are densely crowded together on the same ground, as is the case with the rabbits in the infected districts, one of the conditions for the spread of a parasitic or infectious disease is best fulfilled. When the number of animals is reduced, the danger of infection will diminish.”

Professor Thomas summarizes his conclusions as follows:—

- “1. The reduction of rabbits in the Wairarapa has been chiefly due to measures adopted by man. The most valuable of these measures has been the winter poisoning, which has been followed up during the rest of the year by trapping, &c. Cats and ferrets, too, seem to have done good work.
- “2. Certain parasitic diseases have appeared in the district, and have been widely, though unequally, prevalent.
- “3. Of these parasitic diseases two only—those due to bladder-worm and liver coccidia—deserve special notice as being capable of destroying rabbits. There is reason to believe that these have assisted to a small extent in destroying rabbits in the district.
- “4. The employment of the liver coccidia for the destruction of rabbits cannot be advocated, as in rare instances the parasites have been known to attack man. They are, however, present in the district, and it would probably be impossible to suppress them. Fortunately the danger to human beings is very small indeed, and the disease may prove of further use in killing rabbits.
- “5. The bladder-worm may be usefully employed against the rabbit pest; but it must not be expected that it will destroy more than a small percentage of the rabbits in the district. Like all parasitic diseases, it is variable and apparently capricious in its distribution, and its propagation is limited by conditions which will vary with the locality and season. It would be more useful in a moist climate than in one which is hot and dry. It assuredly cannot be regarded as furnishing alone a sufficient means of dealing with the rabbit pest, nor will it render unnecessary the ordinary methods of the destruction of rabbits, but must be looked upon as simply a minor and auxiliary means of destruction.”

A rabbit suffering from bladder worm was brought from New Zealand by Sir James Hector, for examination by the Commission. It was received at the station on June 16th. Since then the bladder has increased in size, but otherwise the rabbit seems in a normal state.

Mr. Hawkins, of North Wairarapa, in a letter recently addressed to the Commission, states that, during the past seven years, rabbits have not decreased in numbers in his district, though the bladder worm has been prevalent. He states that ferrets thrive exceedingly well in South Wairarapa, but did not multiply freely in the North. He holds that the great diminution of the rabbit pest

pest in South Wairarapa has been due, not to the bladder worm disease, but to the great multiplication of ferrets. His letter will be found in Appendix IX.

In the opinion of the Commission, the receipt of Professor Thomas' full report renders it unnecessary that the Commission should make any further inquiry concerning the bladder worm disease.

SARCOPTES CUNICULI OR RABBIT SCAB.

In March 1887, Professor Watson, of the University of Adelaide, succeeded in importing from Germany six rabbits suffering from the *Sarcoptes cuniculi* or rabbit scab. He placed them in an enclosure about 50 feet square with a number of Australian wild rabbits. The latter contracted the same disease and died, some in two, some in three, and some in six months. The *Sarcoptes cuniculi* is the itch-mite of the rabbit, an animal parasite which lives in the fur, the female burrowing and depositing eggs in the skin. The insect is only a quarter of the size of the scab insect in sheep. It causes great irritation of the skin, and enlargement of the lymphatic or absorbent glands. The affected animals die of wasting and exhaustion. In Germany, where the *sarcoptes* has been chiefly studied, septic poisoning usually occurs, with suppuration in the absorbent glands; but this complication was absent in the rabbits subjected to experiment in Adelaide. The fur of rabbits infested with the *sarcoptes* was repeatedly inserted in the wool of sheep without any ill effect. Attempts to communicate the rabbit scab to man, and to a dog and cat, failed. It thus appeared probable that the *sarcoptes* could be utilised for the wholesale destruction of rabbits. But the spread of the parasite from infested rabbits to healthy rabbits, and the fatal development of the disease, occurred in the wet season. As soon as the dry season set in, the infested rabbits, which had been suffering severely, proceeded to recover in the most thorough manner. Professor Watson satisfied himself that the *sarcoptes* would not be of any practical utility for the destruction of rabbits in the dry parts of Australia, but he is not satisfied whether it might not be of service in districts which possess a moist climate. While the results were still favourable, Professor Watson sold all his stock of infested rabbits. The subsequent history of these rabbits, as described by several witnesses, did not encourage any hope that material assistance in dealing with the rabbit plague would be obtained by use of the *Sarcoptes cuniculi*, at all events in the dry districts of Australia.

OTHER SCHEMES FOR THE DESTRUCTION OF RABBITS BY DISEASE.

Suggestions for the destruction of rabbits by disease were submitted by one hundred and fifteen correspondents for consideration by the Commission. Of these, 26 were from New South Wales, 8 from Victoria, 3 from South Australia, 3 from Queensland, 6 from New Zealand, 2 from Tasmania, 1 from Fiji, 15 from England, 4 from Scotland, 1 from Ireland, 12 from France, 3 from Belgium, 2 from Germany, 2 from Switzerland, 2 from Spain, 1 from Italy, 1 from Austria, 1 from Roumania, 17 from the United States, 1 from Canada, 1 from India, 1 from Netherlands India, and 2 from South Africa. Most of these schemes were classified and reported upon by a special committee, and the results of the labours of that committee are recorded in Appendix 1, pages The remaining schemes came under the notice of the Commission at a later date, and were classified by Mr. Pearson, whose report appears in the supplement to Appendix I, page According to these reports, in which the Commission fully concurs, many of the schemes are vague, no specific disease being mentioned, or merely "a disease" said to be peculiar to rabbits. In many instances the use of diseases dangerous to man or to domestic animals is recommended, such as small-pox, syphilis, glanders, hydrophobia, tuberculosis, &c. Other correspondents suggest the employment of nasal catarrh, which is mentioned by Leuckart as peculiar and fatal to rabbits; of the liver-worm, which is said to have killed great numbers of rabbits in Colorado; of diseases which have decimated the wallabies and opossums in certain districts, &c. In all cases in which there seemed to be any possibility that the disease mentioned would prove useful, letters asking for further information were sent

sent to the correspondents concerned. Communications were also addressed to Professor Ribbert, of Bonn, and Professor Loeffler, of Greifswald, requesting fuller details concerning diseases recently described by them as peculiar to rabbits. In two instances replies were received stating that the original correspondents had disappeared. A letter from M. Laplanche, of Fismes, was unfortunately lost in transit, and a request for a copy of the same has been forwarded. One proposal was that as disease always breaks out when animals are crowded together, rabbits should be placed in an enclosure, fed well, and encouraged to breed freely, and that when any disease manifested itself among them attempts should be made to spread it widely.

The Commission has found no evidence to warrant the belief that any known disease can be so employed as to exterminate rabbits. Probably many diseases will be found useful auxiliaries in reducing the rabbit plague within manageable proportions. Further inquiry by competent observers into the epidemic and parasitic diseases of rabbits should be encouraged. But even when much fuller information concerning these diseases shall have been obtained, it will still be necessary, in the opinion of this Commission, to continue the methods of suppressing the pest which are now generally adopted, subject to such improvements in detail as may from time to time be discovered.

SCHEMES FOR THE DESTRUCTION OF RABBITS OTHERWISE THAN BY DISEASE.

About fourteen hundred schemes for the destruction of rabbits by means other than disease have been referred to this Commission. It was intended that the schemes should be classified and reported upon by a special committee prior to the publication of this Report, but the mass of the correspondence has rendered it impossible to complete this labour. The Commission trusts to be able, within the space of six weeks, to submit this classified list of schemes, with notes on the merits of the several proposals.

On certain points, however, the Commission has arrived at definite conclusions, the chief of which may be formulated as follow:—

- (1.) That the responsibility for the destruction of rabbits, whether on freehold or on leasehold land, must rest on the landholder. That, with respect to unoccupied Crown lands, the State must accept similar responsibility.
- (2.) That the rabbit pest has made the continuance of the system of annual leases of Crown lands impossible.
- (3.) That no finality in rabbit destruction will be obtained without making the erection of rabbit-proof fences compulsory.
- (4.) That there are very large areas of land so poor that the erection of rabbit-proof fences around individual holdings might cause financial failure. That the Department administering the Rabbit Destruction Acts should be empowered to permit the fencing of such poor holdings in groups. That in dealing with land of very poor carrying capacity the State should show special consideration to the lessees in respect of tenure.
- (5.) That in all infested country, but especially in such poor districts, simultaneous operations for the destruction of rabbits should be made compulsory.
- (6.) That netting fencing, 3 feet high, with a mesh of $1\frac{1}{2}$ inch, forms a practically efficient barrier against the incursions of rabbits.
- (7.) That the system of compulsory trapping, with professional trappers and State bonuses, is radically bad.
- (8.) That legislative measures should be taken compelling land owners or lessees in districts infested by rabbits to join, subject to the above provisions, in payment of the cost of rabbit-proof netting fences or in the addition of such netting to existing fences.

In the opinion of the Commission these propositions require little explanation or argument in their favour. Responsibility for the destruction of rabbits must be placed somewhere. To whom can it be assigned but to the holder of the land, whether owner or lessee? Boundary fences would then be paid for jointly by neighbours. The State must take all the responsibilities of ownership with reference to unoccupied Crown lands, both as to destruction of rabbits and joint payment of the cost of boundary fences. In infested country the leasehold occupiers of Crown lands must have certainty that, if they expend the money necessary for the destruction of rabbits and for the protection of their lands, they will enjoy for a fair term the fruit of their labours. The contest with rabbits is most difficult in the huge resumed areas of poor land now held under ordinary squatting tenure. To break up these large holdings at once into small blocks is to postpone the adoption of effective measures for the destruction of rabbits. The first work in saving these lands must be done by large holders; and the necessary expenditure will not be incurred unless there is a reasonable security of return. In every large leasehold of this character it should be arranged that at intervals a certain fraction of the whole should be open for resumption. There would then be no sound reason for complaint either by the State, the lessee, or the selector. The necessity for rabbit-proof fencing scarcely needs demonstration. However stringent supervision may be, action on adjoining holdings will fail in certain cases to be simultaneous, and the holder who acts promptly will find in the absence of fencing that the respite from the plague is but temporary, while the holder whose lands abut on unoccupied hilly or scrubby country will see all his operations futile. When once rabbit-proof fences are erected the reduction of the pest within manageable proportions is a question simply of time and money. Yet, with large areas of land of very poor carrying capacity, the erection of rabbit-proof fencing around individual holdings may not be financially practicable. These areas must be fenced off from the better land around, and the *simultaneous* pursuance of the best known methods of rabbit destruction must be made compulsory. The Commission, realizing that the cost of netting fencing was a great difficulty, made careful inquiry concerning the minimum height and the maximum mesh which would prove effective. Abundant evidence will be found in the proceedings in favour of the decision of the Commission: that netting fencing 3 feet high, with 1½ inch mesh, is for all practical purposes an effective barrier. Such was the almost unvarying testimony of those witnesses who had practical experience with netting of this width and mesh. Rabbits die of starvation when their warrens are encircled with this netting; gardens protected by it are free from invasion, though the infested country around is dry and bare. Little weight can be attached to the opinions of witnesses who never used such netting, and still less to experiments in which rabbits are chased in small enclosures.

The system of compulsory trapping, with professional rabbiters and State bonuses, is radically bad. Rabbiting parties settle down in thickly-infested country and speedily kill multitudes of rabbits; as soon as the numbers are greatly thinned, a longer stay is unremunerative. No attempt at extermination is made. The party moves on to another place favourable for its operations, leaving the remaining rabbits to multiply ready for its next visit. Large sums are paid to such parties *per capita*. The station hands are demoralised. The State treasury is depleted of hundreds of thousands of pounds, and with what result? The rabbits are as numerous as ever; the operations of the trappers simply drive them more and more widely over the country; the landholders are disgusted at being forced to assist in a practice which they condemn; and no good whatever is done except to the rabbiters themselves, who fatten on a pernicious system. The Commission expresses its satisfaction that the Rabbit Department of New South Wales has resolutely turned its back upon this wasteful policy. It must not be inferred that the Commission objects to traps and trapping parties *per se*. Trapping is, without doubt, a useful method, but should be carried out by station hands, and with a view to the extermination of rabbits, not to profitable employment.*

It

* This limited recommendation of trapping must be held to apply only to areas enclosed by wire-netting fences, and in which the propagation of natural enemies of rabbits is not being encouraged.

XXXIII

It remains only to record that the first-appointed President of the Commission, Dr. MacLaurin, was able to attend but few of the meetings; that Professor Allen, as acting-Chairman, undertook the general direction of the business of the Commission; that on August 18 it was notified to the Commission that Dr. MacLaurin's resignation of membership had been received, and that at the repeated request of the Commission, Professor Allen finally accepted the office of President.

Certified under our hands and seals this third day of April, 1889,—

(L.S.)	H. B. ALLEN (PRESIDENT),
(L.S.)	W. CAMAC WILKINSON,
(L.S.)	EDWARD QUIN,
(L.S.)	E. H. LASCELLES, <i>per</i> H. MAHON,
(L.S.)	A. D. BELL,
(L.S.)	HENRY TRYON,
(L.S.)	THOMAS A. TABART, <i>per</i> H. MAHON,
(L.S.)	JOSEPH BANCROFT, <i>per</i> H. MAHON,
(L.S.)	ALEX. S. PATERSON, <i>per</i> H. MAHON.

DISSENT I.

In opposition to the majority of our colleagues we submit that M. Pasteur's representatives should not be permitted to make experiments with chicken-cholera microbes in infested inland country protected only by netting-fencing.

The experiments made under the direction of the Commission show that chicken-cholera has very little tendency to spread from infected to healthy rabbits. This result agrees with the fact that in France and elsewhere the disease has not been known to prevail among rabbits when it was devastating the poultry farms. Hence, if used for the destruction of rabbits, the microbes of chicken-cholera must owe almost all their value to their action as direct poisons to the rabbits which eat them. A certain quantity of a broth culture of these microbes will kill a rabbit, but so also will a certain dose of phosphorus, arsenic, or strychnine. For the preparation of cultures and their maintenance in full virulence the services of experts are necessary. The cultures lose their virulence on drying at ordinary temperatures or on short exposure to the sun's rays on a warm summer day. Hence as a direct poison the microbes must be more expensive, less stable, less manageable, than the poisons now in use. So far as this paragraph is concerned we believe that our statements have the concurrence of our colleagues.

In our opinion, a small experiment with chicken-cholera on an inland area is of no service, except as a preliminary to the wide dissemination of the microbes through the huge areas of infested country. Such dissemination would entail risk to wild birds, though the experiments of the Commission show that the risk is not so great as might have been anticipated. The chief risk is the remote one to domestic fowls. It has not been shown that chicken-cholera exists among fowls in Australasia. The introduction of any new disease should be forbidden unless some decided benefit is clearly to be secured; the wide dissemination of a new disease is specially objectionable. In face of the final conclusion of the Commission that chicken-cholera should not be disseminated broadcast in the infested parts of Australia, we regard any limited experiment in open country as useless and not devoid of danger.

DISSENT II.

I dissent from the decision arrived at by the majority of my colleagues to withdraw opposition to the introduction of fowl-cholera microbes into the country; and the following are the reasons for my dissent:—

The action of the Commission as set forth in this resolution is opposed to their past action, as especially set forth in the proceedings, and report of the Experiment Committee, page 130 at the top, and page 135, 23rd line from the top.

The chain of reasoning by which my colleagues endeavour to link the present with the former action of the Commission may be briefly presented as follows:—

Although the experiments at Rodd Island have throughout indicated that chicken-cholera has so low a degree of contagion amongst rabbits that there is next to no probability of its possessing any special merits as a means of destroying these pests, yet, it is just possible that there may be in the open country some condition, not existing at Rodd Island, which would operate in favour of the contagiousness of the disease. And, because this is possible, it would be more conclusive to have the experiment tried under entirely natural conditions.

The

The original objection to admitting the microbes into the interior for the purposes of experiment in the open was that there might perhaps be danger to the public health, to sheep, cattle, and other domesticated beasts, and that there certainly was danger to poultry, and perhaps to many useful wild birds. The experiments at Rodd Island are held to have shown that there is no danger to the public health, nor to domesticated beasts, and that the danger to birds is much less than was anticipated, that, in fact it is so small as to be practically out of the reckoning. Therefore these objections having been removed, there is no reason why an experiment in the interior should not be allowed.

To me, however, this chain of reasoning appears seriously imperfect. Leaving out of consideration the danger to man and to beast (which, for general reasons, may be regarded as *nil*) the true logical position is as follows:—

- (1.) The contagion amongst rabbits at Rodd Island was less than desired.
- (2.) The danger to birds at Rodd Island was less than anticipated.
- (3.) In the open country the contagion amongst rabbits may be greater than at Rodd Island.

Here the argument of my colleagues ends. But to complete the chain the following is necessary:—

- (4.) In the open country the danger to birds may be greater than at Rodd Island.

Whatever line of reasoning be applied to the question of contagion amongst rabbits must just as rigorously be applied to the question of danger to birds, and indeed also to the danger to stock and to the public health.

If, however, the position be abandoned, and it be admitted that no hope whatever can be entertained of there being greater contagion in the open country than there was at Rodd Island, then it must be asked, what is the object of introducing the disease at all? The only answer which can be given is that it is out of courtesy to M. Pasteur, and that his agents may be allowed to perform the experiments of demonstration, which they came to perform. But, as a matter of fact, the experiment which the majority of the Commissioners have decided not to oppose, is not the experiment which these gentlemen came to perform. It is in substance an experiment on a large scale, which the Commission have repeatedly requested to have performed, but which M. Pasteur's agents have strenuously declined to carry out. And even supposing that the experiment were precisely that which M. Pasteur has laid down, it seems to me entirely unjustifiable to permit, out of mere courtesy to anyone, and with no practical object, the introduction of a disease into the country, when that introduction, as shown by the Rodd Island experiments, will undoubtedly, in a degree, be dangerous to poultry, and to some other birds.

If it be said that the probabilities of any real danger to birds are so small as to be practically out of the reckoning, I cannot agree with the statement. By arguing from probabilities, it is easy to arrive at any conclusion which may be desired. The conclusion where possible should be based, not on probabilities, but on known facts. And what are the known facts? They are, on the one hand, that chicken-cholera has never been known to prevail, or even to occur, naturally amongst rabbits; and that in the experiments at Rodd Island, the contagion was so small as to be of no practical utility; and these experiments it is important to bear in mind were specially devised so as to be eminently favourable to contagion amongst rabbits; devised not only by the Commission but also by M. Pasteur himself. Then, on the other hand, the facts are, that chicken-cholera, according to M. Pasteur's own statements, has prevailed naturally as a virulent, devastating, and highly infectious disease in poultry-yards; and that, according to the experiments at Rodd Island, birds do contract the disease from rabbits. If then the disease be once admitted into the country, there is a risk that it may become established amongst birds, and by slow degrees be carried about both by birds and by insects, until at last it reaches the poultry-yards. To attempt to estimate the amount of this risk is useless, whether that attempt be in the direction of exaggerating it or of minimising it. But one thing is clear, while the disease is not in the country there is no risk; if it be introduced there will be risk.

If,

If, finally, it be said that fowl-cholera already exists in the colonies, then it is to be answered that the investigations of the Commission all go to show that the disease now in the colonies is not the same as M. Pasteur's *choléra des poules*; and it is undesirable to supplement one disease by the importation of another.

For these reasons, and as being officially interested in poultry farming, I am obliged to dissent from this resolution.

In all the rest of the report I concur.

3 April, 1889.

NOTE BY THE COMMISSION ON DISSENT II.

The Commission has decided to print Mr. Pearson's dissent with its Report, although such dissent did not reach the Commission till a few minutes before the hour appointed for the signing of the Report, Mr. Pearson having already left Sydney. It is absolutely necessary to state that the general opinions, arguments, and conclusions attributed by Mr. Pearson to the Commission have never been entertained for a moment, so far as the Commission is aware, by a single member; at any rate the Commission utterly repudiates them. The Commission has already given its final judgment against M. Pasteur's scheme. Its position with regard to an experiment with chicken-cholera in the open is simply that no sufficient reason exists why M. Pasteur's representatives should be forbidden to perform such an experiment if they so desire. In development of this position, the Commission has briefly indicated, for the guidance of the Government, if it should be decided to permit any such experiment, certain leading conditions, which would be indispensable if the experiment is to be worthy of the slightest attention. The Commission is of opinion that no advantage can be gained by such an experiment, other than that M. Pasteur's representatives would not be able to complain that any part of the demonstration which they were sent to perform had been prohibited by Government.

Inserted by order of the Commission,—

(L.S.)

H. B. ALLEN,
President.

3 April, 1889.

DISSENT III.

In nearly every respect I agree with the conclusions embodied in the general report of the Commission; but I desire to record my separate opinion upon two points:—

I. Assuming that the experiments carried on by the Commission on Rodd Island have shown that the microbes of chicken-cholera are—

- (a) Innocuous to human beings and domestic animals;
- (b) To some extent dangerous to wild birds, but not so dangerous as was supposed;
- (c) Highly fatal to many kinds of domestic birds;

I should still not have hesitated, in face of the grave evils of the rabbit pest, to recommend that further trials in the open country should be permitted, if only it had been shown that there was a reasonable probability that the disease (which is admittedly very fatal to rabbits when the microbes are directly consumed) would freely spread amongst them by infection. The extensive experiments, however, which have been made on behalf of the Commission, though carried on under conditions far more favorable to the spread of the disease from rabbit to rabbit than those which exist in the open country, have not shown that this is likely to be the case. On the contrary, the experiments show that the disease will not freely spread. I am, therefore, of opinion that it is not advisable to give permission to spread broadcast a disease which

which, while it is assuredly fatal to many kinds of poultry, has not been shown to be at all likely to have the effect of aiding to any practicable extent in the work of rabbit extermination.

In this respect, therefore, I agree with the dissent of Professor Allen.

II. In regard to the conclusion of the Commission as to compulsory fencing: while I agree with the general opinion that some sort of subdivision of the land into suitable areas is an essential element in any scheme for the wholesale and complete extermination of rabbits, yet, in view of the heavy relative expenses of this operation, necessitated by the enormous areas of comparatively poor land that have to be dealt with in South Australia, I am unwilling to subscribe to a recommendation for compulsory legislation that might, by suddenly throwing heavy burdens upon the pastoral lessees, have the effect of bringing upon them disasters to a scarcely less extent than is now threatened by the rabbits themselves.

In all other respects I agree with the report of the Commission.

(L.S.) E. C. STIRLING.

NOTE ON NETTING-FENCING BY MR. BELL (NEW ZEALAND).

While (as a member of a mixed Australian and New Zealand Commission) I do not dissent from the emphatic declarations made in the Report with regard to the value of "rabbit-proof" fences as an aid to rabbit destruction, I desire to say that I do not consider this part of the Report to be entirely applicable to the circumstances of New Zealand. My Australian experiences in connection with the work of the Commission have satisfied me that wire-netting is an agent of considerable value in Australia, where there are no heavy snow-drifts, no mountain torrents, no great streams and rivers changing their course with every flood, no extensive landslips, glaciers, mountain crags thousands of feet high, and so on. In New Zealand, where all these special conditions prevail, its usefulness must, I think, be proportionately less. Moreover, there are few districts in New Zealand where the country is not considerably intersected by road lines, which introduce obvious difficulties into the wire-netting question. This is not the case in Australia, where vast tracts of infested country are traversed by at most two or three lines of road. I do not dwell upon the well-known danger of the wilful introduction of wild rabbits into netted areas by persons interested in the maintenance of the pest, because such a practice could scarcely be carried out on a scale of serious magnitude in the case of an already infested district subdivided into netted enclosures. Where, on the other hand, what is called a "barrier" is attempted, by the erection of a "rabbit-proof" fence between an infested district and a clean one, this practice of dropping rabbits over the fence from the infested side must certainly be taken into account in weighing the probabilities as to the efficacy of the plan.

(L.S.) A. D. BELL.

3 April, 1889.

NOTE BY DR. BANCROFT.

To me it appears important that the diseases so destructive to multitudes of rabbits, that arose in Tasmania, at Tintinallogy, and elsewhere in Australia, should be scientifically studied, in order that their value as exterminating agents may be understood, and, if possible, utilized. The great number of rabbits that can be driven into wire-net enclosures offers a means of communicating Coccidium disease.

The female rabbits being destroyed, the males could be fed with Coccidia, and afterwards set at liberty. I consider such trials worthy of consideration, as in all probability some of the outbreaks so destructive to rabbits were caused by the Coccidium parasite.

A convenient plan of communicating Coccidium disease on a large scale could be easily devised.

(L.S.) JOSEPH BANCROFT.

ERRATA.

In page 4, Report of Proceedings, the sentence beginning on the 7th line from the bottom should be—"If this were done we should have some useful information, gained under the conditions which have to be faced." The words "gained under the," in 5th line from the bottom, should be omitted.

Page 91, question 1098—The concluding sentence of answer to this question should be—"I have been told that occasionally odd rabbits get over it."

REPORT OF PROCEEDINGS AND MINUTES OF EVIDENCE

OF THE

ROYAL COMMISSION

OF INQUIRY INTO

SCHEMES FOR THE EXTERMINATION OF RABBITS IN AUSTRALASIA.

SECTION I.

REPORT OF PROCEEDINGS.

MONDAY, 16 APRIL, 1888.

The Commission met at 10 a.m. at the Colonial Secretary's Office, Sydney.

The members of the Commission present were:—

<i>New South Wales:</i>	HENRY NORMAN MACLAURIN, Esq., M.D. WILLIAM CAMAC WILKINSON, Esq., M.D., M.P. EDWARD QUIN, Esq.
<i>Victoria:</i>	HARRY BROOKES ALLEN, Esq., M.D. ALFRED NAYLOR PEARSON, Esq., F.R. Met. Soc., F.C.S., A.I.C.
<i>South Australia:</i>	EDWARD CHARLES STIRLING, Esq., M.D. ALEXANDER STUART PATERSON, Esq., M.D.
<i>Queensland:</i>	JOSEPH BANCROFT, Esq., M.D.
<i>Tasmania:</i>	THOMAS ALFRED TABART, Esq.

Dr. MACLAURIN stated that the usual practice hitherto had been that the President of any Royal Commission should be appointed by the Government; but in this case, owing to the presence on the Commission of representatives from other colonies, it was deemed desirable that the Commission should appoint its own President.

Professor ALLEN, on behalf of the Victorian representatives, moved that Dr. MacLaurin be elected President of the Commission.

Dr. PATERSON seconded the nomination. No other candidate having been proposed, Dr. MacLaurin was unanimously elected.

It was decided that the Press should not be admitted to the meetings of the Commission, but the President was authorized to convey such information to the Press representatives as he might deem desirable.

Dr. PATERSON presented a Commission from the Government of South Australia appointing him and Dr. Stirling representatives of that Colony on the Commission.

Mr. TABART stated that a Commission from the Government of Tasmania, appointing him as the representative of that Colony on the Commission, had been forwarded to the Colonial Secretary.

Dr. BANCROFT stated that a Commission appointing him as the representative of Queensland had also been forwarded to the Colonial Secretary.

Professor ALLEN stated that in reference to the appointment of Messrs. Lascelles, Pearson, and himself, as representatives of Victoria, he understood some less formal communication had taken place with the Government of New South Wales.

On the motion of Mr. TABART, it was decided that the Commission should meet at 10 o'clock each morning and at 2:30 each afternoon on sitting days.

Professor ALLEN said:—Mr. President,—When first I was invited by the Victorian Government to act as a representative of Victoria on this Commission, I was informed that the object of the Commission was to examine and report upon the proposals of M. Pasteur for the destruction of rabbits. I replied that, owing to the pressure of my University engagements, I could not undertake more than to discuss the evidence immediately obtainable, and to advise what steps should be taken thereupon. I accepted therefore only this limited responsibility. Subsequently, learning that the disease at Tintinallong was destroying great numbers of rabbits, I induced my Government to make provision for the conduct of my University work during my absence. But I must return to Melbourne on Wednesday for the first public session of the Royal Commission on the sanitary condition of Melbourne and its suburbs, which will be held on Thursday afternoon, as two very important witnesses, who are on the point of departure to England, will then be examined. It will, however, be possible for me to return on Friday, or if the Commission should determine to examine the Tintinallong outbreak, I can proceed thither directly from Melbourne.

1. The problem before us is far more urgent in New South Wales than in Victoria. The difficulties which beset it become great when enormous areas of poor thinly settled land are dealt with. In Victoria, even in the Mallee Country, in parts once given over to rabbits, my colleague, Mr. Lascelles, will be able

to tell you how the rabbit plague has been successfully combatted without resort to the introduction of disease. But I can readily understand that in the back blocks of New South Wales, and even in more settled parts adjoining infested hill country, it would be a great boon to landowners if some disease could be introduced which would propagate itself among rabbits without doing serious injury to other animals, and which could be maintained in active spread among rabbits with a minimum of trouble and expense. In estimating the probability that any disease will disseminate itself among rabbits so as substantially to thin their numbers, several distinct questions must be considered—firstly, the spread of disease in a large warren; secondly, its transmission from one warren to another; thirdly, the effect of disease upon the multitudes of rabbits, which, under favourable circumstances, are said not to warren at all, or at least not during a great part of the year. The problem also will vary according as the remedy is to be applied in the dry arid plains of the interior, or in parts where food and covert are abundant. Even the season of the year will be a factor of considerable importance.

2. After these preliminary remarks, I may be permitted shortly to discuss the use of chicken-cholera for the extirpation of rabbits, so that members of the Commission may be aware of the reasons for which, in my opinion, great caution should be exercised both in conducting experiments and in drawing inferences from them. M. Pasteur's proposals must be viewed from two distinct standpoints, firstly with regard to their effectiveness, and secondly with regard to their safety.

3 It may be admitted that the bacterial broth employed by M. Pasteur will destroy any rabbits to which it is administered. This has been established for many years, and has been demonstrated recently on a large scale by M. Loir in the destruction of rabbits on the Pommery estate. But this fact would not in the least degree justify us in propagating disease in these colonies, for the extent of action of such a disease, direct and indirect, is beyond our power of prediction, and other poisons, such as arsenic and phosphorus, whose action is known and measurable, will fulfil the same purpose. The introduction of any new disease is specially open to objection; but it is probable that chicken-cholera is no new thing among us. Many proprietors of poultry-yards appear to have suffered severely from outbreaks of rapidly fatal disease among their fowls, the symptoms being drowsiness, balling of the feathers, weakness and diarrhœa. Information on this point is very desirable, and should be obtained as soon as possible.

4. The next question, and a most important one, is—*Would the chicken-cholera spread freely from rabbit to rabbit?* On this point more evidence is necessary. The experiments of M. Pasteur already published tend to show that the disease may be communicated from infected rabbits to healthy rabbits kept in the same hutch; but of the degree of this tendency, I have not been able to obtain any sure knowledge. As regards the spread of the disease among fowls, we find that it has prevailed in devastating epidemics; but still it has not exterminated fowls in France or other countries most subject to chicken-cholera. On the other hand, it may be effectively replied that the result would be very different if constant attempts had been made to spread the disease and to maintain its virulence in the poultry-yards, instead of struggling to suppress it. It is certain that among fowls the disease is virulently infective, and that the chief vehicle of infection is furnished by the droppings of infected fowls. As to its power of spontaneous spread among rabbits, no evidence, so far as I am aware, is yet available. We cannot argue with safety from the analogy of fowls. It is not certain that the disease would effectually thin out the rabbits in a crowded warren. The opportunity which the Pommery estate afforded for a crucial experiment was thrown away. If a number of diseased rabbits had been introduced into the warrens on that estate, conclusive evidence might have been attained; but instead of proceeding thus, the rabbits, which were dependent wholly for their subsistence on food daily provided by Mme. Pommery, were apparently destroyed at one swoop by adding infected broth to their stated meal on one particular day. There is no evidence as to whether the disease would spread from warren to warren, or seriously affect the rabbits which do not warren.

5. The next question which arises concerns the perpetuity of the disease when once started. In the first place, chicken-cholera kills very rapidly—so rapidly that a diseased animal would not long be in contact with healthy animals. Thus Pasteur tells us that nothing can be more easy than to stop the progress of the disease in a poultry-yard. The fowls should be isolated for some days only; the yard freely washed with water, especially with water acidulated with a little sulphuric acid, which readily destroys the microbe. All the excrement should be removed from the yard, and then the animals which survive may be brought together again. (*Comptes Rendus*, vol. 90, Feb. 9, 1880, pp. 239 *et seq.*) It is generally stated that when disease becomes prevalent among rabbits in any district they move into adjacent districts. The diseased animals would remain behind, and thus the progress of the outbreak would be checked. Again, a moderate heat, below the heat in the sun on a hot Australian summer day, suffices to kill the microbes, so that another hindrance to the perpetuation or wide spread of the disease is thus afforded. Then, too, the microbe is not known to form spores, and, in the absence of these specially resistant forms of development, less persistence in the spread of the malady can be expected. It may therefore be questioned whether, without frequent reinforcement, the disease would prevail more than in circumscribed epidemics, such as those of measles and scarlatina among children; and, if continual sowing of the disease be necessary, the element of expense at once acquires importance. It seems to me that we might fairly ask M. Pasteur to make his case clear—to give it some of the fulness and certitude with which he presented the results of other inquiries which have made his name famous. However, he may well reply that, in sending his agents to experiment in the locality where the remedy is to operate, he is doing the best thing possible, so that the Governments of these colonies may determine the nature of the test which will be accepted as conclusive. If it be determined to conduct a series of experiments, the operations may be divided into three groups—laboratory experiments; experiments on an island, preferably already infested with rabbits; and experiments on a portion of the main land, under the natural conditions which will obtain in ordinary cases.

6. *Is it safe to use chicken-cholera for the extirpation of rabbits?* M. Pasteur seems confident that it would be safe. But it is well known that the disease may be transmitted to fowls, ducks, geese, turkeys, pheasants, pigeons, and other birds. Thus Professor Zürn has reported on the examination of the bodies of 365 dead birds, namely, 237 fowls, 56 pigeons, 14 ducks, 16 geese, 10 turkeys, and 32 cage birds. Fowl typhoid (chicken-cholera) was found to have caused death 122 times, namely, in 79 fowls, 1 tragopan (a kind of pheasant), 3 ordinary pheasants, 17 pigeons, 8 turkeys, 5 ducks and 9 geese (see notice in the "Jahresbericht über die Leistungen auf dem Gebiete der Veterinär-Medicin, 1885," from the "Dresdener Blättern für Geflügelzucht"). Moreover, the real nature and affinities of chicken-cholera do not seem to be thoroughly understood. The disease appears to be a hæmorrhagic form of septicæmia; and

and some doubt has been expressed whether this form of septicaemia affecting fowls and rabbits is distinct from forms affecting larger animals. Thus, in the *Comptes Rendus* of the French Academy of Sciences, for July 8th, 1878 (vol. 87, pp. 69 *et seq.*), Professor Toussaint, of the Veterinary School at Toulouse, reported that he had been able to produce a peculiar septicaemic disease in a rabbit, by inoculating its ear with blood with a horse, which died from symptoms of anthrax sixty hours before the operation. A second rabbit was inoculated from the first, and subsequently fifty rabbits were inoculated in different places with similar results. Toussaint found special organisms, quite unlike those of anthrax, swarming in the blood, the tissues, and the excreta of the inoculated animals. Three rabbits died eighteen to twenty-four hours after eating oats moistened with the blood of infected animals. The excrement of diseased rabbits, powdered and mixed with food, killed two rabbits out of six, after one feeding. Two vigorous rabbits, placed for one night with inoculated animals, died next day. Three adult rabbits, placed in cages near those in which animals under experiment were kept, died in the same way without any direct contact with inoculated animals. In the *Comptes Rendus* of August 2, 1880 (vol. 91, p. p. 301 *et seq.*), about six months after Pasteur described the microbe of fowl-cholera with accuracy, a note from Toussaint was presented containing the following statements:—"When one studies fowl-cholera and acute septicaemia, one is quickly struck by the analogy which exists between these two diseases; two animals of the same kind, inoculated with the blood of the one and the other disease, and in the same way, present identical symptoms, die in the same time, and show exactly similar lesions I can say after several series of experiments, including more than 250 cases, that in the disease which kills the rabbit in ten to twenty hours, and which is inoculated so readily into birds, a microbe exists of well-determined form, whose action is always identical, which is the same that M. Pasteur has so perfectly studied and whose existence I had already demonstrated in the disease called fowl-cholera The cholera of fowls is, therefore, nothing else than acute septicaemia, contracted spontaneously by these birds in the places which they inhabit, and it is necessary, for cholera to exist, that putrefying matters should have been within their reach." Toussaint produced his septicaemia in rabbits and fowls with the blood of a horse which died of septicaemia, with that of a horse which died of typhus (*typhose*), and with blood of a sheep which died of anthrax. In the *Comptes Rendus* of July 25, 1881 (vol. 93, page 219), he reiterated his previous statements, and notified two fresh series of experiments, in one of which blood from a case of anthrax was used, in the other blood from a tuberculous cow. He inoculated rabbits with the blood from the case of anthrax; they died in seven or eight hours of septicaemia, and their blood contained a microbe exactly similar to that of fowl-cholera. It could be inoculated into pigeons and fowls, and passed readily from one bird to another. He obtained from Pasteur cultures of the microbe of fowl-cholera, and made separate experiments with these and with his own cultures from various sources, using different places and different instruments for the two series of experiments. The most minute observation could not establish any difference in the symptoms, the lesions, or in the cultures of the microbes. If we accept these experiments of Toussaint, an observer to whose ability Pasteur has borne testimony, we must believe either that chicken-cholera is simply a form of septicaemia which may be produced by microbes obtained from various animals dying of diverse diseases, or that there are two diseases affecting rabbits and birds, one genuine fowl-cholera, the other an ordinary acute septicaemia, the symptoms, lesions and microbes being almost, if not quite, identical in the two diseases. Moreover, Böllinger, a distinguished German observer, announced in 1878 that a plague, which was then causing great devastation among cattle and wild animals, was distinct from anthrax, though closely resembling it. Kitte subsequently confirmed Böllinger's observations, and discovered what he thought to be a new bacterium, very similar to those of rabbit septicaemia, chicken-cholera, and of the swine plague prevailing on the Continent of Europe. Hüppe has recently conducted a series of observations from which he concludes that all these diseases are varying expressions of hæmorrhagic septicaemia; that the disease is transmissible to domestic animals, especially to oxen, horses and swine; that rabbits and mice are specially adapted for experiment with the disease; that sheep and guinea-pigs are less liable. He describes the microbe as a short rod with deeply stained poles and a clear centre, thus resembling that which Pasteur has shown to be the cause of chicken-cholera (Schmidt's *Jahrbucher* for 1887, vol. 213, page 231). The reviewer of Hüppe's observations very properly notes that it is difficult to believe that there is such unity in the causation of these various diseases. In the *Comptes Rendus* of November 26th, 1883 (vol. 97, page 1,163), Pasteur presented the report of an investigation into swine plague, conducted by himself and M. Thuillier. He discovered a micro-organism which he believed to be the cause of the disease; he says that it resembles the microbe of fowl-cholera; "the form is still that of a figure of 8, but more delicate and less visible." He writes as follows:—"The inoculation of pigeons and rabbits with swine plague yielded the following very curious result:—If an inoculation with the micro-organism of swine plague was made into the pectoral muscle of a pigeon, the bird, after showing the ordinary outward symptoms of fowl-cholera, died in six or eight days. When the blood of this first pigeon was used for inoculating a second, the blood of a second for inoculating a third, and so on in a series, the micro-organism became acclimatized in the pigeon. The drowsiness and the tendency to roll itself up into a ball, which are the customary symptoms of the disease, appeared after a much shorter interval than in the first pigeons of the series. Death also occurred more quickly, and the blood of the later pigeons in the series was much more virulent to the pig than even the most infective products from a pig which had died of the so-called spontaneous swine plague. If the micro-organism of swine plague is passed through a series of rabbits, the result is altogether different. Rabbits inoculated with the infective products of a pig which has died of swine plague, or with cultivations made from them, are always made ill, and in the majority of instances die. If the disease is inoculated from rabbit to rabbit, the micro-organism becomes acclimatized in the rabbit. All the animals die, death supervening in a few days. . . . If the blood of the last rabbit of the series . . . be used for inoculating pigs it is found that the virulence has been progressively diminishing from the first to the later rabbits of the series. Very soon pigs inoculated with the blood of the rabbits are not killed, although they are made ill by it. After recovery they are found to be vaccinated for the fatal form of swine plague." (*Microparasites in Disease, New Sydenham Society's publications* for 1886, pp. 624-5). Loeffler, of Berlin, states that, from his own observations, swine plague is due to a minute bacillus, astonishingly like the bacillus of Koch's mouse septicaemia, but in one case he found quite a different organism. Schütz also found a similar bacillus to be the cause of the disease, and he found this bacillus in M. Pasteur's vaccine for swine plague, along with the figure of eight organisms, which Schütz regards

* For the references to Zürn's Statistics and to Schmidt's *Jahrbucher*, Professor Allen desires to express his indebtedness to Dr. James Jamieson.

regards as a mere contamination. Schottelius agrees with Schütz, and the general conclusion of Dr. Loeffler is, that under the name of swine plague several diseases etiologically distinct, though perhaps identical in symptoms, have been confused together. (*Microparasites in Disease*, page 627). Similarly, it appears, from the evidence already quoted, that the nature and affinities of chicken-cholera are not well understood.

7. It seems necessary, therefore, that further evidence be obtained, especially in the way of testing whether chicken cholera is communicable to horses, cattle, sheep, and native birds. It does not follow that native birds must be affected because domestic birds are prone to the disease. But the presumption is that all birds will be liable. A quotation from Pasteur's paper on the attenuation of anthrax virus (*Compte Rendus*, vol. 92, page 429, translated in *Microparasites in Disease*, pages 566-7) will furnish evidence on this point, and will also show how the microbe of a disease may gain in virulence in passing from one animal to another of different age or of different kind. Pasteur has shown how the germs of anthrax may be weakened by cultivation at high temperatures, until the virus once fatal to a sheep will not kill a guinea-pig. But though it will not kill an adult guinea-pig, it kills one a single day old. If now we pass from the first guinea-pig one day old to another, by the inoculation of the second with the blood of the first, and from the second to the third and so on in series, its habit of developing in the economy is strengthened progressively. In consequence, we can soon kill guinea-pigs three days, four days, one week, one month, several years old, and in the end even sheep. The bacterium has returned to its original virulence.

In the case of the microbe of fowl-cholera, when it has arrived at the point at which it has no action on fowls" (in accordance with Pasteur's special method of weakening the virus of this disease) "its virulence can be restored by operating with it on small birds, canaries, sparrows, &c; all these species it kills at once. By passing it thus through the bodies of the animals, we can little by little cause it to take on a virulence capable of once more producing an effect on adult fowls." Other curious cases have been recorded showing that the virulence of a microbe to one kind of animal may be wonderfully altered by passing it through another kind of animal. Hence we should make sure, not only that the microbes of chicken-cholera are not injurious to higher forms of life, but that they cannot gain in virulence by repeated transfer through rabbits or through other animals so as to be able to affect sheep.

8. Generally, I cannot but feel that there is great weight in the argument, that while chicken-cholera is a natural disease among birds—"a disastrous disease, showing itself everywhere in the poultry-yards," as Pasteur wrote in 1880—it has never prevailed as a natural epidemic among rabbits; and that, therefore, if we attempt to maintain and spread the disease in Australia, we may decimate our birds without sensibly affecting the rabbits. M. Pasteur's representatives may, however, have valuable evidence to submit with which I am not familiar. The whole domain of bacteriology is still beset with obscurity; facts are often doubtful, and inferences uncertain. It is clear that if the microbes of chicken-cholera are to exterminate rabbits, great care must be taken to maintain the disease in activity, and the old modes of rabbit destruction must not be omitted. Difficulties will be presented by rabbits which do not warren, and by rabbits in hilly country. Repeated exposure of poisoned food or introduction of infected rabbits will be necessary, and the risk to bird life will be great. Still, I am of opinion that the remedy should be tested, but with every possible precaution to prevent mischief. If the Governments of Australia do not provide for the full testing of such proposals under proper precautions, I fear that land-owners, driven to extremity, may try them without any precautions. I therefore suggest that the service of such experts as are available be retained, so that experiments may be conducted without delay under the general guidance of the Commission. In this way it would be possible (1) to ascertain by laboratory experiments what animals may be affected by chicken-cholera, with cultures not only from the fowl, but also from the rabbit and other animals; (2) to conduct experiments under natural conditions, either on an island or in a protected area on the mainland, or both. With the results of such experiments before it, the Commission would be able to advise the Government finally. An island, to be thoroughly suitable, should be fairly accessible, and yet so far from the coast that birds would not fly across, unless in perfect health. Shortly before leaving Melbourne I was informed that an island in the Kent group, between Victoria and Tasmania, is already infested with rabbits. Many of the suggestions which I have made apply to other diseases which may be recommended for rabbit destruction, as well as to chicken cholera; but I feel that I have already trespassed too long on your attention, and can only thank you for your patient hearing.

Dr. BANCROFT having stated that it was desirable the Commission should have the facts mentioned by Professor Allen in convenient form for reference, Mr. QUIN moved, and Dr. BANCROFT seconded, "That the address of Professor Allen be printed, and that the other speeches thereon should be reported *verbatim* and also printed." The motion was agreed to, and the Chairman directed that two copies in proof, marked "confidential," should be supplied each member for revision before being finally printed.

Mr. QUIN said:—I should like to say something with reference to what Professor Allen has said about rabbits not burrowing. It is true they lie in form as hares do during the greater portion of the year, but there are three months during the winter in which they do take to the burrows that are already made to their hands, and what is known locally as beelby, wombat, and other holes, which are of great extent, some several hundred feet across them, and in some cases being 22 feet deep. I think, with dogs during the winter months, the bulk of the rabbits could be driven to the burrows, and they no doubt would then become infected with any disease that was being experimented with. I should like to say that I do not think any experiments carried on on an island such as is proposed would be satisfactory, the conditions are so different. We have in the interior such a different climate, a small rainfall, and positively no dews for a period of six months. Now this cannot and does not happen on islands on the sea coast. The herbage of the interior is of a salsolaceous character which is not to be met with out of it. I should like to see some practical experiments carried on such as fencing in an area of country of (say) a couple of miles square, and within such an enclosure small enclosures of an acre or more each, which could be fenced over these vast burrows which I have referred to. Stock of all descriptions could be kept within the outer fence for purposes of experiment. If this were done we should have some useful information, conditions which have to be faced. I am quite sure if the Government were asked they would be gained under the prepared to do what they can towards having such experiments carried out, and the sooner they are asked to do so the better. I shall leave the pathological contingencies to be dealt with by the professional members of the Commission.

Dr. PATERSON said that recently his official duties brought him, he being Government Medical Officer for South Australia, to the Teetulpa Gold-field. His visit was made about six months ago, and he travelled

travelled between Yurta, the last station on the railway, and Teetulpa, a distance of over 30 miles, by coach, and, consequently, he had had a good opportunity of observing the country. The whole of the district was rabbit infested. He visited one of the largest stations in South Australia (the Parctoo), the lease of which had expired or was on the point of expiring, and he was assured by a practical man, who knew very well the value of things and who was perfectly disinterested, being a Government official, that the country was simply worthless. At Teetulpa he had driven round with the warden of the Gold-field for 15 or 20 miles, and there again he had witnessed the devastation which these wretched little creatures had caused. In one bit of country, where there was good food and water, the rabbits were simply hopping about in great numbers, leading disinterested men to the conviction that the country was practically worthless. It was not only the pastoralists who were affected in this way, but the agriculturalists also, because the rabbits were now invading their northern areas. Perhaps they did not know, but he would tell them that South Australia had suffered from the drought very badly, and for some time there had been very bad crops, though last year there had been a good one. The farmers were now looking to this, and these creatures came along, exhausted from starvation, and eat down everything. In fact they eat everything before them and were nearly as bad as locusts. This question had hitherto been treated as if it only affected pastoralists, but there were many other interests—the agricultural interest for one—which would be affected by the pest if it went much further. Take the interest of the Crown and the general Government. If the large stations had to be abandoned—and a good deal of country was being abandoned, as they might know—the Crown would lose its revenue, and what was worse, though he did not know what the law might be here, but in South Australia the occupation of the waste lands would not yield enough to keep down the rabbits. Therefore, if these runs had to be abandoned the Crown would not only lose its revenue, but it would have the responsibility of keeping down the pest thrown on it. It seemed to him that the very existence of the pastoral interest was threatened, so that this was a very serious matter indeed. People seemed to hardly realize the value of the pastoral interest, but, whatever it might be now, it was the pastoral interest that had made these Colonies what they are. This was true, not only of one Colony, but of every Colony in the group. The food supply of these communities was dependent on the pastoral interest. Supposing that large tracts of country were abandoned, how were the markets of these large cities to be supplied with food? If the encroachment of the pest on this country continued there was not a single man, woman, or child in the country that would not feel it? As for himself he did not own a single sheep, nor had he any interest whatever in the pastoral industry, but he was only telling the Commission the opinion which his judgment had led him to form, after having witnessed the rabbit infested country for himself. Well, what the pastoralist, as well as the unfortunate farmer, wanted, as Mr. Owen had pointed out, was a cheap and effective remedy of destroying these rabbits. This was the opinion not only of men connected with the pastoral industry in South Australia—men of sound judgment, and men who, like himself, were not in any way interested in stations, and who did not possess a single sheep—that the remedy must be provided by science, and that they look to it to provide some remedy; some virulent and spreading disease which would go through and infect the healthy animal and destroy it. If they could not have such an ideal disease made to order, then they should have some infectious disease which would be limited to rabbits, &c. This was what was wanted. He was somewhat sorry to say that he did not have the very sanguine expectations that had been formed by the promoters of the various schemes—M. Pasteur's scheme, the Tintanalogy scheme, the scheme of Professor Watson—as to the effectiveness of the disease, or as regards its exterminative powers. He reasoned from general principles in this way, that the rabbits in the first instance were artificially pushed on from time to time; and they were not likely to be destroyed effectually in a short period. What he thought might safely be expected was that the rabbits would be artificially kept up from time to time by persons interested. Some of these diseases might, however, become a powerful auxiliary in dealing with this wretched pest. What was the use of talking about rabbit-proof fencing to an impoverished pastoralist? He could not afford such a thing. A friend of his, interested as one of a syndicate in a station on the Murray, proposed to put up £6,000 worth of fencing before a single rabbit had been destroyed. He mentioned this fact to show the magnitude of the evil that they had to contend with. He asked them to look at the amount of capital invested in pastoral enterprise, and the employment it afforded, because it was necessary to do this in order to realize the calamity which would occur if this pest made much more headway. He had to repeat again, and with regret, that he did not entertain very sanguine expectations about the exterminative power of any disease; but still he thought it might take its place fairly with hunting with dogs, with trapping, and other measures that had already proved most valuable and useful auxiliaries. He might notice one objection which Mr. Quin had also dealt with, that it was difficult to spread any infectious disease when the rabbits did not burrow. The rabbits would burrow in good parts of country, for "bunny" knew when he came to a good tract of land; but in rocky country they would not burrow. As Mr. Quin had said, they lie in form. But they would see that infectious disease must be propagated not only by animals sleeping together, but when they came in contact in other ways. They might not get a sort of disease which would prove as instantly fatal amongst animals that did not burrow as amongst animals that did, still the disease would do a great amount of good by thinning the pest to some extent. He had listened with very great interest to Professor Allen's description of M. Pasteur's scheme, and he thought Professor Allen had handled his subject very thoroughly and completely, so that it was quite unnecessary for him to say much more. There was one scheme, however, which he had had an opportunity of investigating, and which he had thought a good deal out; and he would give the Commission, at all events, the results of his study on the matter. This was a report written by him in response to instructions from the Chief Secretary of South Australia, who called on him to report whether the introduction of Professor Watson's scheme would be injurious to human life, or to the life of stock. He knew that one or two Members of the Commission had seen this; but others might not have done so, and therefore he would hand it in for printing with the other proceedings of the Commission.

REPORT ON INTRODUCTION OF DISEASE AMONGST RABBITS.

REPORT of Dr. Paterson (Colonial Surgeon) relative to the danger to stock through the introduction of disease amongst rabbits.

Sir,

Colonial Surgeon's Office, 8 November, 1887.

I have the honor to report that, in pursuance of your instruction, I conferred with Professor Watson on the subject of the disease which he proposes to introduce for the extermination of rabbits—

1st

1st, in reference to the nature of the disease; 2nd, with a view to expressing an opinion whether the disease in question was communicable to man, horses, sheep, cattle, and pigs. I had an interview with Professor Watson, who readily furnished the information asked for, showed me the infected animals, and demonstrated the nature of the disease under the microscope.

The rabbits experimented on are confined within the precincts of the old powder magazine at the rear of the University buildings. They occupy a small area of ground, which is intersected with their burrows. A high wall, with deep foundations, prevents any possibility of escape either above or below the surface. I counted eight rabbits in this enclosure, of which, judging by the colour, two were wild, the remainder domesticated animals. Lying about were the dead bodies of a considerable number of young ones which had come to their full time, but were either stillborn or had died immediately after birth. This effect of the disease in checking fecundity should not be overlooked. One rabbit—a white one—was in an advanced stage of the disease: it was inactive and emaciated, the fur was falling off its body in places, and the face, about the nose and eyes, was without hair and covered with a scurfy incrustation. The animal having been caught, and a pinch of fur removed from its body, the scurf adhering to the roots of the hair was separated and placed under the microscope, and the presence of an insect parasite revealed. This parasite is the *Sarcoptes cuniculi*. Its existence denotes that the animal is affected with rabbit itch, or rabbit scab.

Sarcoptes cuniculi belongs to the family of the *Acarina*, or true "itch mites." Itch mites infest the bodies of a large number of animals, including man, horses, cattle, sheep, pigs, camels, dogs, cats, goats, lions, tigers, and others. They differ in size and external appearance, according to the species of animal whose body they inhabit. They are confined to the skin exclusively, never penetrating to the tissues below the skin. Their bodies and eggs cannot be taken up into the circulation, as they are larger than the capillary vessels, and so cannot effect an entrance. The itch mites of man and the lower animals have been variously estimated to live from twenty to forty days, and even two months, according as they are placed under unfavourable or favourable conditions. The total number of eggs laid by the female in the burrow, which she makes for herself in the skin, has been computed by Gerlach not to exceed fifty, but Hebra says he never saw in one burrow more than fourteen eggs besides ten or twelve empty shells.

The disease in question, rabbit scab, is rabbit itch. In the rabbit it corresponds to itch in the human subject, mange in horses, cattle, pigs, and dogs, and to scab in sheep; all of which diseases are dependent on the presence of an insect parasite. Itch in the human subject is due to an itch mite which has been variously named *Acarus scabiei hominis*, *Acarus exulcerans* (Linnaeus), *Sarcoptes hominis* (Raspail). In the horse it is called *Sarcoptes equi*, in the ox *Sarcoptes bovis*, in the pig *Sarcoptes suis*, in the dog *Sarcoptes canis*, in the cat *Sarcoptes catorum*. It is an eminently contagious disease. In the human being it is communicated from person to person by contact in eight cases out of ten, according to Bourguignon, by their sleeping together. It would be a waste of words to describe at length the extreme contagiousness of mange in horses, cattle, pigs, and dogs, or that of scab in sheep. Reference to any veterinary work will confirm what is said here both as to the virulence and nature of these affections.

In rabbits itch is not only a virulent but a fatal disease. Professor Watson assures me that every animal which has been exposed to the contagion has caught it and died. Its remarkable influence in restraining increase has been already mentioned. But the rabbit in captivity and the rabbit in its natural state in the open country are under very different conditions. The itch mite is said to be fond of warmth and to display increased liveliness when exposed to the rays of the sun; and the warmth engendered by the contact of two living bodies, as of two persons sleeping in the same bed, is believed to play a prominent part in the spread of the disease by inducing the creature to leave its burrow and wander about. The heat of our climate may operate in a similar way. But as a set-off against this it is to be borne in mind that itch, as observed in man in Europe, is not confined to warm latitudes, but is prevalent in the northern countries of that continent in an aggravated form. There the disease has been chiefly observed in rabbits reared in hutches. So far as I have been able to ascertain, it has not been observed in the wild rabbit, but my information on this point is scanty. There are many things in the environment of the wild rabbit, especially in certain localities, which would make against the virulence of the disease, some of which may be surmised, others, and these probably the most important, might escape conjecture—contact with saline or sulphurous substances in the earth, brackish water, the contact of fresh earth in the formation of new burrows, brushing the coat against aromatic shrubs, or, when the herbage fails, an enforced diet of leaves, like those of the eucalyptus, containing essential oils which are known to be poisonous to the mite, and the increased resisting power to the effect of the disease imparted to the animal by an active open-air life. All these would modify, and perhaps in the end render, the vitality of the mite impossible. Anyhow this can be said that history records no plague, however desolating, which by itself and unaided by other causes has exterminated man or animal.

2.—As regards the communicability of the disease to man, horse, ox, sheep, or pig.

As to man, as regards the human subject, there need be little or no ground for apprehension. The skin and fur of infected animals as articles of commerce are valueless, and therefore would not be handled; the carcase would be rejected for food, or if used, would be innocuous, as the disease did not penetrate below the skin.

Itch in man is a curable disease, and neither endangers life nor injures the health of the patient. Persons are known to have it from youth to old age without impairment of their general health. At the same time it is a disreputable and loathsome malady.

Kuchenmeister, in his manual of human parasites, states that the itch mites of the following animals have been accidentally transferred to man, and have been found upon him—*Sarcoptes cati* (cat); *Sarcoptes bovis* (ox); *Sarcoptes canis* (dog); *Sarcoptes equi* (horse). He also states that the *Sarcoptes catorum* may be transferred to a variety of animals, and among others to sheep, and quotes his authorities. Professor Watson has experimented on himself both with live rabbit mite (*Sarcoptes cuniculi*) and its ova without effect, and emphatically denies that rabbit itch is communicable to human beings.

With regard to the transference of certain itch mites from the lower animals and the communication of itch by them to man, some observers are of opinion that the insects so transferred die out without being able to reproduce themselves in their new locality. When the disease is of longer duration than is warranted by this belief, they explain its persistence by the repeated introduction of fresh batches of the creature by constant contact of the patient with the animal from which the contagion was derived in the first instance. Kuchenmeister expresses his belief that, if mites from the lower animals are able to establish

establish themselves permanently on man, it will apply only to those which have a close resemblance to the human parasite. Hebra, another eminent dermatologist, holds that there is no difference between the mites which infest man and the lower animals; that they are not different species of one family, but only variations of one and the same animal; that, in fact, the mites of the lower animals and man are identical. On this point Hebra is entirely at variance with veterinary surgeons of the English school. The following extract shows his views:—"Certain writers, among whom are Gerlach and Fürstenberg, have, in their very valuable works, given descriptions and figures of various kinds of *acari*, some of which has been found in different species of animals, while others had been taken from the human subject, and had been associated (as was supposed) with distinct forms of *scabies*. But, although I have the highest respect for the writers to whom I have referred, I cannot agree with them in this matter; my observations on the lower animals as well as on the human patients have led me to believe that not only several of the *acari* said by Gerlach to have been taken from different animals, but those described by Fürstenberg under the names of *Sarcoptes scabiei*, *S. scabiei crustaceæ* belong to the same genus and to the same species, or (it is better to say) are specimens of one and the same animal. Differences in length, thickness, breadth, or in the degree of transparency of the body, slight variations in form which is in some instances, a little more rounded, in others a little more elongated, these all seem to be an utterly insufficient basis for the creation of several distinct species of a little animal which cannot be seen plainly until it is magnified at least 100 times, and which undergoes several moultings and metamorphoses. On this question the opinion expressed by Gudden is similar to my own. There is no better proof of the identity of the *acari* which have hitherto been found in different animals, than the fact that the diseases produced by them have always been communicable, whether by design or accident, from those animals to man and *vice versa*. This I have myself observed both in the Vienna Museum of Natural History, and in the Imperial Menagerie at Schönbrunn. I am, then, firmly convinced that the different *acari* described and figured by Gerlach under the names of *Sarcoptes equi*, *S. canis*, *S. suis*, *S. cati*, and *S. cuniculi*, as well as those which Fürstenberg termed, *S. scabiei crustaceæ*, *S. vulpis*, *S. capra*, *S. squamiferus*, and *S. minor*, are identical. In other words, they do not form different species of one genus, but are merely varieties of the same animal, which (according to its seat, and according as it is found upon different animals) is sometimes retarded in its development, and at other times becomes larger and more rounded. It must be remembered that similar differences are observed in other *Epizoa*, and, indeed, throughout the organic kingdom. Species, whether of plants or animals, are commonly found to vary in different localities, being now strongly developed, presenting a more ample form, and more powerful members—now retarded in their growth, and (as it were) on a lower level of vitality. Surely, then, we may venture to apply these facts to the itch mite, and to assert, without hesitation, that the various forms of that animal belong to the same species, in spite of their apparent difference in shape and size."

Is Sarcoptes cuniculi transferable to the horse, ox, or pig?

Professor Watson replies to this that there are no experiments in the country, but that Krause, a recent German writer on the rabbit, denies its communicability to horses, cattle, or pigs.

Mange in horses is a highly contagious disorder, and is due to the presence of an itch mite, *Sarcoptes equi*. Mahew, author of various treatises on the horse, figures the mange insect, and at the conclusion of an excellent article on mange, expresses himself as follows:—"The question has been much debated whether man can derive the itch from an animal? Imaginary proofs, favouring the possibility, are every now and then confidently promulgated, but all doubts seem to have been put to rest by the investigations conducted by M. Bourguignon. That gentleman demonstrated the unfitness of one creature to support the parasite generated by another. Horses may be violently irritated by insects bred by fowls, but remove the birds, the supply ceases, and the irritation dies away. So an individual, handling many horses, may get some of the *acari* upon him, and cause vexatious itching, but let the man keep away from the contaminated stable, and the sensation is quickly lost. The repeated and repeated renewal of the pest gives a seeming warranty to the popular belief. Certain disorders assuredly are communicable throughout every species of life, as though to prove the stubbornness of mankind that all nature is akin. Such are hydrophobia in the dog, and glanders in the horse; were all affections, however, equally interchangeable, the inhabitants of this world would speedily become one breathing mass of disease."

I quote this extract because, though not bearing expressly on the transference of rabbit itch to the horse, it shows the wide divergence of opinion which prevails on the subject of the interchange of the disease.

Is Sarcoptes cuniculi communicable to sheep?

Professor Watson replies emphatically, no; and, in confirmation of his opinion, refers to experiments on three sheep belonging to the S. A. Stockowners' Association, which were under the care of M. Marceau. The sheep were in a pen in M. Marceau's backyard. They were young healthy animals, unshorn. About a month ago they had been inoculated by separating the wool all down the back, and applying the contagious material copiously to the skin of the back and other parts of the body. The animals were rather wild, but M. Marceau caught and threw one so as to allow of a careful examination. There was no disease apparent, and I believe none was present.

Professor Watson admits that, according to Krause, *Sarcoptes cuniculi* is communicable to cats. Now, Kuchenmeister states that *Sarcoptes catorum* is communicable among other animals to sheep. If Kuchenmeister is correct, there is a presumption that *Sarcoptes cuniculi* may also be communicable to sheep, either with or without passing in the first instance through the cat, and it would tend to confirm Hebra's view of the identity of the various itch mites, and that they are not different species, but only variations of one and the same animal.

Is the disease communicable to marsupials?

Professor Watson replies, possibly—yet to try.

I do not share Professor Watson's confident opinion that *Sarcoptes cuniculi* is not communicable to sheep, so far as it is based on the experiments that have been made here. The literature of itch contains numerous instances of unsuccessful experiments to communicate the disease by inoculation. For example, Hebra says:—"I have, for instance, often been unsuccessful when I had simply placed impregnated females on the skin at different spots, although I had already seen the animals penetrate the cuticle." To be of any value the experiments should be of more varied character and under more varied

varied conditions. They should be made on shorn as well as unshorn sheep, and the contagious material applied on a loose bandage round the body; quiet animals accustomed to be handled, such as have been brought up about a farm, would be preferable to those reared on a run. The natural mode of conveying the contagion might be imitated by introducing infected rabbits into the pen, and experiments should be made, not only with sheep, but with horses, cattle, and pigs. An instance is related of a cat communicating mange (*Sarcoptes*) to a horse by perching on its back in the stable.

So far as I can see the weight of evidence inclines to Hebra's view, that the itch mites in different animals are identical, and therefore interchangeable. But opinion on a matter of this sort is nothing but conjecture. The question can only be decided by direct experiment. If the scheme is to accomplish its purpose centres of infection must be multiplied indefinitely over the country infested by rabbits. The dissemination of scab and mange would be too high a price to pay even for bunny's annihilation, and before the Government can sanction such a step it should be in possession of evidence to satisfy the most sceptical minds that the disease is not communicable.

I do not see much force in the sentimental objections to the scheme, bunny's undue multiplication in outlying country being attributable to the absence of his natural enemies—man, dogs, and birds of prey; the reduction of his numbers by disease is only a scientific way of restoring the natural balance of life.

Professor Watson's scheme deserves further investigation. If it is harmless to stock, it may prove a useful auxiliary in dealing with the rabbit pest, even if it fails to eradicate it.

I have, &c.,

ALEX. S. PATERSON,
Colonial Surgeon.

The Hon. the Chief Secretary.

HE did not think it was necessary to go any further into the details of this scheme than had been done in that paper; but he might say that, on the recommendation which he had then made, in the circumstances of South Australia, the Government in the concluding sentence of their minute expressed the opinion that "Professor Watson's scheme deserved investigation." He had already stated that the question raised could only be settled by experimental inquiry. He was glad to see that Professor Allen also had recommended experimental inquiry; and if the various Governments took this matter up at all, they would have to conduct it in a scientific way to the end. They had spent thousands of pounds already to no purpose; and there was no reason why facilities for conducting a strict and proper scientific inquiry into the matter should not be given. Professor Watson's scheme was of the nature of scab, and he had reported to the South Australian Government that he considered the risk of injury to the human subject was next to nothing at all. The parasitic animal that was the cause of the scab in the rabbit was of the same class as the itch insect in man, and the scab insect in sheep, and the scab that affected swine. Professor Watson asserted that this parasite was not transmissible from one animal to another; on that subject he had consulted Hebra, and also Kuchenmeister's manual on parasites. Hebra expressed a different opinion from Professor Watson, but the other authorities were not explicit on the point; but the veterinary surgeons were all agreed that the insect was not transmissible, or capable of causing disease in another animal. The question that they now had to settle was this:—As to whether one of the schemes, including *sarcoptes*, was capable of producing scab in sheep. What was the position of the pastoralists now in reference to this? They were willing, he understood, rather than have this pest let go on, to run the risk of having scab in sheep, at least so he was informed. This, at all events, would give them an idea of the magnitude of the evil that these men were disturbed by. He had no doubt that this scheme would engage the best attention of the Commission, and that the matter would be determined by experiments as to whether the disease could be communicated to stock or not, or was capable of producing scab in sheep. Then as to its effectiveness, that, too, would, of course, have to be settled by direct experiments. That was the burden of his report to the South Australian Government. His colleague, Dr. Stirling, would give the Commission further information on the subject. Until the contrary was proved he would hold to his opinion, that the question could only be settled by experimental inquiry,—only in this way could it be definitely settled whether these *sarcoptes* were capable of being transmitted from one animal to another. Should the Commission decide to test Professor Watson's scheme by experimental inquiry, he thought it should be done under natural conditions, and in the country which had to be dealt with. He would say distinctly that he apprehended no danger for experimental inquiry conducted with this scheme, if some portion of the country were fenced off, in which infected animals should be placed with sheep. The first point, of course, was as to whether the disease would be destructive to the rodent, and, next, was it communicable to the sheep. He thought they might fairly leave swine and horses out of the question. These points would certainly have to be dealt with and approved by the Commission before anything could be done.

MR. PEARSON did not think that M. Pasteur's disease was the best one with which to begin experiments for the extermination of the rabbits. In the first place it was doubtful whether the disease existed in the colonies or not. Now there was a number of diseases in operation in Australia, and they knew pretty well what their action had been hitherto. Everyone that was spoken to about rabbits would say that there had been diseases amongst them. It would surely be safer first of all to inquire into the nature and action of these diseases. But in any case he did not think that one disease would be sufficient, because there must always be a certain number of the pest that would not be susceptible to one disease, and therefore there should be two or three diseases working together in order to get at the others. It would be specially important to obtain evidence as to the disease that was known here as fowl-cholera; as for all they knew it might act on the rabbits in just the same way as M. Pasteur's disease. There was another matter that was against Pasteur's proposal, which was, that chicken-cholera was too quick in its action. It killed the rabbits in from twelve to twenty-four hours. They wanted some disease that would last for a sufficient period to enable other rabbits to catch the disease from the infected ones and spread it about. It appeared to him that before they decided upon giving M. Pasteur's proposal a trial in the Colony they should first of all ascertain whether there was or was not any chicken-cholera in the Colony. It did not matter as to whether the disease were precisely the same as the disease known as fowl-cholera in Europe. If it could be used for killing rabbits, it should be used in preference to the European disease, as then they would escape the risk of introducing a new disease into the country. They must also bear in mind that there were entirely different conditions of climate, &c., to be met with in different parts of the country where the schemes would have to be tried. Although it had been said that the rabbits in
Victoria

Victoria were kept in check, yet there were many farmers in the coast districts who would be very glad of some easier method of keeping the pest down than the ordinary methods of fencing, poisoning, &c. The disease that would be effective in a moist coast district would almost certainly not be effective in the hot dry districts of mallee country, which was, he believed, the country where the question was most pressing. It was very important that the experiments should be tried in two places,—one might be an island, which would represent the moister districts of the colonies, and the other might be some district in the back blocks. He should say it was more important to take some locality in the interior first, because the difficulty in the interior was the most pressing. There were a great many other things that might be said, but they would no doubt come out in the discussion that would ensue. In conclusion, he would say that before they tried M. Pasteur's method they should endeavour to get something better in the colonies, if such a thing existed.

Dr. STIRLING remarked that what he had to say would be in confirmation of the statements made by Mr. Quin and Dr. Paterson as to the severity of the evil that they had met to combat, if they could. He thought the remarks which had fallen from these gentlemen ought to make it clear that it was a matter of the most extreme urgency, and he would like to add his testimony to that fact too. There was not the slightest doubt that large parts of the Colony of South Australia were being abandoned in consequence of this plague. He was fairly well acquainted with the same kind of country that Mr. Quin had spoken of, and he could confirm what had been said as to the utter desolation that now prevailed in these districts. There was one question which, however, he was surprised Mr. Quin did not allude to in his address, and that was, that one of the great reasons why the rabbits were spreading was because of the fact that the men who were paid for destroying them were directly or indirectly the means of it. He knew very well that rabbits were being carted about by hawkers and others, that captured does were turned loose, and that the greatest pains were taken to destroy all enemies of the rabbits. These men, as many Members of the Commission must know, made large sums of money out of the destruction of rabbits, and there could be no question that so long as people got paid for the destruction of rabbits, on the scale on which they had been paid, the rabbit pest would break out again as fast as they were killed. He would now turn to the address of Professor Allen, which he thought showed considerable carefulness in preparation. The only objection that he could see to Professor Allen's address was that it suggested an inquiry of a far more complete character than the Commission had been called on to perform. He did not think that they would investigate the life history of the chicken-cholera or any other bacteria. It was hardly to be expected that the Members of the Commission, who were drawn from the ordinary walks of life, should attempt to settle matters which had been under the consideration of the professional bacteriologists for many years. There were certain diseases which it was said were capable of destroying the rabbits, and what they had to inquire into was would these diseases destroy rabbits in the natural conditions under which rabbits lived, and would they pay under the conditions in which they would have to be tried in this country, with safety at the same time to man and other animals. Was it practical, and could the country afford to pay the cost of it? As Professor Allen had already stated, if these microbes had to be put before each batch of rabbits, the disease would be far too expensive to apply. The question which now appeared quite clear and to which the Commission should devote all their attention was the contagiousness of Pasteur's disease. Would the disease spread from rabbit to rabbit as ordinary infectious diseases spread? It seemed to him that while they would be occupied in the inquiry, which Professor Allen suggested, the rabbits would keep on increasing, and the difficulty would become even larger than it now was. Now in regard to the safety of the disease, he thought they must consider it in the light of its reasonable safety. There was more or less danger in everything, and risks must be run in all experiments of this kind; all they could do was to reduce these risks to a minimum. He wished to bring into prominence the question of the practicability of the diseases in the conditions under which it would have to be applied in these colonies, and while Professor Allen had addressed his remarks to M. Pasteur's disease, the same remarks would apply to any other. Professor Allen had merely taken this for a text, but what he had said on this head was equally applicable to the other diseases as well as to M. Pasteur's. A great many other schemes of extermination by disease had been suggested. He was informed that there was a disease suggested by Dr. Ellis, and, here he might say, was a case where they might satisfy themselves, and might learn something without going so far as Tintinology. Dr. Ellis had some infected rabbits at his residence at Double Bay, which, he believed, was quite handy to Sydney. But he wished again to insist on one point, and that was the necessity of experiments being carried on under natural conditions. There was no doubt they might have different conditions of things where experiments would produce entirely different results; and while no one could raise any objections to experiments being carried on on an island, they could hardly be satisfactory so far as the interior of the country was concerned. As to the disease introduced by Professor Watson, he thought its efficacy was a matter entirely dependent on climate. It was, he knew, exceedingly fatal in wet weather, but in hot weather it stood almost still and tended to recovery. They all knew that the interior portions of Australia were exceedingly dry and hot, and these were the conditions which must stand out for in any experiments that might be attempted. The risks, of course—he would return again to that point, because it was a very important matter—were of such a character that he did not see how they could be determined, so far as man was concerned, unless some one was willing to swallow the microbes; but they might be tried, at all events, on the ordinary animals. And so far as the pastoralists of the country were concerned, their interest would be chiefly confined to whether the disease was capable of being transmitted to sheep, horses, and cattle. They knew that a great many birds might possibly be affected; and he supposed if they conducted experiments they would find that to be the case. But even so, there would not be any reason, to his mind, for opposing a scheme if otherwise it could be proved to be acceptable. He did not know that there was at present any information as to how wild birds were affected by any epidemic of chicken-cholera; and he believed it would be found that the disease was not the all-devastating element that it was thought to be by some people. With regard to Professor Watson's disease, he had frequently seen his rabbits die from extreme emaciation and enlargement and suppuration of abdominal and inguinal glands. More than one parasite could be detected upon them; but he did not think he need go further now into that subject. Several experiments were made as to the communicability of the disease to sheep, and he had seen three sheep which were inoculated some six times. They were shorn, and the parasite put in five or six times—twice, he believed, by Mr. Stanley, who belonged to this Colony and who would confirm what he said. He (Dr. Stirling) saw the sheep when he came away from Adelaide, and they were quite well. There had been six attempts at infection and were six months under observation, and yet they were now free from any disease. Professor Watson had tried this disease

upon himself, with nothing as a result but a temporary irritation—so confident was he that the thing was not communicable to man. The whole of his remarks, then, came to this: He thought they should be willing to give the most favorable consideration to any disease which would help the country in this matter of extreme urgency. And, although he did not believe that one single disease would be sufficient, they might by one or more produce a general effect on the vitality of the race of rabbits, which, coupled with the severity of the climate, would materially help in reducing the number of them. Although they might not be able to discover an absolute specific, they might get assistance from these diseases. So far as Dr. Paterson and he were concerned, what they should like to see done was a general scheme of experiments tending in the direction which he had indicated, in those diseases which seemed to be worthy of their consideration.

Dr. BANCROFT said that it appeared this disease of M. Pasteur's propagated itself amongst fowls, but not amongst rabbits. It would have to be worked up again and again if it were used against the rabbits. They had no history of its having been spontaneous in its action. They were aware that fowls obtained the disease, and that it passed from fowl to fowl in the old country, and the probability was that if introduced here it would act in the same way. It was purely a disease of fowls, and it struck him that it would not propagate itself amongst rabbits without very considerable assistance—such assistance as might possibly render it too expensive and too difficult to be carried out. He would like to see some island selected where experiments with this disease could be carried on without fear of mischief to other animals. It should be very fairly and very carefully considered, and he believed the Queensland Government would be glad to help in any way to have the question determined. Fortunately they had no rabbits in Queensland at the present time; but every effort would, he gathered, be made to help the other colonies to get rid of the plague. But except the experiments were very carefully carried out, he feared they might distribute more diseases than they wanted to distribute. It would be better if the whole of the knowledge to be acquired by any scientific Commission should be obtained before any efforts were made towards the distribution of the disease inland. He should much prefer to see all that they could get done, done on an island first, and they would then be free from all risks. They should be careful not to proceed too hastily, for this was a work which could not be done in a day, or in a week, or perhaps in a year. They might at least hope to reduce the pest, and there may be diseases perhaps which would assist them in doing so. He remembered having kept rabbits in Queensland which had diseased livers. A parasite existed in the liver, and the eggs discharged were in millions. All the rabbits that took it died. It propagated itself amongst young rabbits; and perhaps after the lapse of a month or two, if the livers were examined, a number of white spots were observable, showing where the destructive action was going on. The condition of the liver became worse and worse until the animal died. He had no doubt but that the scab disease spoken of by Professor Watson would help to reduce the pest. He had seen it at home, and it affected the rabbits very considerably. No doubt a drier country was more protected, because diseases would not spread so much where everything had a tendency to dry up. Wherever moisture was present, of course, life was more active. The influence of disease, in the matter of birds, was a very serious point. He did not like the idea of birds being destroyed, and he thought it would be very much safer to first carry out the experiments suggested by Professor Allen. He was very glad indeed to hear that there was an island in Bass's Straits where this experiment could be fairly tried, and where the experiments need not cost very much.

Mr. QUIN: Then there is Dangar Island, in Broken Bay.

Dr. BANCROFT thought that if a few men of ability were placed on this island, who had a medical and scientific education, good results would be obtainable from their observations. They could easily get up a history of the disease in twelve months time—in fact, of all possible diseases on rabbits; and then the Commission would be in a far better position to introduce disease into the back country. He thought this would be much the safer course, and therefore he would earnestly urge it on the Commission.

Mr. QUIN asked,—What was to become of the pastoral interest during those twelve months?

Dr. BANCROFT: Well, a perfect remedy could not be obtained in one month. If they did not apply the remedies with their eyes open, there was no use in going on with their eyes shut. It was far better to learn first what could be learned, and then proceed to action.

Mr. TABART said: I look upon the rabbit pest as the great question of the Australasian Colonies, and one that requires to be dealt with vigorously and stringently. At the same time, I do not consider it judicious to allow any foreign disease to be introduced, with the view of rabbit extermination, until it has been conclusively proved beyond a shadow of doubt that the disease introduced will not be communicated to sheep or other animals. The pastoral interest is an important one to tamper with, seeing that New South Wales numbers this year 47,000,000 of sheep, Tasmania, 1,500,000, and in the other Colonies correspondingly large numbers are depastured. Tasmania is suffering from this rabbit plague; the sheep have decreased during the past ten (10) years at the rate of 30,000 annually. I consider the primary cause is increase and extension of rabbits. I am pleased to find that Dr. Stirling holds the same opinions as to the extension of the rabbits, viz., the employment of trapping and hunting labour. This, with the bonus system, is conclusive evidence to me that these methods simply mean *rabbit farming*. Disease has upon several occasions attacked rabbits in different localities in Tasmania. About five years past, the late Mr. Willows, V.S. for New South Wales, and Mr. Archibald Park, V.S. for Tasmania, reported upon an outbreak of disease amongst rabbits upon the Ellenthorp Hall property. I believe the report is now in the possession of the present administration of the Rabbit Act of New South Wales. Small numbers died upon the first appearance of the disease, but the form was not sufficiently fatal to destroy all rabbits upon the property. I may also mention that upon two other occasions disease appeared upon two estates 60 miles from each other, and had the effect of killing all the rabbits. Unfortunately no investigation as to the nature of the disease was instituted, or how it originated. In conclusion, I consider that whatever experiments are made as to the efficacy to destroy rabbits by introduced disease, tests should be first conducted upon an island, and, if found that sheep and other stock are not susceptible, then it could be introduced with caution on to the mainland, and further trials made within a tract of land enclosed with rabbit-proof fencing.

Dr. WILKINSON complimented Professor Allen on the delivery of an able and exhaustive address. He went with Professor Allen a very long way in the points which he had considered as to the effectiveness of the methods of destroying the rabbits. But there were certain points in Professor Allen's address to which he desired to take exception. In the first place Professor Allen likened the action of this poison to the action of phosphorus or arsenic. Now there was a very essential difference between these poisons and a living germ capable of destroying life. In the one case we have to deal with a fixed quantity of dead

EXTERMINATION OF RABBITS IN AUSTRALASIA—REPORT OF PROCEEDINGS. 11

dead matter, and in the other with living matter which increased and multiplied to an enormous extent. Further, Professor Allen seemed to take exception to the experiments which had taken place on the Continent on the Pommeroy vineyard, because in this case the disease was communicated through food, and not apparently from rabbit to rabbit. Unfortunately he had not a description of those experiments with him, but he was quite certain that the wholesale destruction of the rabbits on that estate could not have been caused directly by the small quantity of the poison which had been spread on their food. This was his recollection of that particular experiment; but if this disease did not spread amongst the rabbits from one to the other, then from all they could learn there could be very little danger in introducing such a disease. One of the most important matters which the Commission would have to take in hand would be to recommend certain means by which it could be positively proved that this disease would be effective. He quite agreed with the remark which had been made by Dr. Bancroft, that this disease had not shown any natural affinity for the rabbit. There was no instance of any spontaneous outbreak of the disease amongst the rabbits, while there was evidence of a certain amount of value which made them believe that the disease could not spread itself amongst rabbits as effectually as it did amongst fowls. Therefore, if the disease were to be introduced, it would not only exterminate rabbits, but other animals would be endangered by it. He knew that this disease in fowls would kill mice. He had had an opportunity of making experiments in Berlin under Koch, and he remembered perfectly having introduced these germs into mice and killing them. The recommendations which Professor Allen had made were practically the same as those which he had made in a letter addressed to the Government some weeks ago. He would add something further, that as many as possible of the ordinary useful animals should be taken to this island to live with the diseased rabbits. They would have an opportunity of observing in such a case whether the disease would spread from one animal to another. If it were true that in this particular case the disease did not spread to any of our useful animals, it would be worth trying elsewhere. He quite agreed with Dr. Paterson and Mr. Quin with respect to the enormous harm that the increase of these rabbits in the back-blocks was doing. Professor Allen had made several other statements of a purely scientific nature to which he could not help taking exception. One of these was in regard to experiments which had taken place in 1878. Well, he would say that experiments made in 1878 were not experiments upon which the Commission could place absolute reliance. The whole question of bacteria was then in its infancy, and when experiments were made no precautions were taken to exclude contamination. The very history of investigations into the nature of tuberculosis was an instance of what he stated, for by many authorities in 1878, and even up to 1882, it was supposed that tuberculosis could be produced by irritative matter. But by more perfect and exact methods it was now proved, beyond doubt, that in all these cases there had been external contamination with tubercular matter. He was sorry he had been unable to carry the statement of Professor Allen fully in his mind, because it was necessary to examine details when considering a question like this. Professor Allen implies by his statements that there is such a close resemblance between the symptoms of swine plague, when conveyed to rabbits and birds by inoculation, and fowl-cholera, that even the best bacteriologists hesitate to say that the two diseases are distinct, indeed they seem to be cases of septicæmia. Now the Commission can place no trust in such statements. There may indeed be identity of symptoms, but that does not show the symptoms to be due to the same cause, to the same form of organism. If this were true, it would mean that all the work of Koch, and other leading bacteriologists, was to be upset. Klein has proved, beyond all question, that Pasteur was wrong, that his conclusions were drawn from experiments open to the gravest objections. If then, at this time, the Commission is to be swayed by the results of faulty and inexact experiments, we can come to no scientific conclusion in the important matters placed before us. Identity of symptoms is not proof of identity of cause. And it is not wise to use the term septicæmia or hæmorrhagic-septicæmia. We know that septicæmia means only the presence of certain bodies (ptomaines) in the blood which act prejudicially upon the red corpuscles and tissues. This condition may arise in mice and rabbits from different causes. But when we speak of mouse-septicæmia, we mean a form of septicæmia which is produced by a well defined, easily recognized fine bacillus, a bacillus so small that 10,000,000,000 of them can rest on the surface of a penny. Further, this bacillus is extremely fatal in house-mice—it is even said that one bacillus is enough to kill—and yet, strange to say, this same bacillus will leave quite unharmed a field-mouse. There then we have a change of function in the bacillus, not only most extraordinary, but developing in the most unexpected manner. Now it is such an unexpected change in the action of such bacilli that render it necessary for us to be extremely cautious in our investigations. Further illustrations of the altered virulence of organisms under different conditions are to be found in connection with symptomatic anthrax. It is found that a few drops of lactic acid have the power of enormously increasing the virulence of an attenuated virus from a case of symptomatic anthrax. On the other hand the virulence of malignant anthrax can be diminished, even it would seem, destroyed by the cocci of erysipelas, and, stranger still, by the colour producing micrococcus—the micrococcus prodigiosus. These then are good instances of altered virulence from entirely unexpected causes. But alteration of function is a very different thing to alteration of form. Practically it is now acknowledged by all the best bacteriologists that each variety of these minute forms of life has a fixed form always the same for the same variety. Thus the bacillus of anthrax has always a definite form, varying only with the stages of its existence. At first a rod of definite thickness, though varying in length, then a long filament joined from the rod by elongation, and finally a spore-containing filament, from which spores are liberated. These definite phases can always be defined, and under the same conditions are always the same for the same variety. Thus too the microbe of the cholera of fowls is always an oval micrococcus—never a bacillus or rod. This is a very important point that a bacillus cannot become a micrococcus nor a micrococcus a bacillus. If experiments seem to point otherwise, as has been often stated, it has so far always been proved that the change of form is really due to the introduction of contaminating micro-organisms through accident or want of skill in making these experiments. Therefore it is that I say that Professor Allen's account of Toussaint's experiments, and experiments of a similar kind may have a historical interest but cannot be of any practical value to the Commission in its important work. No doubt there are numbers of organisms of apparently the same form, which can be distinguished only by the minutest tests. Thus we know there are a score or more of micro-organisms which cause suppuration—all differing from one another in certain definite points, and yet all identical in their action of causing suppuration. Further there are organisms of the same appearance, some of which have distinct chemical, others physical, others physiological, others pathogenic effects. Yet all these forms can be separated

separated from one another with certainty by certain methods. But it is only by the very strictest precautions and constant care that exact work of this kind can be done. Without such precautions misleading results follow such as those of Toussaint and the other investigators to whom Professor Allen has referred. The practical question to his mind was that the Commission should be in a position to be able to pick out the best of the different methods of destruction. The question of funds was not a matter for the Commission, and there was no doubt that the Government would be willing to grant a sufficient allowance to enable the Commission to carry out its inquiries. Still this was a matter which chiefly concerned one great industry and one great class of the community, and they had a right to expect that this class would contribute a proportion to the cost of the experiments. Of course, the Government would supply the money from the public funds; but yet, as the matter was one chiefly affecting a particular class, they had a right to expect some contribution from that class.

Mr. QUIN: It is a matter of general interest.

Dr. WILKINSON: Yes, it did in some way affect every individual in the community; but, while it affected one particular class immensely, it affected another particular class very little. The greatest gain, undoubtedly, would be to the pastoralist and those engaged in trade connected with the pastoral industry.

Mr. QUIN: The question affected the general government, and of course the whole people. Was not the £50,000 paid by the squatters every year under the Rabbit Bill a contribution towards it?

Dr. WILKINSON: Yes, that is certainly something towards it.

Mr. QUIN: Surely, you do not want any more out of us?

Dr. WILKINSON said he wanted all that could be obtained. He was quite sure that the Government would do all that they could to assist the Commission in their work. It would have been unwise for them to bring scientific men from the different colonies unless they really wished to do some practical work, and this work should take the form of experiments under conditions which would ensure the country from disaster.

Mr. QUIN said he would like to move, that the speeches which had just been delivered, be printed and distributed to the Members of the Commission.

Dr. BANCROFT: I shall be glad to second that. Facts—such as those mentioned by Professor Allen—disappear quickly from people's minds, and I think they should be printed just as the proceedings of Parliament are printed.

The motion was agreed to.

Mr. QUIN moved,—“That, in order to test the safety, efficiency, and practicability of the application of disease to the purpose of rabbit extermination, experiments are necessary. The Commission therefore recommends that the Government permit the use of an island as well as an inland tract of land for the purpose, where the experiments may be conducted under proper supervision, and that the necessary funds be provided.”

Dr. STIRLING seconded the motion.

Mr. PEARSON supported the motion, but he thought they could get a block of land in the interior equally as isolated as any island could be.

The motion was agreed to.

It was moved by Dr. STIRLING, and seconded by Dr. PATERSON,—“That M. Pasteur's representatives are invited to meet the Commission at 10 a.m., and Dr. Ellis at 2 p.m., the next day.”

The motion was agreed to.

The Secretary was directed to obtain a map of the country infested by rabbits, and also returns of the cost of rabbit destruction.

At 5:30 p.m. the Commission adjourned until 10 a.m. on the following day.

TUESDAY, 17 APRIL, 1888.

The Commission met at 10 a.m., at the Colonial Secretary's Office, Sydney.

Present :—

New South Wales : WILLIAM CAMAC WILKINSON, Esq., M.D., M.P.

EDWARD QUIN, Esq.

Victoria : HARRY BROOKES ALLEN, Esq., M.D.

ALFRED NAYLOR PEARSON, Esq., F.R. Met. Soc., &c.

South Australia : EDWARD CHARLES STIRLING, Esq., M.D.

ALEXANDER STUART PATERSON, Esq., M.D.

Queensland : JOSEPH BANCROFT, Esq., M.D.

Tasmania : THOMAS ALFRED TABART, Esq.

In the absence of the President (Dr. MacLaurin), the Chair was taken by Professor ALLEN.

Dr. BANCROFT moved,—“That this meeting recommends that the methods of destroying rabbits by M. Pasteur's scheme, or by other diseases not now existing in Australia, be tested, in the first instance, and without delay, on an island, and that experiments inland in connection with each scheme be delayed until its safety and practical value have been demonstrated. Provided that this resolution shall not prevent the Commission from conducting laboratory experiments from time to time under such precautions as the Commission may determine.”

The motion was seconded by Dr. STIRLING, and carried.

It was moved by Dr. BANCROFT, and seconded by Dr. STIRLING,—“That experiments with any rabbit disease already existing in Australia be conducted without delay in some suitable inland areas.”

The motion was agreed to.

Mr. QUIN moved,—“That the Government be asked to enclose with rabbit-proof fencing an area of country not exceeding 10,000 acres in the infested portions of the interior of the Colony, and that all preparations that the Commission may deem necessary be made at once, so that experiments under their direction may be carried out without delay.”

Dr. PATERSON seconded the motion, which was carried.

Dr.

EXTERMINATION OF RABBITS IN AUSTRALASIA—REPORT OF PROCEEDINGS. 13

Dr. STIRLING moved,—“That the Government be advised that M. Pasteur’s representatives be permitted to introduce into the Colony of New South Wales the cultivation of microbes of chicken cholera, provided that they undertake to conduct no experiments therewith without the sanction of the Commission.”

The motion was seconded by Dr. WILKINSON, and carried.

Dr. WILKINSON moved,—“That the Government be advised to provide a laboratory where experiments can be made under the control of the Commission, with a view to the investigation of the scheme of Pasteur, and any other of a similar kind.”

Dr. BANCROFT seconded, and the motion was carried.

Dr. STIRLING moved,—“That the resolutions hitherto adopted be transmitted to the Colonial Secretary at once, and that a reply be requested at his earliest convenience.”

The motion was seconded by Dr. WILKINSON and carried.

Frank Hinds, M.D., was called in and stated that the representatives of M. Pasteur would probably arrive in Sydney on Thursday.

Henry Augustus Ellis, M.B., was called in and examined concerning the so-called Tintinology disease.

Dr. STIRLING moved that the commission meet at 10:30 a.m., on the morrow, to proceed to Dr. Ellis’s residence to view the *post-mortem* examination of an infected rabbit and such specimens as Dr. Ellis may exhibit. Dr. WILKINSON seconded the motion, which was carried.

It was decided on the motion of Dr. STIRLING, seconded by Mr. PEARSON, that the commission at its rising should adjourn until Monday next at 10 o’clock, when the representatives of M. Pasteur would be afforded an interview.

A communication was received from the Under Secretary for Lands enclosing copies of letters from Dr. Hinds (M. Pasteur’s representative) and Messrs. Butcher and Ellis, in respect to their several schemes; also return showing cost of rabbit destruction.

It was moved by Dr. STIRLING, and seconded by Dr. PATERSON, that the commission requests the Honorable the Secretary for Lands to inform Messrs. Butcher and Ellis that, in accordance with the request contained in their letter, all particulars submitted by them concerning their suggested disease will be considered confidential, but that the commission will require its representatives to be associated with Messrs. Butcher and Ellis in the conduct of any experiments that may appear to it necessary. The motion was agreed to.

It was decided also to inform the Honorable the Minister for Lands that, in accordance with the terms of the proclamation of the Government of New South Wales, and with the request of M. Pasteur’s representatives, the commission would treat as confidential the details of any method that might be examined but not adopted for trial by the Government; and to request that Dr. Hinds be so informed.

It was decided to obtain from the Lands Department copies of all reports by Messrs. Vindin, Clarke, Tully, and Stanley concerning Drs. Ellis and Butcher’s experiments.

The Commission at 4:30 p.m. adjourned until Monday next, at 10 o’clock.

WEDNESDAY, 18 APRIL, 1888.

The Commission met at 10 a.m., at the Colonial Secretary’s Office, Sydney.

Present :—

New South Wales : WILLIAM CAMAC WILKINSON, Esq., M.D., M.P.
EDWARD QUIN, Esq.

Victoria : HARRY BROOKES ALLEN, Esq., M.D.
ALFRED NAYLOR PEARSON, Esq., F.R. Met. Soc., &c.

South Australia : EDWARD CHARLES STIRLING, Esq., M.D.
ALEXANDER STUART PATERSON, Esq., M.D.

Queensland : JOSEPH BANCROFT, Esq., M.D.

Tasmania : THOMAS ALFRED TABART, Esq.

In the absence of the President (Dr. MacLaurin) the Chair was taken by Professor ALLEN.

Dr. PATERSON inquired if the disease referred to as bladder fluke in New Zealand was one of the modes of destroying rabbits submitted for the consideration of the Commission. He alluded to a report which had appeared in one of the South Australian papers concerning the destructiveness of this disease, and there was also a remark in the same journal attributed to the Minister of Crown Lands in South Australia, to the effect that he thought that this was one of the disease schemes which would engage the attention of the Conference.

The question was postponed, pending the production of papers already asked for. It was understood that Dr. Bancroft would telegraph to Dr. Hector of New Zealand for specimens of bladder fluke.

Dr. STIRLING requested that all information possible should be obtained relative to the disease which had prevailed among rabbits in Tasmania, as mentioned by Mr. Tabart.

Mr. TABART stated that the papers relative to the inquiry into the disease conducted by Mr. Willows were in the office of the Rabbit Department in Sydney. He believed it was the same disease which had appeared at Tintinology.

It was agreed that application be made for these papers.

It was resolved to instruct the Secretary to summon Dr. Hinds and his colleagues representing M. Pasteur to give evidence on Monday next at 10:30 a.m.

It was resolved to instruct the secretary to telegraph to Professor Watson, Adelaide University, asking him to furnish in writing, as soon as possible, a short statement of particulars concerning his experiments with rabbit scab in reference to its effects on various forms of animal life.

Dr. BANCROFT suggested that the Hon. Mr. Macleay, Mr. Haswell, and Mr. Stanley be invited to give evidence before the Commission.

The suggestion was agreed to, and the Secretary was instructed to inform these gentlemen that the Commission propose to take their evidence during next week, on a day to be hereafter named.

It

It was also resolved that a copy of the Commission be supplied to each member thereof.

The Commission then proceeded to the residence of Dr. Ellis, and examined certain rabbits suffering from the disease which Dr. Ellis had described. Several rabbits were killed—some healthy, some diseased,—and *post-mortem* examinations were conducted.

MONDAY, 23 APRIL, 1888.

The Commission met at 10 a.m., at the Colonial Secretary's Office, Sydney.

Present :—

<i>New South Wales</i> :	HENRY NORMAN MACLAURIN, Esq., M.D. (President.) WILLIAM CAMAC WILKINSON, Esq., M.D., M.P. EDWARD QUIN, Esq.
<i>Victoria</i> :	HARRY BROOKES ALLEN, Esq., M.D. ALFRED NAYLOR PEARSON, Esq., F.R. Met. Soc., &c. EDWARD HAREWOOD LASCELLES, Esq.
<i>New Zealand</i> :	ALFRED DILLON BELL, Esq.
<i>South Australia</i> :	EDWARD CHARLES STIRLING, Esq., M.D. ALEXANDER STUART PATERSON, Esq., M.D.
<i>Queensland</i> :	JOSEPH BANCROFT, Esq., M.D.
<i>Tasmania</i> :	THOMAS ALFRED TABART, Esq.

A communication was read from the Under Secretary for Lands having reference to the request that an island and an inland tract of country should be placed at the disposal of the Commission. The writer stated that Montague Island seemed most suitable, but if this did not meet with the views of the Commission the Broughton Isles might be examined. The Secretary of the Commission was directed to obtain further information about Montague Island. Subsequently a letter from the Secretary of the Marine Board was read giving the information required.

A further communication was received from the Under Secretary for Lands stating that the Government had received two offers of station holdings for carrying out experiments—"Tarella," and "Roto." The former was near Wilcannia and the latter adjacent to Hillston. Dr. Paterson proposed that the offer of Tarella station, which was near Tintinallong, should be accepted. The motion was seconded by Dr. Stirling and carried. Mr. Quin stated that he declined to vote on the matter, as Tarella was his property. He had offered to assist the Minister for Lands in any way he could, and had offered the use of Tarella run, the fences, plant, homestead, &c., free of any cost to the Government or to the Commission.

A further communication was received from the Under Secretary for Lands stating that the Principal Under Secretary had been requested to arrange with the Board of Health the fitting up of a laboratory where experiments could be carried out. The President stated that so far as the Board of Health was concerned nothing had yet been heard of the matter. Subsequently Dr. STIRLING moved, "That the Chairman (Professor Allen) be requested to see Mr. Macleay to make arrangements for the use of the Linnæan Society's laboratory if possible." Mr. BELL seconded the motion, which was carried.

It was resolved that a telegram be despatched to Dr. Oscar Katz, requesting his attendance on the Commission during the afternoon.

M. Loir, Dr. Germont, and Dr. Hinds, the representatives of M. Pasteur, were then introduced.

In the presence of the representatives of M. Pasteur the Secretary read the following letter:—

The Pasteur Institute, Paris, 20 February, 1888.

To the President of the Commission entrusted with the consideration of the scheme for the destruction of rabbits, proposed by M. Pasteur,—

Mr. President,

Paris, 20 February, 1888.

By a letter addressed to the journal *Le Temps*, of Paris, on the 29th November, 1887, I proposed a scheme for the destruction of rabbits in Australia, based on the employment of the disease known as chicken-cholera.

After the communication of my letter to the journal *Le Temps*, I made various experiments, both in my laboratory and on a more extensive scale, which allowed me to believe that the application of chicken-cholera to the destruction of rabbits would answer all the conditions of the scheme of reward proposed by the Government of New South Wales.

Consequently I decided to send to Sydney, at my own expense, three young *savants* entrusted with making, on my behalf, all the experiments of demonstration calculated to prove that the scheme in question for the destruction of rabbits is at once efficacious and practical.

Should the reward be adjudged to me when the Commission arrives at its decision, the delegates shall be bound to reveal to the Commission, in all its details, the process which shall have been applied, especially certain particulars without which it could not be made practical.

In the scheme of reward of the Government of Sydney, published in Europe at the end of the year 1887, it is stated 'that the scheme should not be judged by the Commission nominated for that purpose, until after a year's trial.'

I do not believe that so long a time is necessary, and I am persuaded that the Commission will share my opinion on this point.

I think that the Commission entrusted with adjudging the reward will be able to arrive at a conclusion after a month or six weeks trial.

Please accept, Mr. President, the assurance of my high regard.

L. PASTEUR,

Member of the Institute of France, of the Royal Society of London and of the Royal Society of New South Wales.

Annexed are two copies, one in English and one in French, of my note to the Agents-General.—

L.P.

Dr.

EXTERMINATION OF RABBITS IN AUSTRALASIA—REPORT OF PROCEEDINGS. 15

Dr. Frank Hinds was then examined, and undertook, at the request of the Commission, to prepare a written statement concerning M. Pasteur's proposals. In answer to questions, he specified what provision M. Pasteur's representatives would require for the conduct of their experiments.

Professor ALLEN moved,—“That, after hearing the statement of Dr. Hinds, the Commission recommends that permission be granted to the representatives of M. Pasteur to cultivate the microbes introduced by them by inoculation into suitable animals, the place and details of the experiments to be approved of by the Commission.” Dr. BANCROFT seconded the motion, which was carried.

Mr. LASCELLES moved,—“That the netting to be used in erection of fence around the 10,000 acres, and on the small pieces to be enclosed within the large area shall be 48 inches in width, 16 or 17 gauge, and 1½ inch mesh, and that the Government be requested to at once procure the necessary material.” The motion was seconded by Mr. QUIN, and carried. The following was added on the motion of Dr. STIRLING, seconded by Mr. PEARSON, “That, in the first place, six enclosures of 50 or 100 acres each, be constructed in localities to be indicated by persons appointed by the Commission, to be within the larger general enclosure.” Direction was given that the Under Secretary for Lands be requested to furnish fifty rabbits for the purpose of conducting experiments.

It was then moved by Dr. STIRLING, and seconded by Dr. PATERSON—“That Professor Watson be asked to secure and forward to the Commission six rabbits infected with *sarcoptes cuniculi*.” The motion was carried.

Mr. PEARSON moved,—“That an advertisement be inserted in the newspapers inviting information from persons who have observed rabbits dying off as if by disease; also that the Commission desires to buy fowls suffering from fowl cholera.” Mr. LASCELLES seconded the motion, which was carried.

It was moved by Dr. STIRLING, and seconded by Mr. BELL, “That experiments be at once made on behalf of the Commission with the disease suggested by Drs. Butcher and Ellis.” The motion was carried.

Dr. WILKINSON moved,—“That application be made to the Government, through the Minister for Lands, for an advance of £500 to defray the necessary expenses of carrying on the work of the Commission.” Mr. QUIN seconded the motion, which was carried.

Dr. OSCAR KATZ, of Linnean Hall, Elizabeth Bay, was accorded an interview, and stated his qualifications for conducting such experiments as the Commission might require to be made. It was resolved to request Dr. Katz to attend again at 11 a.m. to-morrow.

It was also resolved,—“That Dr. Wilkinson, Dr. Stirling, Prof. Allen, Dr. Bancroft, Mr. Pearson, and Mr. Dillon Bell be a Committee to prepare a list of test experiments.”

Mr. LASCELLES moved,—“That facilities be given to M. Pasteur's representatives to conduct preliminary experiments at the laboratory of the Central Board of Health under such precaution as Dr. MacLaurin may prescribe.” The motion was seconded by Dr. STIRLING, and carried.

Professor ALLEN stated that he believed that the disease suggested by Drs. Ellis and Butcher was *coccidium oviforme*, and as he knew where a description of the disease was to be found he would, if the Commission so desired, prepare an abstract of it for the use of the Commission. Professor Allen was accordingly requested to prepare such an abstract.

It was directed that twelve copies of Report of Board of Health, and other papers *re* rabbit destruction, laid upon the Table of the Assembly in March, 1888, should be obtained. Also a copy of Dr. Mackellar's report, dated December, 1883, on “Tuberculosis in Rabbits.”

The Commission, at 5 o'clock, adjourned until 10:30 a.m. next day.

TUESDAY, 24 APRIL, 1888.

The Commission met at 10:30 a.m. at the Colonial Secretary's Office, Sydney.

Present:—

New South Wales: WILLIAM CAMAC WILKINSON, Esq., M.D., M.P.

EDWARD QUIN, Esq.

Victoria: HARRY BROOKES ALLEN, Esq., M.D.

ALFRED NAYLOR PEARSON, Esq., F.R. Met. Soc., F.C.S., A.I.C.

EDWARD HAREWOOD LASCELLES, Esq.

New Zealand: ALFRED DILLON BELL, Esq.

South Australia: EDWARD CHARLES STIRLING, Esq., M.D.

ALEXANDER STUART PATERSON, Esq., M.D.

Queensland: JOSEPH BANCROFT, Esq., M.D.

Tasmania: THOMAS ALFRED TABART, Esq.

In the absence of the President (Dr. MacLaurin), the Chair was taken by Professor ALLEN.

The CHAIRMAN stated that he had already seen the Hon. Mr. Macleay, who informed him that Dr. Katz was a member of the Linnean Society, and was entitled to the rooms, appliances, and instruments in the Linnean Laboratory. The question of admitting an assistant to Dr. Katz, must, however, be referred to the Council of the Society.

The CHAIRMAN stated that a difficulty in the use of the Linnean Society's Laboratory would arise from the necessity that M. Pasteur's representatives, and Drs. Butcher and Ellis, should have access to all experiments conducted in pursuance of their schemes.

The CHAIRMAN next submitted a schedule of experiments prepared by the Committee appointed at the previous meeting for that purpose.

CHICKEN-CHOLERA.

1. Infect 9 rabbits with food containing microbes of chicken-cholera:—Place 3 in wooden hutches, each with 2 healthy rabbits. Place 3 in wire-bottomed cages, each with 2 healthy rabbits. Place 3 in artificial burrows, each with 2 healthy rabbits. Place fresh excrement from diseased rabbits in a clean hutch, and introduce 2 healthy rabbits.

Report

Report condition of all rabbits every eight hours till time of death, or, failing death, till close of third day in the three first experiments, and till the end of a week in the last experiment.

2. The following animals to be fed once a day for six days with food containing microbes (cultures):—2 sheep, 2 cattle, 2 calves, 2 lambs, 2 horses, 2 pigs, 2 goats, 2 dogs, 2 cats, 2 rats, 2 mice.

If death or serious illness occurs in the case of any animal, 6 other such animals to be experimented upon—2 by inoculation with cultures; 2 by feeding with cultures; 2 by adding excrement of diseased rabbits to food. Special cultures to be made from such animal, and preserved specially marked.

3. Place the following birds in one large aviary:—2 fowls, 2 ducks, 2 geese, 1 turkey, 1 wild duck, 1 teal, 1 quail, 2 parrots, 1 magpie, 1 jackass, 1 crow, 1 sea-gull, and any other obtainable birds. Let infected broth be added to their food once a day for six days. If any bird do not contract the disease, inoculate it with cultures.

4. Infect 20 rabbits in successive series one from another, and test the comparative virulence in the 5th, 10th, 15th, and 20th cases by transmission to fowls. Report also on the history of each rabbit so infected. In this series transmission to be in every case by inoculation.

If fowl-cholera be discovered in the Colony, the symptoms, *post-mortem* appearances, cultures of organisms, and inoculation results should be at once compared with those observed in connection with M. Pasteur's microbes.

In experiments 2 and 3 all animals to be placed together in the same enclosure, so far as is practicable consistently with the object of the experiments.

THE TINTINALLOGY DISEASE.

1. Obtain 9 rabbits suffering from the disease, and conduct an experiment with them on the lines of Experiment 1 under Chicken-cholera. Keep diseased and healthy animals together for not less than a week. Keep animals under observation for at least three weeks.

2. Inoculate healthy rabbits with blood, pericardial fluid, discharge from nose and eyes, bile, and excrement from diseased rabbits. Eliminate carefully every other possible source of infection.

3. Feed healthy rabbits with food on which the following substances from diseased rabbits have been dropped:—Discharge from eyes and nose, excrement.

Feeding experiments on other animals to be postponed until the nature of the disease is made clear.

Dr. BANCROFT moved, and Mr. PEARSON seconded,—“That the Commission recommend that a house, approved of by them, having at least six rooms, with half an acre of land attached, having gas and water laid on, with stabling and other appurtenances, be rented for four months, and that officers appointed by the Government, on the advice of the Commission, be authorized to conduct experiments thereat concerning the various schemes proposed for the destruction of rabbits by disease.”

The motion was carried.

Mr. BELL moved,—“That the schedule of experiments as read be adopted as a general basis of direction to the chief expert to be appointed by the Commission, provided that such expert shall be invited to revise the schedule, and make suggestions thereon to the Commission.”

The motion was seconded by Mr. PEARSON, and carried.

Dr. KATZ was then introduced and the Chairman explained to him the resolution of the Commission, and stated that full discretion would be given him in the carrying out of experiments.

Dr. STIRLING moved,—“That the Commission recommend the appointment of Dr. KATZ, Ph.D., as chief expert officer for the conduct of experiments under the direction of the Royal Commission; that Dr. KATZ receive a salary at the rate of £60 per month, and be provided with such assistance as the Commission may think necessary.”

Mr. PEARSON seconded the motion, which was carried.

Dr. STIRLING moved,—“That the representatives of New South Wales, Dr. MacLaurin, Dr. Wilkinson, Mr. Quin, and Mr. Dillon Bell, of New Zealand, be a Committee to watch the proposed experiments on behalf of the Commission, and that the Committee be authorized to convene the Commission at the earliest convenient date for the consideration of the whole question.”

The motion was seconded by Dr. BANCROFT, and carried.

Dr. PATERSON moved,—“That progress reports of experiments be furnished to each member of the Conference at the discretion of the Committee.”

Mr. LASCELLES seconded the motion, which was carried.

It was ordered that a copy of the Schedule of experiments should be sent to Dr. KATZ. It was also resolved that Dr. HINDS should be informed that the Government and the Board of Health had been urged to give M. Pasteur's representatives facilities for as speedily as possible carrying out their experiments.

The three representatives of M. Pasteur were then introduced, and submitted a written statement, which was read, and upon which they were further examined.

The Chairman informed them that a portion of the Government Laboratory had been placed at their disposal.

Dr. HINDS stated that the cases containing their microbes would not arrive till the 26th inst.

The Chairman then inquired whether anything could be done in the meantime to facilitate their work.

On the motion of Mr. BELL, the Secretary was requested to place his services at the disposal of the representatives of M. Pasteur, so that no delay should take place in making arrangements with Mr. Hamlet, the Government Analyst.

Dr. STIRLING moved,—“That Dr. Bancroft, Mr. Lascelles, and Mr. Pearson be appointed a Committee to examine the correspondence and bring up a report on the subject; the report to be incorporated in the final report of the Commission.” Mr. BELL seconded, and the motion was agreed to.

Dr. STIRLING moved,—“That the name of Mr. Pearson be added to the Committee which has already been appointed to watch the experiments about to be conducted.” Mr. BELL seconded the motion, which was carried.

The Secretary was directed to send a letter to the Minister for Lands asking that immediate attention be given to the resolution adopted by the Commission having reference to the laboratory.

The Commission adjourned until 10:30 a.m., on the following day.

WEDNESDAY,

EXTERMINATION OF RABBITS IN AUSTRALASIA—REPORT OF PROCEEDINGS. 17

WEDNESDAY, 25 APRIL, 1888.

The Commission met at 10 a.m., at the Colonial Secretary's Office, Sydney.

Present:—

New South Wales: WILLIAM CAMAC WILKINSON, Esq., M.D., M.P.
EDWARD QUIN, Esq.

Victoria: HARRY BROOKES ALLEN, Esq., M.D.
ALFRED NAYLOR PEARSON, Esq., F.R. Met. Soc., &c.
EDWARD HAREWOOD LASCELLES, Esq.

New Zealand: ALFRED DILLON BELL, Esq.

South Australia: EDWARD CHARLES STIRLING, Esq., M.D.
ALEXANDER STUART PATERSON, Esq., M.D.

Queensland: JOSEPH BANCROFT, Esq., M.D.

Tasmania: THOMAS ALFRED TABART, Esq.

In the absence of the President (Dr. MacLaurin), the Chair was taken by Professor ALLEN.

Dr. PATERSON moved,—“That Dr. Bancroft's name be added to the Committee appointed to watch experiments.” The motion was carried.

The following motion, of which notice was given by Mr. Bell, was then called on by the Chairman:—“That in the opinion of this Commission the conditions requisite for a thoroughly practical and conclusive series of experiments to ascertain the value, for the purposes of the Commission, of any infectious disease are not consistent with the condition of an absolute guarantee of safety against the contagion of such disease spreading beyond the area devoted to the experiments; but that no real danger is to be anticipated from any such experiments under reasonable precautions. That in the opinion of this Commission the necessary experiments may be conducted, with all the possible safeguards obtainable, quite as safely, and far more conveniently, upon securely-fenced areas in the interior than upon small islands; and that the results of such tests will be of far greater practical value if recorded in connection with areas in the interior than if merely performed upon small islands. That this Commission therefore abandons its proposal to experiment upon islands, and resolves that its experimental investigations shall be concentrated firstly upon available areas on the mainland under such precautions as may be deemed sufficient, and secondly upon laboratory experiments under the proper conditions.”

Mr. Bell stated that he wished to give precedence to Mr. Lascelles' amendment, and on that account would not move the motion which stood in his name.

Mr. LASCELLES: I beg to move “That with a view to saving of time in determining results—and the equal or greater safety to be obtained—it is now decided that the first experiment (in addition to laboratory experiments) with Monsieur Pasteur's disease be tried in a wire netting enclosure of about 100 yards square, which shall also be roofed over with wire netting—and at a distance of two chains an outside netting fence to be erected.” I would like to enlarge upon my proposal still further, by explaining the nature of the enclosure which should be made. I would suggest 100 yards square, closed around with a $\frac{3}{4}$ -in. mesh. The area of this would be about $2\frac{1}{2}$ acres, and I would also propose that this 100 yards square enclosure shall be roofed with $\frac{3}{4}$ -in. mesh, and that at a distance of 2 chains from this enclosure an outer ring of wire netting fence $1\frac{1}{4}$ -in. mesh and 4 ft. high shall be erected. Into this enclosure I would put 200 rabbits, and then outside the enclosure in some adjacent place I would feed 20 rabbits on Pasteur's microbes. I would then turn the diseased rabbits into the enclosure. Of course the enclosure must be in a place suitable for the habitation of rabbits—burrows should exist there; and I would also have brushwood, hollow logs, and other things put into the enclosure. My contention is that experiments conducted in this way would be much safer than experiments conducted on an island a short distance from the coast, and that experiments in connection with the laboratory would not be nearly so satisfactory as those carried out under the scheme which I suggest, and for this reason: that, while rabbits, when placed in a cage, are naturally apt to huddle together, and possibly communicate the disease from one to another much more effectually than they would under their natural conditions, which I propose. The great fault that we have found hitherto with the method of M. Pasteur, as propounded by his representatives here, is the uncertainty which must be felt as to whether the disease will spread from diseased rabbits to sound ones. It may be that the disease will only spread by the direct eating of the poison. I feel confident that if, after such an experiment as I speak of, 200 rabbits, or a great portion of them die, that would be held to be a satisfactory experiment so far as disease goes by my brother pastoralists. I beg now to formally move this resolution.

Dr. Bancroft: I would like to know from Mr. Lascelles whether he proposes that this shall be done before the laboratory experiments shall have been completed or afterwards.

Mr. Lascelles: My proposal is that it shall be done after the laboratory experiments have been tried and completed. It may be, in case the representatives of M. Pasteur are not successful in the laboratory experiment, that we need not go any further. But it may be necessary for us to order the material for fencing, or to offer some intimation that it will be required, because the manufacturers point out that their machinery is inadequate to the demands which are likely to be made upon it. An order of this sort would take some three weeks in preparing, and we should let the makers know what in all probability will be required.

Mr. Bell: What is the smallest mesh they make regularly?

Mr. Lascelles: The smallest is $\frac{1}{4}$ of an inch.

Mr. QUIN: I will second this resolution. I have not the same fear that some members of the Commission appear to have that this disease will spread to other animals, because after that trial in the Pommery vineyard, in France, no fowls in the immediate neighbourhood suffered. I am quite sure if any fowls had been destroyed by this disease that we would have heard of it, because the French are a thrifty agricultural people, not likely to overlook any danger following an experiment of this kind. And it seems to me that no precautions were taken in that case that the germs of the disease should not be carried away

by birds or by other means. After such a public trial as this, in which it is quite evident no care was taken that the germs should not be scattered about, I am amply satisfied that we are quite safe in doing as Mr. Lascelles suggests.

Mr. Pearson: I think I am in a position to give some evidence on this point, as to the spread of contagion. Before I came here, I came across an account of some extensive experiments in connection with fowl-cholera in America, conducted by Dr. Salmon, the chief veterinary surgeon to the United States Agricultural Department, and also by Dr. Detmers and Dr. Laws. In one instance it was noticed that a case of fowl-cholera broke out some 200 yards distant from the spot where the experiments were being conducted. That case was stamped out, but by and by another case broke out very near the same spot, though immediately around the place where the experiments were being conducted fowls were congregated, but no disease spread. It had been inferred that in these two cases the disease had been carried away by the flies, and that the flies were eaten by fowls outside. It was not a matter of much consequence in a place like France, where fowl-cholera already existed, that no precautions should have been observed, but we are not certain that fowl-cholera does exist in this country, and therefore we must be more careful. Until we are satisfied on that point, I think we should take into consideration the feelings of alarm which have been expressed by the public, and we should take all possible precautions in the preliminary experiments to avoid the spread of contagion. The first experiments that we have proposed are in the nature of a test as to whether the disease is worthy of further inquiry or not—whether it is sufficiently contagious to be worth further inquiry. Then we have experiments Nos. 2 and 3 which will have for their object to ascertain what may be the possible danger of this disease to other forms of life. I may say that these experiments, conducted in a somewhat confined enclosure, will be performed under more severe conditions than will ever occur outside the enclosure, because animals congregated in that way in a confined area are more liable to be attacked by germ diseases than animals living in the usual way. And I believe it is an acknowledged fact that disease germs are nearly always more apt to become virulent when kept in a confined space than when exposed freely to the air and the sun. So that experiments Nos. 2 and 3 carried out in this way will be performed under much more severe conditions than will ever occur in nature. Then, when it has been shown that no danger exists to the forms of life mentioned in the schedule, it will be time to go on with the experiments which Mr. Lascelles proposes, and if that be admitted on the part of Mr. Lascelles I am perfectly willing to support his resolution.

Mr. Lascelles: I understand that the laboratory experiments will be first tried, and also whether the microbes are alive, and whether rabbits can be directly infected by them or not. Those experiments are to be made to ascertain whether sound rabbits can be infected. I do not propose to wait until we see whether sheep or cattle can take the disease, but that when these other experiments are complete we should proceed to use this enclosure.

Dr. Wilkinson: It seems that the object of Mr. Lascelles is only what we have considered already, because we decided several days ago that after the experiments that have to be made in the laboratory have been completed, then further experiments shall be made under other conditions, one of which experiments will possibly be carried out in the interior. Now, what directed my attention to this notice of motion was that this should be the first experiment; that is, before the laboratory experiments, not after. Well, naturally I strongly object to such a motion as this, but it seems now that Mr. Lascelles does not mean it in that way, and therefore I do not wish to press my objection.

Mr. Lascelles: I am quite willing to alter the phraseology of the motion, in order to make its object more clear if necessary.

Dr. Wilkinson: But even then we will be in the same position prior to this resolution coming before the Commission. It seems to me that this preliminary must come sooner or later, if the experiments which are to be conducted in the laboratory bear out what M. Pasteur and his representatives have told us. But we have to prove or disprove what they state, and until we do that any motion of this sort is premature. (Hear, hear.) The experiments, for instance, of M. Pasteur in the Pommery vineyard are not absolutely conclusive.

Mr. Lascelles: Far from it.

Dr. Wilkinson: Now, the object of the laboratory experiments will be to complete the experiment which was begun in the Pommery vineyard. We want to find out by actual experiment whether any other animals can directly or indirectly become affected with this fowl-cholera. If the experiments in the laboratory prove that all other animals are immune, then the only point at issue is whether further experiments should be conducted on an island, say one of those in the harbour which are close by, or whether they shall be conducted in a stretch of land where rabbits already exist. We cannot lose sight of the fact that not only the public but also the scientific bodies are opposed to the introduction of this disease into the Colony until it has been proved with scientific accuracy that there is no danger to the public now or in the near future. If we gain that point, then we practically can proceed further; but until that point is proved we must not attempt to introduce the disease into any inland parts of the Colony. This is the essential point, and this is what the Commission have already decided not to do. Until it is proved with scientific accuracy as perfectly as it is possible to prove anything, that there is no danger of this nature, we must hold our hands and keep the disease from entering the Colony. It has been said it is likely that fowl-cholera exists here already, but there is absolutely no scientific proof whatever of its existence, and the mere fact that fowls have been affected with certain symptoms is no proof of the identity of that disease with the disease known as fowl-cholera. So that if the resolution means merely this, that we shall proceed with our experiments in the laboratory under the usual conditions, and that we shall not proceed further until we are sure that the disease cannot be transmitted, no member of the Commission can have any objection to the resolution. But I would strongly oppose a resolution framed in words capable of being construed into a direction that we should, without waiting for the result of the laboratory experiments, proceed at once to commence experiments inland with this fowl-cholera.

Dr. Stirling: I think it is abundantly clear that no member of this Commission wishes to proceed rashly. If there be any division amongst us at all it is merely in connection with the question as to the degree of safety. There is no question now, so far as I can see, about disease being introduced into the Colony, because we have recommended that it shall be done. We can only judge of the experiments suggested by Mr. Lascelles in conjunction with other suggested experiments. For my part I feel that the experiment which he suggests is certainly as safe, if not safer, than any similar experiment conducted on

EXTERMINATION OF RABBITS IN AUSTRALASIA—REPORT OF PROCEEDINGS. 19

an island—that is if there is to be a comparison between these two. I would go even further and say that I do not think there is any greater degree of danger in experimenting as Mr. Lascelles has suggested than in experimenting as we are now proposing to do in Sydney. I do not think that the animals to be experimented on down here will be as safe under lock and key as they will be under the experiment proposed by Mr. Lascelles. The insect element is a danger which has been alluded to and which must exist in any experiments that we can ever devise. It certainly will exist on an island just the same as it will exist with horses and cattle confined in a back yard.

Mr. Pearson : I think by the use of wire gauze that could be prevented.

Dr. Stirling : Well, I do not think that that element of danger can be got rid of under any circumstances, and although it has been suggested that we should yield to strong popular opinion, we must remember that public opinion on this question practically amounts to nothing. If experts who have investigated this question here and in Europe have not been able to reach fixed conclusions, it certainly is not to be expected that the ordinary public can have any complete knowledge, and I think that that danger is altogether exaggerated. I may fairly make this statement because we have some data to go upon. We know that chicken-cholera exists in America, and I believe in every country in Europe, but we have never heard of any wholesale destruction of birds. We know certainly that this disease is fatal to poultry-yards, but so are other diseases; and I say that there is no evidence before us where decimation or any wholesale destruction of birds has taken place in neighbourhoods where chicken-cholera epidemics have been frequent. So that, as I have said, we have some experience to go upon. And, so far as wild birds are concerned, I think it will be generally admitted that in Europe and America they have a great many more birds than we have here. And supposing there to be any risk of birds catching the disease, that risk would not be eliminated by carrying out our experiments on an island which is only a few miles off the coast. I am continuing my remarks entirely on the element of safety because it needs no argument to demonstrate the immense superiority, so far as convenience is concerned, of inland experiments over experiments conducted on a distant island. And in conclusion, I venture to suggest that the greatest danger in the consideration of this matter lies in extreme caution. We know that steps are now being taken to introduce diseases of this character without authority and without the safeguards of ordinary prudence. Those who have read through the correspondence will see that in several instances the introduction of rabies has been suggested. And supposing steps were taken to introduce it, who is to prevent it? So that while we wish to act as prudent men let us remember that there is an extreme of cautiousness which is a part of imprudence. As to the management of infectious diseases we have some knowledge of how these act and what we are to do with them. The Quarantine Ground is on the mainland, and is handy to the city, and yet diseases there are sufficiently well controlled. But I am glad to think that possibly there will be after all an almost unanimous feeling in this matter. As I understand Mr. Lascelles' proposal, it means this—that when we have gained some knowledge by laboratory experiments, we shall then as the next thing to be done proceed to experiment in the open. This is what I understand by the motion, and these are the reasons why I support it. I believe that in so doing I am acting with the same amount of prudence that has actuated myself in common with others in conducting in the laboratory the preliminary experiments already authorized.

Mr. Lascelles : I understand that this enclosure will take some time in erection. We cannot get wire of this kind within a week, and by the time that we got it erected the first laboratory experiments will to a certain extent be proved. We should now lose no time, but take such steps as are necessary to have the wire ready when the time comes.

Mr. Quin : Might it not be better if some primary experiments were tried first? If this were done we might be able to save some expense.

Dr. Stirling : That question should be raised by and by, and might be given as an instruction to the Committee who have been appointed to watch experiments.

Dr. Bancroft : If I understand Mr. Lascelles correctly, he means that this experiment is to be proceeded with before the sheep and cattle experiments are concluded. That, I believe is the statement, and as to that I would say that there are objections. First, let us make the experiment with animals, and let us make ourselves quite certain that animals are not likely to suffer; and then we may be at liberty to consider out-of-door experiments; but until that question is settled, I think we should be hastening into danger if we allowed any other experiments. Now, as to this area of $2\frac{1}{2}$ acres which it is proposed to fence in. A very considerable quantity of netting will be required to cover this enclosure in, and this will cost a great deal of money. It may possibly turn out, as Mr. Quin states, that as there have to be very careful experiments carried out on birds in the laboratory, there may be no necessity at all to keep birds out; and that we shall be able to carry out our experiments inland without any overhead netting. I would like that some attention were given to what Mr. Pearson has said in regard to flies spreading the disease. In making experiments in the laboratory of course it could not happen, but the expense of a mosquito net over a small area of ground would not be very much. But having satisfied ourselves that the thing will be perfectly safe, I think we may dispense with this overhead wire netting and mosquito netting as well. Now, with regard to disinfecting the country: suppose we introduce a disease, and that we afterwards wish to remove it from a piece of country—say $2\frac{1}{2}$ acres—from which we are anxious to wipe this disease out again. Now I hold that such a thing never can be done. Even if we destroy everything else, the destruction of the grass seeds over that particular piece of country will be impossible. The spores of diseased secretions are equal to seeds when they get buried in the earth. We know that though fire goes over a piece of country yet it does not destroy the seeds which yield again and again; and disease, I think, would stand pretty much on the same footing; so that until we are quite sure that the introduction of this disease inland is perfectly correct and safe, I think we should hesitate. With regard to the island experiment that has been spoken of rather unfavourably by several gentlemen, I think it would be very well worth the consideration of this Commission. An island test would be the safest test to which you can ever put the scheme of M. Pasteur. It would be far more safe than any inland experiment; and if, as I understand, there is an island in Bass's Straits which is infected with thousands of rabbits, I am of opinion that it should be used. Dr. Cox told me that when he was passing by train through Tasmania on one or two occasions he noticed that the ground seemed to be in motion, and on looking closer he found that this arose from the movements of swarms of rabbits. For a long time he could not believe that this terrible upheaval was caused by live rabbits; but so it was. Now, suppose that an island in Bass's Straits were placed

at

at the disposal of this Commission, or any other island possessing this enormous development of rabbits, I should say, take Pasteur's disease and give it a fair trial on that island. Ascertain, if possible, what has been overlooked in the vineyard experiment—because no inspection was made for a fortnight afterwards—in what way the rabbits were killed. Now, if on an island you cannot kill all the rabbits, if you leave there a few dozen pairs, we will know what is the value of Pasteur's scheme. We will know that it has pretty much the same action as phosphorus—that it kills well, but not altogether. I do think the island scheme is the grandest scheme that we could adopt, and though it might not be necessary to keep the representatives of M. Pasteur there, still some one might be delegated by us to see whether the island could be decimated of its rabbits. A steamer could get to one of these islands in a few hours, and the experiment could readily be tried. The experiment, besides being a great value to the scientific world, would give the Commission a valuable amount of information. Our functions here seem to be two-fold—to get rid of the rabbits and to protect the public health, as well as to save domesticated animals. I can assure the gentlemen who proposed this motion that, with a little patience, this pest will be got at—and very soon, too. I cannot quite support his motion, because I want to see animals experimented on before the inland experiments are undertaken.

The Chairman asked Mr. Lascelles to make his motion clear, that no experiments inland should be undertaken until after the laboratory experiments were completed.

Mr. Lascelles agreed to do this.

Dr. Bancroft: Then, in that case, I quite agree that no overhead netting will be required. I would like to know what is the good of buying this overhead netting if the Commission are not afraid of birds suffering. I do not see, under these circumstances, what is the good of buying the wire netting.

Mr. Bell: We know already that birds will suffer.

Mr. Tabart: A motion has already been passed that after the laboratory experiments have been completed, the other experiments shall be tried on an island, about which the Government of New South Wales have taken the trouble to gain information for us, and also have been inquiring as to whether rabbits exist on it or not. Now, so far as I am personally concerned, I may say that I do not intend to stultify myself by voting for any motion to abandon the scheme of experimenting on an island. I intend, therefore, to oppose this motion of which notice has been given by Mr. Lascelles. I am quite of opinion that in the interests of pastoralists, every possible precaution that can be taken should be taken by this Commission. We have at stake here some 50,000,000 of sheep which now exist on this continent. Of course it signifies very little to Mr. Bell or myself whether this disease be introduced or not, so far as it can have any effect on our stock. We are situated upon islands; but I believe the mainland here would suffer materially if it is found that Pasteur's disease is communicable to other animals than rabbits. I have here an extract from *The Mercury*, a newspaper published at Hobart, commenting on the proceedings of the Royal Society of Victoria, where this question was discussed. It is said:—"Dr. Wigg, who seems to have made a careful study of the question in all its bearings, maintains that M. Pasteur's remedy for the rabbit pest is uncertain and full of elements of danger. The spores of the chicken-cholera microbes, he says, with which the distinguished French scientist desires to infect the rabbits might be scattered broadcast in dust storms from one colony to another without losing any of their virulence, and disease and death would thus be carried thousands of miles. The microbes are practically indestructible. They can live in water heated nearly to boiling point, and can be frozen without endangering their existence, and once admitted into the colonies this disease would be virtually uncontrollable. It is idle to talk about carrying out experiments in these colonies safely within walled paddocks. We might as well erect a post and rail fence to keep out the cholera, or attempt to enclose small-pox within open wire network. Even an island would not ensure safety, for the germs might be blown across to the mainland, or carried in a boat or in the clothes and hair of the experimenters. Many of M. Pasteur's experiments with a view to determine whether the disease would effect other animals, have been made under conditions as to climate, &c., totally different from the conditions which obtain in Australia, so that they cannot be considered a safe guide. Other results of a disastrous character might follow similar experiments in the fierce heat of the Australian summer. No information is vouchsafed as to the particular kinds of birds the disease attacks, but it is almost certain that we should lose our domestic fowls and native insectivorous birds, and suffer a plague of locusts, grasshoppers, and other insect pests that would most certainly prove worse than the rabbit pest. A disease is generally most virulent and spreads with the greatest rapidity on virgin soil, whether it be small-pox in man or brambles and thistles in the earth. After a time the disease consumes the whole or a large portion of the material it requires for its growth, and either disappears altogether or is kept within bounds. This was exemplified in Fiji with regard to the measles. When introduced there that disease spread with appalling rapidity, and was singularly virulent, no fewer than 40,000 persons dying from its effects. Now, this disease is not more virulent in Fiji than it is in England. In France the plants and animals have been adapting themselves to each other for centuries, and have established a *modus vivendi*, whereas here the chicken-cholera would find new birds, new animals, a virgin soil, and new climatic conditions differing widely from those of Europe. Different conditions would probably produce different results, and no one can say for certain what would follow the introduction of a new choleraic disease into these colonies. Typhus, which was so virulent in England and Ireland, died out in Australia, and the yellow fever of America could not exist in England. These are facts, the significance of which can hardly be overestimated, and most people will be disposed to agree with Dr. Wigg that the Governments of the various colonies ought to seriously consider the possible danger to the flocks and the health of human beings before risking the prosperity of Australia by introducing the chicken-cholera. In the discussion that followed the reading of this paper Dr. Jamieson observed that the so-called fowl-cholera was not cholera at all. In Germany it was known as fowl typhoid. There was fair evidence that it would spread to any birds, and could not be limited to fowls and rabbits. In Germany it had killed pigeons, geese, turkeys, ducks, and pheasants, so that it was certain that the disease would make havoc with the bird life of the colonies. A most important point was the relation of fowl-cholera to diseases in other animals. In Germany a few years ago a disease destroyed large quantities of game, especially attacking deer. The organisms found in the animals affected were similar to the microbes of chicken-cholera. This would seem to indicate that there was some risk of the disease spreading to other animals. A similar view of the matter was taken by Mr. C. R. Blackett, the Government analytical chemist, and the following resolution was carried unanimously:—"That the Royal Society respectfully advises the Australian Governments to refuse their permission to any person to introduce

introduce any form of disease for the purpose of checking the rabbit plague until the whole question has been fully considered." Now, if this be the case—if this disease spreads, as is indicated in this paper—what would be the result if we once introduce it on to the mainland? It would be a most difficult matter to destroy it or to get rid of it if it were once introduced. We know what pleuro-pneumonia has cost these colonies, and I estimate that if chicken-cholera is once introduced—if it is found to be communicable to sheep—the result will be most disastrous. Therefore, upon these grounds, I shall oppose this motion.

Dr. Paterson: It seems to me that the question which we are now discussing is as to the locality where, under natural conditions, these experiments are to be made. This is a question which resolves itself into two parts—whether the experiments are to be carried out on an island or on an inland station. The advocates of the scheme for making experiments on an island say that the island will give safety. Now I do not see that there is any absolute safety on an island—very far from it. It is quite possible that birds and insects will communicate the contagion from the island to the mainland. I have not heard any of the advocates of the island scheme speak of adopting any precautions of having an overhead netting for birds or insects, and therefore, on that ground, I fail to see wherein the safety of the island consists. Then it is said that the distance from the coast renders it safe, and that a fence will not be necessary; but I am of opinion that any experiment made in an inaccessible place will lose a great part of its value from want of proper supervision. My idea is that sufficient precautions can be taken for almost perfect safety on an inland station. Of course there is always a certain amount of risk in everything we undertake. There is a certain amount of risk involved in travelling in a railway train—there is risk even in crossing a street—in doing many of the things which we do daily in our lives. There are remote risks in all these things, but I am of opinion that if reasonable precautions are adopted such experiments (under natural conditions), as are absolutely necessary to test these schemes, may fairly be carried out on some inland tract of country. The risk of communication—of the propagation of the germs by insect—has been alluded to; but, as was pointed out by the previous speaker, there is risk even in the laboratory experiments, and yet this reason has never been urged against our undertaking laboratory experiments. The conclusion which I have come to on this matter is this—that it is simply impossible to secure the conditions required by some speakers, and that if their ideas are to prevail no experiments at all may be made until you have shut out every possibility of every sort of risk. I think that these risks—whatever they may be—have been very much exaggerated. M. Pasteur's representatives told us yesterday—I think it was Mr. Loir who spoke—that he had witnessed three epidemics of chicken-cholera, and that he was not aware that in any case the epidemic had spread to wild birds. There have been epidemics of this sort in France, where the disease is well known, and yet there is not a record of an instance to show that in any of these epidemics in France, in Germany, or in part of the world, wild birds have been in any way affected. I think it is possible to exaggerate and to take an alarmist's view of a matter of this kind. I have known in my own personal experience a good deal of this sort of thing. I remember that when Torres Island, which is close to the city of Adelaide, was first recommended to the South Australian Government as a place of quarantine, a similar cry of alarm and danger was raised by a certain section of the community. It was pointed out then that smallpox was an excessively contagious disease, and that the currents of the atmosphere would carry the germs to the city, and that Adelaide, which is only 8 miles distant, would be infected with smallpox. Then a cry was raised about quarantined vessels lying a few miles off, and there were numbers of letters in the papers stating that the health of the people at the Semaphore was being endangered because the wind would carry the contagion into the town. Now, I need scarcely say that none of these accidents happened. Torres Island is still the quarantine station. The smallpox has never spread to the city, and the disease has never once been wafted from the vessels lying in the stream to the people at the Semaphore.

Dr. Bancroft: All that argument is in favour of adopting the island scheme.

Dr. Paterson: Well, if so, I can only say that my arguments were intended to prove something totally different. Dr. Bancroft has alluded to the impossibility of totally disinfecting an area of the germs of chicken-cholera which had been used for experimental purposes.

Dr. Bancroft: I said germs generally, not those of chicken-cholera in particular.

Dr. Paterson: Well, in that case I can hardly understand the force of my friend's argument. I made a note of that, and also his comparison between the vitality of these germs and the vitality of grass-seeds. Now, I know that Dr. Bancroft is a very good naturalist, and I would like, therefore, to ask him whether any reasonable comparison can be instituted between the vitality of Australian grass-seeds and the vitality of these germs, whose resistance, so far as temperature is concerned, is small. Mr. Pearson also brought forth an argument that he had discovered, that in some parts of America where experiments had been instituted insects carried the disease 200 yards away from the place where the experiments were made. Now, I fail to see what connection there was between the two things. The explanation or inference is that the disease had been carried by insects. Now, this is the *post hoc propter hoc* kind of logic, and we know how unscientific is this kind of argument. Because one occurrence took place after another, because one accident precedes another in point of time, the inference is drawn that one is the cause of the other. Now, I wish to say, that on an isolated instance of this sort, founded upon insufficient data, I place no reliance whatever. Another objection to the island scheme seems to be that, in addition to its inconvenience and the points that have already been indicated, it hardly possesses the conditions which exist inland; and I think if experiments are to be conclusive in this way, inland conditions should be observed as much as possible. There cannot be the slightest doubt that the inland conditions, as regards moisture, &c., are very different from those which exist on an island; on these grounds, and because I believe the proof of a laboratory experiment to be ample to allow us to proceed—I think that inland experiments, conducted with proper precautions, are safer, as regards public health, than experiments on an unguarded island. I shall support the motion to have these experiments conducted under natural conditions in the interior of the Colony.

Mr. Bell: In bringing forward the original motion of which I gave notice on Monday, and upon which, before it was discovered that it could not be discussed except upon notice given, I had already spoken my mind, I took an opportunity of stating to the Commission my views on the whole subject. But as none of my remarks were reported, and as the discussion upon Mr. Lascelles motion, which, by agreement between that gentleman and myself, I have permitted to replace my own for the present, has been ordered to be reported, I must to some extent repeat what I then said. Nevertheless, my opinion

opinion is before the Commission as fully as I could put it; and I do not propose, merely for the purpose of getting my words into print, to take up your time in repeating all of what I then said, more especially as many of the arguments which I then addressed to you have been urged with much more ability than I can command by the speakers who have preceded me to-day. It would not be desirable to occupy the time of the Commission in repeating such arguments—my object not being to impress you with what I have to say, but rather to further, in the best way that I can, the work which the Commission has been called on to perform. (Hear, hear.) It is, however, necessary for me to remark that in bringing forward the motion which I submitted the other day, my object was principally to eliminate the element which previously had been considered essential by the Members of the Commission in the conduct of experiments—the supposed necessity to conduct these experiments upon an island. You will remember that prior to my arrival here the Commission had passed a motion requiring as a condition precedent, that all such experiments should be carried on on an island some distance from the mainland. I could not, myself, agree with this condition as being either practically efficient or necessary, or in accordance with the conditions that it was desirable should be secured, or with the purpose of the experiments intended to elucidate the questions referred to this Commission. But I also thought it right that I should specially draw the attention of the Commission, in my former speech, to the fact that in this matter my opinion should be received with a certain amount of caution, inasmuch as I myself came from a distant island, which could not be affected by experiments conducted in the Australian mainland. The reasons which led me to bring forward the motion of which I gave notice, and which would have the effect of rescinding a previous resolution of the Commission, were shortly these. In the first place, I did not consider the choice of an island really secured the conditions of safety, which up to that time, it had apparently been thought to secure. The fact alone, that the disease with which we propose to experiment was originally derived from bird life, appeared to me to render it highly improbable that any experiments conducted upon an island would secure the element of safety at all. For it must be remembered that chicken-cholera originated in bird life, and that only in a secondary condition has it been transmitted to rabbits. We are dealing with animals that move through the air, and which cannot be restricted in their movements by small belts of sea. Another reason is this, that I do not think the conditions to be secured upon an island, or the ocean, bear a sufficiently close relationship to those attached to an inland station, to enable us to say whether the things which may be done on an island may also be done on a station in the interior. That I hold to be a very serious objection indeed. Then there is another reason, but as I do not attach very much importance to it, I will deal with it in a few words. I refer to the statement that perhaps the disease proposed to be introduced (though I do not assert it) already exists upon the Australian Continent.

Dr. Wilkinson : Then in that case we should proceed to the inland experiments at once, without waiting for the result of the laboratory experiments.

Mr. Ball : Quite so; that would certainly be a reason (if the disease existed) for not going on the island idea. A further reason of mine for objecting to this was that I am perfectly certain that the necessary precise scientific and practical attention could not possibly be given to experiments conducted upon an island in anything like the same degree as to experiments carried on in the mainland. It is proposed that this Commission should superintend such experiments and record the results in such a way that, being recorded, there could be no loose ideas about them. I am sure that the Commission fully recognize the necessity of this. They cannot desire that the records of their experiments should be of that extraordinarily loose and unsatisfactory kind—loose and unsatisfactory alike from the scientific and from the practical point of view—which, I regret to say, is characteristic of the published experiments of Mr. Pasteur on this subject, so far, at any rate, as we have been permitted to learn them from the mouths of his own representatives. Those experiments cannot be held to be in any sense decisive experiments; and the same kind of looseness would inevitably attach to any experiments carried out on an island, if such alone were allowed. Suppose, for instance, that a chemist were ordered to hold an investigation into poisoning by phosphorus, and that his laboratory was at the rooms of the Board of Health, which I visited this morning; and supposing that one of the conditions of his experiments was that he should live in Tasmania, and that a steamer called once a week to take him backward and forward. How, under such circumstances, could he watch and record the result of his experiments? I think the matter only requires to be stated in such terms as these to show that a record of any experiments to be conducted on an island would really be worthless; and for this cogent reason, that great doubts must attach to the experiments, I could not help feeling it my duty to traverse the previous resolution with the one which I had the honor to bring forward the other day. It has been pointed out to me in a particularly kind way that it was traversing a previous resolution of the Commission, and I at once expressed my regret that I should appear to be presumptuous enough to come to this Commission, after missing the first days of its work, and ask it, as one gentleman puts it, to stultify itself. If I have been forced into this position, it is with regret. I have acted simply in response to what I feel to be my duty as representing one of the parties to this Commission; and if I have been so unfortunate as to appear presumptuous in this matter, I can only regret it, and say that it was a sense of duty which induced me to take the stand I did. Now, Dr. Bancroft has very properly pointed out that there can be no possible objection to conduct experiments on an island. I quite admit that it would be a very interesting and instructive *additional* experiment to introduce upon an already infested island rabbits inoculated with Pasteur's disease, after the laboratory experiments, conducted under convenient conditions, have given results sufficiently encouraging to make it worth while to proceed with the matter at all. Dr. Bancroft has done valuable service in drawing our attention to this. But he would appear to think that of itself the island experiment would be sufficient and satisfactory, and to that I have pointed out several objections. A further one indicated already by Mr. Lascelles, consists in the fact that such an experiment, though it would have a considerable value of its own, would in some respects be like M. Pasteur's at Pommery. No exact numerical record of results could accrue: whereas, supposing that we introduced 200 rabbits into an enclosure, and allowed twenty diseased ones to go amongst them, and a number of these remained alive, we would then have some definite particulars and figures to go upon; we could count the number of dead and live rabbits on the place. This is one element of difference between the island experiment and the experiments which I recommend. Then as to whether chicken-cholera exists here already or not—and if it does, this extremity of precaution becomes absurd—I do not presume to offer a decisive opinion: all I can say is, it seems to me that the dreaded thing does already exist here. Now if that is the case, surely we can look at the matter in an altered way. Where fowl-cholera has prevailed for a long time, say in France for instance, in a natural

way,

way, we have an opportunity of seeing what is the worst result to be feared from its existence in the open country, under the very loosest possible conditions as regards precaution and disinfection. Fowl-cholera has admittedly existed for years in France, practically unchecked. Where are there any records of disastrous and horrible consequences to stock and to human beings? Where fowl-cholera has prevailed for a long time, we have nothing to show that there has ever been an epidemic amongst horses, amongst sheep, or amongst human beings; or that any one has died of fowl-cholera. Such a thing would at all events be new to the general public if not to the scientific world. It would be an indication for what it is worth of the possible danger of experimenting under careless conditions, and we are anxious that those extremely careless conditions shall have no existence, because we propose that every precaution shall be taken. In my original motion I inserted an expression which I thought would really elicit the opinion of the Commission upon this point—whether it was really possible to conduct an experiment which, on the one hand, would be absolutely satisfactory with regard to practical conditions, and, on the other, would be absolutely immune from any risk whatever. Now, in my opinion, that cannot be done; a certain amount of risk must be taken. All I required to be understood by the motion which I brought forward originally was that the element of confinement on an island which was prescribed as a condition precedent in a previous resolution adopted by the Commission should not be insisted on. And, as I think that the motion brought forward by Mr. Lascelles is a somewhat less aggressive one than mine, I am willing, in deference to his opinion, to adopt it, as it avoids a direct attack upon a previous resolution of the Commission. I therefore intend, although not withdrawing my original motion, and on the understanding that it will be placed on the minutes, to support the motion moved by Mr. Lascelles.

The Chairman reminded the members of the Commission that, according to the proclamation in which the reward of £25,000 was offered to the inventor of any effective scheme of exterminating rabbits, it was expressly provided that the execution of the scheme should involve no danger to horses, cattle, sheep, dogs, and other useful animals enumerated. Birds, however, were not mentioned in the proclamation. The Commission had therefore to determine, in respect of every scheme proposed, whether it would be effective and whether it would be safe. In order to test the efficiency of M. Pasteur's method, the Commission had resolved that a series of laboratory experiments should be conducted, which would demonstrate whether chicken-cholera would spread freely from one rabbit to others kept in close proximity in hutches, cages or artificial burrows. It might be that the cultures brought from France would be found dead or enfeebled, in which case delay would be unavoidable. It might be that the disease communicated to the first rabbits would not spread easily from them to other rabbits, though all the conditions were made as favourable as possible. In that event, M. Pasteur's proposal would be out of court at once. If the disease did spread, the mode of communication would be ascertained. While these experiments were in progress it should be possible to ascertain whether chicken-cholera now exists in New South Wales or Victoria, or perhaps even in other more distant colonies. If it were shown that the disease is now prevalent among poultry, the objections which had been expressed to an extensive trial of the disease among rabbits on an inland area would be largely removed. But if evidence of this character were not forthcoming it would be wise to proceed at once to test whether chicken-cholera in the fowl or in the rabbit is communicable to other animals. Very little time would be lost if the experiments on mammals and birds set forth in the schedule of experiments were conducted simultaneously or in immediate succession. If it were proved that horses, sheep, or cattle could be infected, M. Pasteur's proposal would probably be rejected. If it were shown that the disease could not be communicated to any useful animal, other experiments must be conducted under natural conditions. The question then remaining was whether these experiments should be conducted on an island or in some inland area completely enclosed in bird-proof netting. As he had been the first, during the meetings of the Commission, to suggest that the chicken-cholera be tried upon an island, he would shortly state his views on this part of the question. For the present purpose, islands might be divided into three classes: firstly, those in the harbour, which were suitable only for laboratory experiments; secondly, an island such as Montague Island, about 3 miles from the mainland, sufficiently accessible and already stocked with rabbits; thirdly, islands like the Kent Group, in Tasmanian waters, about 80 miles from the Port Phillip Heads, one of which was reported to be similarly infested. As to Montague Island, it was so near the coast that if the disease did spread to the wild-fowl upon it, they might decamp to the mainland taking the cholera with them. Concerning the risks of extermination of wild birds he would speak later; but the selection of such an island would not satisfy those whose fears had been aroused. If the Kent Group proved suitable for purposes of experiment, no danger whatever would arise. The procedure might be as follows: A Government Inspector, with assistants, would examine the island and estimate roughly the degree in which it was infested. Subsequently Dr. Katz, with the representatives of M. Pasteur, and any members of the Commission who were at liberty, would proceed to the island, taking with them a sufficient number of healthy rabbits so as to save time. These rabbits would then be infected and turned out on the island. After the lapse of a sufficient time the island would again be examined. If the rabbits were greatly thinned in number, if many were found dead, and if no evidence of great mortality among birds were discoverable, M. Pasteur's proposal would be viewed with great favour. If, on the other hand, the rabbits were as numerous as ever, the experiment might be repeated; and if it again failed, the scheme should be rejected. The success of chicken-cholera on an island would not guarantee its efficiency under the very different conditions which prevail in the interior of Australia; but its failure would probably be conclusive in the opposite direction. Even if an inland experiment were also conducted without delay, an island trial would give valuable information as to whether chicken-cholera would spread among the rabbits which are so abundant in the sands-hills and plains on large portions of the Victorian coast. He therefore submitted that, if the laboratory results were favourable, an experiment should be conducted on an island somewhat on the lines which he had described. With regard to testing the spread of the disease in an infected inland area under the precautions described by Mr. Lascelles, he did not think that any considerable danger would be incurred. If diseased rabbits were turned loose in an infested area of 2½ acres, shut in around and over-head with bird-proof netting, and protected by a neutral zone two chains wide surrounded by a rabbit-proof fence, surely the most timid critic must admit that all the conditions of reasonable safety were fulfilled. Even without such rigid precautions, a temporary experiment in an area enclosed in the ordinary way would be very different from a persistent attempt to sow the disease all over the colonies. But, adopting Mr. Lascelles' method, the danger was infinitesimal; assuming that there was a remote possibility that little local outbreaks of the disease might occur in the immediate vicinity, these could be easily suppressed. From what was known of the life history of the microbes of chicken-

chicken-cholera, it did not appear that there would be any difficulty in disinfecting the area within which the experiment was conducted. Too much might be made of the danger to wild-fowl. Birds flying at large were not liable to fowl-cholera and other septicæmic diseases in the same degree as poultry shut up in yards and sheds; and even if a few were infected, the disease would probably have a very limited spread. On the other hand, if the proposals of M. Pasteur and others were not fully tested, there was great danger that land-owners would experiment for themselves without any precautions; and it was not a little suggestive to find in the correspondence submitted to the Commission suggestions that the introduction of hydrophobia might be an effective solution of the rabbit question. Generally, therefore, he was in favour of the following procedure:—Firstly, test by laboratory experiment whether chicken-cholera can be passed freely from rabbit to rabbit; if it can be so passed, test whether it can be transmitted from rabbits by infected food, and if necessary by inoculation, to horses, cattle, sheep, and other animals mentioned in the proclamation. At the same time test its power over birds, including specially the native game and insectivorous birds. While these experiments are in progress, obtain information about a suitable island; and if the laboratory experiments are favourable, proceed to infect it in the manner described. As soon as it is proved that the disease can be transmitted freely from rabbit to rabbit, purchase bird-proof wire and make preparation for the experiment described by Mr. Lascelles. If that experiment is successful, test the method on a large scale at Tarella or some other suitable locality. If any difficulty were found in proceeding with the trial of M. Pasteur's scheme, attention should be concentrated chiefly on the method of Drs. Butcher and Ellis, in the manner already specified in the schedule of experiments.

Mr. Pearson: I wish to explain, in reference to the American case which I mentioned, that Dr. Salmon brought one fowl from a distance of over 100 miles into a district where fowl-cholera had never been known before. He put this fowl into an enclosure for experimental purposes, and it was after this that fowls 200 yards away, which were not to be experimented on, caught the disease, and after discussing the matter in detail he came to the conclusion that the disease had been carried by flies.

Dr. Wilkinson: If this motion is not to be withdrawn, I shall ask the mover to reverse the conditions.

Mr. Lascelles: I wish to draw attention to the fact that in these colonies the pastoral interest is being nearly ruined by the spread of the rabbits. The pastoralists are looking to see some substantial resolution adopted by this Commission. As a practical man, I say that the test under this resolution will amply satisfy us as to whether there is any good to be obtained from M. Pasteur's proposal or not. Harm and delay are, no doubt, caused in this way—that the people are neglecting the ordinary precautions which people should take, and are waiting for a miracle to come off. As pointed out by Mr. Bell, no such certainty can be obtained from any island experiments as may be obtained by the introduction of a certain number of diseased rabbits amongst a large number of sound rabbits in an enclosure under natural conditions.

The Chairman: There is one matter which I had overlooked, and which I would like to speak of—it is the matter of expense. I do not think we should order any fine netting until our preliminary experiments show that we can transmit the disease from rabbit to rabbit. When we have proved this, we can push on our arrangements without delay. If we wait, we will only lose a short time, and will be spared the risks that have been indicated elsewhere of having incurred expense without any necessity.

Mr. Tabart: Before this resolution is put to the vote, I think we ought to settle what is to be the voting power of the Commission, and it should be arranged before going further that three votes be given to each Colony. At the Australian Stock Conference, the Colonies were represented in a similar manner to that which I now suggest.

The Chairman: I think there is quite time to get our island experiments performed if we obtain exact information about the island which we select. If we at once infect the island, then in a short time—by the time our enclosures are ready—we shall be ready to proceed with our inland experiments.

Dr. Bancroft: We seem to be contending for carrying out inland experiments before experiments had been completed with the domestic animals. This seems to be the exact point of contention. Shall we conduct experiments with domestic animals before carrying out experiments inland? I think it would be very injudicious to omit doing this before we go inland to perform our other experiments.

The Chairman pointed out that there was no question about Montague Island, and if any island were to be taken, there must be a wide strip of sea between the island and the mainland.

Mr. Bell: There is nothing at all inconsistent in this resolution with the simultaneous trying of the Montague Island with the mainland experiments. I quite agree that it ought to be done, so long as it is not considered absolutely the whole thing, and that other experiments, more directly under our control, will be allowed. If the Minister for Lands and the lighthouse authorities have no objection to the introduction of the disease on to Montague Island, I should like to see experiments tried there.

Dr. Bancroft: I would suggest, with the Chairman, that the information with respect to the island which he formerly mentioned in Bass' Straits would be of value to this Commission and worth obtaining.

The Chairman: I am under the impression that the Kent group of islands are within the waters of Tasmania.

Mr. Tabart: I know that they are at least very close on the boundary.

Dr. Stirling: There is an idea amongst members now that these laboratory experiments should be antecedent to other experiments. Now, if sheep were found to be seriously affected by the disease, we would doubtless say that we would have nothing to do with this disease. But, supposing that we found, from a very vigorous application of this poison, that birds are affected, that is no reason why we should not use the disease, nor why we should not try it in the open.

Dr. Paterson: I think the laboratory experiments should be proceeded with first of all, because if certain contingencies happen, these other experiments may never be necessary. If the laboratory experiments show that experiments under natural conditions are required, all we need do is to be prepared to conduct experiments under natural conditions. But if it is proved that the disease is contagious to other animals, then these experiments in the open may be unnecessary, and the material to be used for fencing could be resold. I think we had better stick to the resolution originally tabled.

Dr. Wilkinson: I would propose that the following words be inserted in the resolution: "After it has been demonstrated by laboratory experiment or otherwise that there is no danger to animals other than birds or rabbits." A place with wire netting could be provided, because then the fatality of the disease as regards birds could be proved.

Subsequently

Subsequently the motion proposed by Mr. LASCELLES was verbally amended, and carried in the following form:—"That, in order to save time in determining results, and in view of the fact that inland experiments can be conducted with precautions rendering them as safe as, or safer than, experiments on an island, the Commission determine that so soon as it shall have been demonstrated by laboratory experiments or otherwise to the satisfaction of the Committee already appointed that the introduction of fowl-cholera among rabbits would entail no danger to horses, cattle, sheep, goats, swine, or dogs, experiments be conducted with chicken-cholera in a wire-netting enclosure measuring about 100 yards square, which shall, if the Committee deem necessary, be roofed over with similar wire netting, an outer rabbit-proof fence being constructed at a distance of 2 chains around the central enclosure."

It was moved by Mr. LASCELLES and seconded by Mr. QUIN,—"That $\frac{3}{4}$ -inch netting be obtained for the construction of the said enclosure as soon as the virulence of the microbes brought by M. Pasteur's representatives has been established, and as soon as the power of the disease to spread from rabbit to rabbit has been demonstrated." The motion was carried.

Dr. STIRLING moved,—"That the two foregoing resolutions be an instruction to the Committee already appointed to watch the experiments." Dr. PATERSON seconded, and the motion was carried.

It was moved by Dr. BANCROFT, and seconded by Mr. TABART,—"That this Commission request the Tasmanian Government to obtain information about rabbit-infested islands on their coast, and the suitability thereof for experiments in connection with the destruction of rabbits—special attention being drawn to the Kent Islands." The motion was carried.

Mr. LASCELLES moved,—"That the Experiment Committee have full discretion in all matters concerning the conduct of experiments within the original terms of the Commission, and in all matters regarding the prosecution of the inquiry subject to the limitations already determined by the Commission." Mr. TABART seconded, and the motion was carried.

Correspondence addressed to Professor Allen was received from the Lands Department, Victoria, giving cost of rabbit destruction in the Colony.

The Committee was authorized to inspect memoranda and see what similar information could be obtained from other Colonies.

Mr. Lascelles promised that he would see the Minister for Lands, during the day, with regard to the question of taking evidence as to the utility of wire-netting fencing.

The Chairman mentioned, in conversation, that the Minister for Lands had promised to submit to the Commission all the mechanical devices that had been submitted to him for the purpose of rabbit extermination.

The Commission adjourned to 10 a.m. on the following day.

THURSDAY, 26 APRIL, 1888.

The Commission met at 10 a.m., at the Colonial Secretary's Office, Sydney.

Present :—

New South Wales : WILLIAM CAMAC WILKINSON, Esq., M.D., M.P.

EDWARD QUIN, Esq.

Victoria : HARRY BROOKES ALLEN, Esq., M.D.

ALFRED NAYLOR PEARSON, Esq., F.R. Met. Soc., &c.

EDWARD HAREWOOD LASCELLES, Esq.

New Zealand : ALFRED DILLON BELL, Esq.

South Australia : EDWARD CHARLES STIRLING, Esq., M.D.

ALEXANDER STUART PATERSON, Esq., M.D.

Tasmania : THOMAS ALFRED TABART, Esq.

In the absence of the President (Dr. MacLaurin), the Chair was taken by Professor ALLEN.

Dr. STIRLING moved,—"That the Commission is of opinion that licenses to prosecute their experiments with the so-called Tintinology diseases may be granted to Drs. Butcher and Ellis with safety to the public health." Mr. BELL seconded the motion, which was carried.

Correspondence having been forwarded by the Under Secretary for Lands embracing a resolution passed by the Board of Health suggesting that the Commission should draw up regulations for the issue of licenses, and the subject having been considered,—

Mr. LASCELLES moved,—"The Commission is further of opinion that the drafting of regulations of general application under the Animals' Infectious Diseases Act of 1888 is within the function of the Central Board of Health, and the Commission cannot undertake more than to make recommendations in connection with any special scheme for the destruction of rabbits which is submitted for their consideration." The motion was seconded by Mr. QUIN, and carried.

A letter was read from the Under Secretary for Lands stating that in order to comply with the Act, the licenses should state where microbes were to be propagated and also where the infected animals were to be kept in security.

Dr. Wilkinson stated in reference to this that he had verbally informed the Under Secretary for Lands that M. Pasteur's representatives would keep their microbes, animals &c., in the laboratory of the Board of Health. It was ordered that a formal intimation to this effect be conveyed to the Under Secretary for Lands.

A memo. was received from the Rabbit Department and a minute of Under Secretary for Lands thereon forwarding various mechanical devices for rabbit destruction. This having been submitted,

Mr. BELL moved,—"That the consideration by the Commission of the various mechanical schemes for the destruction of rabbits now submitted to the Commission be postponed until the completion of experiments upon diseases. That in the meantime the Minister for Lands be requested to cause the various appliances to be stored in some suitable room, if possible, so that they may be viewed by members of the Commission as opportunities present themselves."

Mr. LASCELLES seconded the motion which was carried.

Mr. LASCELLES moved,—"That application be made through the Minister for Lands for free railway passes for Dr. Frank Hinds, Dr. Germont, and M. Loir."

Mr. TABART seconded and the motion was carried.

A letter was read from Mr. J. P. Abbott, M.P., covering telegram from Mr. W. L. Reid, of Tolarno Station, offering the use of a 2,500 acre paddock, wire-netted and thickly infested with rabbits.

Dr. STIRLING moved,—“That in connection with Mr. W. L. Reid’s offer of a 2,500 acre netted paddock, at Tolarno homestead, and all labour for M. Pasteur’s experiments—Tolarno being described as one of the most heavily-infested districts—the Commission recommend that proceedings in the purchase of wire-netting be stayed until full information is obtained as to the suitability of Tolarno or any other netted paddock which may be offered for the experiments to be conducted by the Commission.”

Mr. LASCELLES seconded, and the motion was carried.

A further communication was read from the Under Secretary for Lands, stating that the difference in cost between the wire mentioned in the resolution adopted on Monday—48 inches in width, and 1½ mesh—and that of the standard wire used for boundary fences, would be £320. It was also stated that an order had been given for the latter to enclose the 10,000 acres previously determined on by the Commission, and that some of it had already been constructed.

Mr. LASCELLES : “That the attention of the Under Secretary for Lands be directed to the letter containing the offer made by Mr. W. L. Reid, and that he be informed that the Commission were led to recommend the use of special netting by the fact that such special netting is being employed in large quantities for the barrier fence between New South Wales and South Australia.”

The motion was agreed to.

A minute was received from the Hon. the Secretary for Lands inviting the Commission to take the question of width and mesh of wire fencing into consideration.

Mr. LASCELLES moved,—“That as it is impossible to obtain suitable evidence in Sydney as to the proper width and mesh of wire netting for rabbit proof fences, a committee be appointed consisting of Professor Allen, Mr. Pearson, and the mover, to any other member or members of committee who may choose to attend, to take evidence in Victoria of those who have had practical experience on the subject.” The Under-Secretary for Lands had stated in a letter just received that the regulation netting adopted by the Government will cost about £38 per mile. Now, I am prepared to sell wire which, I contend, will be equally as effective at the rate of £21 per mile. Of my own knowledge I know this can be done; and I can actually quote a figure to you, and I think I can prove by evidence taken in Victoria, that this would result in a saving of a quarter of a million of money to your Colony. Of course we have got to see whether the evidence will bear out what I say; but I think you will find it to be simply overwhelming in favour of using netting of a smaller height and a lesser mesh. In connection with this matter I may mention, that the Hon. Thomas Cumming, of Victoria, a gentleman of large experience, had used a 15-inch netting around his garden, and even at that small height the rabbits were kept out. I need hardly say any more, because in the letter which I wrote to the Minister for Lands, and which is contained in these papers, I fully explained my reasons for advocating the use of netting of the height and mesh that I have mentioned.

Mr. Quin said : I beg to second this motion, and in doing so I think the motion will be found to be in keeping with the land legislation proposed to be enacted in this Colony. We have now a Land Bill before the Parliament of New South Wales which proposes to offer a loan to the squatters for the erection of rabbit-proof fences, the amount advanced to be repaid by them over a period of years. Now, what I wish to point out is this : that this Land Bill proposes to make it compulsory upon the squatters to fence their runs; and if that Bill becomes law, the squatters will be forced to expend a large sum of money in fencing, although the great majority of them are not in a position to expend half-a-crown more than is actually necessary. I think the motion proposed by Mr. Lascelles is a very timely one. Why should a man be forced to pay £5,000 for fencing if he can do the same work, and do it just as effectually for £3,500. And I am of opinion that the estimate of the amount which will be saved made by Mr. Lascelles is considerably under the amount which will actually be saved. I think the saving in the western division alone will be over half a million of money, and therefore I have much pleasure in seconding this motion. It commits the country to nothing, while opening at the same time a useful field of inquiry, where we may obtain facts which will enable the country to get the work done at a considerably less cost than would otherwise be the case.

Mr. Tabart : I am very glad that such a motion as this has been proposed. It is one of the most important motions, in my opinion, which has yet come before this Commission. I have been for the past two years endeavouring to move my Government in this matter, trying to induce them to have these fences erected in Tasmania. I propose to do it in this way : For the Government to become the importers of wire netting; that they should supply this wire netting to those who are willing to enclose their properties with it, charging them a low rate of interest on the money expended and making the repayment of the loan a preferential charge on their properties. If this mode were adopted in a country like that which I have the honor to represent here, I consider that we would save the properties, fencing being in my opinion the backbone of rabbit destruction. Of one thing am I convinced that whatever means may be adopted in New Zealand, in Tasmania, or in any of the other colonies, the erection of rabbit-proof fences will be the primary step in the rabbit extermination. If you want to destroy this pest effectually you must limit the area in which it can exist, because apart from the mere disproportion between the areas, it will be far easier to clear 500 acres than to clear 5,000. The great thing in all these methods is to prevent the rabbits from travelling about, and so escaping from the efforts which are being made to destroy them.

Dr. Wilkinson : Before this question is put, I would wish to say that I have no objection to the collection of evidence, because all evidence of this nature must be of great value; but I have certainly heard it stated—and stated by men of very considerable experience—that low fences are not sufficient to keep out rabbits. I heard Mr. Lascelles speak just now of a 15-inch fence.

Mr. Quin : That was merely an allusion to one particular case.

Mr. Lascelles : 15 inches is too low, I admit; but the fence which I would propose would be 3 feet high.

Dr. Wilkinson : Well, I have heard of rabbits climbing up where the fence was placed at an angle.

Mr. Lascelles : But if a fence is properly constructed it will not be at an angle. I have had a great deal of experience with rabbits, but I have never yet known rabbits to climb, and I think I have made every possible inquiry on the subject.

Dr. Wilkinson : Of course I have no practical knowledge of this question, but the point which strikes me is this : that although fences under the condition which Mr. Lascelles has seen them working in small districts in Victoria may be very useful, still they would not be so here. We have larger areas to deal with, and the chances of the netting being knocked down by animals would be very great.

Mr. Lascelles : Well, as to that, I must say that my experience in connection with rabbit extermination has been gained on 500,000 acres of land. And I think I have erected more netting fences than any other man in the Colonies.

Dr.

EXTERMINATION OF RABBITS IN AUSTRALASIA—REPORT OF PROCEEDINGS. 27

Dr. Wilkinson: I admit, of course, that this question is of vast importance, especially in view of the fact that the Government, under our proposed legislation, is to bear 50 per cent. of the cost of the material. In that respect that question is a most important one. It will mean that the Government of this Colony will have to order netting of an entirely different character to that which it is now using.

Mr. Lascelles: Well, but I contend that therein they will save money.

Dr. Wilkinson: Under those circumstances, then, I have no objection at all to this motion.

The Chairman: If this motion is carried it will be necessary for this Royal Commission to authorize a committee to issue advertisements in Victoria requesting those gentlemen who have had experience in connection with rabbit-proof fences to appear in Melbourne and give evidence. If it were done in any other way, it is quite possible that it might be said that the proceeding is a hole-and-corner one. I think, therefore, that there should be a public notification that the Commission propose to obtain Victorian evidence, and then a session can be held in due course. All the members of the Commission will receive notice of this meeting—the representatives from Victoria definitely undertaking to be present. I may add, in conclusion, that this would not tie the hands of the Commission at subsequent meetings from taking further evidence, if it were thought necessary to do so.

The motion was then unanimously carried, and the Committee were authorized to issue advertisements calling for evidence to be taken in Melbourne at such time as the Committee may appoint.

Dr. Wilkinson reported that he had made inquiry concerning a building suitable for experiments on animals to be conducted by the Committee. The Biological Institute, formerly occupied by Baron MacLay was unsuitable, as it was not provided with gas. It was possible that rooms in every way suitable might be placed at the disposal of the Commission in the new Physical Laboratory at the University by Professor Threlfall, with the sanction of the Senate. It was resolved that *Dr. Wilkinson* be authorized to confer further with Professor Threlfall on the matter.

Letters were read from *Dr. Marano* and *Mr. William Darchy*, the former asking to be allowed to obtain rabbits for experiments, and the latter requesting permission to enclose rabbits to experiment on them with various poisons. It was ordered that the letters be returned to the Under Secretary for Lands; that *Dr. Marano* be informed that he has not shown that his experiments in any way concern the work of the Commission; and that in respect of *Mr. Darchy's* application the Committee see no reason why his request should not be granted. Referring to a letter from the Under Secretary for Lands requesting that the particular purposes for which the advance of £500 was required should be stated for the information of the Treasury, *Dr. Wilkinson* was empowered to furnish schedule showing the approximate character of the expenses which will be incurred by the Commission.

Dr. Stirling moved,—“That cheques payable from the account of the Commission be signed by the President (*Dr. MacLaurin*) and one other member of the Commission, and be countersigned by the Secretary.” *Dr. Wilkinson* seconded, and the motion was carried.

Dr. Stirling moved,—“That on or about the 23rd of May the Commission meet in Adelaide, and investigate the action of the disease known as rabbit scab, and subsequently proceed to Silvertown, and if necessary to Tintinallong or elsewhere, to take evidence concerning the effects of the disease submitted for the consideration of the Commission by *Drs. Butcher* and *Ellis*; that the New South Wales Government be informed of the intention of the Commission, and be requested to instruct the Rabbit Inspectors who have had experience concerning the Tintinallong outbreak to be prepared to give evidence at Silvertown, and be requested also to invite the South Australian Government to provide facilities for the work of the Commission in that Colony.” The motion was seconded by *Dr. Wilkinson*, and carried.

Dr. Stirling moved,—“That Professor Allen be the convener of such meeting.” *Dr. Wilkinson* seconded, and the motion was carried.

Mr. Pearson moved,—“That two shall form a quorum of the Committee appointed to watch experiments.” *Dr. Stirling* seconded, and the motion was carried.

It was ordered that as soon as the report of the Correspondence Committee be completed it should be printed and circulated amongst the members; also that it be incorporated in the final report of the Commission.

It was also decided that the committee appointed to watch experiments should be requested to scrutinize the correspondence received bearing on the mechanical devices now in possession of the Minister for Lands.

It was also decided to request the same committee to elect a chairman to take general control of the experiments about to be conducted.

Dr. Ellis was then afforded an interview, and in reply to his questions the Chairman gave him certain information with respect to the intention of the Commission in dealing with the Tintinallong disease.

Mr. Bell proposed,—“That the thanks of the Commission be tendered to Professor Allen for his conduct in the Chair.” The motion was carried by acclamation. Professor *Allen* replied briefly, thanking the Commission for the vote.

The Commission then adjourned.

FRIDAY, 18 MAY, 1888.

The Commission met, informally, at 10 a.m., at the Crown Lands Office, Melbourne.

Present:—

Victoria: HARRY BROOKES ALLEN, Esq., M.D.
ALFRED NAYLOR PEARSON, Esq.
EDWARD HAREWOOD LASCELLES, Esq.
New Zealand: ALFRED DILLON BELL, Esq.
Queensland: JOSEPH BANCROFT, Esq., M.D.

In the absence of the President (*Dr. MacLaurin*), the Chair was taken by Professor *Allen*.

Robert Fawell Hudson and Alfred Lamb Gilbert were called in and gave information concerning the progress of the alleged disease amongst rabbits at Tintinallong.

The Commission adjourned.

MONDAY,

MONDAY, 21 MAY, 1888.

The Commission met at 10 a.m., at the Crown Lands Office, Melbourne.

Present:—

New South Wales: WILLIAM CAMAC WILKINSON, Esq., M.D., M.P.
EDWARD QUIN, Esq.
Victoria: HARRY BROOKES ALLEN, Esq., M.D.
EDWARD HAREWOOD LASCELLES, Esq.
ALFRED NAYLOR PEARSON, Esq., F.R. Met. Soc., &c.
New Zealand: ALFRED DILLON BELL, Esq.
Queensland: JOSEPH BANCROFT, Esq., M.D.
Tasmania: THOMAS ALFRED TABART, Esq.

In the absence of the President (Dr. MacLaurin), the Chair was taken by Professor ALLEN.

The following witnesses were called in and examined:—Charles Myles Officer, Agar Wynne, Joseph M'Gaw, John Bertram, Andrew Anderson, George Henry Greene, Edmund Hayes, James Finlay, Alexander M'Edwards, William Cumming, Hugh M'Cann, Robert Blyth Kerr.

Dr. WILKINSON moved,—“That the same questions regarding wire-netting fences be asked of the witnesses who may be examined at Silvertown.”

Mr. LASCELLES seconded. The motion was agreed to.
The Commission then adjourned.

WEDNESDAY, 23 MAY, 1888.

The Commission met at 10 a.m., at the office of the Commissioner of Crown Lands, Adelaide.

Present:—

New South Wales: WILLIAM CAMAC WILKINSON, Esq., M.D., M.P.
EDWARD QUIN, Esq.
Victoria: HARRY BROOKES ALLEN, Esq., M.D.
ALFRED NAYLOR PEARSON, Esq., F.R. Met. Soc., &c.
EDWARD HAREWOOD LASCELLES, Esq.
New Zealand: ALFRED DILLON BELL, Esq.
South Australia: EDWARD CHARLES STIRLING, Esq., M.D.
Queensland: JOSEPH BANCROFT, Esq., M.D.
Tasmania: THOMAS ALFRED TABART, Esq.

In the absence of the President (Dr. MacLaurin), the Chair was taken by Dr. STIRLING.

The following witnesses were called in and examined:—Allan M'Farlane, Archibald Watson, James Francis Cudmore.

Dr. Stirling then left the Chair, which was taken by Professor ALLEN.

The following witnesses were then called in and examined:—Andrew Smith, Herbert Bristow Hughes.

Dr. STIRLING then resumed the Chair.

The following witness was then called in and examined:—George Riddock.

Dr. Stirling again left the Chair, which was taken by Professor ALLEN.

The following witness was then called in and examined:—Peter Waite.

Mr. TABART moved,—“That with a view to economize the time of the Commission, and in order to enable the Sydney experiments to be proceeded with at the earliest possible date, leave of absence from the further sittings of the Commission at Adelaide and Silvertown be granted to Dr. Bancroft, Dr. Wilkinson, Mr. Bell, and Mr. Tabart, and that they be instructed to proceed forthwith to Tintinallong Station, to make investigations there on behalf of the Commission, into the rabbit disease existing in that locality.”

Dr. WILKINSON seconded, and the motion was carried.

Prof. ALLEN moved,—“That the members so appointed be constituted an Executive Committee of the Commission, and be requested to furnish a written report to the Commission.”

Dr. STIRLING seconded the motion, which was carried.

The Commission then adjourned.

SATURDAY, 26 MAY, 1888.

The Commission met at 10 a.m., at Silvertown.

Present:—

New South Wales: EDWARD QUIN, Esq.
Victoria: HARRY BROOKES ALLEN, Esq., M.D.
EDWARD HAREWOOD LASCELLES, Esq.
South Australia: ALEXANDER STUART PATERSON, Esq., M.D.

In the absence of the President (Dr. MacLaurin), the Chair was taken by Professor ALLEN.

The following witnesses were called in and examined:—William Hogarth, Arthur Torrens.

MONDAY,

MONDAY, 28 MAY, 1888.

The Commission met at 10 a.m., at Silverton.

Present :—

New South Wales : EDWARD QUIN, Esq.
Victoria : HARRY BROOKES ALLEN, Esq., M.D.
 EDWARD HAREWOOD LASCELLES, Esq.
South Australia : ALEXANDER STUART PATERSON, Esq., M.D.

In the absence of the President (Dr. MacLaurin), the Chair was taken by Professor ALLEN.

The following witnesses were called in and examined :—Herbert Pickering Butcher, M.R.C.S. Eng., Charles William Reid, Herbert Pickering Butcher (recalled and re-examined), Alexander Bell, Harry Edmund Viudin, Abram John Clarke, John Andrew O'Flaherty, John Lynden M'Maugh, Mark James Curry Tully, David Brown, James Charles Wilkinson Crommolin, Henry Prideaux Richardson, John Andrew O'Flaherty (recalled and re-examined), Thomas Henry Elwin, George Urquhart, John Binnie.

The Commission then adjourned.

TUESDAY, 29 MAY, 1888.

The Commission met at 2:30 p.m., at the office of the Commissioner of Crown Lands, Adelaide.

Present :—

Victoria : HARRY BROOKES ALLEN, Esq., M.D.
South Australia : EDWARD CHARLES STIRLING, Esq., M.D.
 ALEXANDER STUART PATERSON, Esq., M.D.

In the absence of the President (Dr. MacLaurin), the Chair was taken by Dr. STIRLING.

The following witnesses were called in and examined :—Charles Jonas Valentine, Samuel Graü Hübbe, John Miller.

The Commission then adjourned.

WEDNESDAY, 6 JUNE, 1888.

The Commission met at 10:30 a.m., at the Crown Lands Office, Melbourne.

Present :—

Victoria : HARRY BROOKES ALLEN, Esq., M.D.
 ALFRED NAYLOR PEARSON, Esq., F.R. Met. Soc., &c.
Queensland : JOSEPH BANCROFT, Esq., M.D.

In the absence of the President (Dr. MacLaurin), the Chair was taken by Professor ALLEN. Edward Micklethwaite Curr was called in and examined.

The Commission then adjourned.

TUESDAY, 19 JUNE, 1888.

The Commission met at 2:30 p.m., at the Colonial Secretary's Office, Sydney.

Present :—

New South Wales : WILLIAM CAMAC WILKINSON, Esq., M.D., M.P.
Victoria : HARRY BROOKES ALLEN, Esq., M.D.
 ALFRED NAYLOR PEARSON, Esq.
 EDWARD HAREWOOD LASCELLES, Esq.
New Zealand : ALFRED DILLON BELL, Esq.
Queensland : JOSEPH BANCROFT, Esq., M.D.

In the absence of the President (Dr. MacLaurin), the Chair was taken by Professor ALLEN. The Commission deliberated, and adjourned to Thursday next at 11 o'clock.

THURSDAY, 21 JUNE, 1888.

The Commission met at 11 a.m., at the Colonial Secretary's Office, Sydney.

Present :—

New South Wales : WILLIAM CAMAC WILKINSON, Esq., M.D., M.P.
Victoria : HARRY BROOKES ALLEN, Esq., M.D.
 ALFRED NAYLOR PEARSON, Esq.
 EDWARD HAREWOOD LASCELLES, Esq.
South Australia : EDWARD CHARLES STIRLING, Esq., M.D.
 ALEXANDER STUART PATERSON, Esq., M.D.
Queensland : JOSEPH BANCROFT, Esq., M.D.

In the absence of the President (Dr. MacLaurin), the Chair was taken by Professor ALLEN.

The evidence taken at Tintinallogy by the Executive Committee was received and ordered to be embodied in the printed evidence taken by the Commission.

Dr. BANCROFT and Dr. WILKINSON offered to furnish reports in writing of their individual observations during their visit to Tintinallogy. It was resolved that such reports be accepted with thanks, and be printed among the proceedings of the Commission.

Dr. PATERSON handed in, on behalf of the Government of South Australia, papers *re* Bladder Fluke, by Mr. Coleman Phillips, of New Zealand.

It was ordered that the papers be placed with other correspondence 2421, on same subject, and that receipt of same be acknowledged.

A deputation was received from the Wynne-Hudson Rabbit Trapping and Preserving Company, introduced to the Commission by Mr. Sydney Burdekin, M.P., asking that a 5-mile block of land should be set apart for the use of the Company, and that the Commission should test the trap patented by Mr. Wynne.

After discussion, the CHAIRMAN informed the deputation that their scheme would have the consideration of the Commission.

Dr. WILKINSON having made a statement of the negotiations between the Experiment Committee and the representatives of M. Pasteur,* and the correspondence and reports of proceedings of the Committee having been read and considered,

Dr. STIRLING moved:—"That the representatives of M. Pasteur be informed that the experiment which they propose to perform is not satisfactory to the Commission—that even if it be attended with positive results the Commission will not be able to infer that the disease will spread from rabbit to rabbit under natural conditions; that the Commission refuses to permit any broadcast dissemination of chicken-cholera microbes on any inland area until satisfactory proof shall have been given by experiments approved by the Commission, (1) That the disease is capable of spreading freely from rabbit to rabbit; (2) That the disease is innocuous to domestic animals; and that the Commission express its surprise that as M. Pasteur is seeking to obtain a reward of £25,000 for his scheme, his representatives should have absolutely declined to permit the fullest testing of its merits. The Commission will not object to the conduct of an experiment on the lines laid down by M. Pasteur; but it requests a final answer without delay whether M. Pasteur's representatives will allow the experiments proscribed by the Commission to be conducted, and whether they will furnish rabbits suffering from chicken-cholera for the purpose of experiments under the direction of the Commission. If M. Pasteur's representatives do not assent to these conditions the Commission will report accordingly to the Government of New South Wales, and will recommend, (1) That correspondence with M. Pasteur and his representatives be suspended; (2) That the permission granted to M. Pasteur's representatives to introduce into New South Wales and keep in New South Wales the microbes of chicken-cholera, and to perform experiments on rabbits with a view of maintaining a supply of the microbes in active state, be withdrawn; (3) That steps be taken to obtain the microbes of chicken-cholera from other sources, so that the utility of this disease for the extermination of rabbits may be tested in a satisfactory manner."

Dr. PATERSON seconded. The motion was unanimously carried.

Dr. BANCROFT moved,—“That Dr. Stirling be requested to obtain 12 tame rabbits (10 does and 2 bucks) from Adelaide, for the purpose of experiment.”

Mr. LASCELLES seconded. The motion was carried.

Dr. PATERSON moved,—“That the Commission advises that Drs. Butcher and Ellis be granted permission to employ the so-called Tintinology disease among rabbits in such districts as they may desire, provided that the places in which the disease is being employed be notified to the Commission.”

Mr. PEARSON seconded. The motion was carried.

It was ordered that a copy of this resolution be forwarded to the Minister, and that the Minister be requested to give the required permission to Dr. Ellis as soon as possible, as fears have been expressed that the control of the disease may be lost.

A minute having been received from the Hon. the Secretary for Lands, drawing attention to a complaint by the Parliamentary representatives of Balmain, that the rabbit experiments at Rodd Island might prove dangerous to the health of their constituents,

Mr. PEARSON moved,—“The Commission begs to report that all possible precautions have been taken to prevent the carriage of contagion from Rodd Island; the experiments will be conducted in an enclosure already surrounded and roofed with fine wire gauze; the drainage from the enclosure will be caught in a disinfecting tank; there is a broad belt of water around the island; and the Commission is satisfied that public health will not be endangered in the least by the experiments which will be conducted.”

Dr. BANCROFT seconded. The motion was carried.

The report of the Correspondence Committee† was adopted on the motion of Dr. STIRLING, seconded by Dr. WILKINSON; and the thanks of the Commission were given to Mr. Pearson for his services in the compilation of the report.

Dr. WILKINSON moved:—"That letters be addressed to Messrs. Bishop, Lanferon, Laplanche, Graham, and Richardson, asking for further particulars in support of their statements."

Dr. STIRLING seconded. The motion was carried.

The Commission adjourned to 10 o'clock on the following day.

FRIDAY, 22 JUNE, 1888.

The Commission met at 2 p.m., at the Colonial Secretary's Office, Sydney.

Present:—

New South Wales: WILLIAM CAMAC WILKINSON, Esq., M.D., M.P.

Victoria: HARRY BROOKES ALLEN, Esq., M.D.

ALFRED NAYLOR PEARSON, Esq.

EDWARD HAREWOOD LASCELLES, Esq.

South Australia: EDWARD CHARLES STIRLING, Esq., M.D.

ALEXANDER STUART PATERSON, Esq., M.D.

New Zealand: ALFRED DILLON BELL, Esq.

Queensland: JOSEPH BANCROFT, Esq., M.D.

In the absence of the President (Dr. MacLaurin), the Chair was taken by Professor ALLEN.

Mr. BELL said that with regard to the resolution adopted yesterday, dealing with the correspondence and interviews between the Experiment Committee and the agents of M. Pasteur, he wished to

* See Section VII. of Report.

† See Appendix I. to this Report.

to express his entire concurrence with that resolution. The work of the Experiment Committee had been very much hampered by the trouble that had arisen with M. Pasteur's agents; and their desire had been to consider the nationality of these gentlemen and the distance they had come. The Committee had used every possible means of arriving at a *modus vivendi*. The Committee had gone a great deal further in that than they would have gone had they had to deal with ordinary people and ordinary circumstances. The resolution was one which he had been personally anxious to see carried in almost the identical form in which it appeared, and he had great pleasure, as a member of the Experiment Committee, whose action was reviewed by this resolution, in expressing his complete concurrence with it.

Mr. BELL moved,—“That Dr. Ellis be requested to forward to Dr. Katz, as soon as possible, fifty rabbits suffering from the so-called Tintinallgy disease; and if fifty are not quickly available, to send, in the first instance, such number as may be forthcoming.”

Mr. LASCELLES seconded. The motion was carried.

Mr. LASCELLES moved,—“That this Commission recommends the Governments of the respective Colonies to issue licenses, under suitable conditions, to responsible persons, who may desire to keep rabbits in confinement for the purpose of poison experiments.”

Dr. PATERSON seconded. The motion was carried.

Dr. BANCROFT moved,—“That the Commission recommends that licenses to keep rabbits in confinement be granted by the Governments of each Colony to any competent persons who may desire to conduct pathological inquiries concerning the destruction of rabbits.”

Dr. STIRLING seconded. The motion was carried.

It was ordered that these resolutions be transmitted to the Honorable the Secretary for Lands, and that he be requested to forward copies of them to the Governments of the other Colonies.

Dr. BANCROFT moved,—“That Sir James Hector and Professor Thomas, of New Zealand, be requested to confer with the Experiment Committee when visiting Australia, and be thanked for the assistance already rendered.”

The Chairman of the Experiment Committee reported that on 2nd May the following resolution was adopted by the Committee:—“That the expenses of the Executive Committee be defrayed by the various Governments represented on the Commission, in a proportion to be fixed by the said Governments,” and that such resolution was at once forwarded to the Government of New South Wales. He desired to move that the action of the Committee be confirmed.

In answer to a question the Chairman of Committee explained that the motion referred only to the personal expenses of members of the Experiment Committee in connection with the conduct of experiments on behalf of the full Commission during its first adjournment.

Subject to this explanation it was resolved, on the motion of Dr. WILKINSON, seconded by Mr. PEARSON,—“That the recommendation of the Experiment Committee be adopted, and that a copy of this resolution, and of the explanation relating thereto, be sent to the Minister for Lands.”

Dr. STIRLING moved,—“That, subject to the explanation of the Chairman of the Experiment Committee on the question as to the personal expenses of its members, the report of the Committee be taken as read, adopted, ordered to be printed, and incorporated with the proceedings of the Commission. (2.) The Commission expresses its thanks to the members of the Experiment Committee for the thorough and satisfactory manner in which they have discharged the important duties committed to them.”

Mr. LASCELLES seconded. The motion was unanimously carried.

Mr. BELL moved,—“That the Commission tender to the Government of New South Wales its thanks for the readiness and liberality with which the necessary assistance has been rendered to the Commission, especially in respect to the rapid and satisfactory completion of the works at Rodd Island.”

Mr. PEARSON seconded. The motion was carried.

The thanks of the Commission were then unanimously tendered to Professor Allen for his services as Chairman.

On resuming in the afternoon the chair was occupied by Dr. BANCROFT, and subsequently by Dr. STIRLING.

Dr. PATERSON moved,—“That Dr. Wilkinson be the convener of the next meeting of the Commission.”

Mr. LASCELLES seconded. The motion was carried.

Dr. STIRLING moved,—“That the Government of New South Wales be asked to accelerate the printing of the proceedings of the Commission to date; that after correction of the proofs six copies be forwarded to each member of the Commission; and that the Government of New South Wales be asked if they have any objection to the same being at the disposal of the Commissioners as part of any progress report they may desire to forward to their respective Governments.”

Dr. BELL seconded. The motion was carried.

It was ordered that, in conformity with this resolution, the Secretary ascertain from the Government of New South Wales whether the request of the Commissioners as to the use of the report as progress report for the various Governments has been acceded to, and that an intimation to this effect be forwarded with the documents.

Mr. LASCELLES moved,—“That the Secretary be instructed to write to the Minister for Lands stating that the evidence regarding the use of wire netting has been obtained; and that if he desires it the Commission is now prepared to come to a decision and send in an advance report on the subject.”

Dr. PATERSON seconded. The motion was carried.

Mr. BELL moved,—“That the Experiment Committee be authorized to subject to experiment, on the general experimental lines already laid down, any disease that may be submitted to them for examination, and that may seem to them to be worth investigation.”

Dr. STIRLING seconded. The motion was carried.

Dr. STIRLING moved,—“That in case of the representatives of M. Pasteur acceding to the proposals of the Commission embodied in the resolution of the 21st June, it be an instruction to the Experiment Committee to carry them out according to the instructions laid down; and in the case of the representatives of M. Pasteur declining to accede to such proposals or to such reasonable modifications thereof (not in any way traversing the general principles already determined in the resolution of the 21st June) as may seem to the Experiment Committee to be acceptable, the said Committee be instructed to make arrangements for getting a supply of the microbes from Europe, and to proceed with the authorized experiments.

Mr. PEARSON seconded. The motion was carried.

The

The Secretary submitted correspondence received since last meeting—the correspondence including a large number of applications for the Government reward.

It was ordered that the documents be referred to the Correspondence Committee for report to the Commission at its next meeting. The first report, already printed, to be headed "Interim Report."

It was also ordered that two rubber stamps be procured—one (small) inscribed "Correspondence Committee Rabbit Commission, Sydney, N.S.W.;" the other (large) inscribed "Intercolonial Rabbit Commission, Sydney, N.S.W."

The Commission then adjourned.

SATURDAY, 18 AUGUST, 1888.

The Commission met at 10 a.m., at the Crown Lands Office, Melbourne.

Present:—

New South Wales: WILLIAM CAMAC WILKINSON, Esq., M.D., M.P.

Victoria: HARRY BROOKES ALLEN, Esq., M.D.

ALFRED NAYLOR PEARSON, Esq.

EDWARD HAREWOOD LASCELLES, Esq.

In the absence of the President (Dr. MacLaurin), the Chair was taken by Professor ALLEN.

A letter was read from the Government Printer, stating that the delay in printing the evidence of the Royal Commission arose from the necessity of completing work left over by Parliament. It was decided that the Secretary should urge the Printer to hasten the printing of the proceedings of the Commission.

A report was read from Dr. Katz, chief expert, on the experiments carried out at Rodd Island by the representatives of M. Pasteur.*

The report was received, ordered to be printed, and embodied in the transactions of the Commission.

A statement was made by Dr. WILKINSON to the effect that Sir Henry Parkes, Acting Minister for Lands, had sent for him, and stated that the representatives of M. Pasteur had expressed a wish to sever their connection with the Commission. Dr. Wilkinson added that he had submitted a memo. to Sir Henry Parkes, explaining the situation. He had previously received an application from the agents of M. Pasteur, asking to be allowed to make experiments in the open country. To this he had replied that no experiments in the open could be allowed until the laboratory experiments were completed. Since giving this reply no further communication had been received from the agents of M. Pasteur.

It was resolved to obtain from the Colonial Secretary's Office, a copy of the memo. forwarded to Sir Henry Parkes, the same to be included in a written report by Dr. Wilkinson to be embodied in the proceedings of the Commission.

Mr. PEARSON proposed,—“That a copy of the resolution already adopted by the Commission ‘That no experiments would be permitted in the open until the laboratory experiments proved that chicken-cholera would spread effectively from rabbit to rabbit,’ be forwarded to Sir Henry Parkes in confirmation of the action of the Chairman of the Experiment Committee.”

Mr. LASCELLES seconded. The motion was agreed to.

In answer to the Chairman, Dr. WILKINSON reported that cultures of microbes of chicken-cholera were in possession of Dr. Katz, and that Dr. Katz was now making experiments with them.

Dr. WILKINSON also stated that the experiments specified by the Commission in its schedule concerning chicken-cholera were on the point of being carried out; that the necessary cultivations had been in progress for some days; that M. Pasteur's representatives were aware that such experiments were about to be conducted; that a difficulty had arisen concerning the right which M. Pasteur's representatives had been disposed to assume of visiting the laboratory at any time in connection with the experiments of the Commission; that Dr. Wilkinson had pointed out that such indiscriminate visiting to experiments of this nature could not be permitted, but that stated times for visits must be arranged.

Dr. Wilkinson's report was received, and his action confirmed.

Dr. WILKINSON also reported that no further communications had been received from Drs. Butcher and Ellis, with regard to the so-called Tintinology disease. He was unable to say when rabbits affected with this disease would be available, adding that no experiments with this disease had been conducted under the Commission, owing to rabbits not having been supplied.

It was resolved that a communication be addressed both to Dr. Butcher and Dr. Ellis, asking whether their experiments are being conducted in any new country, in accordance with the permission granted on 21st June last, and inquiring when they would be able to provide twenty rabbits, suffering from the said disease, for the purpose of experiments under the direction of the Commission; that Messrs. Butcher and Ellis be also reminded that the permission granted to them to establish this so-called disease in fresh country was merely intended to prevent the disease from being lost, and did not involve approval of their scheme by the Commission.

At the instance of the Commission, Dr. WILKINSON undertook to cause progress reports of each series of experiments to be distributed to the members of the Commission as soon as possible.

Dr. WILKINSON reported that Dr. Fischer had recently arrived in Sydney, and had handed to Dr. Katz specimens which he said were the microbes of chicken-cholera and of rabbit septicæmia. On examination, Dr. Katz found that the cultures of chicken-cholera microbes were contaminated, and that those of rabbit septicæmia were dead. Hence no experiments were made with such cultures.

Letters were read from Dr. MacLaurin, resigning, on account of the pressure of official duties, his position as President of the Commission, and from the Principal Under Secretary, intimating that Dr. MacLaurin's resignation, as a member of the Commission, had been accepted.

It was decided that Dr. MacLaurin's resignation be accepted with regret, and that he be so informed.

Mr. LASCELLES moved,—“That the Chairman of the Experiment Committee (William Camac Wilkinson, Esq., M.D., M.P.) and the Secretary be empowered to sign all cheques on behalf of the Commission; and that the Treasury be informed accordingly.”

Mr. PEARSON seconded. The motion was agreed to.

Regarding

EXTERMINATION OF RABBITS IN AUSTRALASIA—REPORT OF PROCEEDINGS. 33

Regarding the classified list of mechanical contrivances submitted to the Commission, the Secretary reported that, in accordance with the wish of the Under Secretary for Lands, he had engaged the assistance necessary to make out the lists required; but was then informed, by direction of the Under Secretary, that the list would be prepared in the Department of Lands.

It was decided that a meeting of the Commission should be held in Melbourne towards the end of September next, on such date as the Chairman of the Experiment Committee may determine, for receiving a progress report concerning experiments with disease, and to take the evidence of landholders from the Lower Darling concerning the rabbit plague.

It was further resolved that preliminary notice of the intended meeting be at once forwarded to the representatives of the various Colonies, and to the Government of Queensland.

The Commission then adjourned.

SATURDAY, 13 OCTOBER, 1888.

The Commission met at 12 (noon), at the Crown Lands Office, Melbourne.

Present:—

<i>New South Wales:</i>	WILLIAM CAMAC WILKINSON, Esq., M.D., M.P.
<i>Victoria:</i>	HARRY BROOKES ALLEN, Esq., M.D. ALFRED NAYLOR PEARSON, Esq. EDWARD HAREWOOD LASCELLES, Esq.
<i>New Zealand:</i>	ALFRED DILLON BELL, Esq.
<i>South Australia:</i>	EDWARD CHARLES STIRLING, Esq., M.D. ALEXANDER STUART PATERSON, Esq., M.D.
<i>Queensland:</i>	HENRY TRYON, Esq.
<i>Tasmania:</i>	THOMAS ALFRED TABART, Esq.

The Chair was taken by Professor ALLEN.

Mr. TRYON presented a document from the New South Wales Government appointing him one of the representatives of Queensland on the Commission.

In reply to the Chairman, Mr. TRYON stated that Dr. Bancroft, of Queensland, was still a member of the Commission.

The Secretary stated that the usual notice of meeting had been forwarded to Dr. Bancroft.

The Secretary read a letter from Mr. Quin stating that it was impossible for him to attend the present meeting.

The CHAIRMAN read letters from various members of the Commission, and from the Secretary, with regard to the progress of experiments, &c., at Rodd Island. Also letters from H. P. Butcher, Esq., M.D., and C. W. Reid, Esq., of Tintinallong, complaining that their accounts for expenses had not been attended to by the Secretary, and intimating that no infected rabbits would be forwarded until such accounts were paid and a guarantee given to refund the cost of the carriage of such rabbits to Sydney.

The Secretary handed in the claims of Dr. Butcher and Mr. Reid for £47 5s. and £18 18s. respectively; also a claim by Dr. Ellis for £25 for expenses; and a further claim by the Commissioner for Railways for £5, value of a pass over the railways which had been issued to Dr. Ellis.

The claims referred to, and the correspondence between Dr. Butcher and Mr. Reid and the Secretary, having been considered,

Mr. BELL moved,—“That the allowance to witnesses giving evidence before the Commission be as follows: The actual value of coach fare, or in lieu thereof a mileage allowance of 1s. 6d. per mile one way, together with £1 1s. per day for personal expenses.”

Dr. STIRLING seconded. The motion was carried.

It was further resolved as follows:—“That as a matter of routine those witnesses only shall be paid their expenses who have been summoned by the Commission of its own motion; and that the expenses of other witnesses be dealt with as the cases arise;

“That the expenses of C. W. Reid be paid on the above scale;

“That the claim of Dr. Ellis for £25 be allowed to stand over;

“That, with reference to the cost of the free pass issued to Dr. Ellis, a letter be addressed to the Under Secretary for Lands, inquiring what was the exact nature of the representations alleged to have been made by the Commission to the effect that Dr. Ellis' presence at Silvertown was necessary; whether such representations were in writing; and, if so, to ask for a copy thereof;

“That, in the opinion of the Commission, the Secretary had no option but to hold over these accounts for the consideration of the Commission.”

Dr. STIRLING moved:—“That the Commission again requests Drs. Butcher and Ellis, as speedily as possible, to forward to Sydney fifty rabbits suffering from the so-called Tintinallong disease, or such less number as may be forthcoming, the Commission undertaking to defray the expenses of conveying such rabbits to Sydney.”

Dr. PATERSON seconded. The motion was carried.

In response to a request by the Chairman, Dr. WILKINSON, M.P., made a statement with regard to the progress of experiments at Rodd Island.

A similar statement was made by Mr. TRYON, who had visited the experimental station.

Further consideration of this matter was postponed till Monday, 15th October.

A letter was read from Dr. Marano, of Sydney, asking for the use of Rodd Island for a fortnight to carry out a series of experiments for the extermination of rabbits. A minute of the head of the Rabbit Department thereon was also read, stating that in the event of such application being complied with, Dr. Marano was willing to defray any expenses incidental to his use of the Island.

It was resolved that in this and in all similar applications a sketch of the process to be adopted must be, in the first place, supplied to the Chairman of the Experiment Committee, and that the Chairman of the Experiment Committee should be authorized, at his discretion, to give or to withhold permission for the conduct of such experiments.

The CHAIRMAN read a statement (made in lieu of evidence) by Mr. E. H. Lascelles on the Rabbit Question.

It was ordered that the statement should be inserted in the Report of the Commission.

Mr. LASCELLES moved:—"That as the evidence from practical landowners or lessees who have erected wire-netting fences for the purpose of checking the spread of rabbits is almost unanimous in agreeing that netting 36 inches wide and of 1½-in. mesh is a sufficient fence, this Commission recommends the Minister for Lands to allow the use of such netting."

Subsequently the motion was withdrawn, and the following substituted by the mover:—"That this Commission is of opinion that in view of the great saving in cost, and almost equal efficiency for practical purposes of wire-netting of 3 ft. in height and 1½-in. mesh, as compared with netting of 3 ft. 6 in. in height and 1½-in. mesh (this being shown by a considerable proportion of the evidence taken), the use of netting of 3 ft. in height and 1½-in. mesh might be permitted by the Government of New South Wales."

Mr. BELL seconded. The motion was carried.

The Commission adjourned.

MONDAY, 15 OCTOBER, 1888.

The Commission met at 9.30 a.m., at the Crown Lands Office, Melbourne.

Present:—

<i>Victoria:</i>	HARRY BROOKES ALLEN, Esq., M.D. ALFRED NAYLOR PEARSON, Esq.
<i>New Zealand:</i>	ALFRED DILLON BELL, Esq.
<i>South Australia:</i>	EDWARD CHARLES STIRLING, Esq., M.D. ALEXANDER STUART PATERSON, Esq., M.D.
<i>Queensland:</i>	HENRY TRYON, Esq.
<i>Tasmania:</i>	THOMAS ALFRED TABART, Esq.

The Chair was taken by Professor ALLEN.

A letter was read from Mr. A. N. Pearson stating that information was required concerning the preference which rabbits have for different kinds of poisons and for different flavouring substances, and remarking that Dr. Katz was willing to undertake experiments if desired to do so.

It was resolved, on the motion of Mr. BELL,—“That, provided such experiments be not allowed to interfere with, or delay experiments concerning disease, the Commission authorizes their performance, and requests Mr. Pearson to give the necessary instructions as to the nature of these experiments to Dr. Katz.”

Mr. Pearson also wrote drawing attention to two diseases recently discovered, and said to be peculiar to rabbits—namely, rabbit enteritis, discovered by Professor Ribbert, of Bonn; and a disease analogous to swine plague, but distinct from it, described by Professor Loeffler.

On the motion of Dr. STIRLING it was resolved,—“That Dr. Katz be requested to address letters to Professor Ribbert and Professor Loeffler, asking for particulars concerning these diseases; and, if possible, obtaining cultivations of the organisms of such diseases.”

With regard to the theory published by Dr. Gammaleia, of Odessa, that the microbes of chicken cholera existed naturally in the intestines of birds, it was resolved that Dr. Katz be authorized to make such experiments as he may think fit to test this theory.

James Ormond was called in and examined.

Mr. BELL moved,—“That the following experiment be tried at Rodd Island: That the Rodd Island enclosure be divided into two equal parts—A and B—by rabbit-proof netting, the two divisions to be separated by a clear space of one yard. Division A to include, as far as possible, existing burrows; new burrows to be formed in division B. That fifty healthy rabbits be turned loose in each division. That the rabbits in each division be fed and sheltered in like fashion. That five (5) rabbits, specially marked, be separately fed with green stuff, to which, in the case of each rabbit, 2 ccm. of broth, containing chicken-cholera microbes, have been added; and that after the meal these rabbits be placed in division A. That at the close of a week five other rabbits, differently marked, be similarly fed and placed in division A. That at the close of another week the process be repeated. That at the close of another week the experiment be terminated. That the five rabbits first fed with microbes, if they should die, be left in the enclosure. That other rabbits subsequently dying in either enclosure be also left, provided that great nuisance does not arise. That as soon as possible after the death of any rabbit in either enclosure, some blood be obtained from it with as little disturbance of the body as possible; and be examined so as to determine whether death was due to chicken-cholera. That, subject to the general intent of this experiment, Dr. Katz be authorized to exercise his discretion in matters of detail.”

Dr. STIRLING seconded. The motion was carried.

It was resolved, on the motion of Mr. TRYON, seconded by Mr. PEARSON,—“That the Secretary write to the Department of Lands, stating that a crucial and possibly a final experiment with chicken-cholera is about to be performed by the Commission; and ask that 150 rabbits be delivered, *alive*, at Rodd Island as speedily as possible. Also, to state that the date on which this crucial experiment will be completed will depend, in the first instance and mainly, on the promptitude with which rabbits can be supplied.”

It was further resolved,—“That from time to time, during the term of the large experiment just ordered, rabbits infected with chicken-cholera be placed in the aviary and allowed to die and remain there. That some fowls, with pigeons and other birds, be kept in that aviary during the term of the large experiment. That in case of death of any birds the cause of death be ascertained;

“That”

EXTERMINATION OF RABBITS IN AUSTRALASIA—REPORT OF PROCEEDINGS. 35

“That Dr. Katz be requested to ascertain, by laboratory experiments, what is the influence of simple desiccation, at various temperatures, on the microbes of chicken-cholera;

“That a letter be sent to Mr. Reid, of Tolarno, asking whether Boolka Island is still available for experiments as to the use of disease for the extermination of rabbits; whether the island is still infested with rabbits; whether the rabbits are now healthy; and what arrangements would be necessary if experiments on the island were to be conducted.”

The CHAIRMAN drew the attention of the Commission to the difficulties experienced in the prompt conduct of its business, arising from the resignation of the President and the non-appointment of a successor. He suggested that the Government of New South Wales be requested to appoint, as speedily as possible, a representative who would be fully competent to undertake the duties which Dr. MacLaurin had been compelled, by pressure of his official work, to relinquish.

MR. BELL reviewed the past proceedings of the Commission. He concurred with the Chairman that the appointment of a President was essential to the prompt and effective conduct of the work of the Commission; but, speaking for himself, he would move that Professor Allen be requested to accept the office of President. He felt sure that every member of the Commission appreciated the energy and ability with which Professor Allen, as Chairman, had conducted the business of the Commission; and he was satisfied that no other appointment would lead to equally satisfactory results.

Dr. STIRLING seconded the motion, and several other members having spoken,

Professor ALLEN thanked the members present for their appreciation of any services which he had been able to render; but said that, in his opinion, it was in every way advisable that the President should be a representative of New South Wales, and should be resident in Sydney. His own time, too, was already engrossed. He therefore was unable to consent to his nomination as President, unless the Government of New South Wales found it impossible to induce any competent gentleman in that Colony to accept the position.

Dr. STIRLING moved:—“That the Government of New South Wales be informed that the work of the Commission has been, and is still being, greatly hindered by the absence of a President to actively direct the work of the Commission. That this Commission respectfully urge the immediate appointment of a thoroughly qualified representative of New South Wales as President, possessing the scientific attainments, the business ability, and the time to act as working President of the Commission, in the room of Dr. MacLaurin, who has resigned. That in the opinion of this Commission the appointment of either the Hon. Dr. Mackellar, Professor Anderson Stuart, or Dr. F. Norton Manning, would meet these requirements. That in the event of all these gentlemen declining absolutely to undertake the important duties of President, the Commission requests that Professor Allen, of Melbourne, be without delay appointed to the position. In the event of such appointment of Professor Allen, it is still advisable that the vacancy in the representation of New South Wales be filled at once, and the Commission suggests that Dr. Ashburton Thompson be appointed. The Commission has considered the letter from the Under Secretary for Lands, dated 25th August, inquiring as to the time and expenditure which will be involved in its further work; but is unable to reply explicitly until the difficulty concerning the Presidency shall have been removed. The Commission, therefore, urge that immediate action be taken in accordance with its request, so that unnecessary loss of time may be prevented.”

MR. BELL seconded. The motion was carried.

The Commission adjourned.

TUESDAY, 16 OCTOBER, 1888.

The Commission met at 9:30 a.m., at the Crown Lands Office, Melbourne.

Present:

<i>Victoria:</i>	HARRY BROOKES ALLEN, Esq., M.D. ALFRED NAYLOR PEARSON, Esq.
<i>New Zealand:</i>	ALFRED DILLON BELL, Esq.
<i>South Australia:</i>	EDWARD CHARLES STIRLING, Esq., M.D. ALEXANDER STUART PATERSON, Esq., M.D.
<i>Queensland:</i>	HENRY TRYON, Esq.

The Chair was taken by Professor ALLEN.

It was resolved that the Chairman should be empowered to examine the minutes of previous meetings, and sign them after any needful amendment.

The CHAIRMAN submitted a plan for the rearrangement of the evidence and papers to be included in the Report of the Commission.

The Secretary was instructed to write to the Commissioner of Crown Lands, Adelaide, asking for a statement of the annual expenditure, by Government only, for the last seven years on rabbit destruction in South Australia.

It was resolved that Dr. Katz be requested to furnish a description of the symptoms and post-mortem appearances in fowls suffering from *choléra des poules*, as detailed by M. Pasteur, and to add thereto any comments which he may think necessary.

It was further resolved that Professor Thomas' report on the disappearance of the rabbits in the Wairarapa district of New Zealand be printed in full.

The CHAIRMAN then submitted a draft of the general lines on which a progress report might be drawn up. General discussion ensued.

MR. BELL moved,—“That the Chairman be requested to draft a progress report on the lines now agreed upon; that copies of the progress report in duplicate be sent to each member of the Commission; that members be requested to return one copy with such alterations or additions as they individually think necessary;

“That the Chairman be authorized to have the progress report printed under his own supervision.”

Dr. STIRLING seconded. The motion was carried.

It was resolved that the name of Mr. Tryon be added to the Correspondence Committee.

It

It was also resolved that the Correspondence Committee examine the classified list of mechanical contrivances, &c., prepared by the Lands Department of New South Wales, and the original letters on which the list is based; and if necessary reduce the list to such form as will render it serviceable to the Commission.

With respect to the further information that was requested from certain gentlemen regarding diseases proposed for the extermination of rabbits, the Secretary reported that no replies had yet been received.

It was resolved,—“That Dr. Katz be requested to forward notes of any additional inquiries made by him into the question whether chicken-cholera exists in the Australasian colonies, with a view to the incorporation of such additional inquiries in his report already received;

“That Dr. Katz be requested to forward any reports available of further experiments conducted at Rodd Island as soon as possible, as a progress report will shortly be submitted to the Government of New South Wales.”

It was resolved that the proceedings of the Commission, the evidence, and the appendices, be printed in the form indicated by the Chairman.

It was further resolved,—“That the Under Secretary for Lands be informed, in reply to his letter of 25th August, that a progress report on the whole work of the Commission to date is now being finally revised, and that such report will be forwarded as speedily as possible.”

The CHAIRMAN read the following:—

“Crown Lands Office, Melbourne, 16 October, 1888.

“My Dear Professor Allen,

“In consequence of my having become the inventor of certain improvements in wire-netting and in fences to be constructed thereof, these improvements being of so fundamental a character that there is reasonable cause for supposing that I may become largely interested in the manufacture and sale of wire-netting, it has appeared to me that my position as a member of the Royal Commission of Inquiry into Schemes for the Destruction of Rabbits has become materially altered. Even should the report of the Commission be confined to the question originally referred to it, namely, the use of diseases as a means of extirpation, still the usefulness or otherwise of wire-netting as an adjunct in the application of disease must be dealt with.

“I do not desire that there should be any possibility of my fellow-commissioners being compromised by my remaining amongst them under these altered circumstances; and it has appeared to me desirable that I should express my willingness to resign my commission.

“I beg, therefore, to place this matter before you; and should feel obliged if you would do me the favour of conveying to me the feeling of my fellow-commissioners with regard to it.

“Yours very truly,

“A. N. PEARSON.”

The foregoing having been considered,

Mr. BELL moved,—“That in the opinion of this Commission the interests of the work in hand are likely to be more seriously affected by the withdrawal of Mr. Pearson at the present stage than by any possible conflict of his private interests with the work of the Commission; and that he be, therefore, asked to retain his seat.”

Dr. PATERSON seconded. The motion was carried.

With reference to the memo. from Dr. Wilkinson to the Premier, explanatory of the relations between the Commission and the agents of M. Pasteur, the Secretary reported that application had been made, as requested, to the Colonial Secretary for a copy. His letter had been since returned with a verbal intimation that no trace of the document could be discovered. Application had since been made to M. Pasteur's agents for a copy, but no reply had as yet been received.

It was resolved,—“That the accounts of the Commission with the Lands Department be adjusted as soon as possible; and that the Secretary for Lands be then asked for a further advance of £500.”

It was further resolved,—“That the next meeting of the Commission be held in Melbourne; and that Professor Allen or the newly-appointed President be the convener.”

The Commission adjourned.

SECTION II.

MINUTES OF EVIDENCE.

TUESDAY, 17 APRIL.

The Commission met at 10 a.m., at the Colonial Secretary's Office, Sydney.

Present:—

<i>New South Wales :</i>	WILLIAM CAMAC WILKINSON, Esq., M.D., M.P. EDWARD QUIN, Esq.
<i>Victoria :</i>	HARRY BROOKES ALLEN, Esq., M.D. ALFRED NAYLOR PEARSON, Esq., F.R. Met. Soc., &c.
<i>South Australia :</i>	EDWARD CHARLES STERLING, Esq., M.D. ALEXANDER STUART PEARSON, Esq., M.D.
<i>Queensland :</i>	JOSEPH BANCROFT, Esq., M.D.
<i>Tasmania :</i>	THOMAS ALFRED TABART, Esq.

In the absence of the President (Dr. MacLaurin), the Chair was taken by Professor ALLEN.

Henry Augustus Ellis called in and examined:—

1. *Professor Allen.*] What is your professional qualification? I am a Bachelor of Medicine of Trinity College, Dublin.
2. How long have you been in this Colony? About two years and eight months.
3. Where do you now reside? At Double Bay, near Sydney. I am practising my profession there.
4. When did you first become acquainted with this disease amongst rabbits at Tintinallogy? The first information that I obtained on the subject was in October of last year. The exact date is in a report laid upon the Table of the House. That was a report written by Dr. Butcher and myself in a general way to the Minister for Mines, who at the time had charge of the Rabbit Department. I think Dr. Butcher has known the disease since July of last year.
5. *Dr. Wilkinson.*] Was it Dr. Butcher who first noticed the disease? Yes; he knew of the disease sometime before I did.
6. *Professor Allen.*] I presume that you are authorized to speak here on behalf of Dr. Butcher? I am.
7. Can you give us the particulars about Dr. Butcher's first observations? I am under the impression that at the time Dr. Butcher was making experiments with poisons as to the effect of strychnine and arsenic on rabbits, he then had occasion to use a considerable number of rabbits, and one was brought to him which was caught by the dogs which developed some very curious external appearances of ulceration with scabs on the surface of the body. He and I had had a conversation about two years before on the question of disease, and we came to the conclusion that disease would probably some time spring up amongst the rabbits.
8. *Dr. Wilkinson.*] Where did he make these experiments? The experiments were made at Tintinallogy. All the original experiments were made there. He found then that the disease presented by this rabbit was a very infectious one. It not only contaminated healthy rabbits placed in contact with diseased ones, but if the bag or crate which contained a diseased rabbit were subsequently used for the keeping of a healthy rabbit, the healthy rabbit contracted the disease. Practically that was the position of affairs when the Minister for Mines, or rather the head of the Rabbit Department, telegraphed up to destroy all our rabbits, which was done.
9. *Professor Allen.*] On what date was that? It was some time in September. We knew then that the disease existed on a very isolated portion of the run, near the woolshed. Shortly after the rabbits were destroyed Dr. Butcher came down to Sydney, and we had an interview with the Minister for Mines on the subject, with the result that we then got leave—it having been proved that the rabbits had been destroyed in consequence of a departmental error—we again got leave to make our experiments. Dr. Butcher returned to Tintinallogy, and having obtained some diseased rabbits recommenced his experiments with the disease.
10. *Dr. Wilkinson.*] When was that? Dr. Butcher must have gone up there about the time the reward was offered by the Minister for Mines, or about two weeks afterwards. He continued to conduct experiments until I went up there, and he sent me down a batch of rabbits when he got back. I had them put at my place down at Double Bay and looked after.
11. Were these rabbits animals which had got infection from the rabbits that had been previously experimented on, or did you kill all diseased rabbits when directed to do so? We did not kill them; it was the Government Inspector who did that. He arrived one night and killed all our rabbits next morning.
12. *Professor Allen.*] Will you give us a connected history of the disease so far as you can? I got my first batch of rabbits only about ten days before I started for Tintinallogy. I went up there on the 20th November. I made the journey principally with a view to prove the fact that the disease did not affect stock. At that time we had not begun to disseminate it over the run, and my object was to see whether it would affect stock. Besides this, we had a sort of guarantee from the Government that if we could kill all the rabbits on the land which we had fenced with rabbit-proof wire, and where we kept all kinds of stock—if the veterinary surgeon said the stock had not been affected—then we would have perfect leave to use the disease broadcast over the country, if we thought it advisable. This was the condition under which I went up. I then infected some stock and made more accurate experiments.

13. What stock did you inoculate? A record of the infections are in the report which we made to the Government. At the same time we inoculated rabbits with the same virus to prove that there could be no mistake in the material that we were using. We inoculated sheep on the inside of the thighs, and also horses. To inoculate the horses we used one of the old machines for wet cupping. We thought it would make a proper scarifier. Besides this we had a calf and some poddy lambs, and kept them in an enclosed place with the diseased rabbits—to make quite sure that they would have an opportunity of catching the disease. None of these animals presented any symptoms of the disease, even at the seat of the inoculation. They were inspected from time to time while I was up there, and Mr. Stanley, who made a subsequent inspection, came, I believe, to the same opinion.

14. *Dr. Wilkinson*] How long after this did Mr. Stanley see the stock and arrive at the same opinion? I think it was about three weeks subsequently.

15. And were the animals under observation during these three weeks? They were under my direct observation for five weeks. We also inoculated a cow, and the milk of the animal was used in the camp. We likewise had a cat and dog and some guinea pigs. I do not remember what other animals we actually had.

16. *Professor Allen*] And in all cases the animals presented no symptoms of the disease? Not the slightest symptoms of the disease developed in them—either general or local.

17. *Dr. Bancroft*] You did not give the milk of the cow to the rabbits? No; we only wanted to prove that the disease did not infect stock in any way.

18. *Professor Allen*] Have the animals which had been inoculated in this way been watched for any length of time? Yes; they had been under observation for some three months altogether, and Mr. Vindin sent in a report the other day to the Minister for Lands, which will be supplied to you. I think he refers in it to the stock that had been inoculated. With regard to the rabbits I then instituted much more careful experiments than had been made up to that time.

19. When was this? That was when I was on the station, where I remained until the end of December. I made some investigations as to the form in which we should find inoculation most virulent, and the result was that we found no one form of inoculation produced greater virulence than another. One of the best cases that I had was from intravenous inoculation with the blood of a diseased animal. This produced the best case I had while I was up there. We were in the habit of using for inoculation the abdominal fluid and the pericardial fluid or the substance of the liver broken up in a mortar with sterilized water, or the substance of the mesenteric glands broken up in the same way. Subsequently to this Dr. Butcher used setons dipped in all of these fluids, and that almost gave more certain results than the other methods.

20. Then you found the fluid of the peritoneum, the pericardium, the braised extract of liver and of the mesenteric glands all thoroughly active? Yes; and we found that an alteration occurred in the disease while in our hands. I may say that while I was inoculating no local symptoms appeared at the seat of inoculation in the rabbits. But we had some changes occurring in the disease; the great change was that the ulceration and scab so marked in the earlier cases almost entirely disappeared. Dr. Butcher at first thought that this might be a rabbit scab. So far as I know the only certain symptom of the disease which has never been absent is the extreme emaciation, which is of a most peculiar and marked character. In a proper case after infection, on the second day, there is generally a watery discharge from the nose and eyes and the fur looks a little ruffled. On the question of temperature I have had a great deal of difficulty; and I have not yet made up my mind whether the temperature is raised or not, owing to the discovery of the fact that a rabbit in struggling raises its temperature. Its temperature may rise four or five degrees, and in consequence of this we were a good deal put out at first.

21. *Dr. Bancroft*] Can you tell me what is the normal temperature of the rabbit? Well I have never been able to find that out. I believe it varies from 101 to 103. We never operated on the station without the temperature rising over 102; and we found in all the cases that we tried on the station that there was a marked rise in the temperature a few days after the disease had started. Down here this is not by any means so apparent, so that I am very doubtful on this question whether there is a rise of temperature or not. Down here there is always a fall of temperature at the end of disease, the temperature sometimes falling as low as 95.

22. *Dr. Wilkinson*] That is shortly before death? Yes; two, three, or five days before death. This I attribute to the extreme emaciation from the want of tissue change which takes place. The rabbit begins to show its emaciation about the fifth or sixth day, and the emaciation continues with varying rapidity, subject to the food and temperature under which the animal is placed.

23. Could any loss of weight be noticed before the fifth or sixth day? I think it could be detected by weighing, but not by general appearance. That is an extremely difficult point, because a rabbit eats so much that you have to be very careful all the time. We tried some experiments in feeding the rabbits up there, just to show the difficulty of accurate weight-taking, and we found that the rabbit eats from 1 to 2½ lb. of green food in the course of the day; but even while eating this enormous quantity of food he is still emaciated.

24. *Dr. Paterson*] I presume that was an infected rabbit? Yes.

25. And the emaciation went on? It did, and towards the end of the disease the emaciation became very marked, and gave some very peculiar and characteristic symptoms. Dr. Butcher and myself can tell at once on seeing a rabbit in the open whether he has been attacked by the disease or not.

26. *Professor Allen*] You mean you can tell when you see the rabbit in an advanced stage of the disease? Well it is very difficult to make an exact statement about the date. You can tell fairly early that a rabbit has the disease from the peculiar way in which he runs. He loses power in the hinder extremities from the absence of muscular tissue. It is very difficult to describe the way that he runs. Rabbits that are diseased always droop their tails, and, though it is impossible to describe their run, there is an obvious weakness in the hind limbs. They go on getting so weak that they can no longer pull the hinder legs up after they have been stretched out, but push themselves back by their front legs in order to rise.

27. Is there a visible wasting of the limbs? Yes; but in the fore limbs you cannot observe the waste so well. If you grasp the hind leg of one of these diseased rabbits you feel no muscle at all.

28. *Dr. Bancroft*] Do not all animals lose power in their hind legs when they become paralytic? Yes; but this is not a case of paralysis at all. I paid very great attention to that point. I have not tried the electrical reaction because I have not had time to do so down here. The rabbit displays no want of power to use its legs if you do not put a weight on them, and it is just as sensitive to touch; but the instant

instant you put a weight on it cannot move, simply because it has no muscular power. This emaciation goes on until the animal slowly dies. In one case I made a *post-mortem* examination immediately after death, and I found the heart beating although respiration had ceased. From that indication, together with the dark color of the blood, I came to the conclusion that the rabbits die from asphyxia—from loss of muscular power to breathe.

29. *Professor Allen.*] Before leaving this, are there any other symptoms that you can tell us about? There is the discharge from the eyes, the increase in temperature, and emaciation in progressive stages to the end.

30. Are there any other symptoms you can tell us about? I might perhaps give you the weight of the animal in one of the most remarkable instances that occurred. The rabbit, when I inoculated him, was a very fine animal, weighing $3\frac{1}{2}$ lb. When I killed him ten days subsequently he only weighed 2 lb. 6 oz.—that is, he had lost one-third of his weight in ten days although he ate rapaciously the whole time.

31. *Mr. Tabart.*] Where were these rabbits secured? I got the first lot from Liverpool and the rest from the Hay district, so as to make sure that they could not be rabbits that were already infected. At present I get my rabbits from Hay.

32. *Dr. Stirling.*] You said something about the mesenteric glands? Yes; I am going to go fully into the details of the *post-mortem* examination.

33. *Professor Allen.*] And as regards the scabs and ulceration? We got that in greater numbers of those affected by the natural disease than we did in those having the inoculated disease. I do not know why, unless it is that the rabbits scratch each other, which they do to a tremendous extent in the open, thus causing those sores which in diseased rabbits at least have little tendency to heal. The sores are very characteristic; they are perfectly cleanly cut and go right through the skin, sometimes through the adjacent muscle. They vary in size. We have one rabbit which is covered all over with these sores.

34. Then you have these circular sores with clear-cut edges? Yes; the base of them is of fascia or of any tissue to which the sore reaches. It is covered with a thick, hard scab.

35. *Dr. Wilkinson.*] Does this sore affect any particular part of the rabbit generally? No; at least not so far as we can make out. The matter inside the sore is very peculiar and characteristic. It is sometimes there in great quantities, and sometimes it is barely present at all. It is more like a caseous gland than anything else; it is softer, but of cheesy, homogeneous matter. Wherever you find these sores original, there you will find this matter.

36. *Professor Allen.*] Are these crusts prominent, or do they extend deeply? It goes right under the skin and has a tendency to calcify, so that you get hard lumps in the muscles occasionally.

37. Then collections of this cheesy matter occur in the muscles? Yes, and some of them come to the surface and break out. We used a lot of this for inoculation in our early stages, and we found that the rabbits so inoculated, if properly done, took the disease all right, but presented no local symptoms of a very serious nature.

38. Then these calcified deposits are not at all essential to the disease? So far as I know they are not.

39. And you also state that in your laboratory experiments you do not get them at all? No. Of the animals that run in the open a good many present these deposits and a good many others are free from them. Dr. Butcher has paid a good deal more attention to this than I have, and he shows that how they commence is by a falling out of the hair over spots on the skin. Then they get red, and eventually I think they burst.

40. *Dr. Wilkinson.*] Has he ever observed these consecutive appearances in one animal? Yes; but I have never seen one case right through. We do not get nearly the same number now that we did at first.

41. *Professor Allen.*] You think these sores might be attributed to irritation? Yes; with the disease together. But it is very difficult to say, because it sometimes occurs in places on the body of the animal where they could not be scratched; in other places about the face and the inside of the thigh. Indeed they frequently get it where they could not be scratched at all, so that I can really give no account of the cause of these deposits. And I am not aware what is really their connection with the disease. The duration of the disease depends very much upon the nature of the food. It depends also upon the virulence of the disease, and so far as I have observed it is more rapid in the well-nourished animal than in the animal which has been poorly nourished. If you feed a rabbit on lettuce and carrots, as I feed mine, you will rarely get a death in twenty days, and frequently they last from thirty to fifty days. On the other hand up at Tintinallong, where the rabbits get the food that they are accustomed to—grass cut and put into them—the duration of the disease is much more certain. It is almost always between fifteen and twenty days—in fact it takes only seventeen days with by far the largest number of rabbits.

42. *Dr. Bancroft.*] In what time would the ordinary rabbit, in the natural way, die if he did not get the disease? Well, I got down from Tintinallong six rabbits, four of which were diseased. I got from Hay six more. As regards the deaths of some of these I cannot give you information, because I made a mistake when I came back from Tintinallong, and boxed them all together. Some of the rabbits that had been separated got mixed, and the result was that they killed each other. As regards the disease I cannot say that one died certainly from that. I have got three of them still alive. Of the uninfected ones I infected two, and another died; but all the other rabbits remained healthy until I returned from Tintinallong. There was not a single death from the beginning of November until the middle of January.

43. *Professor Allen.*] Then this disease is not necessarily a fatal one? Not necessarily.

44. Have you any idea to what extent it is fatal? Well, recoveries are by no means common. The whole of the first lot sent down to me recovered. The next lot I got down from Tintinallong—I got eight down—and there is one alive now. The rest all died of the disease; and of the last batch I got from Tintinallong I think there are two alive at present.

45. In animals that recover, what is the general duration of the disease? They take two or three months before they begin to get back their condition or any power to run.

46. Do you find that in both kinds of the disease—those that have the deposits and those that have not—recoveries take place? I cannot give you any facts about those with deposit; but I have known one or two to recover.

47. In your own inoculated cases you had no deposits? No.

48. How about the recoveries in your inoculated cases? In inoculated cases recovery is very rare. They take sometimes a long time to die, and only very rarely do they ultimately recover. I have only one rabbit that I have inoculated which is in good condition—only one which caught the disease by infection, and which is at all in good condition; and that rabbit has a contracted leg from the disease.

49. *Dr. Wilkinson.*] Are there any instances of absolute resistance to the disease? I will come to that later on.

50. *Professor Allen.*] You say that in some cases in which you inoculated the disease death occurred only after a very long time? Yes.

51. About how long may life be prolonged? The longest that we had was a little over two months. But when you get into these long periods you are introducing an element of doubt, because death may have ensued from another disease, owing to the condition of the rabbit. I count nothing as certain in the long cases when a rabbit dies.

52. *Dr. Paterson.*] Do you know whether during a case where the disease is prolonged copulation takes place? I cannot say that; but I take it that it would not, on account of the want of muscular power. At the *post-mortem* examination the first thing you notice after you have taken off the skin is the extreme emaciation of the animal, and on opening the abdomen, which I always do, there is generally a considerable quantity of abdominal fluid present. This fluid is perfectly clear. There is almost a complete absence of omentum; and the fluid varies from a few drops up to about 2oz. I think the food has something to do with that. In all the cases I have seen there is generally about from 1 to 2 drachms of abdominal fluid. You would never notice the omentum, and if you hunted for it you would probably find it, but without any fat at all.

53. *Dr. Stirling.*] But the vessels would be there? Yes; but the omentum is very thin and shrivelled, and without any fat. The intestines are perfectly healthy, and there is plenty of food in them to show that the animal has not died of starvation. In some instances there is local inflammation, but that is likely to be misleading. The next thing is the liver, which is certainly the most infected organ, so far as I can make out.

54. What appearance does it present? I am not very well up in the size of the liver, but I think it is rather small; and it is very friable. I have examined healthy rabbits, but, as I have said, I am not up in the size of their livers. In any case it is almost impossible to give an opinion, as the liver varies so much. Still I think in this disease the liver is really very small. It is more than usually friable, and it is almost impossible to take it out without tearing it. It has peculiar points all over it—they look more like tubercle than anything else, at a first glance. These things are on the surface, and through the substance of the liver as well. And when you come to examine them you find that they are abscesses, filled with some kind of matter.

55. Also tending to calcify? In some instances they have undoubtedly calcified. I have never seen any particularly large ones in the liver, but Dr. Butcher has. But I always took Dr. Butcher's statements about the result of *post-mortem* examinations with some degree of caution, as some of these may be septic cases.

56. *Dr. Wilkinson.*] But did you find these conditions with rabbits which were inoculated or which caught the disease spontaneously. It is the most certain pathological condition of this disease. It is present in nearly all cases—whether it is due to the disease or not is a matter of doubt. I have some doubt myself whether it has any real relation to the disease or not. There is just this element of doubt left, because I got it once in a rabbit which I had every reason to believe was healthy. Whether it was of a similar character or whether the rabbit had caught the disease in some way that I could not trace, I cannot say.

57. You did not try any inoculation experiments with these abscesses? Dr. Butcher did it from the abscesses perfectly in the larger ones. I do not know the size, but he got some very big ones. The usual abscess is about the size of a millet seed—about the size of a small tubercle. I found them and put them under the microscope. And I believe that they will be found to be present in all instances if a sufficiently careful examination can be made.

58. *Professor Allen.*] Is there any inflammation of the capsule of the liver? Yes; but there is no peritoneal inflammation at all, even over these abscesses in the liver. It is not actual pus which forms in them—at least under the microscope it does not appear to be fluid. They are round and perfectly circular as far as I saw, in the liver. But Dr. McCormack, who is making a microscopical examination, will give you better evidence.

59. *Mr. Tabart.*] Have you seen this in young rabbits? Usually the young rabbits died—their life tenure under experiments is very doubtful. They die from confinement without being inoculated at all. Occasionally the mesenteric glands are found to be degenerated. I have never noticed these spots pigmented. They are of whitish color. I have never seen these mesenteric glands affected, but Dr. Butcher says that they are more or less choosy, with a tendency to cysts. I have only seen one or two of these. They were very common at the first before I got to the station, but since then they have disappeared. The disease in our hands is tending to have fewer and fewer symptoms.

60. *Dr. Stirling.*] Are you aware whether these cysts can be the cystercerci to which the rabbit is liable? I am not aware.

61. *Professor Allen.*] Now we will take the other organs? There are two glands near the kidney in the abdomen—two little whitish bodies between the kidney and the spinal cord. These glands certainly show signs of alteration. They are red and even black—at least Dr. Butcher says so. I have seen them more marked, red in colour, instead of being white. I have not made a sufficient examination of rabbits before I took up the question—almost all my examinations have been made on diseased rabbits. The experiments that I made here cost me 10s. 6d. per rabbit, and I was not anxious to make experiments at that price.

62. Now with regard to the chest? The lungs were perfectly healthy and the spleen very small. I have once seen some of these little tiny yellowish spots, but I unfortunately spoiled them in making a section. The lungs were healthy, and there was no congestion, they being of uniform pink colour. Of course before I came to the lungs of the rabbit the blood had all been let out of the abdomen and the pericardial sac always contains a considerable amount of fluid, but I cannot say how much. I think it goes up very close to a drachm.

63. *Dr. Wilkinson.*] Never only a few drops? I have always seen them well lubricated. There is a certain amount of clear fluid between this and the heart.

64. What about the cavities of the heart? I have noticed nothing about them except this fluid, which is one of the common things which we always used for inoculation. The cavities of the heart always contain blood—generally dark-coloured blood—but I have not examined it carefully enough to say whether it is on both sides.

65. *Professor Allen.*] Now, about the nervous centres? The few spines that I have taken out have had fluid in them, but whether the quantity was abnormal or not I cannot say. This was under the membranes, and so far as I can roughly say there was not an abnormal quantity present. I have had some brains and spinal cord in spirits for some time.

66. Now, with regard to the general character of the blood? I have examined the blood very carefully, but on a great many occasions I was looking for germs in it. As regards its general characteristics, as to white corpuscles, I do not know what is their number in the healthy rabbit. I have only looked at this question so far in a commercial way, as it were, and I am not aware what is the natural proportion of red corpuscles to white corpuscles in the rabbit.

67. *Dr. Wilkinson.*] Have you found any fat in the sub-cutaneous tissue? Not in the advanced stages of the disease.

68. And the muscles? The fat is entirely absent from them. The wasting away is something extraordinary. No ordinary case of phthisis comes near it.

69. *Professor Allen.*] And you have noticed this cheesy or partly calcified collection of matter in the muscles? Yes. The calcified ones grow only in the muscles with the exception of the liver. There are no hæmorrhages in the organs, and the animal dies without any violent convulsions. There is no vomiting or diarrhœa, and the excreta are natural.

70. How, then, do you account for this disease spreading itself from rabbit to rabbit? The disease is very infectious. I have examined the hair and fur, and have never found any scab in it.

71. *Dr. Bancroft.*] I think it is of very great importance that we should have tame rabbits here for investigation. Wild rabbits will die in confinement, and they do not give us an opportunity for making experiments.

72. *Dr. Stirling.*] Professor Watson has found that the wild rabbit possesses greater power of resistance to scab than the tame rabbit.

73. *Professor Allen.*] Now, in regard to infection. Will you kindly give us some information about it? The best experiment I have had with regard to infection occurred the other day in a very virulent case of disease—that one I mentioned of a healthy rabbit being infected from being confined in a box where a diseased one had been kept. The rabbit was out of the box for about ten days, and there were so many in the last batch that I got down, that I had no place to put all the rabbits without using this box. I put a rabbit into this box, and it is now dead. It was put in on Easter Monday, and it died last Saturday.

74. How do you think this disease spreads from one animal to the other? It goes partly by infected burrows, but whether by the breath or excrement or the nasal discharge I cannot say.

75. Have you tried inoculation with this discharge or excrement? We used the discharge from the nose frequently for inoculation and for scarification, and it caused the disease. I never tried inoculating with the excrement or urine. The discharge from the nose passes away about the fourth day. It is very mild, but it is always present in some degree. If kept in confinement a rabbit has the tendency to get its eyes sore. I do not know why this should be so, but it certainly is so.

76. Is there any period of latency? There is a period of about two days in which I think the disease remains latent. I am speaking now from my experience of a large number of rabbits.

77. Can you tell us now something about the history of the disease, and the manner in which it first originated? I have not the remotest idea of its origin. Dozens of diseases have sprung up in the same way, worked for a time and then disappeared. There was one in Tasmania some years ago and another on the Darling last year.

78. Have you had any reason to think that this disease has existed before? I have no reason to think so, and no evidence to lead me to say so. The disease which worked on the Darling decimated the opossums. I do not know how long ago, but the district between Bourke and Broken Hill was alive with them some years ago, and they have now disappeared.

79. What about kangaroos and wallabies? We cannot get any of them. We tried the disease on each.

80. *Dr. Paterson.*] Is this disease confined to Dr. Butcher's station? At first it was confined to one paddock on Tintinallogy, but since then we have been inoculating all over, and the disease has spread to a much larger area. We have heard of it near, and then further and further away.

81. *Dr. Wilkinson.*] And has that area become free from rabbits? No; no area that we know of is perfectly free, but I have heard to-day from Mr. Taylor, of the Rabbit Brauch, that a squatter had told him that the rabbits on his station were ten times less than they were three months ago. They must have diminished very considerably.

82. *Dr. Stirling.*] Can you give us any collateral evidence to bear out what you say? We can give you the Government reports on the subject, and I do not think there can be anything better. In addition I have some private letters at home which bear on the point.

83. *Professor Allen.*] Do you think that this disease would spread, apart from maintaining it by keeping up the stock of infected rabbits? We propose to infect every block in twenty places, and to put down a single rabbit in each place. Two months subsequently we would do the same, and three months afterwards we would repeat the same experiment, and the same again if the rabbits showed in any place on the run more than they should show.

84. *Dr. Stirling.*] What area do you mean when you speak of a block? I mean a block of ten miles square.

85. *Professor Allen.*] When did Dr. Butcher commence these experiments? He commenced in July last, but he did not begin inoculating until December, and that was not done until we were sure that the disease did not affect stock. Tintinallogy has been carefully inoculated everywhere, but we have not had the necessary time to go any further. It has been repeated a couple of times since, as we thought it important that inoculation should be properly carried out. There can be no doubt but that there is a mild form of the disease; that is to say, that some rabbits will recover from it. If the disease is allowed to go on its own course it is sure to develop a mild form in some corner or other, which will give protection to them.

86. Have you any evidence of that? Yes: we have had some rabbits down here which we could not give the disease to. They were fat and strong and healthy—as fine rabbits as you ever came across. I fancy they had had the disease and had got over it. An experiment which first proved that conclusively was made during February. I took two rabbits which came to me in November,—one had the disease, and another one had been sent down without catching it. I inoculated both of them with setons steeped in the

the blood of diseased animals. The one rabbit that had had the disease previously never lost in weight more than 2 oz., and showed no other symptoms of the disease, but the other rabbit steadily lost weight and died, I think, in about three weeks. That, to my mind, was a very satisfactory experiment. That rabbit I inoculated again the other day, and I have another one which I inoculated at the same time, to prove that the fluid that I inoculated with was virulent; so that this last one will practically settle the matter. But it had been practically settled before, because we have had several rabbits on the station that would not take the disease.

87. *Dr. Stirling.*] Then if you had 1,000 miles of country to deal with you would require twenty rabbits for every 10-mile block, which would be 2,000 diseased rabbits for the whole area? Yes; and I would repeat it at stated intervals, as I have already said, so that you would require about 6,000 rabbits. I do not think that an excessive number. The inoculation would have to be repeated two or three times, which would make it necessary that 6,000 diseased rabbits should actually be turned out. We have passed through our hands already over 1,000 diseased rabbits. It may only require a lesser number, but I consider this a very fair estimate. It might, of course, require even more.

88. How do you get the rabbits for this purpose? Well, that is a matter to which we have given a good deal of attention. Apertures are made in the wire-netting around the tanks; but sometimes we were in the habit of riding them down on horseback. In that way we could ride down about twenty-five rabbits in two hours. That is, I should say, the best way of getting big ones. By making apertures in the wire-netting around his tanks, Mr. J. Riddock, of Weinterriga, caught 2,000 to 3,000 in a night.

89. *Professor Allen.*] Have you any burrows in the Tintinallongy country? Yes; but when you go back into the black soil country there are no burrows except small slip burrows. In those parts of the country where there are no burrows we ride the rabbits down. I am not sure whether they burrow in winter or not.

90. Do you know how the rabbits propagate while diseased? While I was up at Tintinallongy there was next to no propagation going on. We found many nests with rabbits dead in them, but we never knew what was the cause of death. In one case, in the open country, we found three abortions.

91. *Dr. Stirling.*] But you have not told us anything about their confinement? They brought forth young, but the young died while in confinement with us. I have had three batches of rabbits in my own house, but they always died all the same. As far as I can ascertain, there is no record of the size of the Australian rabbit, which I think is an important matter in regard to wire netting.

92. *Dr. Paterson.*] Have you ever inoculated the pregnant doe? One of our rabbits which the Government were kind enough to destroy was a pregnant doe, and she was destroyed before we could do anything with her. Mr. Reid, the owner of the station, offered £25 for the rabbit, but we could not give her to him. The diseased rabbit cannot possibly bring forth healthy young in the open country.

93. *Mr. Tabart.*] Were any other methods adopted for destroying the rabbits while this was going on? Yes, by poisoning; but that was stopped since the end of December. All the experiments by poisoning were done in fenced-in areas.

94. *Mr. Pearson.*] Are there any rabbits at all which are not susceptible to the disease? We have had, I think, only one rabbit out of 1,000 that was not susceptible to the disease. We have had one in hand that was not susceptible, but we think it likely that this one has had the disease at a previous period. However, this is merely a surmise.

95. *Professor Allen.*] Have you paid any attention to any possible bacterial origin of the disease? Well, as regards bacteria, I have made very careful examinations, and I have gone through every organ of the body dozens of times, with stains and other fluids. I have also examined the blood and stained it, and practically the result was a negative one; I found no organism which I could say was connected with the disease. I have gone further, and made cultivation experiments; but all the known methods have yielded absolutely a negative result. Even with matter taken from an ulcer with a scab over it the results have been negative.

96. And then, speaking generally, apart from the emaciation, the only strongly defined feature of the disease is the presence of this cheesy mass under the skin, in the muscles, in the liver, and sometimes in the mesenteric glands; but you are not absolutely certain that these are a part of the disease? Well, in the few cases that I had of livers I found that it was probably bacterial disease which had caused the degeneration of the liver. You can account for the emaciation on three grounds. One is that the food taken in is not properly prepared in passing through the glands before arriving at the muscles. The view I take is that the liver will not work, and that the animal starves owing to the food not being properly assimilated. If this is not what causes the emaciation, it must be that the micro-organisms in the blood take up the food which ought to go to the muscles; but to imagine that you must imagine such a large quantity that it cannot be overlooked on microscopical examination, unless the bacteria directly attack the muscular tissue.

97. *Dr. Wilkinson.*] Then in your opinion this disease is bacterial? Yes, it is probably so.

98. *Professor Allen.*] What papers did you speak of as being the best for us to apply for in connection with this disease? Well, I think Mr. Vindin's report is the most recent on the subject, and probably the most satisfactory. It can be obtained from Mr. Oliver. I think it would be well if you got all the papers that are in the hands of the Government on the subject. The reports of Messrs. Clarke and Tully, stock inspectors, and of Mr. Stauley, the Government veterinarian, are amongst the other recent publications.

The Commission adjourned.

MONDAY, 23 APRIL, 1888.

The Commission met at 10 a.m., at the Colonial Secretary's Office, Sydney.

Present :—

New South Wales : HENRY NORMAN MACLAUREN, Esq., M.D. (President).
WILLIAM CAMAC WILKINSON, Esq., M.D., M.P.
EDWARD QUIN, Esq.

Victoria : HARRY BROOKES ALLEN, Esq., M.D.
ALFRED NAYLOR PEARSON, Esq., F.R., Met. Soc., &c.
EDWARD HAREWOOD LASCELLES, Esq.

New Zealand : ALFRED DILLON BELL, Esq.

South Australia : EDWARD CHARLES STIRLING, Esq., M.D.
ALEXANDER STUART PATERSON, Esq., M.D.

Queensland : JOSEPH BANCROFT, Esq., M.D.

Tasmania : THOMAS ALFRED TABART, Esq.

Dr. Frank Hinds (with M. Loir and Dr. Germont) called in and examined :—

99. *The President.*] I understand that you, gentlemen, come here as the representatives of M. Pasteur, in regard to the claim which he has made for the reward of £25,000 offered by the Government of New South Wales to the person who introduces a successful means of exterminating rabbits? That is so.
100. Have you brought any written credentials? No, excepting the letter which you have had from M. Pasteur himself. We have not received letters to the Commission, but we have brought introductions to Sir Henry Parkes and the President of the Royal Society.
101. You have brought a letter to the Government? Yes, a letter to Sir Henry Parkes.
102. Have you the letter here? No; it has been presented to Sir Henry Parkes. I understand that a telegram was despatched by your Government to Sir Daniel Cooper, asking that M. Pasteur should send some microbes to Australia, and also directions as to how they were to be used. It is partly in response to that telegram that we have come here.
103. Are you fully and completely acquainted with the details of the scheme which M. Pasteur has discovered? Yes.
104. And you are prepared to put it in operation, if need be? Yes.
105. Have you been long associated with M. Pasteur? I was only with M. Pasteur for ten days before starting from Paris.
106. Have you made a study of micropathology during the course of your education? Not particularly; but rather incidentally and generally. I have studied the subject a good deal in London.
107. In what laboratories? I have worked with Professor Horsley at the Brown Institution, and also at University College.
108. Then, with regard to M. Loir, has he been long with M. Pasteur in matters of this nature? Yes.
109. How long? Some eight years.
110. In the study of this department of micropathology? Yes.
111. And Dr. Germont? He has been with M. Pasteur for one year.
112. With M. Pasteur, in his laboratory? Yes.
113. Are you provided with all the materials required for carrying out this scheme? We are.
114. Have you a sufficient supply of microbes? We believe so. We have yet to make preliminary experiments to see how the microbes which we have brought with us have stood the voyage. There is no doubt about their being sufficient if they have stood the voyage.
115. Then you did not consider it necessary during the voyage to keep the supply fresh? Yes; we took measures to keep it alive, which we believe to be successful.
116. But you did not make any fresh cultures? No.
117. *Dr. Bancroft.*] Were no experiments made on birds during the voyage? No; no experiments were made on the voyage at all.
118. *The President.*] How was the material preserved? It was preserved in hermetically-sealed tubes.
119. Were these tubes completely hermetically sealed? Yes.
120. I understand you to imply that you only imagine there is a possibility that the fluid may have been deteriorated by the voyage? Yes; there is a possibility of that.
121. And you now desire an opportunity of recovering it by a fresh cultivation, if possible? Yes, we do.
122. You find it necessary, in order to do this, to have the authority of the Commission? Yes. We had proposed to experiment directly we arrived in Australia; but in the meantime we found that a law had been passed making this illegal.
123. *Professor Allen.*] Will you be satisfied with the recultivation of the germs in broth, or would the inoculation of animals be necessary? We would desire to inoculate animals.
124. *Mr. Lascelles.*] I think it would be advisable to get a supply of rabbits at once.
125. *The President.*] In carrying out these preliminary experiments, have you made such plans and precautions as may be considered necessary in order to prevent the disease from spreading to other animals? We would simply adopt those precautions that had been adopted in laboratories in Paris and London; that is to say, the animals would be caged; after their death the cages would be disinfected, and the remains of the animals that had been examined would be destroyed by some chemical method, or by burning.
126. In what way would you propose to disinfect the cages? With dilute solutions of sulphuric or carbolic acid.
127. *Dr. Stirling.*] Can you give us any information with regard to the extent of chicken-cholera in Europe?
128. *Professor Allen.*] There is a great deal to do before we come to that.
129. *Dr. Wilkinson.*] Would it not be well to have a direct statement from the representatives of M. Pasteur, and then this statement might be criticised and questions asked.

130. *The President.*] We will first have to give them specific authority to keep up their supply of microbes.
131. *Mr. Bell.*] Permission having now been granted to inoculate suitable animals with the virus, can you say how long it will take before you can report to the Commission whether the virus is now in a satisfactory condition? Two or three days.
132. *The President.*] It has been suggested that time would be saved if we requested the delegates to give a direct statement on the subject;—can you do so? Yes. The method that we propose to pursue is, briefly speaking, to poison the food used by the rabbits in the infested country. The rabbits will eat it and will die; and others will become infected with the disease, and will suffer in the same way as those that actually partook of the food. A great many points have to be considered. The poison will have to be distributed on the food in the same way as mineral poisons are at present distributed; but the action of this disease is much more extensive than that of mineral poisons, because many other individuals are affected besides those that actually take the food. The first thing which we propose to do is to prepare a broth for cultivation of the microbes. That will be done by preparing broth with the flesh of either chicken, rabbit, sheep, or fowl, filtering and sterilizing. Then the cultures will be made in the sterilized broth, and will be put all over the food. It will be easy to make any quantity of cultures at the station itself, and from the station the poisoned *bouillon* could be carried to any district on the station.
133. That is practically the statement you wish to make? Yes.
134. *Mr. Lascelles.*] I suppose you are aware that in the scrub country a great many rabbits do not go into burrows at all, but are scattered about thinly all over the country. In that case would there be sufficient contact to render your scheme effective? Yes; I think so, as with the mineral poisons at present.
135. But how could it act where the rabbits are thinly scattered? If the diseased rabbits do not come in contact with the healthy ones the latter will not suffer.
136. *The President.*] Would there be any modification of this disease in order that it might be applied to the different conditions of Australia? There is no particular modification, and how far it will reach the rabbits that do not live in burrows must be decided simply by experiment.
137. In fact you cannot at present give us any information on that subject? No.
138. *Mr. Pearson.*] May I ask how rabbits contract the disease? Simply by contact with one another. If you place rabbits that have the disease in contact with others, the latter will take it and die.
139. *Mr. Bell.*] Then so far as your experiments go, your disease requires that there shall be absolute contact? No; it is sufficient if rabbits are placed in a cage where diseased rabbits have been.
140. But that is contact with some object which diseased rabbits have touched; that is, contact not with each other but with the poison? Yes; certainly.
141. *The President.*] Have you yourself seen rabbits die from this disease? Yes; I have seen them die in the Laboratory in Paris, but not in the open country. So far as I am aware, only one experiment has been made in the open country.
142. *Dr. Wilkinson.*] If a healthy rabbit is placed in contact with a diseased rabbit, you think the healthy rabbit would contract the disease? It would all depend on what you mean by contact. If you mean by that certain touch together, probably not.
143. In fact the disease has to be conveyed from one rabbit to the other by the excreta; that is, may it reach a healthy rabbit directly in the air, or must the rabbit eat the food which has been contaminated with these microbes? Yes.
144. Then the infectious material is in the tissues, and in the blood, and not in the skin on the surface? Yes.
145. *Mr. Lascelles.*] Have you ever heard that rabbits are in the habit of going to a certain place and dropping their excrement. Would not a healthy rabbit going to a place where a diseased rabbit had dropped his excrement take the disease? Yes; it would get the stuff in its feet, and then probably into its mouth.
146. *Mr. Quin.*] If the germs of your disease are exposed for any length of time to the sun, are they likely to remain sufficiently strong to affect any animal —
147. *Professor Allen.*] A host of such questions will arise by and by. The question is rather premature now.
148. *The President.*] Will you tell us exactly what you have seen done in the destruction of rabbits by these microbes, and the conditions under which it has been done? —
149. *Professor Allen.*] I would suggest that these gentlemen should be allowed to do this in writing.
[The suggestion was agreed to, and the witness promised to prepare a statement on the subject.]
150. *Professor Allen.*] What do you require to carry out your experiments? We would like to have a laboratory—a single room would be sufficient, if it had gas in it, and was big enough to hold a sterilizer. We would have to have the exclusive use of the room, and we would require about twenty rabbits.
151. *The President.*] Are these experiments for the purpose of cultivation? They are for the purpose of demonstrating to you the virulence of the disease.
152. *Dr. Wilkinson.*] I would wish to ask Dr. Hinds one question: Some time ago we heard of there being some secret in the application of this method. I wish to know whether there is not some special method of applying this disease of which we have at present no knowledge. Is there any secret method of application which M. Pasteur has not yet revealed? I will reply to that with the other questions.
153. *Mr. Bell.*] But we all want to know whether such a method exists—we do not want to know the particulars? I would rather wait and answer that question with the other questions.

The representatives of M. Pasteur then retired.

The Commission adjourned.

TUESDAY, 24 APRIL, 1888.

The Commission met at 10:30 a.m., at the Colonial Secretary's Office, Sydney.

Present:—

New South Wales : WILLIAM CAMAC WILKINSON, Esq., M.D., M.P.
EDWARD QUIN, Esq.

Victoria : HARRY BROOKES ALLEN, Esq., M.D.
ALFRED NAYLOR PEARSON, Esq., F.R. Met. Soc., F.C.S., &c.
EDWARD HARKWOOD LASCELLES, Esq.

New Zealand : ALFRED DILLON BELL, Esq.

South Australia : EDWARD CHARLES STIRLING, Esq., M.D.
ALEXANDER STUART PATERSON, Esq., M.D.

Queensland : JOSEPH BANCROFT, Esq., M.D.

Tasmania : THOMAS ALFRED TABART, Esq.

In the absence of the President (Dr. MacLaurin), the Chair was taken by Professor ALLEN.

Dr. Germont, M. Loir, and Dr. Hinds, the representatives of M. Pasteur, called in and examined:—

154. *The Chairman* : Have you prepared a statement in connection with M. Pasteur's proposals for the destruction of rabbits?155. *Dr. Hinds* : Yes; I will read it to the Commission. When M. Pasteur was engaged upon the subject of chicken-cholera ten years ago he noticed accidentally that rabbits were exceedingly susceptible to the disease, they dying when placed in the cages in which fowls suffering from the disease had lived. After seeing in the journals the notice of the Government of New South Wales, with regard to the destruction of rabbits, he resumed experiments on chicken-cholera in its relation to rabbits, he arrived at the conclusion that there was no means more efficacious and rapid for their destruction than chicken-cholera. To establish his convictions, he instituted fresh experiments, some of which the details are published on page 14 of the papers printed by the Government after the report of the Board of Health on the proposal to destroy rabbits by means of disease. Food was sprinkled over with the microbes of chicken-cholera; the rabbits ate of it and died in from fifteen to thirty hours. It is impossible to say the number of times the experiment was repeated, but the result was always the same. A fresh confirmation was furnished by the experiment at Mme. Pommery's.

The ground at Mme. Pommery's was covered with snow, and a little before sunset M. Loir spread on the ground in a field near the burrows three small bundles of lucerne, and on this he sprinkled 4 litres (a little less than 1 gallon) of infected broth which he had brought from Paris. After half an hour he again visited the field: all the food had been eaten. Next day nineteen dead rabbits were found outside the burrows, and on the Monday following thirteen more. No live rabbits were seen after Saturday night. It is impossible to say if every rabbit at Mme. Pommery's actually ate the poisoned food or not, but it is thought that insufficient was spread around for all to have taken it, and that some, therefore, died from the disease which they had taken from their neighbours.

The conclusion derived from these experiments is that the contagion is more or less active according to circumstances, as is evidenced by the mortality of rabbits placed in contact with others who have died from the disease, or who are suffering from it—this mortality being generally more than half.

How is the disease communicated? It is probable that it is generally by means of the excrement, but it has not been shown that this is the only means of communication. Different animals have been fed upon food over which the microbes have been sprinkled in quantities greater than it would be possible for them to obtain in a state of nature and have suffered in no way; microbes have not been found in their blood. These animals were sheep, dogs, goats, horses, cows, or a donkey. As regards man it is, of course, impossible to give direct proofs that the microbe is innocuous. But under natural conditions there is no recorded case of man having contracted the disease. In France chickens which have died of the disease are often sold in the market, and there is no record of any accident among those who have handled or eaten them; on the other hand there are reasons for believing that no danger would result from drinking the milk of a cow which was fed on hay over which the microbes of *choléra des poules* had been sprinkled. In consideration of these facts, M. Pasteur has thought desirable to send us to Australia to demonstrate to the Commission appointed by the Government of New South Wales that the method advocated by him is at once efficacious, harmless to domestic animals, except fowls, and practicable. We have no authority to speak of experiments made by us individually; we are the delegates of M. Pasteur, and our only function is to interpret exactly his idea. It is difficult for us to give in detail the plan to be followed at any particular station before we have actually observed for ourselves the habits of the rabbits and the nature of the country of that particular station. It is obvious that the manner of action will have to be altered according as the rabbits live in burrows or not, and also according to the time of year. If there is grass it will be possible to carry some to the neighbourhood of the burrows and to water it with a cultivation of microbe. It would also be possible to fence off a small piece of land in which grass might be allowed to grow; when there was sufficient grass it could be watered with the infected broth, and the fencing removed, and the rabbits would at once come to feed on the best grown patch of grass in the neighbourhood. If these methods were not available, it would be necessary to spread the microbes on artificial food, as is done with mineral poisons, the artificial food to be the cheapest procurable in the neighbourhood. It must always be remembered that the microbe would lose not only its virulence but its vitality if long exposed to the air. It is easy to prepare any quantity of the broth and cultivations, which will be distributed in the early morn and evening, to obviate, as far as possible, the effect of the sun's heat, which would speedily kill the microbe if excessive. For this purpose, a dépôt would be established for a certain district, at which broth would be prepared and cultures made. From this quantities would be supplied in vessels to the squatters, who would give it their labourers to distribute

in what spots they thought most thickly infected. Depôts could be established at points most convenient for the transmission of the cultivations to the different stations. Of course, details of preparation and distribution would probably be altered as we gained practical experience of the country. We consider that it will not be difficult to free a station of the rabbits which are upon it by the means which we have indicated, but it is impossible to answer, except in a manner somewhat general, to the question as to how we would proceed to clear a large station. The Commission has asked what are the relations between chicken-cholera and swine fever or between chicken-cholera and septicæmia of rabbits. A pig inoculated with chicken-cholera germs has never suffered from swine fever. If there exists a relation between the swine fever and the diseases of other animals it is, according to certain writers, with the septicæmia of mice. (Löffler.) Davaine and Koch have described a malady very like chicken-cholera, known as septicæmia of rabbits, but their identity has not been absolutely proved, though the germs and their action on cultivation are very similar in the two cases. We have said above that heat and desiccation destroy the virulence and then the life of the microbe. It perishes at $51\text{ C} = 124^{\circ}\text{ F}$. M. Pasteur has shown that prolonged exposure to air causes a diminution of its virulence, and it was from studies on this organism that he proved the fact of the attenuation of virus, which he has extended to other organisms.

It is on account of this weakening of the poison by exposure that it is necessary to cultivate it artificially, in order to have a supply of the most active poison, under certain conditions, and it is of this that M. Pasteur has spoken in his letter to the President of Commission, of the knowledge of certain details, without which the method would often prove unsuccessful. This is simply the details of manipulation which we will show to the Commission actually when performing their experiments, as they are difficult to explain, but easily understood when demonstrated. From what has been said of the attenuation of the virus, it is easily understood why the disease has not spread from the farm-yards to the rabbits widely, notwithstanding its persistence among fowls.

The chicken also do not come into immediate contact with wild rabbits, and therefore one would not expect the disease to spread on a large scale among rabbits.

With regard to statistics we know of none; but the vaccine of chicken-cholera is supplied to veterinary surgeons for 3,000 or 4,000 cases every year; and the correctness of diagnosis is proved by discovery of microbes before the vaccine is sent. From this statement and certain idea of the prevalence of the disease, the number of cases has been given in a table up to 1885, in the Health Exhibition in London.

If it is true that, as suggested to the Commission, the *choléra des poules* already exists in Australia, we have not introduced a new disease; and we ask that our experiments may be made without restrictions other than are applied to the methods with other diseases which are now being considered.

We propose to make experiments, and to ask for a paper stating the results and nature of experiments signed by ourselves and members of Commission at end of each experiment:—

- 1st.—In the laboratory, upon ten or twenty rabbits, to prove that the disease is fatal to them. For this purpose we shall make broth, by mincing meat, boiling for one hour; filtering, sterilizing, and neutralizing; and in this we shall sow some of the germs of chicken-cholera. We obtain a cultivation, and feed the rabbits with a little sprinkled on their food.
- 2nd.—To feed sheep and the other animals in the same way, to prove that they are unaffected by the microbes—5–6 feeds.
- 3rd.—To make an experiment on a larger scale in a space in the country, enclosed with rabbit-proof fencing, but otherwise under natural conditions.

For this purpose we would go to a station, prepare there the broth, and make a cultivation; and this we would spread on food (natural, if available; if not, an artificial food—the cheapest to be procured in the neighbourhood) where the rabbits are thickest. From day to day we would go to different parts of the area to spread the disease.

We ask for this purpose an area of not greater extent than about 500 acres, for if we are able to prove that rabbits can be poisoned under natural conditions, the only question for future consideration will be the distribution of the poison.

We consider, that if we practically clear the area given to us for experiments, it will be a fair and good test of the efficacy and practicability of the method advocated by M. Pasteur.

156. *The Chairman*: The most important point appears to be with respect to the conduct of the experiments. This Commission has requested the Government to appoint Dr. Katz chief expert officer under the Commission, and he will be provided with what assistance may be necessary. We have also asked that a temporary laboratory be obtained by renting a house near Sydney with half an acre of land attached, with gas and water laid on, and a complete stock of sterilizing apparatus will be provided there. Our proposition would be that you associate with Dr. Katz, and work with him as our representative in conducting your experiments. We have prepared a list of experiments which we want performed, and if you desire to make any suggestions in connection with this, we will try to meet your views as far as possible; any experiments that you think necessary will certainly be performed, but experiments must be conducted under the direct control of one of our own officers.

157. *Dr. Hinds*: We will agree to that.

158. *The Chairman*: Dr. Katz has been instructed that all work concerning chicken-cholera shall be performed in association with you. In the first place the Government will be asked to assent to Dr. Katz's appointment and he will be appointed, so that you can go on with small experiments directly you get your cultures from Melbourne and have them ready. You, then, associated with the other gentlemen who represent M. Pasteur, will have the laboratory at your disposal and Dr. Katz will associate with you in carrying out these experiments.

159. *Dr. Hinds*: Yes.

160. *The Chairman*: I think that is as satisfactory an arrangement as we can make.

161. *Dr. Hinds*: Yes.

162. *The Chairman*: If you would like time to consult on this point you can obtain it.

163. *Dr. Hinds*: We accept your proposals at once.

164. *The Chairman*: First of all I have a letter here from the Board of Health which I wish to communicate to you. We wrote to the Board of Health asking that a laboratory should be placed at your disposal, and the reply which we have received is as follows:—

Board of Health Office, 127, Macquarie-street,

Sydney, 24 April, 1888.

Sir,

I have the honor, by direction of the President of this Board, to inform you that he has arranged for a portion of the Government Laboratory, in Albert-street, to be placed at the disposal of Mr. Pasteur's representatives. These gentlemen should be requested to call on Mr. Hamlet, the Government Analyst, with a view to the necessary arrangements being made for the carrying out of their experiments under the proper precautions.

I have, &c.,

EDMUND SAGER,

Secretary.

H. Mahon, Esq., Secretary, Rabbit Commission.

165. *Dr. Hinds*: Our cases containing the microbes will not arrive from Melbourne until the day after to-morrow.

166. *The Chairman*: Is there anything we can do meanwhile to facilitate your work?

167. *Dr. Hinds*: I think we would sooner wait until we receive all our material.

168. *The Chairman*: Are you likely to want any animals? We have made a request that fifty rabbits be supplied at once.

169. *Dr. Hinds*: We would like to have a few of those.

170. *Mr. Lascelles*: Dr. Ellis told me that he could spare a number of rabbits, if necessary.

171. *The Chairman*: There are a few points on which I would like to obtain information. I think you said that chicken-cholera was harmless to all domestic birds except fowls.

172. *Dr. Hinds*: I said domestic animals.

173. *The Chairman*: That means that all kinds of poultry are liable to the disease?

174. *Dr. Germont*: We do not know that yet.

175. *Dr. Hinds*: Actual experiments have been made on pheasants, sparrows, and other birds.

176. *The Chairman*: Then the next point is with regard to the spread of the disease from rabbit to rabbit. Most of the evidence is with regard to the spread of the disease to rabbits from food infected; but, as I have said, there is no great evidence as regards the spread from rabbit to rabbit. I presume that requires farther testing?

177. *Dr. Hinds*: Yes; and on a large scale.

178. *The Chairman*: I would wish to read an extract from the report of these experiments. M. Pasteur says:—

“I recapitulate some of the experiments that were made by Mons. Loir, a student attached to my laboratory, at my instigation:—

“On the 27th of November five rabbits were put into a box; they remained there without food until 6 o'clock in the evening. At that hour 100 centigrammes of a virulent growth of chicken-cholera were placed in a small basin where the leaves of a cabbage were soaking. These leaves were allowed to drain, and were then given to the five rabbits to be eaten, and in five minutes they had finished their meal. At midnight three fresh uninfected rabbits are placed with the others.

“At 8 o'clock in the morning of the 28th November, the five infected rabbits seemed ill. At 11 o'clock, that is to say, seventeen hours after their meal, two of them were dead. The remaining three died at 3 in the afternoon, twenty hours after their meal.

“On the 28th of November, at 7 in the evening, one of the rabbits that had been confined on the previous day at midnight with those that had eaten the tainted food was found to be dead. The two other rabbits did not become sick; of those put in the first day none remained alive.”

179. *M. Loir*: In the experiment No. 1, on page 14 of the Board of Health papers, the rabbits which were infected with poisoned food were removed from the boxes directly they died.

180. *The Chairman*: It is said here, “I recapitulate some of the experiments, &c.” Have you had a number of such experiments?

181. *M. Loir*: Yes; I have had a great many experiments, all of which M. Pasteur took an interest in.

182. *The Chairman*: But of experiments of this kind—poisoning rabbits with infected food—then putting fresh rabbits in the place where the diseased rabbits had been?

183. *M. Loir*: Yes; I have made many of these, and the fresh rabbits died.

184. *The Chairman*: Have you satisfied yourself that these fresh rabbits died of chicken-cholera or of something else?

185. *M. Loir*: I have made certain of it, by microscopical examination, that they died of chicken-cholera. The proper tests were applied, and satisfied M. Pasteur that the rabbits were infected with chicken-cholera, and that they died from it. You will see that if you read further on in the same report.

186. *The Chairman*: Yes, I see that now. M. Pasteur further says:—“At 5 o'clock on the evening of Saturday, the 3rd of December, some cabbage leaves—upon which 10 centigrammes of virulent growth of chicken-cholera had been spread, diluted with 100 centigrammes of sterilized water—were given to four rabbits. At midnight all the food had disappeared some hours before, and four fresh rabbits were placed with the others. At 8 o'clock on the morning of the 4th of December, two of the rabbits seemed unwell. At 11 o'clock one of them was dead; at 2 o'clock two others died, and at 4 o'clock the last of those that had eaten was dead. The carcasses were left in the box with the fresh rabbits that were put there at midnight on the previous day. On the 5th of December one of the rabbits was found to be dead; one on the 6th; a third on the 7th; and the fourth died on the 9th of December. All of these were tame rabbits. On the 17th of December 10 centigrammes of the growth of chicken-cholera were administered to a wild rabbit on a cabbage leaf. On the 18th it was dead. In all the foregoing instances it has been placed beyond doubt that death was owing to the microbe of chicken-cholera.”

187. Now, with regard to pigs, Dr. Hinds states that pigs inoculated with chicken-cholera have never suffered from swine plague. Now, has not the inoculation of fowl-cholera or food in which fowl-cholera microbes had been spread, ever produced serious disease in pigs?

188. *M. Loir*: No, never.

189. *The Chairman*: In the experiments that were performed to test whether the disease could be transmitted to sheep have the cultures from rabbits been used as well as the cultures from fowls?

190. *M. Loir*: Yes; the cultures from rabbits have been used.

191. *The Chairman* : Can you give us any definite information as to whether the virus is attenuated by transmission through rabbit to rabbit ?
192. *Dr. Hinds* : No ; it is not.
193. *The Chairman* : It remains as strong as it was originally ?
194. *Dr. Hinds* : Yes.
195. *M. Loir* : If anything it increases, and is not attenuated at all.
196. *Mr. Lascelles* : I would like to hear that question answered again.
197. *The Chairman* : Is there any evidence that the virus becomes weakened by transmission from one rabbit to another ?
198. *Dr. Germont* : No ; the reverse is true.
199. *The Chairman* : Can you tell the Commission whether that increase occurs generation after generation for many generations, or whether the maximum of virulence is soon attained ?
200. *Dr. Hinds* : The maximum of virulence is soon attained.
201. *The Chairman* : And there is no receding or going back from that virulence afterwards ?
202. *M. Loir* : No ; its virulence is fixed. It has been transmitted by experiments from rabbit to rabbit through ten successions. The Pommery experiment was conducted with a culture of the tenth generation ?
203. *Mr. Pearson* : I am not quite clear as to that. Is it the tenth generation of the microbe, or is it that the poison passed through ten rabbits ?
204. *The Chairman* : Does the poison that you now speak of mean that the disease had been ten times transmitted from rabbit to rabbit ?
205. *M. Loir* : Yes ; from rabbit to rabbit.
206. *The Chairman* : Then I understand you that no case is on record in France in which chicken-cholera naturally spreads amongst rabbits ?
207. *Dr. Germont* : We are not aware of any case. Yes, it is a fact that chicken-cholera in France has been more or less prevalent amongst fowls. It has not been observed that epidemics amongst fowls have spread to rabbits in France.
208. *The Chairman* : It has been stated that fowls and rabbits which died of chicken-cholera were sold in the markets, and that no evil results followed. What rabbits were those that were sold in the markets ?
209. *Dr. Hinds* : I think this has been known only in the case of fowls. I am under the impression that it must be a mistake ; it did not occur with rabbits.
210. *The Chairman* : Have you any information about the spread of chicken-cholera in different kinds of districts amongst fowls—as to any difference in well-watered parts and in dry parts ?
211. *Dr. Hinds* : No, we have no knowledge.
212. *The Chairman* : You do not know whether the rainfall largely affects the spread of the disease ?
213. *Dr. Germont* : No ; there is nothing definite known on the matter.
214. *The Chairman* : Have any spores yet been discovered in the microbes ? No.
215. *M. Loir* : At 51 centigrade, the microbe is dead.
216. *Dr. Paterson* : There was a reference to milk with microbes being harmless ?
217. *Dr. Hinds* : No ; but there is a reference to milk sprinkled with microbes. It was stated that there were reasons for believing that the milk of a cow fed on food sprinkled with microbes would be harmless to human beings.
218. *Dr. Paterson* : But that has not been demonstrated by actual experiments ?
219. *Dr. Hinds* : No.
220. *Mr. Tubart* : What became of those sheep that the experiments were made upon—were they watched for any length of time ?
221. *Dr. Hinds* : They were watched for two months and were perfectly healthy then. They were afterwards sold and sent to the butchers. Two of those that were not sold were sent to the veterinary school in Paris.
222. *The Chairman* : And were they examined there or used for dissecting purposes ?
223. *M. Loir* : They were used for dissection.
224. *The Chairman* : Have any further experiments been performed on sheep which are not so thoroughly explained in this paper.
225. *M. Loir* : Experiments have been made on six different sheep at different times.
226. *Dr. Wilkinson* : And were they all perfectly healthy ?
227. *Dr. Germont* : Yes ; very healthy sheep.
228. *The Chairman* : In any case was chicken-cholera or any serious disease produced ?
229. *Dr. Germont* : No.
230. *Dr. Wilkinson* : Did you ever try this disease upon sick or weakly sheep ?
231. *Dr. Germont* : No ; the sheep were good, but not very fat.
232. *Mr. Lascelles* : What evidence is there to show that there were 1,000 rabbits at Pommery. To us it seems as if that amount of poison laid for 1,000 rabbits was insufficient for the purpose ?
233. *Dr. Hinds* : That was an estimate. The number of rabbits was estimated as being more than 1,000 by the work people on the estate of Pommery. The thirty-two that were found outside we know to be a very small proportion of those that were in the burrows. When the burrows were taken up a large number of rabbits was found lying in them.
234. *Dr. Wilkinson* : How long had the place been infested with rabbits ?
235. *Dr. Germont* : About eight years.
236. *The Chairman* : I understand that food containing microbes was placed for the rabbits on the Friday, and on Saturday some live rabbits were seen. No live rabbits were seen after the Saturday. Food not poisoned was set out for the rabbits on Saturday morning, and some of that was eaten. No one went near the place on Sunday, and on Monday food was put out again but was not touched ?
237. *M. Loir* : That is correct. It snowed on the Saturday night, and there were no footprints of the rabbits seen on Monday.
238. *The Chairman* : Was a careful search made for live rabbits during the two or three weeks which followed this experiment ?
239. *Dr. Hinds* : No ; I think not ; but none have been heard of since as a matter of fact.
240. *The Chairman* : Do you believe, then, that every rabbit on the Pommery Estate was killed ?
241. *Dr. Hinds* : Yes.

242. *The Chairman*: Dr. Stirling wishes me to inquire whether any of M. Pasteur's representatives have ever witnessed a natural epidemic of fowl-cholera.
243. *Dr. Germont*: No.
244. *M. Loir*: I have.
245. *The Chairman*: Can you state whether wild birds died when poultry were dying of fowl-cholera?
246. *M. Loir*: I do not know. I cannot say that I have seen it. I have seen two epidemics, and in neither case did I hear of wild fowl being killed.
247. *The Chairman*: Can you say that wild birds were not killed?
248. *M. Loir*: No; I cannot say; I have never heard.
249. *Dr. Stirling*: What fowls were killed?
250. *M. Loir*: I have seen chicken, duck, turkey, pheasant, and pigeon killed, but no geese.
251. *Dr. Stirling*: Was a large number of tame birds killed in the epidemics which you witnessed?
252. *M. Loir*: Yes; at least one-half of them were killed.
253. *Dr. Stirling*: Where was this epidemic?
254. *M. Loir*: I have seen one in Eu, a town on the sea coast near Orleans, not far from the Château d'Eu.
255. *Dr. Stirling*: Do you know the temperature here—how hot it sometimes is in Australia?
256. *M. Loir*: We do.
257. *Dr. Stirling*: And are you aware that it is often as hot as eighty-two centigrades in the sun?
258. *Dr. Germont*: Yes; but it is not necessary to pick the hottest part of day either to prepare or distribute the food.
259. *The Chairman*: Have calves and lambs ever been fed on food charged with microbes?
260. *M. Loir*: Not that we are aware of.
261. *The Chairman*: The next is an important question, and I do not wish you to answer it hastily. In your opinion, are there any reliable means of ascertaining, in regard to the Pommery experiment, whether all the rabbits were poisoned by directly eating the poisoned food; or on the other hand, did some only eat the poisoned food while the rest perished in a secondary way?
262. *M. Loir*: It is impossible to answer that definitely, but we think that the disease must have been communicated from one to the other, as the small quantity of food which was placed there would not have been sufficient for the whole of the rabbits.
263. *The Chairman*: Well, have you had any observations which would lead you to believe that infection could kill off such a large number of rabbits in such a very short time. Did not the phenomena seem more like those of poisoning than those of infection, by reason of the rapid and complete extirpation of rabbits?
264. *Dr. Germont*: It is impossible to give an absolute opinion.
265. *Dr. Wilkinson*: I would like to ask one question with respect to this loss of virulence. You state that the loss of virulence was the effect of exposure to air, and not merely the effect of heat. That also was the opinion said to have been held by M. Pasteur in respect to the virus of anthrax, which has since been proved to be incorrect.
266. *Dr. Germont*: I think it would have an effect from the air in both cases.
267. *Dr. Wilkinson*: But have any experiments been made, excluding the presence of everything else except air?
268. *Dr. Germont*: Yes.
269. *Dr. Wilkinson*: And in that case the air has reduced the virulence of the virus?
270. *Dr. Germont*: It has.
271. *Dr. Wilkinson*: With regard to the septicæmia of the rabbit, referred to by Davaine and Koch—have you worked with it?
272. *Dr. Germont*: No.
273. *Dr. Wilkinson*: Koch has held that that is quite different.
274. *Dr. Hinds*: That is a question which M. Pasteur has left open. He says it is still a matter of doubt whether the *choléra des poules* is like to some form of septicæmia.
275. *Dr. Wilkinson*: But is not the matter of doubt only this—that is to say, whether the micro-organism in the two things is the same?
276. *Dr. Germont*: In septicæmia of rabbit the microbe is larger than that of chicken-cholera, and it requires a higher temperature to cause death.
277. *Dr. Wilkinson*: You have not worked with the cultivation in the solid media—both Davaine's and the other.
278. *Dr. Germont*: Yes; the cultivation is the same.
279. *Dr. Wilkinson*: But does this Davaine micro-organism kill fowls in the same way?
280. *M. Loir*: We do not know that.
281. *The Chairman*: But it seems, at all events, that there is a possibility that several different diseases may kill fowls and rabbits, with very similar symptoms and similar *post mortem* appearances?
282. *Dr. Germont*: Yes; that is true of rabbits, but not of fowls.
283. *The Chairman*: Swine plague kills off fowls with symptoms something like those of fowl-cholera, does it not?
284. *M. Loir*: This is a very different disease.
285. *The Chairman*: Pasteur himself no longer thinks the disease is attributable to any organism resembling that of fowl-cholera?
286. *M. Loir*: The only resemblance is in its very small size. The microbe of swine plague is a minute bacillus.
287. *Dr. Wilkinson*: Have you ever known of a case where a rabbit has resisted this particular disease?
288. *M. Loir*: No, never—not that we have seen.

The Commission adjourned.

MONDAY, 21 MAY, 1888.

The Commission met at 10 a.m., at the Crown Lands Office, Melbourne.

Present:—

<i>New South Wales :</i>	WILLIAM CAMAC WILKINSON, Esq., M.D., M.P. EDWARD QUIN, Esq.
<i>Victoria :</i>	HARRY BROOKES ALLEN, Esq., M.D. EDWARD HAREWOOD LASCELLES, Esq. ALFRED NAYLOR PEARSON, Esq.
<i>New Zealand :</i>	ALFRED DILLON BELL, Esq.
<i>Queensland :</i>	JOSEPH BANCROFT, Esq., M.D.
<i>Tasmania :</i>	THOMAS ALFRED TABART, Esq.

In the absence of the President (Dr. MacLaurin), the Chair was taken by Professor ALLEN.

Charles Myles Officer called in and examined:—

289. *The Chairman.*] What is your occupation? I am a landowner at Mount Talbot, in the Wimmera district, in this Colony.
290. Have you erected wire-netting fences? Yes; about 15 miles, more or less.
291. When did you erect the first line of such fence? I think about 2½ years ago, as near as I can recollect. Five miles of the fence was of netting 3 feet 6 inches wide.
292. Have you altered either the height or width of the netting since? I have not altered the height, but I have altered the mesh to 1½ inch. I find it quite sufficient.
293. Is your land leasehold or freehold? Freehold.
294. What is the value approximately per acre of the land which you have enclosed? About £2 10s. or £2 15s.
295. Have you personally found rabbits to go through a mesh of 1½ inch? I have never known a rabbit to get through myself, but I have been told that small rabbits have got through—a very small rabbit.
296. Do you think that such a small rabbit would be able to live, and establish itself in its new home? No; I do not.
297. What height of netting have you found a rabbit to jump or climb over? I never knew a rabbit to try to jump or climb over. I never tried any lower height of fence than 2 feet 6 inches out of the ground.
298. Have you heard from any trustworthy source of rabbits getting over netting 2 feet 6 inches out of the ground? No.
299. In erecting rabbit-proof netting fences around a large run, say of 100,000 to 500,000 acres, what height of netting and what width of mesh would you use? Three feet netting and 1½-in. mesh, No. 18.
300. *Mr. Lascelles.*] The gauge does not matter? No.
301. *The Chairman.*] How many inches do you reckon the netting should be sunk in the ground? Six inches; but I would point out that in all cases I do not sink it in the ground. In light sandy soil I have found it better to turn six inches of the wire down, with a lap outwards, so as to make a flange.
302. That would prevent rabbits passing in one direction, but would it prevent them from passing in another? No; that is the chief difficulty; but I think there would be very few rabbits inclined to go out. Whatever fence may be erected, it requires constant supervision. Of course, one rabbit occasionally will be more cunning than others. Such a one will get in, and will soon establish a run, so that constant supervision is necessary even with the most careful wire-netting.
303. Then it is your opinion that no matter how you arrange the netting some rabbits will get in from time to time? Yes; and constant supervision is therefore necessary.
304. Is there any other information which you would desire to give this Commission concerning the gauge and mesh of rabbit proof-netting? No; merely with regard to its erection. Later experience satisfies me that it is better in every case to sink the wire 6 inches in the ground.
305. Would the arrangement you suggest for erecting fences in sandy soil be suitable in the case of fences erected at the joint expense of two proprietors? No, I should think not; but in my case Crown land adjoins, and I have not considered the Crown at all, as they do not pay me anything. I had to bear the whole expense myself.
306. In the case of subdivisional fences in sandy soil, what would you do? I would turn the netting down with a lap one way; but with regard to this I may say that I never think of subdivisional fences, merely boundary fences. When once you have the rabbits excluded you can easily deal with them.
307. You do not think that in dealing with very large areas owned by one person it would be necessary to have subdivisional fences? No; I would never go to that expense.
308. *Mr. Pearson.*] What is the value of this land? It is worth about £2 10s., and would carry two sheep to three acres.
309. *Mr. Quin.*] Do you think this plan would be satisfactory in country which carry only one sheep to 10 or 15 acres? No. That would be very poor land. I endeavour to erect fences in the cheapest possible way. You must have the cheapest netting for such land.
310. *The Chairman.*] The question is whether in dealing with very large areas and very poor land it would be possible, as a practical matter, to deal with the whole of a large run at once, or whether some subdivision would not be necessary? I think the expense would be a great obstacle in attempting anything like subdivision on the poorer land, where it is more necessary to practise economy. I would deal with the run as a whole, and merely fence the boundary.
311. *Mr. Quin.*] Would you not think the Government should encourage holders to divide runs into small areas, in which the rabbits could be more effectually dealt with? I think it would be advisable if the Government could be got to assist. I think it should be done in this case; it is a mere matter of expense.

312. *The Chairman.*] Will the country stand the expense? It depends exactly on the position of the leaseholder. If he is in a position to pay the expense, it will pay him to do so.

313. *Mr. Lascelles.*] You have a large run on the Darling, I believe. If it were enclosed, could you not deal with the rabbits better than by any present known method? Yes; a year or eighteen months ago I was firmly impressed with the absolute necessity of getting wire netting to fence the run whether the Government assisted or not. I thought, as the Government was deeply interested in the matter, that it was their duty to help the pastoral tenant. But since that time I have come to the conclusion that wire netting is not necessary at all. There are two reasons for this:—There is a disease prevalent on the Darling. How it was introduced I don't know, but the rabbits have disappeared by thousands, and I am, therefore, under the impression that we are not required to go to the expense of wire netting since the rabbits have decreased, so that it is now hardly possible to see one.

314. *The Chairman.*] Do you know this by personal observation or by hearsay? I heard it from my manager. I have not been on the Darling since the rabbits first appeared there. Although disease is a very powerful auxiliary, I place far more reliance on the methods we have in our own hands, such as destroying the rabbits by poisoned grain; distributed by Messrs. Lascelles and Anderson's machines. With the aid of these distributors I do not fear the rabbits at all, nor did I think we will have to go to the expense of enclosing the run with wire netting.

315. *Dr. Wilkinson.*] Can you give us any idea of the cost of fencing in a run with wire of the description given? When I first commenced fencing at Mount Talbot wire netting was very costly—something like £50 per mile, but I believe the work can now be done at a very considerably less cost. Most of my fences were erected, and all I had to do was to attach the netting to them. I think it can be done now for about £30 per mile. I have not purchased any netting for the last eighteen months, but I think mine has cost me some £50 per mile, including the fixing of it in position.

— — — — —
Agar Wynne called in and examined:—

316. *The Chairman.*] Where do you reside? I am a landowner at Terrinallum, Darlington, near Camperdown, in the western district of Victoria. I have erected 50 or 60 miles of wire netting fences.

317. When did you erect the first line of such fence? Part of it was erected before we purchased the place, in August, 1881. The fence was commenced two or three years before that. I am practically acquainted with the results gained from such fencing since 1882.

318. What height of fence and what width of mesh did you adopt? Part of the fence is enclosed by stone walls. The other part, on the plain country, is open wire fences. On the walls we used 2 ft. 6 in. netting, 1½-in. mesh, and 16-in. gauge.

319. *Mr. Bell.*] What is 16-in. gauge? It is a little stronger than 17 or 18. The gauge has reference to the thickness of the wire.

320. *The Chairman.*] And away from the walls? We used 3 ft. 6 in. netting, placed 9 in. in the ground, of the same mesh.

321. Have you altered either the height of the netting—especially that used in the open—or the width of the mesh since that time? No.

322. *Mr. Lascelles.*] Have you kept to the 3 ft. 6 in. netting all through? Yes.

323. *The Chairman.*] Is your land leasehold or freehold? Freehold. The value is approximately about £5 per acre.

324. Have you ever found rabbits go through wire of 1½-in. mesh? Never.

325. If it were possible for very young rabbits to get through 1½-in. mesh, could they live and establish themselves in their new home? No; I do not think so.

326. What height of netting have you found rabbits to jump or climb over? I have never known them to climb or jump over netting. Around our garden we have netting no more than 2 ft. in height, and we never found any rabbits inside that, although they were there before. That fence is 2 ft. out of the ground.

327. If you were at present called upon to erect rabbit-proof netting fences around a large run of, say, 100,000 or 500,000 acres, what height of netting and what mesh would you use? In my opinion it should be about 2 ft. or 2ft. 6 in. out of the ground, with 1½-in. mesh—this would be ample.

328. Supposing you were using 3 ft. netting, how many inches would you recommend that it should be sunk in the ground? From 6 to 9 inches.

329. Would you vary the mode of erection of the netting according to the nature of the ground, or would you sink the netting perpendicularly to a certain depth? In stony ground it would be almost impossible to do this. Where we have walls we dig trenches and fill them up with loose stones, and the rabbits are never able to burrow under the stones. These trenches are about one foot wide.

330. Do you use any netting whatever? There we have close walls, and the netting is on the top. I would bury the netting in sandy soil. We curve ours a little.

331. Do you use netting only as a boundary fence over the whole estate, or do you subdivide? As an experiment, we netted in a section of 4,000 acres. Two of the boundaries are enclosed by walls—the other two by wire netting sunk in the ground. We turn the flange end of the netting outwards from the paddock to that part very much infested with rabbits. After it was enclosed, we cleared the rabbits that were inside, and it has been free from rabbits ever since.

332. Would a flange erected like that prevent rabbits from passing from the enclosed area into the open ground? Yes.

333. Then you do not think the direction of the flange has very much to do with the power of the rabbit to pass through in one direction or the other? I do not think so. When rabbits burrow, they go close to the object, and when they meet with the netting they go back. I think, however, that netting is absolutely a bar, if sunk 6 inches in the ground.

334. If you were controlling a very large run of very poor land, do you think it would be possible, as a matter of practical expense, to deal with the whole run at once, without assistance from Government, so as to successfully extirpate the rabbits? I can only tell you what we have done. We have 48,000 acres of land. It was covered with rabbits when we purchased it. In three years over 760,000 rabbits were destroyed, and the place is now practically free from them.

335. And the only subdivision which you made was in connection with these small trial experiments? Yes.

336. Do you think the same thing would be possible if you were dealing with 500,000 acres of very poor land? If you spent enough money to clear it, I think it would.

337. In dealing with leasehold, could it be possibly expected that the lessee will spend enough money to clear a very large run, say, of 500,000 acres, apart from subdivisional fences at all? It would be much better to erect subdivisional fences; but still I think that, on a large area, rabbits could be easily kept down if the whole of the boundaries were fenced in.

338. Could the rabbits be extirpated, in the first instance, without a cost that would be ruinous to the lessee without Government assistance? No. I think the Government should assist in fencing; and, if so, the lessee could keep down the rabbits.

339. *Dr. Wilkinson.*] Have you purchased any of this particular class of netting lately? No; not within the last three and a-half years. Three ft. 6 in. netting cost us £48 per mile—this was the first cost. The netting is now about one-half the price that we paid for it. I think you could now purchase and erect the netting at £50 per mile. I am not quite positive about it.

340. *Mr. Pearson.*] How long is it since you cleared the 4,000 acres? About four years. Only three rabbits were found there since. This was caused through the gates being allowed to remain open.

341. How many sheep will your land carry to the acre? We shear about 60,000 sheep, and keep besides a number of cattle and horses. We have altogether 47,350 acres.

342. *Mr. Tabart.*] You consider that a fence 2 ft. 6 in. in height and 1½-in. mesh is absolutely proof against rabbits? I do; and I have never known rabbits to get over that.

Joseph McGaw called in and examined:—

343. *The Chairman.*] You are a landowner in New South Wales? Yes; my land is situated on the Murrumbidgee.

344. Have you erected any wire-netting fences? No; we are putting up the first now, but it is not yet completed. We are preparing for it. We propose to erect 80 miles of fencing, the height of which is to be about 3 ft., and 1½-in. mesh. My land is freehold, principally—that is the portion which I am about to fence.

345. What is the value, approximately, per acre, of your freehold land? From 30s. to 35s. per acre. Some land in the neighbourhood has been sold up to 38s. per acre, improvements included.

346. Have you had any personal experience in the use of rabbit-proof fencing? During a lengthened residence in England I had the opportunity of seeing a great deal of it. I made it my business to see what they were doing there.

347. Can you say whether rabbits will get through a fence of 1½-in. mesh? No; I have never known a case, but I do not say that they could not.

348. If a young rabbit did get through such a fence, would it, in your opinion, be able to establish itself in a new country? I think not; I think it would be too young to live.

349. What height of netting do you think would be an absolute bar to rabbits getting across by jumping or climbing? I do not know that they either jump or climb; but I consider the 3 ft. netting we are putting up, with six inches in the ground, would be quite sufficient to bar their progress.

350. What kind of netting would you use in enclosing very large areas of, say, 100,000 or 500,000 acres? The same kind as I am now about to use.

351. How many inches do you intend to sink it into the ground? Six inches. I would put the netting in straight. I think this is the best manner for general use, so far as I have seen. They do it so in England.

352. Would you vary the depth according to the nature of the soil? Yes; it would cost a little less, where the ground is hard, to put it in 3 or 4 inches, and I would do so, to save expense.

353. Is there other any evidence which you would like to give to this Commission touching the use of rabbit-proof netting? I do not know of anything else which would be of service. I have no object in giving evidence in this matter, except to help my fellow-pastoralists. I have spent more money on that kind of experimenting than I can afford.

354. Is it a fact that before adopting this kind of fence on your own land you visited Mr. Lascelles' station, to satisfy yourself as to the value of this fencing? I obtained permission from Mr. Lascelles to look at the Lake Cooroug property, I went down and spent a considerable time there, and I was so satisfied with what he had done that I adopted his system.

355. *Dr. Wilkinson.*] Did you say that you had purchased netting of this description lately—what is the cost per mile? It cost £21 per mile on board the ship in London, but I could hardly tell you the cost of putting it up. Roughly, I think we put it up at a cost of £3 per mile, as we erect it on existing fences. We had a plough made for shaping the groove, which will lessen the cost considerably. The cost would alter if the fence were erected in timber country, because in the timber country the plough could not be used. The freight out here is 27s. 6d. per ton, which must be added to the cost already stated.

356. *Mr. Quin.*] Now in large areas would you recommend subdivisional fencing, or do you think it sufficient to fence in the boundary? I think subdivision would assist very much. In my own case I intend to divide, although the property to be enclosed is only about 100,000 acres.

John Bertram called in and examined.

357. *The Chairman.*] Where do you reside? On Euston Station in New South Wales, and the property I hold is situated there. I erected about three or four years ago 6 miles of wire netting fence as a trial. I am now erecting a great deal more—about 30 miles.

358. What is the height and mesh? We use 3 feet, and 1½-inch mesh. I have not altered either the height or mesh.

359. What is approximately the value of your land? About £2 per acre. We have about 20,000 acres of freehold which we have wire netted; the rest is leasehold and this is what we are now enclosing. I have never found rabbits get over or through wire 3 feet high, and 1½-inch mesh.

360. If a very small rabbit got through such a mesh, do you think it could possibly establish itself in its new home? No; I do not think so. A rabbit that would go through a mesh 1½ inch would not live. I have never known rabbits to jump or climb over fences.

361. How many inches are your fences sunk in the ground? About 6 inches. If the ground is soft the fence might go a little deeper especially if there were some special attraction on the other side in the way of

of food to draw the rabbits over. If the ground were very hard, I would only put in the fence about 3 inches. I have only found two holes, and these were old burrows that the rabbits had gone through; when they came against the netting they merely scratched.

362. How do you put in the netting? Perpendicularly. I think that is the most simple method. There is nothing more concerning fencing I would care to say. Of course fences require a great deal of care in putting up; a rabbit-proof fence in my opinion wants well looking after.

363. In dealing with large areas would you erect subdivisional fences? It would depend on the size of the run. In dealing with a large block it would save expense to subdivide for future dealing with rabbits. I think that constant supervision over the fences is necessary.

364. Are you actually at present subdividing your runs? Yes; we divide into 200 square miles. I do not think a larger block than that could be worked to advantage. We think this is large enough to make a trial on. Of course, if it can be done better we will subdivide into larger areas. Seven or 8 acres of this land will keep a sheep.

365. What is the cost of the fencing? It will cost about £31 per mile to put the netting on the fences; the cost is from £16 10s. to £18 per mile in London, and the Government of New South Wales charges us £3 per ton as duty. We pay £5 per mile for erection. This run is 145 miles from the River Murray, and we have railway and water carriage to pay.

366. *Mr. Tabart.*] What description of fences do you put this wire netting on? Six-wire boundary fences.

Andrew Anderson called in and examined:—

367. *The Chairman.*] You are a landowner in the mallee district of Victoria? Yes.

368. You have erected rabbit-proof wire netting fences? Yes; about 32 miles. We commenced this line of fence about two and a-half years ago. We used netting 3 feet high, 1½-in. mesh, and 17 gauge. We have not altered the netting in any respect since. My land is partly leasehold and freehold. Some of it we are leasing at 2s. 6d. per square mile.

369. Are you enclosing both good and very poor land? Yes.

370. Have you ever known rabbits to get through a fence of 1½-in. mesh? I have seen very young rabbits get through, but not after they have left their home. Before I began netting at all, I visited a place in the midst of the good country which was swarming with rabbits. This was fenced in with 3 feet netting and 1½-inch mesh, and the rabbits inside that place starved. Within 12 or 18 inches of this fence there was splendid feed, while inside there was no more grass than is on this table. The person who kept the rabbits there put some poisoned chaff inside to put them out of their misery.

371. It is your belief that even if they got through this netting they could not establish themselves in the new country? It might be possible, but the chances against them would be so great that they are not worth considering. A greater risk would be persons throwing them over.

372. What was the character of fence around the land on which the grass had been eaten away? It was simply a few sticks put down, with good posts at each corner for straining posts. It was only put up as a temporary fence. I have known a wire-netting fence to last for seventeen years. The lawn was being constantly watered, yet the netting was as sound to all appearance as when erected. I have seen it in Hawthorn, where wire netting has been used for thirty-five years in an aviary. It is as sound now as when put up.

373. Have you ever known from your own observation, or from trustworthy evidence from others, of any rabbit jumping over fences 2 feet 8 inches out of the ground? No; but I have known them to get over at the corners where posts have been put up as strainers. I have known one fence 1 foot 9 inches out of the ground where the rabbits were in thousands, and I have known only one rabbit to get over.

374. In erecting rabbit-proof fencing around a very large run of poor land, what kind of fence would you adopt? Three feet high and 1½-inch mesh and 17 gauge. We sink the wire from 3 to 4 inches in the ground. Where there are sand hills or pine ridges I would be disposed to put the wire a little deeper, say 6 inches. In dealing with holes near fences, I would have a special piece of netting to go right down into the ground and fasten on to the bottom of the other fences; and also a piece to go right across the depression. I went along a fence that has been erected for over two years, at Waitehie, in the mallee country, and to which nothing has been done for over six months, and yet in the 12 miles I saw not one place where rabbits could get through.

375. Do you put the wire into the ground perpendicularly? Yes; and I think that method is the best for general use. When the rabbit meets the fence and wishes to pass he scratches close to the fence. He does not in the first instance see it, but his toes become entangled with it in burrowing. The toes are thus hurt, and the rabbit tries to pass on to a spot a few inches away. He cannot do so; he hurts himself and relinquishes his endeavour. If a portion of the fence were flanged outward away from the paddock out of which the rabbit was trying to pass, his feet would not get entangled in this manner, and ultimately the rabbit would make his way in. A flanged netting is a protection in one direction but not in the other.

376. In dealing with a very large run of poor country would you recommend the use of subdivisional netting fences. There is a limit of course in this matter. I think we could treat 200,000 or 300,000 acres in that way. If the land were my own I would deal with it just as well as if it were subdivided; but if I had a neighbour who would not begin at the same place and time, the plan could not be worked. Therefore, I think it necessary that each owner should have his own land ring-fenced, but not necessarily into small blocks.

377. Then could you state what area would be outside the limit which could be worked in one block? If the land were my own, and I were not afraid of the negligence of my neighbours, I could deal with 500,000 acres in one block.

378. Do you think that a large leaseholder with very poor land could possibly ring-fence in one block the whole of his estate, and so cope with the rabbits? I have 260,000 acres of leasehold which carries only about 30,000 sheep. If that were not ring-fenced and fenced with rabbit-proof netting, the run must be abandoned. On the better country we have 32 miles of rabbit-proof fencing. The other is wire-fenced for wild dogs with 4-inch mesh.

379.

379. Is there any other evidence that you would like to give? I have been in the mallee during the last few months, and I have noticed a large number of rabbits dying where there is no poison and no disease that I am aware of. In fact the country is as bare as this floor, while inside the netting there is fair grass. We had laid poisoned grain where there is grass, and the rabbits have been thinned out. On the outside we find the rabbits dead in thousands as well. Having made a *post-mortem* examination on some of these rabbits, I have found that they died from a stoppage in the bowels, due to eating bark. I attribute the great numbers that have died this year to the heavy rains that we have had in Victoria, in January, which caused a great growth of scrubs and bushes. Since January and February we have had continued dry weather, and the feed has got dry. The dryness of the grass, and the sappiness of the bark have had much to do with the mortality. The bark is very astringent and fibre indigestible.

380. *Mr. Tabart.*] What was the nature of the country where the wire netting was so durable? It was loamy soil. I may mention that a farmer near St. Arnaud—Mr. Willoughby, of Gree Gree village—told me that several of his fowls had died from disease. Cases have occurred 6 and 7 miles apart. He promised to obtain the intestines of the fowls for me, but I did not yet receive them. I mention this, as I understand you are anxious to find out if chicken cholera exists in the colony.

George Henry Greene called in and examined:—

381. *The Chairman.*] Where do you reside? At Iandra, in the Young district, New South Wales. That is where my property is situated. I had begun to erect wire netting, but discontinued the work until I saw whether the Government of New South Wales would make a more liberal arrangement with regard to the work.

382. When did you commence the work of fencing? About four months ago, and have erected between 6 and 7 miles of it. I originally intended to put up about 30 miles. I use netting 42 inches height, 1½-inch mesh and 16 gauge. I have not used any other kind of fencing except that.

383. Do you purpose, from your personal experience of other kinds of netting, to alter the character of any fence to be put up by you in the future? If the Government of New South Wales give the privileges proposed I would prefer to use 36-inch netting, 1½-inch mesh, and 17 gauge.

384. Have you satisfied yourself by personal inquiry that rabbits cannot pass through such a fence? So far as I have been able to ascertain, rabbits have not gone through 1½-in. mesh. I have been in the neighbourhood of Bacchus Marsh, where the fences are only 3 feet high, 4 inches of which are in the ground, and 1½-inch mesh. There seems, however, to be a difference of opinion as to whether the mesh was 1½-inch or 1¾-inch. I took a rule with me, and in the most careful manner measured the fences in many places. On one portion of the flats I found that the netting was 1½-inch, while on the other I am prepared to say it was 1¾-inch. These fences have been up for eight or nine years, and have been impervious to the rabbits.

Edmund Hayes called in and examined:—

385. *The Chairman.*] Where do you reside? At Ingleby, Winchelsea, in the western district of Victoria; and my property is situated there. I have erected wire netting fences during the last three or four years. I have put up about 20 miles of it; the height of the netting is 36 inches, 1½-inch mesh, and 18 gauge. More recently, we have used 1¾-inch mesh, 17 gauge, and 36-inch high. It is stronger and better than the other. My land is mostly freehold; the value of some of it would be from £20 to £30 per acre. The wire netting encloses some of the worst portions.

386. Have you found rabbits get through 1½-inch mesh? No; I have never seen anything of the kind. It would be difficult to say whether a rabbit could get through or not, but if so I think he would go back again to the burrow. I have never known a rabbit to get over one of these 3 feet fences, 2 feet 8 inches out of the ground. Years ago we proved on the plains that rabbits would not get over such a fence; we erected a mile of it temporarily. I would recommend that fences should be put from 4 to 6 inches in the ground. In sand I should recommend that trenches be piled in with timber. Stone would be better if you could get it; I put netting in perpendicularly. I believe in rabbit-proof fencing as the only reasonable mode of coping with the rabbit difficulty. This applies to country of whatever character.

James Finlay called in and examined:—

387. *The Chairman.*] Where do you reside? At 61, Williams Road, Windsor. I was managing proprietor for my brother in the Wimmera from 1863 to 1888. I have erected some 5 miles of rabbit-proof fencing. The best kind of fence is the 3 feet high, though higher would be better.

388. Do you think there is any risk of rabbits getting over if the fence is sunk 4 inches in the ground? If closely confined they might jump, but in a large paddock I do not think they would.

389. Have you known from personal observation that rabbits have jumped over wire netting 2 feet 8 inches out of ground? Yes; I have seen it myself.

390. Is it not a very rare occurrence? Yes; very rare.

391. Do you think it is worth while to add to the cost of netting in order to meet these very rare occurrences? Yes; I should say it would.

392. You think, then, the netting does not fulfil its purposes unless it proves an absolute bar to the rabbits? I think the additional height would be an advantage.

393. Even to meet the case of a few rabbits that might jump over? Yes; but at the same time a 3 feet fence is very good.

394. Have you known rabbits to get through 1¾-inch mesh? The mesh that I referred to was 1½-inch. I have often seen young rabbits with their heads in the mesh and they could not get them back again. I have known rabbits to get under a fence buried 4 inches in the ground. The fence wants watching. Even if a hole be made it is not likely that many will go through if the fence is watched by a careful man. I still think a fence 4 inches in the ground is sufficient.

395. *Mr. Lascelles.*] Was not the fence at Townaninnie 3 feet high? Yes; and it was fairly effective.

396. If so would it be necessary to have the fence 6 inches higher in poorer country? I don't think it would be necessary.

Alexander M'Edwards called in and examined :—

397. *The Chairman.*] Where do you reside? At Hawthorn Road, Caulfield. I have an estate on the Lower Murray, adjoining Mildura. I am erecting a rabbit-proof fence for about 60 miles; I am using two different kinds of fencing; I use the 36-inch netting, 1½-inch mesh; I had been putting the fence 6 inches in the ground, but at present only 4 inches, as I find it quite sufficient; I put it in almost perpendicularly, but slightly bending out.

398. Have you ever known a rabbit to get through 1½-inch mesh? No; I do not think a very young rabbit would be able to go through and establish himself on the other side. I think he would die if he got through. I have known a rabbit to get over a fence 2 feet 8 inches out of the ground; still I do not think that would be any reason for putting up a more expensive fence. Rabbits could not get under a fence sunk 4 inches in the ground.

399. If a rabbit were to succeed occasionally would this be a reason for burying the fence deeper, or should it be made a matter of extra supervision? I think there should be constant supervision; a boundary rider after a few months would do all the work.

William Cumming called in and examined :—

400. *The Chairman.*] Where do you reside? At Marlbed, Wurrumbirchip, in the mallee district. I have employed rabbit-proof fencing on the southern boundary of my property, on two blocks—about 28 miles. My land is leasehold; the netting I have adopted is 3 feet high, 2 feet 8 inches out of the ground, mesh, 1½-inch, and No. 17 gauge.

401. Have you found rabbits to get through a fence of 1½-inch mesh? No; and if a young rabbit did get through I do not think it would be able to establish itself on the other side.

402. Have you ever known rabbits to go over a properly constructed netting 2 feet 8 inches high? I cannot answer that question directly. I have never known of any case where a rabbit has got over a netting fence 2 feet 8 inches out of the ground. I have occasionally known a rabbit to pass under a fence 4 inches in the ground. I think supervision the right thing, and putting a fence deeper into the ground. Certainly 6 inches would be very effective, but 4 inches is practically sufficient if properly supervised. I think no mode of dealing with the pest is thoroughly effective, unless accompanied by the use of wire netting.

Hugh M'Cann called in and examined :—

403. *The Chairman.*] Where do you reside? I live at Horsham. I am one of the Government rabbit inspectors and Crown land bailiffs. I have personally had some experience of rabbit-proof fencing. I think that a wire fence 3 ft. high, of 1½ in. mesh sunk 4 in. in the ground is a good and effective barrier. I think there is no real practical good to be obtained by increasing the height of the fence, or by limiting the mesh, or sinking it deeper in the ground. It depends on the country, of course. If you have a loose country you will have to sink deeper—to a depth of 9 in. We have a good deal of that class of country—of loose, sandy soil, where the rabbits go down deep into the burrows. I think there should be about 2 ft. 6 in. of wire above the ground. The 1½-in. mesh is thoroughly satisfactory; 1¼-in. I know is not. If there had been any real failure with the 1½-in. mesh I must have known of it. I think it is quite possible that 2 ft. of wire above the ground would be sufficient if there was a barbed or plain wire about 3 inches above the netting on top. Then the expense would be about as much as the other.

404. *Mr. Pearson.*] Do you think that in sandy ground 4 in. is sufficient to sink the fence? No. I have known rabbits to get down and get under. I have seen a case of that kind.

405. *Mr. Lascelles.*] Could the difficulty with regard to loose ground be met by special precautions without modifying the depth which the fence is sunk in the ground? Yes.

Robert Blyth Kerr called in and examined :—

406. *The Chairman.*] Where do you reside? At Bacchus Marsh. I am one of the rabbit inspectors of the Colony, and have had some experience in connection with rabbit-proof fencing. I have seen a great deal of it, and know the results that have been obtained from its use.

407. What kind of fence would be economical and effective as a rabbit-proof fence? The best that I have seen is 3 ft. high, 1½-in. mesh. I think 1½-in. mesh is necessary. I do not think 1¼-in. mesh is quite satisfactory; but that it would be dangerous to adopt it, because the rabbits might get through it. I think, however, this danger could be met by supervision. I do not think the 1¼-in. mesh would be more advantageous than 1½-in. I think the 1½-in. mesh the best that could be adopted. Fences should be sunk in the ground, but not at an equal depth in all kinds of soil. In very hard soil, 3 or 4 in. would be enough.

408. *Mr. Lascelles.*] I understood you to say that you have seen rabbits getting through 1¼-in. mesh? No; I did not see any get through, but I have seen them inside such a fence in a crop of lucerne.

409. *Mr. Pearson.*] Do you know of rabbits getting over such a fence? I have seen rabbits get over a fence 2 ft. high. I have seen it done often. They partly climb and partly jump or fall over. I have also seen a rabbit get up a netting 3 ft. 6 in. high. This occurred at Bacchus Marsh. The enclosure was a small one of about 6 ft. square.

The Commission adjourned.

WEDNESDAY,

WEDNESDAY, 23 MAY, 1888.

The Commission met at 10 a.m., at the office of the Commissioner of Crown Lands, Adelaide.

Present :—

New South Wales : WILLIAM CAMAC WILKINSON, Esq., M.D., M.P.
 EDWARD QUIN, Esq.
Victoria : HARRY BROOKES ALLEN, Esq., M.D.
 ALFRED NAYLOR PEARSON, Esq., F.R. Met. Soc., &c.
 EDWARD HAREWOOD LASCELLES, Esq.
New Zealand : ALFRED DILLON BELL, Esq.
South Australia : EDWARD CHARLES STIRLING, Esq., M.D.
Queensland : JOSEPH BANCROFT, Esq., M.D.
Tasmania : THOMAS ALFRED TABART, Esq.

In the absence of the President (Dr. MacLaurin), the Chair was taken by Dr. STIRLING.

Allan M'Farlane called in and examined :—

410. *The Chairman.*] Where do you reside? At Wellington Lodge, East Wellington, South Australia.
 411. I believe you hold considerable freehold property? Yes; 40,000 acres.
 412. I believe a large portion of this has been infested with rabbits? I never allowed it to be absolutely infested. I met them at the very first, and told the other people what was coming. In 1884 I paid for scalps of 80,000 rabbits, besides what my men killed. I sometimes killed as many as fifty per day myself.
 413. Now tell the Commission what you did? I found that the country surrounding me was unoccupied, which was the first difficulty I had to contend with. The first thing I did was to telegraph to England for wire-netting. I bought all I could get in Adelaide at once. I was compelled to take the 2-inch mesh because I could not get anything else; it was 3 feet wide, and 6 inches in the ground; the bottom part sloped outwards in the direction in which the rabbits were coming.
 414. *Mr. Lascelles.*] How much lower in height did that make the fence? It lowered it about an inch—not more.
 415. *The Chairman.*] Did you fence in the whole run? No; only the northern boundary towards which the rabbits were coming. I fenced in just about 5 or 6 miles; this was in the beginning of 1884. My experience is that large rabbits can get through the 2-in. mesh. I then got 1½-in. mesh from England, having in the meantime had iron fences ready for it. I then removed a large portion of the 2-in. mesh, and substituted 1½-in. mesh for it. I also tried to utilize the 2-in. mesh by doubling it, but that was no good. The meshes now and again came perfectly straight. I took all this up and replaced it by 1½-in. mesh. My experience was that 95 per cent. or more rabbits were kept out by it because the grass inside was good while outside the country was perfectly desolate. Still I do not think that 1½-in. mesh will keep all rabbits out. My object was absolute extermination, and my fences included about 60,000 acres of scrub and open country—all shades of country. I carried on all sorts of experiments with rabbits inside the woolshed. My men told me many times that the rabbits got over the netting, but I would not credit it. Some blackfellows told me that they saw the rabbits walk up the netting in one place. I had twenty or thirty rabbits taken out of the burrows and put in the woolshed, and tried all sorts of experiments with various meshes and slopes of netting. I made the netting fully 3-ft. high in front, and also put it across the middle of the bin, and put food on one side,—cabbages and lettuces, and kept the rabbits starving on the other side. They went over the netting from the sloping side with the greatest ease—they went over it as if it were a ladder. From the other side they could not climb up the netting, but the small rabbits darted right through it. These were good large rabbits, and could get along independently of their mothers. Ten or twelve of them would go through the fence in a moment. Outside this I put up one piece of netting 36-in. high, and one rabbit got over that, and, on another occasion, I found a young rabbit hanging by the head in it, and several others on the floor going about. After searching, I found that the doe had climbed over the netting, and in climbing over it had dropped her young one. I could see plainly enough where she had gone over, because she left some fur on the top of the netting; she must have leaped or climbed some 3½ ft. because the bins are that height above the ground. I put her in again, and next morning she was out over the netting again. Rabbits are perfectly capable of getting over a low netting, and I was told by a farmer near me, that he had most conclusively proved that rabbits had got over the netting. He put a lot of snares on the top of the netting, and next morning three rabbits were in the snares.
 416. *Mr. Lascelles.*] Was that a properly erected fence? No, it was not; it was a slovenly fence. It was fairly well put up, however, and the mesh was 1½ inch. The fence was fairly perpendicular, but it was not like mine. This proves that a fence 2 ft. 6 in. high is altogether too low.
 417. *The Chairman.*] You have never had any experience of this netting in the open country, and seen rabbits get through it? No, not in the open country; but I have heard of them going over it there. I should have said that subsequently I added another width of netting, making my fence 5 ft. 6 in. high, to keep out the wild dogs. I would not say that it would be necessary to make it so high for rabbits. It was the only width of netting that I could get quickly at that time. I telegraphed to England when fairly convinced that the rabbits could get through this fence, and I got 20 miles of netting, 19 gauge, 1½ mesh, and 1 foot wide. This ribbon I put along the surface of the ground on the inside of my netting, and lashed it to the other. This was to prevent the small rabbits from getting through.
 418. *Mr. Bell.*] So that you really had a double netting fence? Yes; and I would rather have anything than have the rabbits.
 419. *The Chairman.*] What was your experience of this fence? It was ridiculously costly, but it was absolutely perfect against rabbits and dogs. Strangely enough, I found the rabbits more inclined to climb, and the dogs to go under. This is very contradictory, but still it is true. Sometimes a dog will manage to get under.
 420. *Professor Allen.*] Is it your opinion that the ordinary fence sunk 6 in. in the ground is a fairly complete protection against rabbits, or not? Well, it depends something upon the nature of the soil. If you trench the ground, or make sufficient soil, the rabbits will tackle it, but not hard virgin ground. If the ground is sandy, they will scrape and get under.

421. Then the danger of getting under is a thing you would deal with by a more strict supervision? Yes I think you might as well put the netting straight down as sloping outwards, if the soil is suitable. In one place where I first put my netting up I had a little trouble: I took some 2-in. mesh and split it, fixed it to the 6-in., and buried the whole thing so that it was out about 2 ft. from the fence. No rabbits came through after that.

422. *The Chairman.*] Did you find, after these fences were put up, that much had to be done in the way of looking after them? Yes; a rabbit fence is no good unless it is constantly looked after. My men patrol the fence nearly every day.

423. *Mr. Tabart.*] I suppose you keep boundary riders for the purpose? Yes.

424. *Mr. Lascelles.*] You have stated to us that you first erected 36-in. netting and 2-in. mesh. How long was it before you discarded that? It remained up for 5 or 6 months.

425. During that time did you ever hear that rabbits jumped over that fence? There was no need of them to jump over, because they could get through.

426. Did you order an exact height? I had no experience when I ordered the 36-in. netting. I wanted to get it quickly and cheaply.

427. *The Chairman.*] Then so far as you can say now, you are satisfied that wire netting protects your run? Yes; and the rabbits have died out since. Before that we could not tell where they were coming from. I never ceased during the whole time to tackle the rabbits in every way except by poisoning.

428. *Mr. Tabart.*] The whole of your land is not enclosed with this 5-ft. netting? No, only along the dense mallee scrub. I put it on the railway fence also.

429. Then the balance of your fences would be 2 ft. 6 in. out of the ground? No; they are the ordinary height of cattle fences.

430. Do you consider that 2 ft. 6 in. out of the ground is an ample height to prevent rabbits getting over? I consider 2 ft. 6 in. out of the ground to be no good whatever.

431. *Mr. Lascelles.*] Then what is the ordinary height of your fence? It is about 4 ft. high, where I bound my neighbours. I cannot put down the netting with a slope, but I put it up to the top of the fences.

432. *Dr. Wilkinson.*] What is the area of land you have enclosed? 60,000 acres. My neighbours at Pottaloch have had rabbit netting, but still they have had ten times the trouble that I have had.

433. *The Chairman.*] Why have they not been so successful as you? I am bound to say that some of them are most successful in the way of destroying the rabbits. Some of them put up netting the same as mine, 3 ft. high, 1½-in. mesh. They were fairly successful, but only by great labour—double the labour that I have had. It was much more than was necessary to kill the few rabbits that they had to deal with.

434. Did that labour induce them to take any other steps to do away with the pest? They have now ordered netting 48 inches wide and 1½-in. mesh and are about to put up other fences just inside the present ones, putting 18 inches, at the bottom and 3 feet above ground.

435. Then the inference you draw is that the first fence did not keep the rabbits out? I am as sure of it as I am of sitting here, because they have now reduced the mesh and have given orders for new netting which they intend to carry down to Lake Albert.

436. *Mr. Lascelles.*] Is the country belonging to your neighbours at Pottaloch more or less difficult to deal with than yours? No, it is not as bad as mine.

437. *Mr. Tabart.*] You say you have 60,000 acres enclosed. Have you any subdivision fences, or is the land in one block? Merely one or two lines by which I have prevented the rabbits from shifting.

438. Then you consider that you can deal with the rabbits much more easily within a small area? Most decidedly, if it were not for the cost I would put netting on the other fences.

439. *Mr. Lascelles.*] If you owned a large run in the interior that was capable of carrying 50,000 to 100,000 sheep would you consider it necessary to put such a fence round that country? No; because you do not go in for extermination. You have to do the best you can to reduce them, but my object was to absolutely destroy them. In that case I do not think there is much difference between 1½-inch and 1¼-inch mesh. The extra cost is nothing approaching £12 per mile. Of course on a large run it would be impossible to put up such fences as I have done.

440. *The Chairman.*] You think, then, that for a large run in the interior a fence with a netting 3 feet high and 1½-in. mesh would afford very great protection? Yes; but why not make it better when you are about it? I would prefer 1½-in. mesh and think it a great deal safer. Here is an estimate of the price of wire netting:—Price in Adelaide, from a wholesale house: 3' x 1½" mesh x 18G, £21 10s. per mile; 3' 6" x 1½" mesh x 18G, £25 per mile; 3' x 1½" mesh x 17G, £27 per mile; 3' 6" x 1½" mesh x 17G, £32 10s. per mile. If I were putting up fences again, I would put up a fence like my own.

441. Give us in a few words an account of what you would do if you had to do the work over again? I would certainly not erect less than 42-in. netting, and then I would put a barbed wire within 4½ inches of the top. The mesh would be 1½ inch, and I would use a uniform gauge. I have suggested to several people that they should get a 2-in. mesh for that which goes into the ground; then 1¼-in. mesh for the next 14 inches, and the balance of the 42 inches should be 1½-in. mesh.

442. *Professor Allen.*] This is what you would put up for the extermination of the rabbits? Yes.

443. Now, in dealing with large areas of very poor land, have you sufficient experience to make any recommendation? No; I cannot really say; but I should be inclined to modify my opinion in a case like that. When rabbits are really shy and you do not expect to exterminate them entirely, a rabbit or two would of course be of no consequence.

444. Then you are clearly of opinion that with any land, such as yours, it is better to have a dear and complicated fence for extermination purposes than to have a cheaper and smaller fence for protective purposes, together with supervision by boundary riders? Yes. The amount expended on rabbits would soon pay for the difference in the fencing. In the one case you make a job; in the other case you make a botch. At the same time I know that poor country will not afford it.

445. *Mr. Bell.*] Then the sole reason for not erecting such a fence as you describe is that the country is poor and will not afford it? Yes. The Government are wasting money as usual upon boundary fences, and I think it is extremely unwise not to put up a proper fence at once. A few pounds difference in price would not be felt. Much of my netting has been put on fences that I have had up already. I would also add that I had about 10,000 acres of mallee scrub, and we found that we could not cope with the rabbits there, but since I rolled it the rabbits are done. Rolling the scrub down is the best plan of all to get rid of the rabbits.

Archibald

Archibald Watson called in and examined:—

446. *The Chairman.*] What are you? Professor of Anatomy in the University of Adelaide and Fellow of the Royal College of Surgeons, England.

447. When did you first think of the idea of disease in connection with the extermination of rabbits, and what did you do? I saw diseased rabbits in the physical laboratory of Prof. Krause, and found that the rabbits always died. Years afterwards I read in the papers of the ravages of rabbits here. Last March I imported some rabbits from Germany, and they arrived in the beginning of winter or about the end of summer. On previous occasions I had failed to get them in alive, owing to accidents on the voyage. Eventually I managed to get in six live rabbits diseased. I bought some Australian rabbits, placed them with the others and they took the disease and died within three months. This was in a very rainy season. I put these rabbits into a small enclosure of about 50 feet square, and noticed that they developed the same disease as I had seen in former years in Germany; and that they died, some in two, some in three, and some in six months. The older and stronger rabbits lived longer than the younger ones.

448. What happened to the original stock? They died during the winter, having previously communicated the disease.

449. *Dr. Bancroft.*] How were the rabbits fed? We gave them plenty of bran, oats, &c.; they were very well fed. They had two years' growth of rye grass there. The rabbits did not burrow at first, because I had wire-netting in the ground. I took them away in about three or four months and allowed them to burrow, which they did after putting in a fresh batch of Australian rabbits. They have burrowed freely ever since.

450. *Professor Allen.*] Did you satisfy yourself at the death of the other rabbits that death was due to *sarcoptes cuniculi*? Yes; I satisfied myself of that—that is beyond any dispute. I made an examination of the internal organs and found that nothing else could account for their death except, perhaps, cysts. These cysts were in both the imported and the Australian rabbits. These cysts were like the *cysticercus cellulose* in the peritoneal cavity in the great omentum.

451. Did they present abundant evidence of scab? Yes.

452. What was the subsequent course? The older rabbits were, to a certain extent, refractory to the disease. They finally succumbed—one of them in seven months. The younger ones took it more quickly and died. They all died in rainy weather. After wet nights some two or three rabbits would perhaps die the next day. Then having kept them for six or seven or eight months, and being satisfied myself that the disease was fatal in wet weather, I handed it over to my assistant, since which time I have had nothing further to say to the matter.

453. *The Chairman.*] During that period how many rabbits do you think died altogether? About sixty, and odd ones that I had given to me. They all died, but all did not show scab. Some of those that die now show no scab.

454. Then you gave up all interest in the concern when you handed the rabbits over to your assistant? Yes. I was away in Turkey for about four months, and when I came back I found the rabbits all well, looking healthy, and in splendid condition. I was absent during the summer months.

455. Did the rabbits seem to get well in summer? Yes; they do get well in summer. There were only three that I could swear to; I had ear-marked them. When I left I ear-marked all my rabbits.

456. *Mr. Iascelles.*] Were they all showing symptoms of disease when you left? No; there were only four showing signs of disease when I left them. Over 100 rabbits were sent down and thrown in with the others, and they began to burrow. This was after I had parted with the disease.

457. *The Chairman.*] Before you parted with the disease I believe you made some experiments to ascertain its communicability to animals and to man? Yes. My man put some of the fur into his hair, and kept it there for days. He also inoculated his dogs, and I inoculated my cat. I tried it very often on myself, and it never affected me; I have also placed the fur on part of my arm, and attempts have been made to communicate the disease from one creature to another through contact and through inoculation. I am not aware of any case in which real inoculation was practised.

458. *Mr. Bell.*] What was the result on the dog and cat that were inoculated? A tram ran over the dog, and the cat was found on the doorstep in tetanic convulsions. I do not ascribe the tetanus to inoculation; I believe it occurred through poisoning with strychnine.

459. *The Chairman.*] Were the dog and cat sufficiently long under observation to enable you to detect any signs of disease? Yes. The cat showed signs of disease. It used to scratch itself, but I examined the fur, and found no scab. My assistant had the dog in his charge. I found hen's lice in the cat, but no trace of the *sarcoptes*.

460. Were there any other experiments with cats? No; not that I have any knowledge of.

461. Nor with any other animals? No.

462. Will you tell us whether this disease affects sheep? I do not know anything about them. I have not seen any of the sheep since I have inoculated them. Three sheep were bought—two young ones, and one old one—to which scab was applied by Mr. W. J. M'Gary, and we separated the wool on the back in three places, then on the belly in three places. We brought a living rabbit down there and placed the fur in the wool. The sheep were unshorn sheep. I did not subsequently apply the disease to shorn sheep, but I have heard that some sheep were shorn and the same thing done. It was applied to sheep three times to my own knowledge, with unshorn wool twice, and shorn sheep once.

463. Have you yourself seen sheep since the scab was applied? Yes; I went there on purpose the other day to see them.

464. Did they show any trace of scab? No; the wool had grown again, and it was about as long as when I saw them before. They had been shorn in the interim.

465. *Mr. Bell.*] Before placing the fur where you state you placed it, did you examine the fur with a view of ascertaining whether it contained any of the insects in question? Yes; and it contained insects in large numbers. I did not examine a large piece, but I got a rabbit that was badly infected; I examined the fur, and every piece that I examined contained several insects.

466. But you did not examine the particular piece of fur which you placed on the sheep? No; I did not consider it necessary; every piece of fur that I did examine contained the insect.

467. *Dr. Bancroft.*] Is this insect as large as sheep scab? No; it is much smaller, you could just see it with the naked eye. It is about one-fourth the size of sheep scab.

468. *The Chairman.*] This insect, then, is the *sarcoptes cuniculi*? Yes; or *sarcoptes minor*.

469. *Professor Allen.*] Have infected rabbits been sent to other places for the purpose of spreading the disease? Yes; I think some were sent to Glenelg, and other rabbits were sent up to the north and north-east.
470. Are you personally aware, or by any sure account, of the results of such tests? Yes; I have heard that the *sarcoptes* were dead and the rabbits alive.
471. *Mr. Bell.*] Reviewing, then, all the circumstances within your knowledge, are you willing to give this Commission an opinion of your own as to whether the disease with which you have been dealing is or is not of probable practical benefit in dealing with the rabbit question? That is a good question. I am quite certain this disease will never do in this dry part of Australia.
472. Either in summer or in winter? No; not in South Australia. Last winter was a particularly wet one.
473. *Professor Allen.*] Is there any probability of the disease being useful in moister climates or in the south-east of South Australia? I do not know; I am in doubt now. I should have said most decidedly yes six months ago, but at present I am in doubt.
474. *The Chairman.*] Give us the course of the disease in fatal cases? In Germany the *post mortem* showed suppuration of the lymphatic glands, but in Adelaide the rabbits seemed to have died of general exhaustion, with a great deal of wasting. There is generally an enlargement of the lymphatic glands, but not so pronounced as in Germany.
475. *Mr. Bell.*] So far as you have examined, this pathological appearance has been general? Yes. The animals lost appetite and were feverish. When a shower of rain came they would scratch themselves, and I have seen a rabbit scratch all the scab off its face during a shower of rain. The moisture seemed to increase the itch.
476. *Professor Allen.*] Is it your opinion from what you have seen in Germany that the suppuration of the glands was due to a distinct septic disease? I am certain of it.
477. Is it your opinion that such septic disease arose from the crusts on the surface becoming septic, and the absorption of septic matter from the surface? I think so. They died from septicæmia.
478. *Mr. Bell.*] Do you think that was the course of the disease in this country? No, not quite.
479. *Professor Allen.*] What, then, was the cause of death in the rabbits under your experiments? Suppuration was wanting in most cases here. There was nothing but general emaciation and loss of fat.
480. Can you state the cause of that emaciation? Only to the unrest of the animals and loss of appetite from external irritation.
481. What do you think was the cause of the enlargement of the glands? Absorption from the lymphatic area drained by the glands. Those in Germany died from septicæmia—that I am certain; and the glandular symptoms were not so pronounced.
482. Was the glandular enlargement absent in some of the cases observed by you in Adelaide? Yes.
483. Could you satisfy yourself with rabbits that died without marked enlargement of the glands that death was really due to *sarcoptes*, and not to some other cause or causes? Only that they died after rain, and that they scratched themselves with the wetting. They died without any suppuration; the glands may have been a little enlarged, but nothing specially. I noticed also that the rabbits that had not scab did not die. We had three scabby rabbits of different ages die in one night.
484. Are you aware of the disease having been tested at all under natural conditions? Only from hearsay; I have no personal knowledge of these experiments.
485. You believe that the specimens sent Mr. W. J. Reid were true *sarcoptes*? Yes; the first specimen was really a louse, but the subsequent ones were the shells true *sarcoptes*. The specimens were smashed, and were too dry.
486. *The Chairman.*] Besides the *sarcoptes minor*, had you seen any other *acarus* obtained from rabbits? My attention was called by Dr. Stirling to a larger animal than the *sarcoptes minor*.
487. You are not aware whether that is *psoroptes* or not? I am now aware of it, because you have told me of it; I understand now it is *psoroptes*.
488. *Mr. Bell.*] Was the rabbit from which the second *acarus* was taken suffering from the disease as well? Yes.
489. *Dr. Wilkinson.*] Is this larger species much like what was sent to Dr. Branson? It seemed to me about the same size, but I did not think of comparing. The shells sent to Mr. Reid appeared to be about the same size as the *psoroptes* shown me by Dr. Stirling, but I did not closely compare the two.
490. *Mr. Tabart.*] Is this rabbit-scab identical with sheep-scab? No.
491. *Dr. Bancroft.*] Do they ever use in Germany this disease known as nasal catarrh, which is considered very destructive to rabbits? I do not remember it; I was a student there, but I do not recollect it.*
492. Are there any other important diseases of rabbits mentioned in anatomy? No, not that I know of.

James Francis Cudmore called in and examined:—

493. *The Chairman.*] Where do you reside? At Paringa Hall, Glenelg.
494. You are a station owner? Yes; I have stations in South Australia, Victoria, and Queensland.
495. Both freehold and leasehold? No; we have no freehold in Queensland or in New South Wales.
496. Have you suffered much from rabbits? Yes; some of my runs have been very much infested indeed. I should say there must have been millions on my Victorian and South Australian properties. The first rabbit that I saw came, I think, from one of the steamers on the Murray, and I think this was about eight years ago, at Paringa. I first thought the rabbit had been wilfully let loose, but since then I have had reason to change my mind. This rabbit evidently came from the scrub from Victoria and was the forerunner of the wave of rabbits that followed. It was fully a year after this when the rabbits were seen in any quantity; they came gradually down upon us, at first their natural enemies kept them in check. I thought that it was a hopeless idea to take up the matter of fencing, as I was under the impression that wire must be put some 2 feet in the ground. I came down to Adelaide and had an interview with Mr. Goyder, the Surveyor-General, and with Mr. Catt, who was then Commissioner of Crown Lands, and waited on them with a deputation to ask that Government should move in the matter. I spoke about this fencing and I found that it would come to something like £200 per mile. Mr. Goyder said he had an idea of fencing the border of the Colony at the time. Having found the cost of fencing my own run to be too great

* In a letter to the Secretary of the Commission, dated April 19th, 1888, Professor Watson stated that the effects of the *sarcoptes* on marsupials, dogs, cats, horses, goats, and oxen, had not to his knowledge been tried in South Australia.

great, I commenced the use of phosphorized wheat and grain, and killed the rabbits off in millions, I might say. The dead rabbits were lying so thickly in the bends of the island that it was impossible to ride through. Even on the verandah of my house the stench was very great; but all I had done seemed to have no effect, and I saw it was hopeless to attempt to resist them. Mr. Catt himself came up and saw what was done and then went to Victoria to invite that Government to do something. We then gave up doing anything there. I had on that run something like 29,000 sheep the year before; and they died off in hundreds for the want of grass. The rabbits destroyed every bush that a four-legged animal could eat. The Commissioners might go through and not see anything but dead scrub so far as the eye could reach. The sheep were reduced from 29,000 to 3,200 on Ned's Corner, the next station to Paringa. On these two stations 147,000 sheep were shorn in one year, which was afterwards reduced to 20,000. I could not now tell from memory the amount of money we spent in poisoning and resisting the rabbits.

497. *Professor Allen.*] What is the area of Paringa and Ned's Corner? About 1,700 square miles. During these two years we worked principally with poisoned grain, but we did not then fence.

498. What do you think would be the cost per year of your operations when you were in full work? I think something like £3,000 on the two stations; that is in poisoning and in labour. It is about three years since we commenced wire-netting, and we have carried it steadily on to completion. The best of the country facing the river was enclosed in a ring-fence and included about 1,100 miles of country.

499. *The Chairman.*] What kind of fencing? Wire-netting about 4 feet wide, 16 gauge, and 1½-in. mesh, 6 inches in the ground. The wire was put into the ground vertically. The result of this was very good indeed. If I had only known that so much could be done by putting the netting 6 inches in the ground, I would have done it years ago. I then knew what Mr. McFarlane had done, but it was too late. This fence is effective in checking rabbits, but then all the useful shrubs had been killed. We finished our fencing in March, 1886; in 12 months after that time I rode through Paringa all one day and I saw but one rabbit. We had been finding out that the rabbits would not use the poisoned grain well. We then knocked that off and started trapping, thinking of keeping the remainder of the rabbits down by this means. Last winter was a good one and the rabbits increased, although they certainly were not coming through the fence. But it is a big area of country, and very scrubby. Now, in six months, there are quite as many rabbits there as before—quite enough to destroy the country. I went up last September, and saw the effect of trapping. We put men on, and at one particular place a man and his family, who were not worth 6s. per week, made £50 per month; yet there were as many rabbits there at the time as when he started. I therefore came to the conclusion that the thing should be knocked off. I could see that the trappers were killing the natural enemies of the rabbit—the iguanas, wild cats, crows, hawks, and others. They killed the crows because they destroyed the ears of the rabbits, so that the trapper lost the scalp for which he was paid. So long as we give a premium for trapping my conclusion is that the trapper will continue to farm rabbits, as I know they are doing now. I think the best method of destroying rabbits (trapping I think should be done away with except where the land is fenced) is with poisoned grain. You can then destroy the rabbit itself. All efforts should be made to destroy the rabbit, but not the rabbit's natural enemy.

500. *Professor Allen.*] Have you any clear idea as to the best method to go to work? We have found that poisoned wheat, distributed by Messrs. Lascelles and Anderson's machine, is a great success. It stirs the ground up, and the rabbit always runs to fresh turned-up ground. I have also found that since we have fenced, our rabbits have colonized. There are certain parts of the country which they like, and there they settle down. This makes their destruction much easier. Where rabbits are concentrated you can deal with them, colony by colony, with much greater facility than otherwise. Rabbits are always on the move—they seem to be constantly travelling. What makes them so bad in our part of the country is this—they came up into an elbow of the Murray and could not get away. They have come through from the scrub and they stopped there. They actually ruined our country, and have done more harm than where they could get away. If you fence in the rabbits they settle down and colonize, and you can then get at them by poisoning. This is the effect at Ned's Corner and Paringa. As I have said, rabbits do colonize when they get a fancy bit of country, but otherwise they are always on the move. If you fence them within a couple of hundred square miles of country they will settle down on a certain spot and give up travelling.

501. How large a block do you think you could deal with effectually without subdivision? It depends on the nature of the country. In scrubby country I think the subdivision should be made on all blocks. But this will not pay the cost—the country is not good enough for it. It is hopeless in scrubby mallee country to look for the extermination of rabbits. If you had good open country it would be different.

502. But yet even in that mallee country a fence would still be of great value in checking fresh inroads? No doubt about it. I would not attempt poisoning, and would give up all hopes of attempting to kill them off without fencing.

503. *The Chairman.*] Are you satisfied with the mesh of netting that you are using? I am satisfied with 1½-inch mesh, but anything larger would not do.

504. *Mr. Lascelles.*] You have only put up this one sort of fence—48 inches wide, 1½-inch mesh? Yes, but we have nearly 200 miles fenced in that country. I have put up also 3 feet netting, 1½-inch mesh, at the same place as a partition fence. I found that fence a good barrier equally with the other, so far as the rabbits going through it; but I really believe if the rabbit gets close up or is frightened he will jump it. If it is to be a ring fence I would put up nothing under 3 feet high.

505. Have you ever had personal knowledge of rabbits jumping over a 2 feet 6 inch fence? Yes; and I could show you where it was done. Of course I never saw a rabbit jump that height under natural conditions. Still, I think such a fence is too low—too low for a ring fence; but it would be useful for subdivisional purposes to bring the rabbits together.

506. *Professor Allen.*] Have you had any experience in dealing with mesh of 1½ inches? Yes, I have; and we found some of the rabbits get through it. Some of my fences ordered are 1½ inches, and some of them 1¼ inches; and I have known many rabbits that would easily get through that mesh.

507. In dealing with large areas of poor land, surrounded by thickly infested country, do you think the Government of any colony should insist on the use of a 4-foot fence and 1½-inch mesh? No; I think it would be rather hard. I do not see why the fence should be 4 feet high.

508. Do you think the Government should insist on any fence at all being used in such lands? Well, perhaps it would be a hardship to do that; but I look at the matter in this light: A man who takes

takes country up must fence it; and if he cannot afford to do that he had better leave the country alone. It is the business of the Government to see that the land is fenced, if they want it to be of any use to the State; and I am sure you can do nothing with a rabbit-infested country unless you have it properly fenced. I can see that the rabbits are largely increasing with us and getting worse—they are becoming a greater danger every day.

509. *Mr. Quin.*] Do you think, from your own knowledge of the country, that the tenants could fence the land, with advantage to themselves, under the present tenures? I do not know about New South Wales, but we could not do it here under our present tenures. Most of our leases are now running out.

510. *Mr. Pearson.*] Can you say at what height from the ground rabbits will go through a fence? Just close to the ground; they do not climb.

511. So that if there were a narrow mesh about a foot out of the ground, a larger mesh might do above that height? There is no doubt about that. My idea was to make a dog and rabbit-proof fence. For the first 2 feet the netting should be $1\frac{1}{2}$ inch, and for the remainder the mesh ought to be 2 inches. You could have a wire on top, and then the fence would be dog and rabbit proof.

512. *The Chairman.*] Have you had some of Professor Watson's diseased rabbits? Yes. I got them last November. They were infected with scab. I took them down and put them in a small enclosure about four times the size of this room, about 50 feet square. It was paved on the bottom. I put other rabbits with them, making at the first start about twelve. I also put in a sheep with them. The original rabbits all died within six or seven weeks after my getting them. None of the fresh ones died; but some of them were very young, and most of the young ones died. Some two of the young ones lived till they were about six weeks old. I cannot say whether or not the others were born dead.

513. *Mr. Lascelles.*] Do you think the conditions of that enclosure were suitable for rabbits that were in young? Well, in one corner I had placed a lot of earth, and a portion of the place was covered as a shed, so that they could go in out of the cold. I sent away two of the diseased rabbits with two fresh ones I had put in with them. I had another enclosure made 100 yards square, with sand hills and bushes, and put in fifty wild rabbits with them. They were all turned out about the 15th December, and one of the original ones died a few days after; another one died very shortly afterwards, but as to the other two I cannot say that they died. It appears that the wild rabbits that were put in bred a little at first; there was no doubt that some of them were in young. There has been no breeding since the first crop, and in April my boy wrote me to say that the rabbits were infected with the disease. He had taken ten out and turned them into an island containing about 10,000 acres of land. He sent on four to Ned's Corner in the steamer, but one died almost before the steamer left the place. I have not heard anything further about them. Then, curious to relate, I am told in the same letter that they intended to turn out ten more on to another island, and that these recovered, not having contracted the disease at all. Thus it would appear that the disease has died out, but I doubt it. Last April we had another batch of twenty rabbits, and they died off down to twelve. On examining the rabbits I could see no signs of disease, though a lot of them were wretchedly poor and miserable. There seemed to be a little scurf here and there, but I do not know whether it is a disease. One of the rabbits showed all along his nose what was evidently scab, and was wretchedly poor like ours.

514. *The Chairman.*] You have not taken any of these rabbits to be examined? No. I have now seven, and out of the seven two are as healthy as can be. The other five are miserably poor, although they get good grass and feed. I cannot explain the reason for this difference in condition. Sheep are running there with them, and have not caught the disease. There is no breeding in this enclosure of 50 feet at Glenelg. I have not much faith in the disease; I do not think it is fatal enough.

515. *Mr. Quin.*] Could it not be applied again and again? I doubt it. I think that in Tasmania, Victoria, and New Zealand the disease would be very useful, but I do not think it will be any value in our north country. I think Riverina also is too dry for it.

Andrew Smith called in and examined:—

516. *Professor Allen.*] Where do you reside? At Netley, Paratoo.

517. What is your position? I am manager for Elder, Waite & Co.

518. Will you state shortly what you know of the rabbit plague on the Paratoo? It is as bad as it can well be. The rabbits first appeared on the Paratoo run, at Netley, about five years ago; but at Paratoo proper they were found eight years since.

519. Have the rabbits been spreading very widely during recent years? Yes. They have decreased the carrying capacity of the country by about one-half during the last two years. They have eaten every vestige of feed off during the last twelve months, and also damaged the bushes, which are dying. The cause is the ringbarking of the bushes by the rabbits.

520. Can you say what has been the expenditure per year in dealing with the rabbits in your district? I cannot give any idea on that head. Nothing is being done just now because the leases fall in this year, and we can do nothing except experiment with the rabbits.

521. What measures were first applied? We put men on and paid them so much per scalp. That system was discontinued about eighteen months ago. It was no good, because as soon as the rabbits got scarce in one place the rabbiters shifted to another part; and while they were away the remaining rabbits multiplied again until the pest was as bad as ever.

522. Do you think there has been any other evil attendant on the operations of the rabbiters, beyond the fact that they became inefficient through their shifting from one place to another? I am not aware of any other.

523. Were the rabbiters responsible for killing any large numbers of the natural enemies of the rabbit? Yes; they killed eaglehawks, cats, iguanas, and crows. The Government paid them for killing eaglehawks and wild dogs.

524. Do you think the rabbiters really attempted to exterminate the rabbits? No, I do not.

525. What next was tried when the system of rabbiters was abandoned? We put men on to send the skins to Adelaide for a time, but that turned out a failure; because it did not pay the men, and we could not keep them.

526. Were any other measures tried? There were no other measures tried except experimenting with different kinds of poisons. This was done on a small scale, and simply as an experiment.
527. Have you any evidence which you would like to give regarding these experiments? Yes. The first thing I tried was in an orchard of 3 acres. I put some strychnine on peaches, and killed 500 rabbits in two nights. Then we extended the experiment to apples; from apples to peaches, and then to olives and sandalwood bushes. We tried the latter with arsenic, and it was very effective.
528. What general result did you get with these experiments—which poison was the best to use? Strychnine. It was the quickest and the best. We also tried it on peaches and apples, and found it good. Peaches are the best for strychnine. We merely ground it up as fine as flour and spread it over the fruit.
529. Have you tried this poison with the natural food of the rabbits? No; only with the sandalwood. I have tried poisoned wheat as well, but not sufficiently to ascertain whether the rabbits liked the change of diet.
530. With regard to rabbit-proof fencing, have you used that largely? Not largely. We have enclosed only 3 acres at present on that part of the run with which I deal. It was commenced in November of last year. I have three acres of garden completely enclosed. The fence we have used is 30 in. wide, 1½ in. mesh, and 17 gauge. It is 30 inches in all with 6 inches in the ground. This fence was put up to keep the rabbits out of the garden. The land around was very thickly infested. No rabbits have got over or under that fence.
531. *Mr. Lascelles*] Were there any means by which the rabbits could get in to that garden? No; except by a flood. About four months after the fence was put up we had a flood and twenty trees were destroyed. On another occasion some rabbits jumped across the fence through getting on a log that was close to it. There is an ordinary wire fence, 6 feet high, and the netting is attached to this. The first wire is 10 inches above the top of the netting. I have had no experience of rabbit-proof netting apart from this.
532. From your experience of this particular case, what kind of fence do you think would be satisfactory as a boundary fence? The same mesh, perhaps 6 inches higher; and the same fence exactly for subdivisions. I mean 3 feet for boundary-fences with same mesh, and 2 feet 6 inches for subdivisional fences. A larger mesh might let rabbits out, but I am confident this will keep them in.
533. *Mr. Pearson*] What is your reason for making the boundary fences higher? I would recommend it for extra safety. I have seen them go over fences such as I speak of, and they might do so again; I think the fence should have also two barbed wires on top, so as to constitute a dog-proof fence.
534. *Professor Allen*] Have you had any experience with rabbit scab? Yes; I obtained some rabbits from Professor Watson on the 28th November. The first rabbit I got showed a little scab on the head, but not on other portions of the body. I put it in a box with three others and took it to the station and allowed the four to go into a yard 30 yards square, where twenty-five other rabbits were confined, and we are keeping them together still. I got another diseased rabbit from Adelaide on the 26th January, and allowed it to go with the others. On the 26th February one rabbit died from injuries caused by our catching them to make an examination. On the 1st March another died, and on the 5th still another. These rabbits did not show any signs of the disease at all. The condition of the other rabbits in the enclosure is very good. Their skins are sleek, and they look well. The rabbits thus retained have not been breeding. Until this last two months they have had no chance to burrow, because I had the burrows dug out. I put bushes in the yard to shelter them. From December to May, while there is no green food, wild rabbits do not breed, as is proved when they are captured and placed in small enclosures. I have not had experience on this point myself, but I have heard it as a fact on what I consider good evidence. The fence around this enclosure was 1½-in. mesh, 30 inches wide, double width, sunk 6 in. in the ground. The extra width was employed to prevent the dogs from jumping in.
535. *Mr. Pearson*] You say you got several rabbits supposed to be diseased. What became of them? They are all alive in the enclosure. They show no signs of disease now. After the second rabbit came the whole twenty-five showed that something was wrong with them; their fur stood up, and the animals looked very miserable. The second rabbit appeared to be very much diseased. It showed spots on every part of the body, and was much worse than the first one I took up.
536. *Mr. Lascelles*] Was it rainy weather when these rabbits looked bad? Yes, it was cold weather.
537. *Professor Allen*] You spoke of having obtained the rabbits from Professor Watson? I obtained the first rabbit direct from M. Marceau, and the others from Elder, Smith, & Co.

Herbert Bristow Hughes called in and examined:—

538. *Professor Allen*] Where do you reside? At Pirie-street, Adelaide. I have station property at Menindie, on the Darling, in New South Wales. In South Australia I have property at Booyoolie Gladstone post town. This is freehold land. I have also station property at Neckatunga, near Thargomindah, in Queensland—a cattle station which is not yet rabbit infested. One half of my property at Menindie is leasehold, and the other is what is called a resumed area; my South Australian property is freehold. In this Colony we have not been troubled very much with rabbits. My property in South Australia is so situated, as regards water, that the cats can travel from the one river to the other.
539. You then attribute your protection against rabbits to the favourable circumstances under which the natural enemies of the rabbits are placed? Yes.
540. How far off is your property in South Australia from any thickly infested district? I suppose about 50 miles. There is thickly infested country to the eastwards of us. I have not adopted any special protection against rabbits in that district—I never had occasion to. At one time, a place about 30 miles distant from us, at Booborowie, was badly infested and men had to be employed to kill the rabbits, and since then I have never heard of any trouble from rabbits there. This was about seven or eight years ago. I was speaking to Mr. Drew, of the Burra, and he said that they were then so thick that you could sit in a bush all day and shoot them until your ammunition was expended, and now they can go out without seeing a rabbit. My Menindie property is very thickly infested from one end to the other; the effect on the carrying capacity of the station has not been very much. About five years ago we noticed some rabbits in a bend of the river, and were quite satisfied that they had been put there by one of the steamers. We did our best to destroy them and we thought we had done so. Two years ago they

they came on the Darling and have since increased like magic. I think this was by the invasion from other districts—they came up from the south. I am satisfied that the original importation was by wilfully placing them on the runs. During October, November, and December of last year, we killed 342,000 rabbits, as this document will show:—

MENINDIE STATIONS.
RABBIT Report for Quarter ended 31st December, 1887.

Month.	Number of men employed.	Number of skins delivered.	Rate of bonus paid.	Amount paid.	Amount expended for quarter.	Rate of subsidy claimed.	Amount claimed as subsidy.	
1887.			each.	£ s. d.	£ s. d.			
October	95	102,671	3d.	1,283 7 9	} 4,278 13 9	13s. 4d. in the £, equal to ½rds.		
November	108	133,342	3d.	1,666 15 6				
December	107	106,282	3d.	1,328 10 6				

We had really no serious trouble with rabbits until two years ago, and practically during that time we have expended £10,206, in addition to the amount voted by the Government.

541. What remedies did you first try? We first tried shooting and trapping. It was first insisted on that we should trap the rabbits. We had then 107 rabbiters, each man with fifty to twenty traps; and you can imagine the state the sheep on the run were in at that time.

542. Was there any other way of obtaining help from Government except by claiming on account of the number of rabbits trapped? No; no other would be recognized. The Government would give no assistance except in regard to trapping operations. The skins were always brought in, counted by the Inspector, and then burned.

543. What is your opinion of the real value of the work done by the rabbiters? It is of no value whatever. I am well satisfied of that. The number of rabbits did not sensibly decrease by their operations. We have been always under that opinion.

544. Do you think from what you have seen that the rabbiters had no intention of causing the pest to decrease? No; none whatever. It was nothing unusual for these men to say: "We must leave this paddock, we will come back in a month or two when there are plenty more rabbits there."

545. Do you think that those rabbiters were responsible for any large destruction of the natural enemies of the rabbits? Yes, and if they could get hold of a good sized tom-cat and kill it, it was a great feature to them. It was the same way with crows and hawks—if they could kill them they would do so.

546. Then the rabbiters did not intend to produce any diminution in the rabbits, but caused the destruction of a number of their natural enemies? Yes; this is my impression. Some time since I went to Sydney to claim the subsidy, and I told the Government that the best thing they could do was to shelve the Rabbit Act and to leave us alone.

547. Have you adopted poisoning on any large scale? No; but we have tried it at various times. We applied the system of throwing out phosphorized wheat. Mr. Riddoch is doing it on a better system, and we will adopt his plan in future. I have not adopted rabbit fencing at all. I did not know what to do. The Government got hold of us, and we were asked to pay a rent more than four times what we had a right to pay. We are now in charge of Inspectors; and, in fact, we do not know what to do. Our money is going to pay for fences I do not need.

548. What is the carrying capacity of your run? It will take a sheep to about 10 acres. At present I am not adopting any means of destruction, because I cannot see any way. The only means we have to adopt is the phosphorus.

549. What has been your experience with the rabbit scab introduced by Prof. Watson? My experience, so far, has been most unsatisfactory. I paid my money like other people to get the diseased rabbits. I got them, and put them with others, but all of them died. They were placed on a large barge on the river, and every one of them died. I found no spread of the disease, and I think it is an utter failure. I obtained two rabbits directly from Prof. Watson, and placed them in a wooden hutch, but the experiment was an utter failure there also. The real *sarcoptes* is so small that I could not see it without a microscope. There is no doubt that when first brought from Prof. Watson's the rabbits were diseased. Mr. Stanley, the Government Veterinarian from Sydney, examined them and said so. I can only say in conclusion that I am in doubt how to deal with this frightful pest. The men on the station are utterly demoralized owing to the large sums made by the rabbiters. We have had as many as 107 rabbiters with traps, with about sixty to each man, besides the men employed to look after the sheep. I may add that the summer weather has had a frightful effect on the rabbits. They have been dying out by hundreds of thousands—some say from Butcher's disease, and others from some disease that has appeared before on the Murray.

550. Mr. Quin.] Could you have carried on the system of trapping and scalping, such as has been done for the last two years, and make your run pay at the rent insisted on by the Government of New South Wales? No; decidedly not.

George Riddoch called in and examined:—

551. The Chairman.] Where do you reside? I live in Adelaide, but I have property at Weinterriga, in New South Wales; and at Glencoe, and Mount Gambier, in South Australia. The latter is freehold, but Weinterriga land is leasehold. My experience with rabbits commenced about thirteen years ago, on property in the Swan Hill district of Victoria. There was a small number in the first instance, but they increased in about two years after that time in such an extraordinary way that they devastated the country. I poisoned them with phosphorized grain with great success. I got the receipt for making up this stuff from an American paper. I used 1lb. of phosphorus to 100 lb. of wheat. The phosphorus was put in water and allowed to stand at night, and in the morning a quantity of flour was put in. It was then eaten by the rabbits, and I found that they died in great numbers from it. In that particular

particular place it reduced the number to such an extent that when I scoured the place afterwards there was, comparatively speaking, only a few rabbits on it. The value of the run was, however, depreciated from about £30,000 to £8,000. I succeeded in killing the rabbits, but the country was so injured that it did not recover for some time. My next serious experience with rabbits was at Weinterriga. Five years ago—I think I am safe in saying—there was not a rabbit on my place. It is a sheep station, and I heard at that time that there were rabbits within about 100 miles of me. I gave instructions that patrollers were to be put on and the rabbits to be watched for. The men were told off simply to watch for the rabbits and discover them as soon as they appeared on the place. After a time traces of them were found. I paid the men thus employed £1 per week, and 2s. 6d. per head for every rabbit. I continued from that time to use every effort to discover the rabbits and kill them. From time to time we had to reduce the rate which we paid for killing. Our really serious trouble began last year (1887). In the month of January of that year we had 100 men employed; they trapped 29,000 in that month alone. We kept 100 to 125 men constantly employed during the whole year doing everything we could to keep the rabbits down, but in spite of this they had increased by December, 1887, to something like an average of 140,000 per month. Judging by the numbers which we got on the run the rabbits must have increased five fold. We killed altogether on Weinterriga something like 1,250,000 of rabbits, costing £12,500 inclusive of the Government subsidy; our share, of course, being quarter of that sum, together with the cost of supervision. I represented to the Minister for Mines in August last that this method of destroying the rabbits was a very costly and ineffective one. I asked to be allowed to use other methods, and I understood that the Minister for Mines gave his sanction to my doing so. I sent up an experienced man with the necessary appliances to use bi-sulphide of carbon. By this method I reduced the cost of killing the rabbits to about a quarter of what it had been before. But when I made application for the subsidy of three-quarters of the cost, I was told that I would only be allowed three-quarters of the cost of the material without any compensation for the cost of application. I may say that the Government have since then refused to give me even that. Since that time I have been using phosphorized grain produced by Raymond's machine for mixing the grain and phosphorus, and Lascelles and Anderson's machine for depositing it. The results have been satisfactory in most cases, but in other cases it has not been so, and I blame the quality of the phosphorus for the want of success. The rabbits eat phosphorized grain invariably, scarcely any of it being left after the first day. I have tried arsenic and other poisons and found that the rabbits did not eat them so readily. I am now trying an experiment of putting arsenic in with the phosphorus, and thus making good the deficiency in the killing power of the phosphorus.

552. Have you had any experience in connection with rabbit-proof fencing? Not very much. I have 50 miles on my place ready to put up, and 150 miles ordered from England. The first 50 miles was 17 gauge, 1½-in. mesh, and 42 in. wide. After the regulation issued by the Government in February, declaring that nothing larger than 1½-in. mesh would be allowed, I ordered another 100 miles of 1½-in. mesh with the same gauge and width, and for the remaining 30 miles I ordered 30 in. wide, 17 gauge, and 1½-in. mesh for subdivision fences—temporary fences to shift about from place to place.

553. *Mr. Lascelles.*] Supposing you erect these fences and find that at the end of twelve months 1½-in. mesh is as good as 1½-in. mesh, will you complain of the action of the Government? I should have very good reason for doing so. I would have been satisfied with the 1½-in. mesh if I had been left to my own judgment. I only ordered the 1½-in. mesh to comply with the conditions imposed by Government. I did this to entitle me to compensation, and in order that I might obtain certain advantages under the proposed legislation.

554. Now, as to the difference of cost? The 1½-in. mesh costs me, delivered in Adelaide, £22 per mile. The 1½-in. mesh of which I have ordered 100 miles, and 10 miles of which have been delivered, costs me £26 10s. per mile in Adelaide. I may state that I ordered this early for the sake of getting it at a low price, and with quick despatch. The difference in the cost of freight may increase the price of the balance of the 1½-in. mesh ordered. I am now in a difficulty as to the erection of the netting that I have already obtained. I have appealed to each of my neighbours in turn to join with me in the erection of the netting along the boundary-fences, and they have all refused, some giving one reason and some another. The chief excuse is, that if the netting is put up on my boundary-fence it will prevent the rabbits travelling on to my run and away from them. Another difficulty is the want of security of tenure for that portion of my run where the rabbits are worst. I refer to the resumed area, which is the southern part of my run and adjoining runs.

555. Do you think a law should be passed compelling owners to join in erecting netting fences in rabbit country? Certainly; I think if wire netting is to be put down at all it should be made compulsory on each man to pay his share. It is absolutely necessary to do this, no matter what other means may be adopted.

556. *Mr. Pearson.*] Have you had any experience with wire netting of 1½-in. mesh? No; except with the few miles I have put up lately. On both sides of the wire-netting there were traps which the rabbits had to pass in getting through the fences. The men who are going backwards and forwards with the dogs found numbers in the traps and the dogs killed them. They were lying about in all directions.

557. *Professor Allen.*] Have you had any experience with Professor Watson's disease? Yes. I have seen the diseased rabbits, and I was present when the attempt was made to communicate the disease to sheep, which I afterwards examined very carefully. On one occasion I found a small fistula and slight discoloration in the skin, as if there were some foreign matter there. On examining the same sheep a second time I could find no signs of the disease. The conclusion I came to was that the insect had caused some irritation, but that it was not able to live on a foreign body and had died. I again examined the same sheep and found no symptom of disease.

558. Have you any experience with regard to the spread of disease from one rabbit to another? Not more than what I gained on infested ground. I have had no part in any subsequent trials with the disease since Professor Watson parted with the rabbits. But I have just returned from Tintinallogy, and also saw the diseased rabbits in Dr. Ellis' charge in Sydney. It was afterwards that I saw other diseased rabbits with Dr. Butcher at Tintinallogy. So far as I could see, the disease affecting the rabbits in Sydney and at Tintinallogy was the same. I found also that rabbits were dying in considerable numbers at Weinterriga, which is on the opposite side of the river to Tintinallogy. Other rabbits were in a very weak state—so weak that numbers of them could be easily caught by a man on foot. I caught several of these rabbits and they presented the outward appearances or symptoms shown by the rabbits in charge of

Drs.

Drs. Butcher and Ellis. On examination I found that the only organ showing signs of disease was the liver. In all cases thus examined by me the liver had white spots or streaks upon it, and was more tender than in rabbits in a healthy state. The only other sign of disease was the emaciation. I saw no scabs on the surface of the body, though there was a slight scurf on the skin. I opened some of the rabbits and examined the intestines, and the heart, and lungs, and liver. There was nothing to indicate the presence of any cheesy matter.

559. Could you satisfy yourself that this disease was really killing off the rabbits effectually? Yes; I found a very large number of rabbits dead on my place. I did not introduce the disease, though I have done a little towards spreading it. We found it on our place and to a certain extent we utilized it. The disease first appeared on Weinterriga at a point some distance away from the river boundary opposite Pintinallogy. A large number of the rabbits that were weakly on my first visit were dead when I went back again. The first appearance of the disease on Weinterriga was about two months ago. I have seen no disease in sheep or other animals to correspond with this disease. It is now scattered all over a large area of country.

560. *Mr. Lascelles.*] Did you notice any results from the spread of the disease that you had? I could hardly say. I was not there to watch experiments. We had the disease with the hope that it would spread, but I cannot possibly say that it has spread. I feel so satisfied that this disease will be a very great boon to us, and such an aid to get rid of the rabbits that I would be very sorry to see it run out. I was afraid it was an epidemic that would run out, and I think that the Government should take steps to keep it alive in the meantime. Of course we cannot ask Drs. Butcher and Ellis to keep it alive at their own expense. I do not think that it was eating the bark which killed the rabbits on Weinterriga. I found the rabbits dead in great numbers on open country where there is no bark, and I found them alive and well in country where the bark had been stripped.

Peter Waite called in and examined:—

561. *Professor Allen.*] Where chiefly is your property situated? I am a member of the firm of Elder, Smith, & Co., and we hold Momba, in New South Wales, and Paratoo, in South Australia. These are leasehold properties.

562. When did you first become personally acquainted with the rabbit plague? About eight or nine years ago, on Paratoo. As long as I have been acquainted with Paratoo rabbits have appeared from time to time; but they never increased, having been kept in check by other animals. About ten years ago a strip of freehold country, from Kapunda to Canowie, became infested with rabbits, and the Government passed a Bill compelling owners to destroy the rabbits. The rabbits were destroyed on those runs, being hunted by dogs, destroyed by bisulphide of carbon, and shot. The result was that the rabbits at once came upon us like a wave. They kept moving ahead, and over-ran our country to such an extent that I was compelled to begin to kill them in 1882. The measures we first adopted were phosphorized grain and bisulphide of carbon. I obtained very good success with these. The country was then resumed; we were given only a yearly annual lease, and we refused to do anything. This resumption took place in 1880, and the land was taken away or selected immediately after we had destroyed the rabbits at great expense. Then after that a scalping Bill was passed, the Government giving 2d. per scalp, and the country was rated at so much per 1,000 sheep, so much per 100 head of cattle, and so much per square mile. A small army of rabbiters thus came into existence. That went on for two or three years, but no satisfactory results were obtained. Independent of the amounts levied on the different districts, it cost the Government of South Australia last year for scalping from £90,000 to £100,000. Then they stopped dead and refused to go on any longer. In some places the rabbits were down pretty low, and in others, the trappers stuck to the thickest spots, and sent rabbits all over the country. The Government then spent some £35,000 on rabbit parties, and with dogs, and bisulphide of carbon. In about six months this money was spent, and nothing has been done since.

563. What results were obtained by these parties? So far as I know there has been no result. Large numbers of rabbits were killed, but some were left behind to multiply. It was the rabbit parties that first drove out the wave of rabbits on us. In all probability if the rabbits had been killed some other way than by dogs this wave would not have come out. At all events had there been rabbit-proof fencing the rabbits would never have come out on us. The wave reached us first in 1880, and kept on coming. Since the trapping and the Government parties in 1884-5, we have done nothing except to experiment, as our manager told you. One of our experiments was a netting around a tank that was nearly dry, by which we caught 6,000 rabbits in a week. At another tank, which we netted, we got 1,100 rabbits in two days.

564. Practically your tenure was lost, and you abandoned operations with the exception of certain experiments which would be continued on a large scale if a more certain tenure was obtained? Quite so.

565. *Mr. Quin.*] Do you now hold that country? We hold it but we do not occupy it; we have had no stock on it for years, we hold it simply in order that we may obtain payment for our improvements at the end of this year. But for the rabbits and dogs this country ought to have had 140,000 sheep upon it.

566. *Mr. Lascelles.*] Have you had any experience with rabbit-proof fencing? No; excepting a small piece mentioned by our manager to-day. We put a 30-in. fence 1½-in. mesh around our garden; we did not find that many rabbits got over this fence. Only two got over; we found that they got over because of a large log that lay against the fence. I have had no practical experience with wire-netting on other runs. 567. In the event of leasing any of that country have you decided what height and mesh you would use? If I were left to myself I would use the 36-in. width, 1½-in. mesh, and I would make the fence dog proof by one or two barbed wires. This would be for the boundary fence. As to the subdivision fences I think a fence like that we have around our garden is quite enough; the extra 6 inches is more as a protection against dogs than rabbits.

568. Is there any Act compelling lessees to join with you in fencing in with rabbit-proof netting? Yes; there is the Act of last year—it has reference to leasehold land. There is no such clause in the new Act, that I am aware of.

569. *Mr. Quin.*] Would you feel inclined to fence in your property in New South Wales on your present term of occupation? No; I will wait for legislation. On the Momba property we have used the trap system until recently, and we have held that country or been interested in it since 1880. The rabbits first

came on to Momba many years ago, but their natural enemies kept them in check until about two years since. We found that trapping was the very reverse of a success. We are now using the wire-netting around the tanks and taking poisoned water out to dry spots that are thickly infested. We are also using arsenic dissolved with potash, phosphorized wheat and wheat steeped in arsenic dissolved in potash, and distributed by Lascelles & Anderson's machine. On Momba we chiefly use phosphorized wheat which so far has been successful.

570. What has been the maximum cost per year of dealing with the rabbits on Momba? I cannot say at this moment. I think last year the cost must have been about £13,000. In October I know we were spending at the rate of £3,000 per month. The pest kept increasing, the best proof of which is that when we reduced the scalp money from 4d. to 2d. the payments were greater than before.

571. What mileage of wire-netting have you ordered? About 150 miles. The width is 42 inches, mesh 1½ inches, and gauge 17. This was ordered before the regulation regarding 1½-mesh came out in the *Gazette*. I do not intend ordering any more—not until something definite is done. The netting which we have ordered will cost £27 10s. per mile at Wilcannia, to which we must add £3 per mile for duty, and £7 for cartage, making in all £37 10s. per mile.

572. *Professor Allen.*] Have you had any experience with disease? I can only confirm what my overseer has said about Professor Watson's disease; we have had no results from it.

573. *Mr. Lascelles.*] You think the tenure of your land is incompatible with rabbit destruction? Yes. I do not see how we can kill rabbits on the resumed area under our present tenure.

SATURDAY, 26 MAY, 1888.

The Commission met at 10 a.m., at Silverton.

Present :

New South Wales : EDWARD QUIN, Esq.

Victoria : HARRY BROOKES ALLEN, Esq., M.D.
EDWARD HAREWOOD LASCELLES, Esq.

South Australia : ALEXANDER STUART PATERSON, Esq., M.D.

In the absence of the President (Dr. MacLaurin), the Chair was taken by Professor ALLEN.

William Hogarth called in and examined:—

574. *The Chairman.*] Where do you reside? At Momba, Wilcannia. I am the general manager of the Momba Pastoral Company.

575. What runs are under your general management? Momba, Mount Murchison, and Purnanga. They include about two million acres of land. The property is generally leasehold, but there are some portions of purchased land; we have altogether about 7,000 acres of freehold. I have been in charge of this property about nine years.

576. Can you state when rabbits first appeared on this property? Yes; about 1883.

577. When did they first become a serious cause of mischief? About 1884.

578. What remedies did you first adopt? We first paid men wages per week and gave them a bonus for scalps. The method adopted was trapping and dogs.

579. Can you give us any information with regard to the number of men thus employed from year to year? They varied so that I could hardly give you anything definite. Sometimes we had 120, and then we reduced the number to perhaps 50 or 60.

580. How long was that system continued? From 1883 to the end of 1887.

581. Was any good result obtained from this system, in your opinion? None whatever.

582. Did the rabbits decrease or increase? They increased.

583. Is it a fact that the rabbits increased notwithstanding that vast numbers of them were killed, and large sums of money expended? Yes.

584. Do you think that the trappers employed in that way had any real intention to eradicate the rabbits? Some of them had; but others had not.

585. Do you think the operations of the trappers, in trapping and hunting, produced evil by spreading the plague? I do.

586. Are you perfectly clear on that point—that serious evil resulted? Yes. After I had knocked off trapping I found that the rabbits had accumulated in colonies and were much more easily dealt with.

587. The operations of the trappers, then, continued to scatter the rabbits, and prevented them from accumulating in colonies where they could be more easily dealt with? Yes.

588. Can you furnish us with any figures showing the extent and cost of operations thus conducted? I can do so for the year 1887 as regards Momba and Mount Murchison. Here are the particulars—

MOMBA AND MOUNT MURCHISON.

Rabbit Expenditure from January, 1887, to 31st December, 1887.

	No. of Rabbit Scalps.	Approximate rate of Payment.	Cost		
			£	s.	d.
January to March 31	51,762.....	5½	1,172	9	5
April to June 30	112,720.....	4	1,879	11	7
July to Sept. 30	300,291.....	3¼	4,449	15	0
October to Dec. 31	317,737	2½	3,287	13	4
	782,510		£10,789	9	4

589. Have you erected any wire-netting fences? Yes; a little—in all 3 or 4 miles. It is 3-ft. netting 1½-in. mesh, from 4 to 6 in. sunk in the ground.

590. Have you erected such fences around the warrens? Yes.

591. Have you had such experience in this way as would warrant you in pronouncing an opinion as to the sufficiency of such a fence? Yes. What caused me to try the experiment more than anything else was that I visited Tintinallogy station, and saw the rabbits running over the netting there, into small enclosures. This was 3-ft. netting and 1½-in. mesh also—though as to the size of the mesh I will not be positive. It was placed perpendicularly, and there was no incline. I saw half-a-dozen rabbits run over it; these rabbits were not being chased by dogs. It was a small enclosure and the rabbits were frightened at my approach, and climbed over the fence. They jumped at the fence and climbed up the mesh.

592. *Mr. Lascelles.*] Was the fence a perfectly straight fence, or was it roughly put up? Well, I should not say that it was the best fence that could possibly be put up; the wire was a little bagged. There was no wire on top to pull it up tight; so that I cannot say it was a first-class wire-netting fence.

593. *The Chairman.*] What experiments did you perform after using this? I was under the impression that netting would be of little use; and I took some of the worst warrens that I had, and put a netting-fence 3 ft. high, 1½-in. mesh around them; it was put 6 inches in the ground, and railed around to strain the netting upwards and keep it quite erect.

594. In this way you enclosed some thickly infested warrens? Yes.

595. What was the result? The rabbits all died of starvation.

596. So far as you are aware, did any rabbits escape from these warrens? I enclosed from twenty to thirty, and in only one case did the rabbits escape. They burrowed underneath in one place. This was the only burrow by which the rabbits could escape, and the reason of the escape was the bad method of erection of the fence.

597. Then in any ordinary case if that had happened the boundary rider would have closed up the burrow? Yes.

598. What general conclusions did you arrive at from these experiments? I have come to the conclusion that netting for boundary fences 3 ft. high, 1½-in. mesh, 6 in. in the ground, and properly put up, is sufficient to stop the influx of rabbits from any other part.

599. Was there good feed round this enclosure? Yes.

600. If a small rabbit could get through 1½-in. mesh, do you think it would be able to live and establish itself in its new home? I do not think so. I do not think there need be any fear of one or two small rabbits going through; not as regards the mesh. I think small rabbits would probably die or go back.

601. Allowing that a few rabbits could possibly get through, or under, or over such a fence, do you think that such occasional occurrences would be any justification for seriously increasing the cost of netting? No; I think it would not, because there are other sorts of danger—of rabbits coming through owing to floods washing the netting down.

602. This risk would be especially great in hilly country? Yes; where the flood waters come together.

603. How do you propose to meet that risk? I have never been able to solve that matter.

604. Do you think that any good result could be obtained by erecting fences, not necessarily along the borders of distinct properties, but following the contour of the country as far as possible, and settling difficulties that might arise about the properties so affected by arbitration? I am afraid that if a line were run along in that way a great many obligations would arise about killing our neighbours' rabbits.

605. Have you visited Tintinallogy to inspect the disease prevailing there? Yes; I went to Tintinallogy for the express purpose of seeing the results of the disease, and I took particular notice on my way down. I started in March last, and on my way saw nothing to speak of more than the ordinary death-rate until I got near the Tintinallogy boundary. After entering the run, and following down to the station itself, the dead rabbits increased.

606. Were rabbits lying about dead in great numbers? Yes; after I passed the head station I was taken to the enclosure where the experiments were being conducted, and I saw the precise method they were adopting. I saw rabbits there diseased; and, from all the appearances of their condition, they were in different stages of disease. While I was there several of them died. A non-professional man could see that they were diseased to a certain extent, but whether death was the result of disease or not I cannot say.

607. What did you notice for yourself? There seemed to be a lot of fluid around the cavity of the belly of one, and on another I was pointed out marks which I would not have noticed had they not been pointed out. I also noticed some little white specks on the liver. The general condition of the rabbits in that enclosure varied from the fat rabbit down to the rabbit that was merely a skeleton. There were no outward appearances in the live rabbit by which I could tell that they were diseased.

608. You noticed that a large number of the rabbits were merely wasting away? Yes; but I could not state whether the emaciation was due to disease or what it was. I did not take any part in the scientific part of the business, but went merely to see the results of the disease.

609. Did you see any experiments performed which satisfied you that the animals could be treated in the way recommended by Dr. Butcher, and would then waste away? I saw animals that had been treated, but I did not see any operation performed. I looked for the seton mark and found that they had been treated with something.

610. But did those rabbits appear to be wasting like the others? Yes.

611. Did you see any in which setons had been applied, but which were not wasting? I saw a few that had been treated a day or two before, but I could not detect much on them.

612. You then passed on beyond the main station? Yes; I instructed the driver to take me to where I pointed out. I did not allow him to choose the place where I was to be taken to. I then went into the bend and saw thousands of dead rabbits. I drove around for about three hours.

613. Were those dead rabbits in very poor condition? Yes. I may state that there were very fat rabbits and very poor ones living in the same bend. I caught a dozen of these poor rabbits while going around on foot. There was a fair amount of feed in this bend, but I would not call it plentiful. The feed was not, however, so scanty as to account for the emaciation and death of so many rabbits.

614. Did you notice in this bend or on adjacent parts of the run whether the rabbits had fed on bark or not? Yes; they had been feeding on bark.

615. Did you see any other parts of the country where the rabbits had fed on bark, but where no remarkable mortality was prevailing? Yes.

616. Does any remarkable mortality prevail amongst the rabbits on Momba? Yes; in one paddock there is. That paddock is about 120 miles from Tintinallogy.
617. What have you noticed in connection with this occurrence? From all outward appearances I should say that the rabbits were dying from the same disease as at Tintinallogy. There was the same marked emaciation, and the condition of the skin of the rabbits was the same.
618. What did you notice about the skin? There was nothing peculiar on the skin of the rabbits that died at Tintinallogy. I was referring to those that died in the White Cliff paddock.
619. How long has this disease been prevalent on Momba? About a month.
620. Could you give any idea of the number of rabbits that died from it, approximately? I should say there were thousands, but it is very difficult to give an estimate merely from riding through the saltbush country. They have so decreased that you can hardly see a live one, although the paddock was thickly infested before. This occurred over an area of about 35 square miles of country. That area is not shut off from the country around in any way.
621. Are you able to give any reason why the rabbits are dying on that part of the run, and not on others? None whatever.
622. Are you aware whether any rabbits with the Tintinallogy disease were imported into that district? I have no knowledge of it.
623. Do you think it possible? I think it possible, but I do not think it is very probable.
624. Is there anything else that you would like to tell concerning the mortality prevalent amongst the rabbits on that area? Nothing further.
625. Do you know by your own observation or from trustworthy evidence that mortality occurs amongst rabbits in other districts of New South Wales? Yes. I have heard from good authority that rabbits on Murtie Station, just across the river from Mount Murchison, are dying in hundreds, and that one of these rabbits was caught and taken to Dr. Butcher, who said it was the same disease which existed at Tintinallogy.
626. Have you any reason to disagree with that opinion? No, I have not.
627. *Mr. Quin.*] Did you open any of the rabbits that you found diseased on Momba? Yes, I opened some of the rabbits, and I should say that the appearances were, in my opinion, substantially the same as those which I saw opened at Tintinallogy.
628. *The Chairman.*] How far is Murtie from Tintinallogy? Between 50 and 60 miles.
629. Have you noticed some kind of scab on the rabbits on the Momba property? Yes? I noticed that in January and February. It prevailed over an area of about 40 to 50 miles. Rabbits with this scab have been found that distance apart.
630. Was it at all unusually prevalent in any part? It was at Purnanga Station, and over an area of a couple of hundred square miles.
631. What were the characteristics of this disease as you noticed it? A scab and a running out of the eyes and nose. The eyes used to appear to be running out of the head and making the rabbits blind.
632. Was it a quick or slow-killing disease? It was very difficult to tell. You might catch one of the rabbits diseased, but you could have no idea of the time of infection. It destroyed some of the rabbits very quickly; therefore I should imagine it was a quick-killing disease.
633. Do you think it killed in days or in weeks? I should say it killed in a few weeks.
634. *Mr. Quin.*] Did you notice any of the diseased rabbits breeding? No.
635. *The Chairman.*] Are you satisfied that breeding was checked in those scabby rabbits? No; I am not.
636. Did you send the skin of one of these rabbits to Dr. Stirling? I sent it to Mr. Waite, and I believe it was forwarded by him to Dr. Stirling. I believe that was the skin of a rabbit that had recovered from this scab disease.
637. Have you noticed any other disease amongst rabbits? No; I have not, nor have I heard of it.
638. *Dr. Paterson.*] Did the fur of rabbits affected with this disease fall off? Yes; the fur all came off on the patches where the scab existed. It came off principally all along the sides and belly, leaving entire bare patches without any fur at all.
639. *The Chairman.*] Did that disease kill off any great number of rabbits? Yes; it killed them out of Purnanga run very largely. The disease is not now in existence, to my knowledge.
640. *Mr. Lascelles.*] Are you allowed to keep any rabbits for experimental purposes, such as poisoning, &c., or using disease in enclosed areas? No.
641. If licenses for that purpose were given, would you avail yourself of them to make experiments? Yes; and I would have done so in this case if I could. I think it would possibly have been of some use.
642. What means have you adopted for destroying the rabbits since trapping was knocked off? I have been using phosphorized wheat, distributed by one of Lascelles and Anderson's machines. I have also used phosphorized oats, carbon, and arsenic solution, with potash for poisoning water. With the phosphorized wheat you do not see the result in dead rabbits, but you can thin them down and practically clear the country. With poisoned water I have poisoned 500 in a night, having had two small burrows opened two miles from where the poison was laid. The poison was put at the entrance to a well. I also put carbon in the burrows.
643. *The Chairman.*] What methods do you propose to adopt now? Well, I am in favour of the phosphorized wheat, and in dry seasons poisoned water, with the use of the carbon in the burrows in winter time.
644. Do you intend to proceed with wire-netting? I intend to go to work and fence in all my horse paddocks with netting and clear them of rabbits. I do not intend netting larger areas unless something is definitely settled about the Land Bill. At present I do not see why we should do anything on the larger areas. My reason for saying this is that our boundary is the leasehold portion, and as it is a zigzag line the cost of fencing would be very great.
645. Then without some secure tenure you regard the erection of any complete system of fencing as a thing impracticable because of the excessive cost? Yes; considering the present value of the country up here. It is not the same as country that would carry a sheep to 1 acre or a sheep to 2 acres.
646. Do you think you can hope to get the rabbit plague thoroughly in hand without the erection of wire-netting fences? No; I do not.

Arthur Torrens called in and examined :—

647. *The Chairman.*] You are a rabbit inspector? Yes, for district No. 36. I reside at Yandarlo, Wilcannia, and the stations in my district are Yancannia, Salisbury Downs, Monolon No. 5, Boota, Yantara, and Tarella. I have been on duty there for about two years. The south portion of my district is heavily infested with rabbits, and the north portion lightly. The district generally is known as a lightly infested district.

648. What methods of rabbit destruction have been chiefly adopted in your district? The chief method has been trapping, but of course that has been done away with now.

649. How many men were employed on an average per hundred miles as trappers when you were in full work? Taking the district from end to end I think I might say the average has been about forty-eight men to 700,000 acres.

650. In your opinion, what was the general result of the system adopted by the trappers? I think it was useless. A number of rabbits might be killed, but all the work had to be done over again. They worked from patch to patch, and when the first patch which they had left was filled up again by rabbits they went back.

651. With regard to the dispersion of the rabbits, do you think that trapping and hunting had evil results in that direction? Undoubtedly; you by this means disperse them into other districts.

652. So your general conclusion would be that although trappers killed vast numbers of rabbits, and although they received very large sums as capitation allowances, yet the rabbits were practically as numerous as ever; while the trapping and hunting tended to spread them over a wide tract of country? Certainly.

653. Have you had any special experience with respect to the poisoning of rabbits? No; I cannot say that I have. I have seen the work done at Tarella within the last few months with phosphorized wheat. I have had no special experience, either, with regard to rabbit-proof netting.

654. Did you watch the system of poisoning at Tarella, and form any opinion as to its efficiency? Yes; the grain is scattered through the largely-infested districts by Lascelles and Anderson's machine, and following its trail I noticed large numbers of dead rabbits. From what I saw there is no doubt that rabbits have decreased very considerably.

655. Do you think this is the best means of distributing poison? Yes; certainly the best method that I know of.

656. Have you visited Tintinallong? No, I have not. I have seen some poisoning at Terawcynia. They poisoned the branches of trees with arsenic dissolved in ammonia.

657. With what results? I did not see much result, having been there but a short time; but I believe the results to have been satisfactory. It seems to me to be an admirable idea. I think if this plan has not been successful the character of the poison used has something to do with the want of success.

658. *Mr. Lascelles.*] Does poisoning with twigs involve much labour? No. The twigs are broken off, stripped of their leaves, and then dipped in the mixture. The rabbits eat the bark and die.

659. *The Chairman.*] Have you noticed any special mortality occurring as if from disease in any part of your district? Yes; I think there are two diseases existing amongst the rabbits—natural diseases. One of them seems to me to be a sort of irritating disease; it is external. There is a scab under the eye and at the nostril, and around the back of the ears. The fur stands erect and in patches is gone. There seems to be a kind of dandruff or scurf, and also an irritation about the crutch; but of this I have not seen many cases.

660. Do you know of its existence at present? No; I cannot declare that it exists at present. I have no notion whether it prevailed over a large area or not; I have only seen a few cases in different parts—three cases were pretty close together and one was many miles away.

661. *Dr. Paterson.*] How long ago is it since you noticed this? The first case I noticed was between four and five months ago, and the last one is within two months.

662. *Mr. Quin.*] Have you seen the disease known as Watson's rabbit scab? No.

663. You say you have seen other diseases amongst rabbits? Yes. I refer to the disease which is so prevalent now. It was supposed by us to be a disease due to the eating of bark and to the absence of moisture. The rabbit gets miserably poor, seems to lose its strength, and cannot go any distance. You can get off your horse and catch them easily. That disease is very widely spread. I think where any rabbits are suffering in this way all the rabbits in that district are more or less affected.

664. Have you noticed the bark eaten away and the shrubs destroyed in any of the districts, and yet that the rabbits remain quite healthy? Yes; I have seen many healthy rabbits where the bark has been eaten down.

665. Can you then explain why in one district the rabbits are suffering from eating bark and in another district where the bark has also been eaten they do not suffer? No; but I consider that it depends a good deal upon the time which the bark has been eaten. It does not seem to affect them at once, but in my opinion it gradually kills them.

666. Then it depends upon whether the rabbit has other food or moisture besides the bark? Yes.

667. In what part of your district have you noticed this disease? I have seen it from time to time all through my district, extending in a direct line about 90 miles.

668. *The Chairman.*] In dry periods is it specially prevalent in one part more than in another. Does it prevail in some parts and not in others? Yes. I fancy it does upon the whole. In some parts you do not see it so marked, but my idea is that it depends upon how long the rabbits have been eating this particular class of food. I fancy the disease varies with the astringency of the bark and I think the rabbits suffer from a sort of constipation.

669. Have you made any experiments at all by feeding with bark? No; but I have opened hundreds of rabbits suffering from this disease and everything inside seems to be dried up.

670. Is there any accumulation of bark in the inside? Yes; a quantity. I cannot say that I have seen any obstruction in the bowels or alimentary passage except this, that the passage is very much shrunk. So shrunk is it that I thought scarcely anything could pass.

671. *Mr. Quin.*] So far have you seen any better mode of dealing with the rabbits than that hitherto adopted? No; I think not. I think what has been done at Tarella is very satisfactory, and if disease is not successful nothing will be successful except fencing.

The Commission adjourned.

MONDAY, 28 MAY, 1888.

The Commission met at 10 a.m., at Silverton.

Present:—

New South Wales: EDWARD QUIN, Esq.
Victoria: HARRY BROOKES ALLEN, Esq., M.D.
 EDWARD HAREWOOD LASCELLES, Esq.
South Australia: ALEXANDER STUART PATERSON, Esq., M.D.

In absence of the President (Dr. MacLaurin), the Chair was taken by Professor ALLEN.

Herbert Pickering Butcher called in and examined:—

672. *The Chairman.*] You reside at Tintinallogy, Wilcannia? Yes; I am a legally qualified medical practitioner.
673. What are your qualifications? I am a member of the Royal College of Surgeons of England, and licentiate of the Apothecaries' Society of London. The date of my qualification is 1879.
674. How long have you been in the colonies? About five years.
675. Have you had any special training in connection with diseases in animals? No.
676. Had you any special experience in connection with animal diseases prior to coming to the colonies? No; but I was brought up on a farm, and knew all the diseases common to stock at home, as far as a young fellow could know them, but nothing specially.
677. After your arrival in the colonies, when did you first commence to pay attention to rabbit diseases, or to methods for dealing with rabbits? Directly I came out to the colonies I went up to the Darling district, where the rabbits were just arriving. I saw the first rabbit caught at Tintinallogy.
678. Did you conduct any experiments with poisons? We started at that time poisoning with arsenic and grain, according to the Government regulations. I saw that done at the time; we used arsenic and sugar on wheat. That resulted in nothing, and trapping was then conducted for about two years; yet the rabbits were increasing in numbers. From conversation with Dr. Ellis I came to the conclusion that, sooner or later, a disease must spring up amongst the rabbits. This was in 1885, and we then agreed to watch for it; but I could not obtain leave to keep rabbits for purposes of experiment.
679. Did you formally apply for such leave? Yes, in 1886.
680. What kind of country is it in which you watched for this disease? There are all sorts of country on Tintinallogy—lignum, sand-hills, &c.—a very mixed country throughout—the usual squatting country of the Darling. I got permission from the Minister for Mines to keep rabbits for poisoning experiments on the 15th August, 1887, there being no idea of any disease. Three days after I obtained this permission I heard of a skin disease which was reported by Mr. Clarke, the rabbit inspector, on the back country of Billilla, which is the adjoining station to Tintinallogy on the north. I did not avail myself of this offer of the Inspector, because I could only obtain the skins of diseased rabbits, and not the rabbits themselves. He asked me if I wanted the green skins of the rabbits, and not the rabbits themselves. I went on with the poisoning experiments, and the result has been published in the Board of Health papers presented to you. The experiments were practically of very little importance, and on the 3rd September, 1887, I got the first rabbit affected with the disease of which we are now speaking.
681. When did you first perform experiments with this disease? Well, I watched the rabbit about a week before I tried to pass the disease on to other rabbits.
682. Were you aware of many rabbits being affected with this disease at the time, or was this an isolated case? This rabbit which I found diseased was caught for the purpose of poisoning experiments. It looked diseased to me, and I made an examination of it. It must have been very early in the disease, because this rabbit then presented what we now believe to be the early symptoms of the disease.
683. What was the general line of the experiments which you then conducted? Contact experiments.
684. For how long did these extend in the first instance? For twenty-five days. I had then orders to destroy the rabbits. A week after I got the diseased rabbit I reported the existence of the disease to the Minister for Mines; and it was in consequence of this report that the rabbits were all destroyed on 28th September.
685. What occurred subsequent to that? I went down to Sydney and interviewed the Minister for Mines, and again got permission to go on. The date of that permission is 4th October. It was granted on the 4th, but not written at that time.
686. Where did you conduct your subsequent experiments? In the bend of the river that we have been working in since.
687. Will you give a short description of that bend? This bend of the river is supposed to contain 500 acres. It is a narrow neck of land, fenced in with an ordinary wire fence, on which wire netting was placed.
688. Did you have that netting erected specially? Permission was granted by the Minister to fence off an area of country with rabbit proof netting, and to continue the work inside the fence.
689. *Mr. Lascelles.*] Did you ever find the rabbits swimming from that enclosure? Never; because they were never disturbed. I believe they do swim sometimes, when dogs disturb them. There had been no stock in this bend for four years when we started experiments.
690. *The Chairman.*] Have you kept stock in it since your experiments have begun? Yes; all the way through.
691. Why was this bend not used for stock before? The bend had never been required for actual use. It was intended as a spell paddock for horses. It was originally used for that purpose, and the fence had been up for fourteen or fifteen years. The feed there was in first-class order. There are lignum creeks in this bend, and box flats, but no red sand, which the rabbits are fond of.
692. At the time of your experiments was it infested naturally? It was the thickest portion of infested country in Mr. Clarke's district, according to his report.
693. Did the rabbits burrow there? There were not many burrows. At that time, the river being low, the rabbits lived in the water cracks in the banks.
694. Have your experiments gone on continuously since the date of that permission? When I obtained permission, I telegraphed up to Mr. Reid, my assistant, telling him to get more rabbits to work with. He got them, and they were, on the 13th October, put into a crate that I had used with the first experiments.

The

The crate had been previously used on the 28th September. For fifteen days the crate had been empty. These rabbits were ordinary rabbits, got from off the run. By the time I arrived home I had the disease going almost as it was when I was directed to destroy the rabbits. The experiments went on from that time up to the 14th May.

695. What persons have been associated with you in the conduct of your experiments? My partner, Dr. Ellis, principally; and Mr. Charles Reid, assisting in the camp; the Government Veterinarian, Mr. Stanley, Stock Inspector Tully, and Rabbit Inspector Clarke. The three Government officers have made formal reports on the subject of the disease.

696. Have official reports been made by any other persons in connection with the disease? I believe no one has any right to make an official report on the subject except those officers.

697. That is not quite an answer to my question. Has anybody else made an official report? I forgot—I believe Mr. Vindin was sent to Tintinallogy to make a special report, and I think he has done so. I did not see him when he was there.

698. Have many persons examined your method? Forty-one persons altogether have examined it.

699. Do you desire that evidence should be taken from any of them? I believe you have already heard Dr. Hudson and Mr. Riddock. I believe that several persons who have witnessed my experiments and the results obtained in connection therewith, will volunteer evidence at Tintinallogy. Having received permission to try the experiments on the whole bend, we released the rabbits on the 8th November, after having inoculated and ear-marked them. We released six first of all, but it turned out to be a failure releasing them, because the rabbits did not belong to the bend, and would not remain there. They worked their way on to the wire-netting fence and not being able to get over or through it, they died under it.

700. What was the character of that fence? It was an ordinary six-wire fence or 4 feet netting, 1½ inch mesh, 6 inches in the ground, and stapled to the posts.

701. Now, will you describe the symptoms of the disease? The first thing noticeable about rabbits affected with the disease is the appearance about the head, the discharge from the eyes, and a slight discharge from the nose, but very slight.

702. What was the appearance about the head? The fur seemed to stand upright and the eyes prominent. Whether that prominence is due to wasting or what, I do not know, nor have I been able to find out. But this is one of the early symptoms, occurring at a time when the general wasting is not well marked.

703. Are there any other early symptoms? At present none which I am certain are distinctly associated with the disease.

704. How long does this running at the nose last? Not more than from three to four days.

705. So that in three or four days these symptoms about the head are no longer noticeable? No.

706. What is the subsequent course of the disease? The rabbit's fur stands up all over him, and he wastes away, losing the power of his hind legs.

707. Is that loss of power in the hind legs marked before the wasting is very advanced? The rabbit tries to sit up on his hind legs very often. The first thing we notice is that when he tries to sit up he cannot do it and falls over. This is noticed about the ninth or tenth day.

708. How soon in the disease is the emaciation clearly perceptible? Certainly by the end of the first week.

709. Have you noticed any further definite symptoms clearly connected with the disease? No; except that when the rabbits die they expire with a scream, which you can hear a couple of hundred yards away. This occurs about ten minutes before death. They die in a sort of convulsions, but it is with a straight movement of the legs inward. They lie on their side; the fore and hind legs come together, and separate again in a kicking motion, the animals dying with their heads arched backwards. It is nothing like ordinary convulsions.

710. At what period does this usually occur? About the seventeenth day.

711. Does that apply to the natural disease as seen at Tintinallogy? That applies to the inoculated disease. The natural disease, we reckon, takes from twenty to twenty-one days.

712. What are the principal circumstances which influence the length of life of any rabbit affected with the disease? We found, in the case of inoculated rabbits, that a sudden change either to heat, cold, or rain, makes a difference of two days—it kills them two days sooner than they would die otherwise. We generally have more deaths after a cold night than at any other time.

713. With regard to the food available, does that make any difference? Not the least, so far as we can find out.

714. Does the original condition of the rabbit affect in any marked degree the result of disease with regard to death or duration of life? We have always picked out the best cases for our experiments—the fattest rabbits we could find—so that I can hardly tell you.

715. Do you think it is possible for rabbits to breed, having once got the disease? There have been no rabbits breeding since we started experimenting—after the first three weeks at least—that is on the whole run. We have never been able to get but one doe with young, and she was destroyed by Mr. Clarke, by orders of the Government, on the 28th September. This doe was fully diseased. We have found aborted young in different portions of the bend.

716. Have you found such abortions in great numbers? Well, they might exist on the run in ordinary seasons. I do not know whether it is a habit of rabbits in their wild state to slip their young, but I should think not; I cannot therefore say whether these abortions were caused by disease. We found them in the bend, but not elsewhere on the run.

717. Did you find several broods of aborted rabbits? Yes; and I found litters of dead rabbits, very young, that were dug out of nest burrows; but I cannot say whether they died from the disease or not.

718. *Mr. Lascelles.*] Up to what time of the year do rabbits breed on the Darling? They have never stopped altogether before. This year they stopped breeding entirely about November. We found no more nests after this.

719. *The Chairman.*] Have you found that any large proportion of rabbits recover from this disease? No.

720. In those that do recover, is convalescence a tedious process? Yes; it extends over months. Two rabbits that appeared to be getting over the disease were given to Mr. Reid's little daughter, and she was told she would get a reward if she made them fat. She gave them all sorts of feed from the garden, but was never able to fatten them; and I have them at the camp now. They are still alive; and I re-inoculated one of them just for the sake of experiment.

721. Will you now describe the *post-mortem* appearances, commencing with the external appearances, and then proceeding to the internal appearances? The first thing to be noticed is the harshness of the hair and
the

the extreme poverty of the rabbit. The head is drawn backward, and is very rigid. The whole rabbit, indeed, is extremely rigid, and on skinning it there is a peculiar mucous, glairy fluid, and we have called it sub-mucous, and used it for inoculation; but it is like as if the flesh were painted with gelatine. This is found between the skin and the carcase.

722. How with regard to the fat and muscle? There is no appearance of fat anywhere. The muscles individually are wasted away.

723. In one part more than another? No; not noticeably so. There is naturally very little muscle on the fore part of the rabbit.

724. And on opening the rabbit? On opening the rabbit there is generally found a fluid in the peritoneum.

725. In what quantity? As high as three drachms, and then varying to a few drops.

726. Is that fluid clear serum? Perfectly clear.

727. It is not, apparently, an inflammatory fluid? No.

728. What is the next appearance? The intestines and stomach were well supplied with food, showing that the rabbit was supplied up to the last; the coats are healthy.

729. Have you ever noticed an unhealthy condition of these coats? I have seen two cases of strangulation in the intestines, but that is all. In one case it was by intussusception, and in the other by a complete twist. This is out of some 4,000 *post-mortems*. Some of these *post-mortems* were, of course, made before I became acquainted with the disease. The liver was blackish-looking, very friable, but not increased in size. In some cases there were these white patches, of which I have never been able to get any history, varying in size from the head of a pin to the size of a pea.

730. Are there patches found on the surface and in the substance of the liver? Yes; both on the surface and in the substance, but generally on the under side of the lobes of the liver.

731. Have you cut across these little deposits? Many times; they contain a white, cheesy mass, so far as I can see.

732. Are you clear that such deposits are not found in all fatal cases? I am sure they are not.

733. Have you made a close enough examination to be certain that they are absent in any large proportion of the cases? For about two months—during February and March—I do not believe we had a single case with a marked liver, that is, a liver marked with whitish spots.

734. How many rabbits do you think you examined during these months? Roughly speaking, about four per day?

735. Have you noticed any marked alteration in the bile or gall bladder? The gall bladder is generally enlarged.

736. Have you been able to distinguish these specks clearly from any possible confusion with tubercle or with some septic mischief due to blood-poisoning? I can distinguish them clearly from septic mischief, but further than that I cannot say. I do not think they are tubercle, but I am not prepared to speak absolutely on that point. On the septic question I am, as I have made experiments to prove it.

737. Is the capsule of the liver inflamed? The capsule is not inflamed or involved in any way, even when these patches abut upon the surface.

738. What is the next organ of importance? There is very little to say about the kidneys. I have never been able to find out anything wrong with them. Just above the kidney there are two small white patches which we have called supra-renal capsules for convenience of name. I am not certain of their exact nature. These are enlarged, discoloured, and caseous in the disease.

739. What is the nature of the discoloration? From blood red to black. They are of a dull white colour—we call it opal—in a healthy state.

740. What is the condition of the mesenteric glands? They are much enlarged, and full of a jelly-like substance—a very clear fluid.

741. That is, they contain cysts? They are not exactly cysts, but the gland seems to have become degenerated and bunched up in a peculiar way. On cutting into that the fluid runs away. There are two fluids irregularly mixed together.

742. Have you found that in the mesenteric glands in all cases? It has been much more marked these last two months, but the glands were enlarged in all cases.

743. Is the change that you have described in the supra-renal bodies a constant one? Yes.

744. Have you noticed any change of importance in any other organ of the abdomen? No; the spleen is very variable both in health and in this disease, so that we have not been able to attach any importance to it.

745. Then turning to the chest—what is the condition of the heart? There is excessive fluid in the pericardium or heart bag, and that is all I can say about it. The heart itself seems to be healthy. I should not think it had wasted much, but then it is a difficult thing to judge of.

746. What is the state of the lungs? Apparently healthy; no engorgement.

747. Then in your opinion death is not due to suffocation or asphyxia? No; and I am familiar with the appearance of rabbits which have died from suffocation.

748. Is there any hæmorrhage on the surface of the lungs? No; I have looked for that very closely, and there is no hæmorrhage on the surface of any of the organs of the body. The rabbit has glands apparently at the root of the neck, which in this disease become enlarged; you get at them from inside the thorax. In skinning the rabbit—lately more particularly—we noticed enlarged glands under the fore and hind limbs. They were very noticeably enlarged—as large as peas—but there was nothing else remarkable in connection with them.

749. Have you examined the nervous centres repeatedly? No; and I am not sufficiently qualified to form an opinion on them.

750. What is the general condition of the blood—is it fluid, or does it tend to clot? It is fluid. It is very black notwithstanding that the lungs are not engorged, and it varies very much in quantity in diseased rabbits. Sometimes there is a large quantity, and sometimes there is hardly any. The fluid is very thin and watery.

751. Have you made any microscopic examinations at all? No; I have left them to Dr. Ellis.

752. *Mr. Lascelles.*] Could you prepare coloured drawings showing the organs in healthy rabbits and the organs of diseased rabbits? No; I could not undertake that.

753. *The Chairman.*] Reference was made by Dr. Ellis to affections of the skin and the superficial parts of the body which were noticed in rabbits in connection with this disease. Will you state the nature of your observations

observations concerning this skin affection? I first heard of this disease on the 18th August, 1887, from Mr. Clarke, the rabbit inspector. Rabbits with this disease were being caught with scabs on them, as he called it. We have found these rabbits on the run as well as where they were first reported. From the history of rabbits dying elsewhere, it appears that this scabby skin seems to come before the breaking out of the disease which is killing them. I am now referring to Glenlyon and Weinterriga, and places on this side of the river where rabbits have since disappeared.

754. I understand that you have learned this not from your own observation, but that it occurred on adjacent stations where some disease had broken out amongst rabbits, and that the scab appeared as far as you can learn before the manifestation of the disease which killed the rabbits? Yes.

755. Now will you state your experience in connection with this scab? I believe, myself, that it has been caused by the food.

756. But what is this scab? It is an eruption of the skin, varying from a branny condition of the skin up to extremely severe forms of scabbing, with scabs an inch thick on them.

757. Does that inch thick of scab project from the skin? Yes, and covers the whole body of this rabbit that I am speaking of.

758. Is that scab disease prevailing at all extensively amongst the rabbits at Tintinallogy in connection with your experiments? No.

759. I understand, then, that the great majority of the rabbits which died from your disease had perfectly healthy skin? Yes; perfectly healthy skin.

760. Do these scabs fall off, leaving ulcers behind them, or are they persistent during the life of the rabbit? I have seen both events occurring. In the very bad case which I have mentioned the scab remained to the end. In other cases the scabs fall off, leaving ulcers with clean-cut edges.

761. Do these ulcers heal? Yes; but not in many cases. The hair never grows again, and a scar remains.

762. Do you think that this skin disease has any relation to the deadly disease to rabbits which you have been describing as in existence at Tintinallogy? No; not the least; but I did think so at first.

763. Have you been able to form any idea of the nature of this scab disease? No.

764. Have you made any experiments with it as to its transmissibility from animal to animal? Yes, I have tried them and got no satisfactory results. Some cases seem to get it, and others with the same experiments do not get it; no two results agreed. The experiments were in all cases intended to transmit the disease by contact from unhealthy animals to healthy animals, and the results were very unsatisfactory.

765. But still in some cases the disease did seem to spread in that way? Yes; but I am under the impression that the animals had it before I put them together, because I believe it to be a matter of feed.

766. Is your belief that the scab disease is due to feed a matter of conjecture, or have you any real evidence which you can adduce in favour of that belief? I have evidence that this skin disease broke out at Billilla, 3 miles off the river, two years ago. Around Willincarie the disease is always more or less prevalent, and the rabbits have been diminishing in numbers; but it never spread from that particular place.

767. Then it appeared also amongst your rabbits in experiments at Tintinallogy? Yes.

768. Are you able to give any explanation of its appearance there? No; none at all.

769. Was it a new disease in the district? It has been there for some years.

770. Is it still in existence? Well, I believe not, because I understand the rabbits are all dead there from something else. They have been largely poisoned with phosphorus and I have heard there are now no rabbits there.

771. Dr. Ellis spoke of a cheesy deposit at the base of these scabs from which a lot of matter comes away, and also of a cheesy deposit in the muscles—will you give us your experience in relation to such appearances? Well, I cannot say that there was a lot of it; you could scrape it up on the point of a knife to inoculate another animal with. With regard to the cheesy masses in the muscles, they were very distinct and were found in rabbits which had had the scab disease, but were not directly connected in position with the superficial eruptions or scabs.

772. You at first took these cheesy deposits to be enlarged glands? Yes; I thought they might be lymphatic glands from the irritation of the skin. I did not find them in rabbits which had not the scab disease.

773. Do you believe the cheesy deposit in the muscles to be a part of this scab disease, whatever it is? There were many cases of skin disease in which there were no muscular deposits.

774. Will you now furnish the Commission with such accounts of your experiments in connection with the Tintinallogy disease as you desire to place on record? Yes; this book contains a record of the experiments conducted, the history of the lymph, the variety of methods of inoculation, and places of inoculation, together with inoculations of stock by Mr. Stanley and others done in my presence, and other various experiments:—

COMPILED RECORDS OF INOCULATIONS AT TINTINALLOGY.

1887.

November 28.

Lymph from natural disease crate E. (See question 694).

Mark 5.	Mode of inoculation:—Scarification.			Hypodermic injection.			
	Virus employed:—Gland solution.			Serum.			
	1	2	3	1	2	3	4

All killed for various experiments.

December 31.

Stanley's inoculation.

Lymph from December 14 (17th day of disease).

Mark 4.	Mode of Inoculation :—	Scarify.		Hypodermic injection.			Intravenous.	
	Virus :—	Liver substance.		Liver infusion.			Blood.	
		1	next day	1	2	3	1	1
Result in day of death...				16	16	18	17	16

With virus from above (mark 16) Mr. Stanley inoculated 6 sheep as under :—

1. Wether—Hypodermic of liver infusion, near flank and brisket.
2. Stag—Hypodermic of blood serum
3. Ewe—Hypodermic of liver infusion off " " "
4. Ewe—Hypodermic of blood serum, off arm and flank.
5. Ewe—Scarify face and arm, blood serum.
6. Ewe—Scarify face and near brisket, liver substance.

All these examined and passed by Inspector Tully.

4 controls.

1888.

January 3.

Lymph from natural disease. Yard A.

Mark 13.	Mode of Inoculation :—	Scarify		Hypodermic.	
	Virus :—	blood clot.		Liver infusion.	
		1	2	1	2
Result in day of death ...		18	18	16	17

With lymph from above rabbit Mr. Stanley inoculated—

- 1 saddle horse—Hypodermic of liver solution, and scarify neck blood clot.
- 1 white calf—Scarify off ear, liver substance; hypodermic of blood serum, brisket; hypodermic of gland solution, fore-arm.

Both these watched by Inspector Tully.

2 controls.

January 4.

To show spread of disease on run at this date.

Of 62 *post-mortems* made by Mr. Stanley on rabbits caught by dogs in "Receiving Paddock," 6 were found diseased. 4 inches rain fell during latter part November and December.

January 6.

Inoculations from cystic tumours in caught rabbit.

Mark 9.	Mode of Inoculation :—	Scarify.		Hypodermic.			
	Virus :—	Cyst matter.		Filtered solution.

Result in day of death	7	16	18	18
4 controls.					
(1 died.)					

775. *The Chairman.*] That statement was prepared by you? Yes; it was prepared for the purpose of this examination from the camp records.

776. Does it contain an account of all experiments that have been performed? Yes; of all that have been performed accurately.

777. Have these experiments all been performed with proper precautions against septic contamination? Yes, all of them.

778. What was the nature of the precautions thus taken? From the start a bichloride of mercury solution for washing the hands was used, and for disinfecting infected crates.

779. Did you take any precautions to see that the instruments and crates were in a thoroughly disinfected state? Well we had control experiments conducted in all cases to test the accuracy of the other experiments.

780. I understand that you performed a number of experiments at earlier dates without employing the septic precautions which you adopted in connection with these experiments? Yes.

781. Did you meet with any difficulties in these earlier experiments from septic contamination? Yes. The rabbit is an animal that gets contaminated very quickly, and a large proportion died in ways not connected with the disease with which I was working. You will find in that record experiments performed with certain septic precautions where rabbits died—at periods earlier than could be explained by the Tintinology disease—with septic symptoms. These experiments have been marked off as unsatisfactory on account of the septic contamination.

782. The book which you have put in gives a general account of all experiments which have been performed under satisfactory precautions? Yes.

783. No experiments have been excluded in which a definite result was obtained? No.

784. Putting the matter shortly for the immediate information of Commission, what methods of inoculation or transmission of the disease did you adopt? There were three—injections beneath the skin with a hypodermic syringe, intravenous inoculation, and the introduction of infected setons.

785. Did you find that all these produced the disease? Yes.

786. Did any one do so more surely than another? Intravenous inoculation was the greatest success, but setons were good enough for all practical purposes.

787. Will you describe the method you adopted in intravenous inoculation? A vein of the ear was dissected down upon, and the needle of a hypodermic syringe introduced into this vein. The blood was drawn from this and transferred to similar veins in another rabbit.

788. Is it not a very difficult matter to introduce a needle into a vein without puncturing both walls of it? Yes.

789. What substance have you introduced from diseased rabbits into healthy rabbits with the effect of producing this disease? Blood clot and blood serum; the so-called supra-renal bodies mashed up with water,

water, and liver substance mashed up with water. Such fluid being called an infusion in that experiment, though really only a suspension in water. The fluid from the abdominal cavity, and what is called the sub-mucous fluid under the skin, were also used. We used the mesenteric gland substance braised up with water. Then, in addition to that, I tried blood.

790. And with these substances you obtained successful results? Well, with regard to the abdominal fluid, I am not sure about it. I would say that the abdominal fluid was not to be depended upon.

791. These were all used in inoculation as distinguished from the use of setons? Yes; but the setons were prepared in the same fluids.

792. Did you use fluid from the pericardium at all? Never.

793. Dr. Ellis, then, has made a mistake? Yes; if he has said so. I left all those fine experiments to him.

794. In your experiments at Tintinallogy what rabbits did you use for infection with disease? The only case of importation was from Weinterriga, and all the rabbits for inoculation experiments were obtained from our own run.

795. Did any rabbits prove refractory or indisposed to take the disease? Out of 282 rabbits the number of failures to inoculate amounted to only one. He was inoculated three times and ultimately broke his leg, and had to be destroyed; but three inoculations were made on him without result.

796. Was reinoculation necessary in many cases? I have only had one—the one I refer to. In all other cases the disease was taken after one inoculation, or the rabbits died without recovering condition. In no case but this one did I resort to re-inoculation. In almost all cases the rabbits took the disease and died in the ordinary way. In a few cases the rabbits lingered on longer than the ordinary period, but in very few cases so long that I was doubtful what they died of.

797. Have you ever made experiments with a rabbit recovering from the disease to see if it still could communicate this disease to other rabbits? No; I never tried that.

798. Will you now give us some short account of what experiments you have performed to test the transmission of the disease by contact of diseased rabbits with healthy rabbits, or by placing healthy rabbits in hutches in which diseased rabbits had been previously kept? We have one crate—that known as crate E—in which rabbits were placed when I telegraphed to Mr. Reid from Sydney. That was empty fifteen days and it gave the rabbits the disease. Only one rabbit since put in that crate has failed to take the disease. I have put in a wire netting yard, 10 × 12 feet, sixteen rabbits and one rabbit from crate E. The result is they all died by the 3rd February, within twenty-three days.

799. Were these rabbits properly fed? Yes; and with every precaution. They had ample shelter in a canvas tent filled in with green boughs. I satisfied myself that death occurred from this disease by *post mortems* made every morning. In another experiment one rabbit on the fifth day after inoculation was placed for twenty-four hours with six clean rabbits—the result was they all died on the 19th and 20th day. In both these experiments control experiments were carried out under exactly similar circumstances, and the rabbits under control remained healthy, except the one that I spoke of as having died of strangulation of the intestines. It did not present the disease in the slightest.

800. *Mr. Lascelles.*] What are we to understand by control experiments? Control experiments mean simply this, that animals are kept under similar conditions without inoculation. In another experiment with contagion, in a yard 20 × 24, one rabbit from the bend of the river was placed with thirty-eight clean rabbits; the result was that the rabbit from the bend died in nine days, and all of the thirty-eight rabbits placed in the yard with it died except one, which was lost sight of. All the others died between the nineteenth and twenty-fourth days; and ten animals were kept under control in a similar yard under exactly similar conditions, and all these lived.

801. *The Chairman.*] Will you now give a short *résumé* of your experiments on stock, with regard to the possibility of this disease being transmitted to them? Yes. On the 4th December two sheep and three guinea-pigs were inoculated with serum and blood of infected rabbits, together with pulp from the white patches in the liver, mixed up with water. These animals were inspected by the Government veterinarian four weeks afterwards, and by the local stock inspector on various occasions.

802. Was any result whatever noticed? No, not in the least; not even at the seat of inoculation. On December 18, a cow and calf were inoculated with liver-substance braised up in water. These animals were subsequently passed as healthy by Messrs. Stanley and Tully. On December 31st and January 3rd, six sheep, a horse, and a calf were inoculated by Mr. Stanley; liver-substance braised up in water being used for the sheep, and with the horse the liver-substance braised up in water was injected beneath the skin, and blood-clot was introduced into the neck by scarification. In the calf the liver-substance braised up in water was introduced by scarification in the ear; blood serum was introduced by hypodermic syringe in the brisket, and the so called supra-renal glands braised up in water were introduced beneath the skin in the forearm by hypodermic syringe. All these animals were watched by Inspector Tully.

803. Did these animals all remain thoroughly healthy? Yes; in every way.

804. Was anything noticed at the place where the poison was introduced? Not the least.

805. What stock were introduced into the enclosure at the bend? Four horses, one cow, two calves, twenty-two sheep, and four goats. These animals were kept over three months in the bend.

806. Was the disease then very prevalent amongst the rabbits in the enclosure? Yes.

807. Did any of the stock die? No.

808. Did any become ill? No. The cow was milked every day, and kept her condition. We used the milk for the camp, and when the stock were taken out we ate some of the sheep.

809. Will you now describe the spread of the disease at Tintinallogy? There are two parts; there is the distinct spread in the bend and from the centres of inoculation. In the bend, the first results obtained were bad on the 8th November, 1887, and were with six rabbits obtained from the outside country. This was apparently a failure, because the rabbits did not mix with the rabbits in the bend, and died against the fence in trying to get out from the area enclosed in the bend. The rabbits being ear-marked we were able to prove this. We then put up a little wire, making a drive in the bend; we got six rabbits, inoculated them with the disease, and the disease spread; we turned them loose at once. The inoculation was all hypodermic injection with blood serum. From that time out rabbits died in the bend.

810. Did you introduce any more? No. One or two got out from the crates, but we do not count them, because we do not know what became of them. Some three rabbits escaped altogether. From that time out the rabbits commenced to die. The last report of the inspector says that he saw only five rabbits after a thorough inspection of the bend, which was very heavily infested before. The number of dead rabbits can be spoken to by the visitors who went down there.

811. Was any poison whatever laid at this time in the bend? There was poison laid just around our experimental wire-netting yards to catch certain rabbits that hung about outside the yard. Some twenty or thirty rabbits had escaped from the yard, and they kept coming back, so we decided to get rid of them by poisoning. We were then using strychnine on cabbage-leaves. This was done to catch these particular rabbits, because we thought they would interfere with our experiments.

812. Was the food for the rabbits abundant in the bend at the time? Yes, as at present, and all through.

813. *Mr. Lascelles.*] Do you think that any of the rabbits got out of the bend? I do not think any got out by water as the river was then very high and running swiftly; and unless worried by dogs rabbits will not cross a river.

814. Would it be a hard matter for any rabbits in that bend to be caught by digging out or by getting at hollow logs? I believe Mr. Reid could go down there now and clear the bend within half-an-hour. Of course there is an immense number of cracks in the river bank, and men could not possibly dig them out.

815. *The Chairman.*] Will you now state what has been done towards putting the disease on other parts of Tintinallogy? From the centre where it originally started, $1\frac{1}{2}$ miles above the home station, it spread in all directions, and in all cases with great fatality.

816. Is there any evidence with regard to that fatality beyond what you have already stated? Messrs. Clarke's and Tully's reports will give the results.

817. Now, have the rabbits been substantially thinned out in this way? So far as Tintinallogy is concerned, I think we might call it extermination. This has been done all over an area of 236,030 acres. On one side the disease has spread only three-quarters of a mile from the point of origin; but on the north side I do not know that there is any limit to its spread. Within this area, then, there has been practically extermination.

818. And within what area, approximately, has the disease spread so as to cause extermination? I should think it had cleared about 10,000 acres without any assistance at all. It is difficult to say, because of the river bends, and I do not know how far back it has gone.

819. Passing now to what you have done yourself, will you give us particulars? If you take the Lignum Creek south of the woolshed, where the natural disease appeared to stop—we infected that first by allowing diseased rabbits from the camp to go on to it. That was a failure, so far as we could see; we then caught the rabbits on the creek itself, inoculated them on the spot and let them go. We used the setons at that place. The seton was steeped in one of the organs of the diseased rabbit, braised up in water, and was then dried and placed in a glass tube for convenience of carrying about. The result of that infection was seen at once. The rabbits started to die on the creek, and from the creek they carried the disease a long way—I should say 3 miles. The creek makes a big turn coming out from the river, and we reckon it 3 miles.

820. What did you do next? We next started to infect the sand hills. As the rabbits were not trapped they congregated together more in colonies, and the colonies being infected in a similar way, the result was seen at once.

821. In the area so dealt with, was anything like practical extermination secured, or were the rabbits simply thinned out? Yes, speaking roughly. The best way for me to answer that question is to show what rabbits were killed up to a certain time.

822. Did you proceed to infect any other parts of the run? We infected all over. Wherever there were large colonies we infected the rabbits, using the same method by seton. We have occasionally done it by hypodermic injection, but it is more complicated. The carcasses of these animals have been lying about all over the run, and have been eaten by dogs, cats, pigs, fowls, crows, and hawks.

823. Have any of these animals been dying? None, except cats, that have died, from what, I am not able to say. They started to die only very lately. I believe them to be suffering from some form of distemper, but there will be evidence as to that.

824. *Mr. Lascelles.*] Have you made any *post-mortem* examination on the cats? No; I have never seen one of them dead, and I am speaking now only from report.

825. Can you furnish any statistics showing the number of rabbits that have been destroyed at Tintinallogy by this disease? No; but I can furnish some showing the number of rabbits that we caught, before the disease started, by the trapping method, showing how thickly the country was infested. During last year there were in all 291,000 rabbits killed on the run. I was at work from October to December. These are the figures:—

Extract from Tintinallogy Rabbit Journal.

1885.—5,061 rabbits killed, at a cost of £231 17s.

1886.—32,163 rabbits killed, at a cost of £804 1s. 6d.

1887.

Month.	No of men.	Rabbits killed.	Bonus.	Cost.
January.....	19	12,685	d. 4	£ 213 17 0
February.....	12	6,128	4	102 2 8
March.....	25	15,757	4	262 12 4
April.....	18	10,012	4	166 17 4
May.....	22	20,333	3	254 3 3
June.....	21	26,623	3	323 15 9
July.....	29	50,246	3	623 1 6
August.....	17	26,346	2	219 11 0
September.....	22	56,510	2	470 18 4
October.....	25	41,599	2	346 13 2
November.....	7	10,000	1½	62 10 0
December.....	11	14,936	1½	93 7 0
Totals.....	291,175	£3,153 9 4

1888.—Half of January, nine men killed 7,597; cost, £47 9s. 7d. Since then, cost nil.
Total cost, 1885 to 15th January, 1898, = £4,236 17s 5d.

826.

826. Were the same number of men employed? Well, I cannot tell you that.

827. *The Chairman.*] In all the area of Tintinallogy have the rabbits now been practically exterminated? Well, I sent out four men to the places where rabbits were supposed to be thick—at places 18 miles from the station—and they were actually on the ground for five hours and only got ten rabbits.

828. Can you give any evidence to prove that starvation had nothing to do with this mortality? The run has been stocked at the rate of one sheep to every 4½ acres. I may say that the run is appraised at one sheep to 7 acres. All the sheep are now in good condition and 13,700 were sold in March last fat.

829. *Mr. Quin.*] Has not this been an extraordinary season in Tintinallogy? Yes. The rainfall has been considerably above the average, 19 in. 19 points, but from the 25th October (when I started the camp) to the end of the year there were 5 in. 29 points of rain, and from January 1st to 14th May, 2 in. 26 points fell.

830. Do you know what is the average rainfall for the series of years? No; but I know that this is far above the average. Further, with regard to starvation, I may say that when the rabbits came to Tintinallogy the feed was something awful. They came on to the run during the worst drought we have had.

831. *The Chairman.*] At the time this disease existed amongst rabbits, was there any mortality amongst sheep on the run that could possibly be attributed, even by way of suspicion, to the disease? No.

832. Then can the death of the rabbits at Tintinallogy be possibly attributable to their having eaten bark? Well, no; because Tintinallogy is not a scrubby run. The plains are miles in length where the rabbits are dying just the same, and the scrub on the run is not much barked. The feed for rabbits, apart from the bark, has been abundant. Rabbits have died miles away from the scrub, where the bark was not eaten.

833. Is there any evidence whatever, even the slightest, to indicate that man may be injured by the prevalence of this disease amongst rabbits? No; not the slightest. There was a report that a man from Balranald had caught the disease, but it was proved that he had never been within 50 miles of the boundary, and that his injuries were due to his having got his fingers cut in a rabbit trap. He did not die, and he went down to Melbourne and saw several doctors there who made a great fuss about it, but Dr. Lawson, of Balranald, explained the case.

834. Were rabbits brought from Murtie station to you suffering from a disease which was thought by others to be possibly identical with the Tintinallogy disease? Rabbits were brought to me, said to be from Murtie. From the general symptoms, I thought the disease was identical with the Tintinallogy disease, but I never said so. I was under the impression at the time that it was a trap being set for me, so I did not give a very decided opinion.

835. Do you know anything from personal observation or personal knowledge of a disease prevailing amongst the rabbits on Momba? No; I have never been on Momba run in my life.

836. Have rabbits been transferred from Tintinallogy to Momba? No; and I do not believe it would be possible to do it without my knowledge, unless a man got the rabbits in the bush. I have had one rabbit sent down to me for examination from far above Momba, and I said that it was suffering from the scab that I have already spoken of.

837. *Mr. Quin.*] Have you infected any other country, apart from Tintinallogy? No; I have not done anything of the sort, although I have had very many requests to do it.

838. *The Chairman.*] In any part of the Tintinallogy run which you infected, did the disease die out of itself, without killing the rabbits off? There is one place where the disease did not spread as fast as it did in others, and when I visited it I was surprised to see so many rabbits alive. On a second inspection, about eight days after, I found the rabbits had disappeared there also.

839. And supposing that you receive no authority to spread this disease more widely, do you think it will die out? I do. I can see that it is very easy to lose control of the disease, even in an experimental enclosure.

840. What do you mean by control of the disease? Being sure that certain lymph or inoculable material will produce certain results.

841. Is it essential, in order to be sure of keeping up a supply of inoculable material, that development of the disease should be going on at several centres, and not in one small area? I can answer that now by saying that we are thinking of shifting our camp to more thickly infested country, as we are not quite certain of being able to keep it going where we are at Tintinallogy.

842. *Mr. Lascelles.*] Have you taken any steps to obtain permission from the Government to take this disease elsewhere? We have made application, but that application has been met by a statement that the matter should be referred to the Commission.

843. *The Chairman.*] In watching the progress of the disease at Tintinallogy have you noticed any variations in its fatality according to the special kind of country in which the disease was prevalent? Yes; I have noticed that on the sand hills it spreads much quicker. On the lignum creeks it requires help from man by mixing the rabbits up together.

844. How would that mixture be affected? I was going to explain that in these creeks we send men and dogs to the head of the creek to drive the body of the rabbits towards the river. We did this when we first saw the rabbits dying in one batch, and the rest making back to their natural run spread the disease better. The difference between the lignum creeks and the sand hills is that in the sand hills the rabbits burrow and associate more closely, and thus the disease spreads more freely than it does amongst the rabbits lying out in the lignum.

845. *Mr. Quin.*] Are the rabbits fond of lignum? Yes; very fond of it.

846. Do you think that lignum acts as an antidote to the disease? No; I do not think so.

847. *The Chairman.*] Have you found the spread of the disease modified at all by the wetness or dryness of the country? We have no moisture at all except in the water-holes, but the large majority of the rabbits seem to die around the water-holes, or near the creeks.

848. Do you think that those who live near water are more apt to die, or that they make for water when about to die? I think they make for the water and are too weak to get back. We have had two falls of rain lately, both of which seemed to kill off the weak rabbits very quickly.

849. Then I gather that you think the amount of food available for rabbits has not very much to do with the disease? No; I do not think so, but I am aware there are many people against me.

850. You do not think there would be a marked difference in the spread of the disease in poor country and in good country, supposing that these districts were equally infested? I do not think so from the way rabbits die when fed with artificial food. My rabbits had grass, lignum, saltbush, lucerne, lettuce, cabbage, carrots, grape-vine leaves, potatoes, apples, turnips, oats, bran, chaff, and bread. The rabbits are very fond of dry chaff; I have seen them leave cabbage and go to chaff.

851. *Mr. Quin.*] Have you ever seen rabbits fed with poisoned chaff? No; but I have heard of it in South Australia where some horses were poisoned with it as well. It has been said that rabbits being sent from Tintinallogy to Dr. Ellis, in Sydney, passed in the coach near a public house at Nelyambo, and that all the domestic fowls died in two days, although they had not previously been ill.

852. Has this matter been looked into at all? No; because I do not regard it as of any importance.

853. Have fowls suffered at Tintinallogy? Not at all; and we have picked up dead rabbits in the fowl-yard.

854. *The Chairman.*] If this disease is to be adopted for general use with a view to the extermination of rabbits, what method do you propose for adoption—how would you deal with a thickly infested run, embracing several hundred thousand acres? We would get to know the most thickly infested portions, catching the rabbits there, infecting by seton say three in each of five places on each block of 64,000 acres, turn these loose on the spot in their own neighbourhood, and in two months go around the same country again in the same way or to every infested centre. I believe that would give the disease a start.

855. Such a method could be pursued on any number of runs by assistants trained by yourselves? Yes; the training required would be to teach them not to kill the rabbits by blood-poisoning instead of by disease.

856. The method in itself is quite simple? Yes. I have found great difficulty in the past in persuading the men of the necessity of cleanliness so as to avoid killing the rabbits by blood-poisoning. Precautions are necessary in the introduction of setons to place them at the right depth, otherwise tetanus may readily be induced. That occurs when the muscle is penetrated by the setons.

857. *Mr. Lascelles.*] In a thickly infested block, where there would be hundreds of large warrens, do you consider that turning out diseased rabbits in five of these warrens would be sufficient? As a start, I do.

858. *The Chairman.*] Do you think that in the end you would have to infect every warren? No, certainly not. I believe there is much more traffic from warren to warren than there is any idea of.

859. And you have satisfied yourself that the disease spreads freely amongst the rabbits that do not warren or that shelter by river side? Yes, in regard to the lignum creek experiment.

860. If your method were to be generally adopted you would I suppose require some central station where you would keep up a stock of infected rabbits and would prepare setons? Yes.

861. Have you thought out the details of the application of your scheme on a very large scale indeed, so that the whole thickly infested portion of the Colony would be brought under it? If we get permission, we intend to send at once to Victoria and South Australia, to try the scheme and make certain places in these colonies centres. We do not yet know what effect climate will have on the disease.

862. How long have you kept setons in preparation and found them effective? Setons prepared on 24th February, were used on the 29th; two killed on the 15th day and one failed. This is the longest we have actually used them.

863. Have you found other setons fail which were kept for some days after preparation? No; I have never tried them over the fifteenth day, and that was the only failure I remember. But blood serum has kept longer than that. On February 18th, the blood serum of infected rabbits was placed in sterilized tubes, and posted to Sydney, to Dr. Ellis, and his inoculations with that, at least a week later, were successful.

864. Now what is your general conclusion with regard to the origin of this disease? Is it some disease that has been prevalent for some time, but which, owing to the peculiar season last year, broke out with great severity; or is it that you have been able to cultivate it with a virulence not known before? I do not think the cultivation has anything to do with that in my case. I have got rabbits down in the bend and used them in inoculations, and the result proved that the virulence was just as great in these rabbits with the natural disease as in those to whom I had artificially communicated it.

Charles William Reid called in and examined:—

865. *The Chairman.*] Where do you reside? At Tintinallogy, Wilcannia.

866. What is your office at Tintinallogy? I am book-keeper and I had charge of the rabbiters and was rabbit overseer during the time the trappers were on.

867. You have also given assistance to Dr. Butcher during his experiments? Yes.

868. You have personally conducted many of these experiments and preserved the records for him? Yes.

869. How long have you been at Tintinallogy? Three and a half years altogether. The rabbits came before my time.

870. Before Dr. Butcher commenced his experiments, Tintinallogy was, I believe, a very densely infested district? Yes.

871. Can you give any figures to show how thickly it was infested? Yes; I have our rabbit journal here showing the general result for 1885 and 1886, and the detailed result for 1887.

872. These figures, then, relate to the allowances made to the trappers for rabbits caught? Yes.

873. What is the general result as to the efficiency of the work done by the trappers? When they knocked off there were infinitely more rabbits than when they started. The rabbits gained on the trappers considerably.

874. Was the full number of men employed which was recommended by the local rabbit inspector? Yes.

875. During the months of November and December I notice that there was a marked reduction in the number of men employed. How do you explain that? Well, that is the commencement of the hot weather, and they saw that they could do no good during the hot weather—that they could not trap the rabbits so as to pay. I think there was also a deduction in the scalp money in that month which would account for it.

876. What is the present condition of Tintinallogy with regard to the existence of rabbits? There are now very few there.

877. *Mr. Lascelles.*] Are there less rabbits there now than at any time since you have been on the station? Yes; less than in the beginning of 1885.

878. *The Chairman.*] Would you now speak of that district as a densely or a thinly infested district? I would say it was a thinly infested district.

879. In how many months has that change been brought about? Well, in from five to six months.

880. During that time has poison been used on the station? There was a little poison laid in enclosed areas during the month of November.

881. For what purpose was it laid? To try the effect of the different poisons—arsenic and strychnine. We wanted to see which was the best.

882. This was not done generally on the run? No; it was done in very small enclosures.

883. Apart from such small experiments I understand that poison has not been laid at all at Tintinallogy? Not at all.

884. I believe that Tintinallogy is a station comprising land of a very varied character—some open and some heavy bush country? Yes; it is.

885. Have the rabbits died off on all parts of the run whether open or thick? Yes; on all parts.

886. Has the food been so abundant during the time of Dr. Butcher's experiments as to wholly put on one side the possibility of rabbits dying for want of food? Yes; I think so. The stock have been well conditioned throughout. We sent away, in March and the first few days in April, between 13,000 and 14,000 sheep. The agent who inspected them for the buyer reported on them as being fat. The majority of these were old ewes, and it requires very fair feed to keep them in anything like condition in this country. Of course there has been infinitely better feed on the run, but it has been very fair throughout this season.

887. Do the rabbits burrow largely on Tintinallogy? They have done it at times; but I have seen no burrows freshly scraped out since last winter.

888. Have you studied the run sufficiently to know the general history of rabbits upon it during recent times? Yes.

889. Did you watch the experiments in the bend? Yes.

890. How many times were inoculated rabbits turned loose in the bend? That I cannot tell you. When Dr. Butcher went down there first he allowed the rabbits to go, but how many times I cannot say. I mean by this that Dr. Butcher started the camp there at first after he returned from Sydney. I do not know the early history of the camp at the bend.

891. Have you made yourself acquainted with any difficulties that were experienced in spreading the disease on Tintinallogy? No.

892. Is it not a fact that at certain times the spread of the disease was checked owing to the natural condition of the country? Not to my knowledge.

893. Was not the spread of the disease in one particular part of the run limited by a lignum creek so that a fresh introduction was necessitated? It was introduced a second time about the lignum creek, but I did not witness that.

894. Taking any experiments which you conducted, will you tell the Commission what you did from beginning to end. Take any experiment you like, and tell us minutely what you did? I will take the first experiment, dated 9th February. This lymph was taken from a rabbit naturally diseased from the Gun's paddock. This rabbit was dug out. We put it first into one of the yards which are wire-netted. Taking the sterilized test tube I took this rabbit, killed it, and put the blood into a small quantity of saline solution. I cut the animal's throat, holding the tube under the stream of blood. Then I corked this up with sterilized cotton wool, and let it stand for about one and a-half hours. I then filtered the serum through the sterilizer—through the ordinary filter papers. These had been already sterilized before Dr. Butcher went away. These were kept in a jar with a lid that screws on, the same as specimens. As soon as this was filtered I inoculated four rabbits with a hypodermic syringe which also had been sterilized. I washed it out before using with corrosive sublimate solution, then with methylated spirits, and then with the ordinary saline solution. I then filled the syringe with serum and forced the needle through the skin—forcing a portion of this serum through the needle into the first rabbit. I washed my hands in the corrosive sublimate before touching the first rabbit. After that I took a second rabbit and did the same thing, inoculating the four rabbits in the same way. I placed these rabbits in one crate which had been washed and disinfected. The crate had been used for wool washing, and after each experiment it was taken out and sunk in the river. After that we used carbolic acid over the crate, inside it and on the board that covered it. I do not know the strength of this solution. Some hours after this the carbolic acid was again sprinkled over the crate, and then the rabbits were put in. We put in fresh grass for bedding. We did the same with every crate, some of them being sunk as many as three days in the river. Sometimes also we used corrosive sublimate and sometimes the carbolic acid solution. The corrosive sublimate is 1 in 1,000, but I am not certain as to the carbolic acid, as it was already mixed.

895. Do you know anything about the transfer of any rabbits from Tintinallogy to Murtie or Momba? No.

896. Did you witness the experiments that were performed by putting healthy rabbits into a crate that had been infected? Yes.

897. Will you tell us exactly what happened with regard to that experiment? I did not see it right through. Dr. Butcher telegraphed from Sydney asking me to get some rabbits for him and put them into the crate, which had been used for the rabbits that were destroyed before Dr. Butcher went to Sydney. These rabbits—I did not see them—Dr. Butcher told me had caught the disease from the crate. I saw the rabbits some considerable time afterwards, but I cannot say how long.

898. Have you yourself seen any other experiments of that kind ending successfully? Yes; I put rabbits, which, so far as I know, were healthy, into the same crate—Crate E—and, though the bedding had all been changed, the rabbits died.

899. You are certain that no attempt was made to communicate the disease by inoculation to these rabbits? Positively. We had "controls" in the yard from the same batch of rabbits.

900. Have you yourself witnessed in any full way any experiments made with rabbits in enclosed areas by introducing infected rabbits amongst them? Yes. I have seen one diseased rabbit placed in a yard with twelve or fourteen or more rabbits which were healthy, so far as I know. I have seen these rabbits brought out dead.

901. Did the death of these rabbits occur at any regular period, or were their deaths scattered over a considerable time? They did not all die on the same day, but the deaths occurred within four or five days of one another.

902. Is it, then, a fact that by spreading this disease over Tintinallogy in an inexpensive manner the rabbit plague has been practically reduced to very small dimensions on that run, where, for years past, trappers had been employed at great expense without sensibly diminishing the pest; the rabbits, on the contrary, being more numerous at the end of the trappers' operations than at the beginning? Yes.

903. *Mr. Lascelles.*] How does Tintinallogy compare with other runs where other means have been adopted to destroy rabbits? I think other runs are more infested. I have not been much about, of course; but we have seen very few rabbits between this place and the river.

904. *The Chairman.*] Can you make some drawings of the livers of diseased rabbits for the use of the Commission showing the diseased spots? Yes.

905. *Mr. Quin.*] Do you know if there are less rabbits on this side of the river than before? Yes; I know there are less at Weinterriga from personal observation, and other places between this and Tintinallogy, but I do not know the reason. On the 6th of March Mr. Affleck, the manager of Weinterriga, brought two rabbits to the camp. I placed one in the yard and one in the crate with other rabbits that were healthy, so far as I know. The rabbits that were in there died, and the result is shown in these experiments. The crate was disinfected previously in the same way as the other.

906. *The Chairman.*] In any experiment which you performed with rabbits in a crate, how do you conduct your "control" experiments? In some cases the rabbits were put into another crate, and in other cases they were put into what we call the "control" yards, which are wire netted.

907. Then the "control" rabbits were not always kept under the same conditions as the diseased rabbits? No, not always; but the conditions were kept exactly the same as regards feeding, water, and bedding.

908. Have you anything further you would like to say? No; except that at the time I was not in charge of the camp I cannot say that the conditions under which the "control" rabbits were kept were not exactly the same as those under which the inoculated rabbits lived.

Herbert Pickering Butcher recalled and examined:—

909. *The Chairman.*] Is there anything bearing directly on the rabbit question that you have omitted to refer to? I would like to refer to the Weinterriga experiment, mentioned in the book which I have handed in. The disease that they had had at that time—early in March—is the same as we had; the results proved that they had the same disease as at Tintinallogy. Two experiments were tried with rabbits from Weinterriga, which is on the opposite side of the river from us; the results of these experiments going to prove that the same disease existed there at that time. I would like also to draw attention to the fact that the opossums on the Darling were killed out by some eruptive skin disease. Almost every opossum died, it was supposed, of the same disease which now prevails amongst the opossums at Narromine.

910. *Dr. Paterson.*] Are there any opossums now on the river Darling? Opossums can be found at a distance of 80 miles from the Darling, but not actually on the river, so that the disease did not spread very far out. I have never seen this disease amongst opossums myself, though I have seen dead opossums in hollow trees.

911. *The Chairman.*] From the description of that disease do you think it possible that the disease in opossums is identical or nearly allied to the scab disease you noticed amongst rabbits? I believe it to be so from the description.

Alexander Bell called in and examined:—

912. *The Chairman.*] What is your occupation? I am manager of Langawirra station, Wilcannia. Langawirra lies about 80 miles east of Silverton, about half-way between Silverton and Wilcannia. The area is about 480,000 acres. I have been seven years in the district, and am acquainted with the whole history of the rabbits here. There were no rabbits when I came here first.

913. When did the rabbits first appear in your locality? About three years ago, or a little more. The country is now very heavily infested. It became heavily infested during the last two years.

914. Has the carrying capacity of the run been affected yet by the pest? Yes; around us and on all sides. It cleaned out our homestead lately, and there is not a blade of grass to be seen.

915. Yet you have had a very favourable season? No; it has been rather dry this season. Last year was a splendid season. I may add that the rabbits are killing the scrub, too, very fast.

916. What methods did you first adopt in dealing with the rabbits? Trapping; we have been trapping for about two years.

917. Did you discontinue trapping at the end of last year? Yes; it was a failure entirely.

918. Have you any idea of the number of rabbits killed on your station by the trappers? I have not got the figures here, but I can say we killed up to 40,000 and over per month.

919. Did the number of rabbits killed and the cost of trapping tend to increase? Yes; it increased continually, in the face of the fact that we reduced the price per scalp.

920. How many trappers did you employ on an average? From about fifty to sixty.

921. What was the general effect of the trappers' work? I could not see any advantage at all. I had the trappers in one camp over four months, and when they left there were just as many rabbits as when they went there.

922. Do you think the trappers killed large numbers of the natural enemies of the rabbit? No, not a great many; they killed a few of them.

923. Do you think the operations of the trappers tended to spread the rabbits more widely and prevented them from forming into colonies? No; I do not think the operations of the rabbiters produced any effects in our country. I am positive they did not.

924. Then, in your opinion, the money spent on the rabbiters was wasted? Simply thrown into the fire.

925. Have you had much experience in the use of poisons? Yes, latterly. I began using them about eight or ten months ago. I used arsenical water, laying it out in troughs. The rabbits drank it freely, and thousands and thousands died. I have also used strychnine and poisoned food. I have also been using the phosphorized grain distributors of Messrs. Lascelles and Anderson with great success. They beat all that I have yet tried.

926. How do you use strychnine? By dipping the bushes into the liquid and throwing them about on the ground. I used to break off the bushes that they are used to, put them in this water, and the rabbits would eat the bark and die almost instantly. We used about one ounce of strychnine to one bucket of water. This is a very expensive method; the grain distributors are less expensive.

927. In using the grain distributors were you not disappointed at not finding dead rabbits at the outset? The first day or two I was; then about the third or fourth day I began to see the rabbits dying in all directions, and now I can hardly find a live rabbit anywhere around the homestead. 928.

928. Have you used wire-netting at all? No, I have not.
929. Have you any personal acquaintance with diseases amongst rabbits? No; I only know what I have heard from others.
930. Do you think you will be able to deal effectually with rabbits all over your run by poisoning and without fencing? I feel confident I would be able to do it if I had eight or nine machines.
931. But will you be secure against any further irruption of rabbits? No; because there is very heavily-infested country all around me that nothing is being done with. I would have no security in this case unless others adopted the same methods, or that I fenced.
932. Do you think there is any chance of getting uniform action by all adjacent proprietors? I am sure I cannot say.
933. But does your experience show you that you can obtain this uniformity of action? It might be done by compulsion and by proper inspection to see that everybody did the same thing. If so, there would be no occasion for fencing at all. I think fencing costs a lot of money which might have been saved; that is, unless you fence in a lot of these barren waste lands that are of no use to anybody.
934. Can you give examples of such waste lands from which it has been necessary to exclude sheep? Well, we have parts ourselves which are largely useless and fit for nothing. This is very heavily-infested land. I would propose to deal with land like that either by poisoning or with disease. Rabbits can be poisoned there as well as anywhere else. It would be a constant expense and no gain to do it, but still it should be done to save the other. One of my neighbours has five miles square of similar waste land fenced off to keep the sheep out, the land being utterly useless and thickly infested with rabbits.

Harry Edmund Vindin called in and examined:—

935. *The Chairman.*] What office do you hold? I am Superintending Inspector of the Rabbit Department.
936. Over what area does your superintendence extend? North and south about 300 miles, and east and west about 280 miles; starting from the south-west corner of Mundi Mundi station, on the South Australian border; thence along the border to the north-west corner of the Colony; thence along the Queensland border to Brenda; thence south from there to Condobolin; and west from Condobolin to point of commencement.
937. How long have you been in charge of this district? Since July, 1885. I was first stationed in the Corowa district, on the Murray, and after remaining there about five months I was appointed to the Balranald district, on the Murrumbidgee. In July, 1885, I was appointed Superintending Inspector for the Western Division.
938. Is the country over which you are Superintending Inspector all infested? Yes.
939. In what degree, or is it uniformly infested? No; some portions are much more thickly infested than others.
940. Can you say what parts are thickly infested? Including all that country within the following boundaries:—Starting from Pooncarie, on the Darling River, east to Mossgiel; thence from Mossgiel north-west to Cultoa station on Darling River.
941. During the time that you have been in charge since 1885 have the rabbits been rapidly increasing in your district? Yes.
942. What effect, if any, has there been on the carrying capacity of the runs? I consider that in the most thickly infested districts the pest has affected the carrying capacity to a great extent. In fact some blocks are nearly eaten out. During my inspection of some blocks on Teraweynia I counted as many as 400 to 500 rabbits on my ride; in fact I might say thousands.
943. Do you think that this evil effect on the carrying capacity of the runs has progressively increased? Yes.
944. Did you notice a decided increase last year? Yes; I noticed a much greater increase during 1887, both in the prevalence of the rabbits and the evil effects on the runs; 1887 was rather a favourable season; there was plenty of feed.
945. Have you watched the trapping operations in your district during the three years passed? Yes; and I have been continually travelling through the district, inspecting the camps and seeing how the work of rabbit destruction has been carried out.
946. Can you give us any rough average of the area that one trapper has been accustomed to deal with, speaking generally? Until last year I always considered that for a 10-mile block of 64,000 acres four or five men were sufficient; but since that, in many cases, as at Teraweynia, on a 10-mile square block we had as many as twelve men; and still the rabbits have rapidly increased.
947. What effect, if any, has been obtained by the operations of the trappers? Well, if anything, I think they have spread the rabbits; they do not appear to have caused them to decrease at all.
948. Has any advantage whatever been got by the operations of the trappers? Yes; I think so—in the very lightly infested districts. The trappers seem to have been able to keep the rabbits down there.
949. What is your opinion about their work in the thickly infested districts? I cannot say that they have made any impression on the rabbits at all. On Teraweynia station, during the quarter ending June, there were 161 men exclusively employed rabbiting, and 500,000 rabbits were destroyed; yet no impression at all seemed to have been made. The rabbits were just as thick as ever.
950. Then in your opinion the operations of the rabbiters did evil by spreading the rabbits more widely? Yes, I think they have. They have driven them into country that was clear of rabbits, and otherwise caused the pest to shift about.
951. Is it a fact that the rabbiters prevented the rabbits from settling down in colonies, and rendered them more difficult to deal with? I considered that the trapping scattered them. In trapping on ridges where the warrens are very numerous I have noticed after the trappers had been at work for a short time that the rabbits have cleared out altogether; and, as a rule, they do not return for two or three weeks afterwards.
952. What, then, is your general opinion with regard to the utility of trapping in the densely infested country? I should do away with trapping, as more effectual work can be done with carbon in the winter, and by poisoning in the dry season when feed is dry.
953. Have you had much experience in the use of poisons? No, I have not.

954. Are you prepared to give any opinion as to what poisons are most useful? I have made an inspection of some of the work that has been done at Tarella station with Lascelles' patent grain distributor, and during my inspection I counted something like 400 rabbits dead along the burrows. We were out riding on that occasion, some seven or eight hours together. Of course there may have been a great number dead in the burrows that I did not see.
955. Have you had any experience with poisons on the natural food of the rabbits—bark, twigs, &c.? Yes; on Teraweynia station the edible shrubs were poisoned with arsenic by Mr. Wynne, but for some time I could not see any result at all. I was inspecting on the run for nine days and I counted something like 140 dead rabbits just around the logs. I did not regard that experiment as satisfactory in its results. I have had no other experience except with carbon. My experience in connection with this is that I have often had the warrens dug out and counted as many as eighty to ninety rabbits that had been suffocated.
956. Are you of opinion that the use of carbon bisulphide should be tried during the winter months? Yes; that is in country which is suitable—where the warrens are very numerous.
957. Have you had any experience with the use of wire-netting? No; but I have seen some in use at Euston, put up by Messrs. Bertram and Taylor. I am uncertain about the height, but it was 1½-in. mesh.
958. Was this netting part of a general enclosure, or was it used for some special purpose? It was a fenced-in paddock that I saw.
959. What success was obtained? I consider it was very successful. Before being fenced in the rabbits were very numerous there, and having inspected the country afterwards I found that they had greatly decreased.
960. Have you watched Dr. Butcher's operations at Tintinallogy? I went there once by instructions of the Department, and remained from the 5th to the 9th March. The special object of my visit was to see to what extent the disease had spread. I have not visited Tintinallogy since.
961. Were you acquainted with the conditions of Tintinallogy before Dr. Butcher commenced operations? No; that was my first inspection. I had sixteen rabbit inspectors' districts to overlook, and as Tintinallogy always carried out satisfactory work I had no occasion to visit that station. I have made a report to the Department concerning my visit and that report is available to the Commission.
962. What condition was the stock in at Tintinallogy Station, in the parts where the rabbits were dying? On the 500 acres that I visited I saw some sheep and goats which appeared to be in fair condition. They were just keeping their condition; but were not in good condition by any means. I cannot say how long they had been in the enclosure. I do not remember seeing any stock along the river frontage. Further out at the back of the run, I saw some sheep which appeared to be doing very well.
963. Generally, then, you came to the conclusion that, although the feed was poor and dry, the mortality amongst the rabbits must have been occasioned not by scarcity of feed but by disease? I cannot say, because I did not understand anything about disease. I thought the disease was caused by the feed. I did not inspect at that time any of the runs further out.
964. But what was your conclusion then? At the time I was there I was under the impression that the rabbits were dying of some disease, and I thought the disease was caused by the feed.
965. Has your subsequent experience caused you to modify your opinion as to the origin of the disease? No; I am still of the same opinion. I think this disease has been caused by the poverty and dry state of the feed, and my inspection of other runs has made me still more strongly of the same opinion.
966. What did you see on other runs that strengthened you in this opinion? Since leaving Tintinallogy I travelled through Kinchega Run and inspected the country on horseback. I saw dead rabbits here and there on Kinchega, but nothing like so many as upon Tintinallogy. Yet I consider the country I inspected on Kinchega was much better off for feed.
967. Have you had any further experience in connection with the Tintinallogy disease? No; not since.
968. Have you had any experience in connection with the disease which has been attributed to the eating of bark? I have examined several of the rabbits in travelling through the different runs, but I have not noticed any particular disease, unless a few cases where the liver seemed to have a few streaks upon it. It was on Kinchega I saw this. These streaks were light-blue and there was water inside in the cavity of the belly.
969. *Mr. Lascelles.* Have you since altered your opinion that disease was more confined to the frontage than to the back country of Tintinallogy? Well I have not inspected the run since. At the time I inspected it there were more dead rabbits on the frontage and in the lignum. Since my inspection at Tintinallogy I have been out on the Wilcannia Common, at one of our Government camps. Some grass had shown up and the rabbits seemed to be as lively as ever; this is upon thickly infested country. There was an increase in one week of from 800 to 1,300 killed with the same number of men employed.
970. Do you attribute that increase of deaths to an increase in the number of rabbits? It is very hard to judge; the men may not have worked so hard at first, though they had the same number of traps, &c. One of the rabbit inspectors came and told me that the rabbits were swarming in from other parts to where there was good feed on the Common.
971. What is the history of the country around Silverton with regard to rabbits? I think they have decreased very much. In July last year the rabbits were very numerous. In driving from Broken Hill to Thackaringa I noticed several hundreds, but recently I did not see one. My opinion is that the decrease is due to the eating of dry feed. They seem to be dying very fast around the Pinnacles and Mount Gipps. All the natural feed is now very dry—much drier than when I last inspected the country.
972. Are you clear that the diminution of the rabbits has been due to their dying, or may it not be due to their passing on to other districts where feed is better? I think they do sometimes shift on to better feed. You can to a certain extent clear a paddock by stocking it heavily with sheep.
973. Have you had clear evidence that rabbits have been dying in this country from want of feed? Judging from the reports that I have received from the inspectors, I should say that the rabbits were dying off in the thickly infested districts.
974. Are these reports based on the disappearance of rabbits or on seeing dead rabbits? Seeing dead rabbits.
975. You are perfectly clear, then, that over a large portion of your district there has been considerable mortality amongst the rabbits? Yes, since the beginning of March, and I think such mortality is due to the poverty and dryness of the feed.
976. You have not noticed rabbits dying off in the same way where the feed has been abundant and good? Yes, I have noticed that in different portions of my district where there is plenty of dry feed; but not where there is green feed.
- 977.

977. Have you opened any rabbits in country where feed is abundant? Yes; and I have noticed that they were very miserable and tucked up, and suffering as if from constipation, which I attribute to the dry state of the feed.
978. When you were at Tintinallogy did you notice any yards where the rabbits were well fed on succulent food? Yes; there were some being fed on cabbage leaves, &c.
979. Were these rabbits wasting away? They appeared to me to look very miserable, just the same as the others. Perhaps they were not quite so bad as the others, though I considered that they were wasting away.
980. *Mr. Quin.*] Do you think well-fed rabbits confined in such an enclosure would remain in good condition, or would they fall away? I think they would fall away, at least for some time.
981. Might they not have had that appearance without being diseased? Yes, they might. This was the first time I had seen rabbits enclosed in that way. I saw the rabbits in the bend twice during my visit; I also saw those in the yard twice when I visited the camp.
982. *Mr. Lascelles.*] Up to the time of your visit to Tintinallogy, were you on other runs barer of feed than Tintinallogy, and were the rabbits dying on these runs without poison having been laid? No. Previous to my inspecting Tintinallogy I inspected Mount Manara, where some of the paddocks were very bare, but I cannot say that I noticed any dead rabbits about, although at that time—it was about September or October of last year—the trees were not barked so much.
983. *The Chairman.*] Did you, during this year, pass through other runs barer of feed than Tintinallogy, without finding the rabbits dying in this way? No; all the runs that I have travelled through since are, I consider, better off for feed than Tintinallogy. I have been out through Kinchega and Mount Gipps, &c., and on all of these the feed is better, with one exception, that of Glenlyon. I noticed several dead rabbits in passing through that run, and to show how numerous they are, I saw 1,000 caught in a trap at one of the tanks. The number of dead rabbits that I saw at Glenlyon did not at all compare with the number I saw at Tintinallogy. I was inspecting on horseback at Tintinallogy, whereas at Glenlyon I only travelled along the road.
984. What is now your general conclusion with regard to the mortality amongst rabbits at Tintinallogy—how was it caused? Well, since I have travelled through other stations, I think it is caused through eating dry feed and astringent barks, and through a want of nourishing food.
985. Therefore, when the feed improves the disease will disappear? Yes; I think so to a great extent, and the rabbits will recover.

Abram John Clarke called in and examined:—

986. *The Chairman.*] What is your occupation? I am a rabbit inspector at Wilcannia, for No. 9 district. The chief runs included in that district are Teraweynia, Murlee, Baden Park, Tintinallogy, Goonalgna, and Billilla. I have been in charge of this district since August, 1885.
987. Was this country infested with rabbits on your arrival? Yes, the whole of it.
988. Was it thickly infested? No; not so thickly infested as it has been since.
989. Is the country now very thickly infested? The rabbits have been decreasing lately.
990. Are you clear that the diminution is due to increased death-rate amongst the rabbits and not to shifting from one district where feed is poor to a district where feed is abundant? I think it is due to an increased death-rate, as you can see the dead rabbits lying about.
991. You are then clear, that there has been an increased death-rate all through your district? Yes.
992. Has that mortality been more marked in some parts than in others? Yes. At Tintinallogy there is the biggest death-rate I have seen. At Billilla, on the Tintinallogy boundary, the death-rate has also been very marked, and also at Teraweynia on the adjoining boundary.
993. To what do you attribute this mortality? To disease; I have been told so. On some of the adjacent runs I think the rabbits are dying from eating bark. On making an examination of the rabbits afterwards I found that the appearances inside were different from those that had what I understood was disease. I have from the first watched Dr. Butcher's operations at Tintinallogy.
994. Has your supervision of these experiments been continuous or merely occasional? Occasional; as I went about. I visited the station about once a month. I had to go around the rest of my district, but I stayed at Tintinallogy as long as I could on every round.
995. Were you acquainted with the condition of the Tintinallogy run before this disease was first taken up by Dr. Butcher? Yes; it was then very heavily infested with rabbits. The rabbits began to perceptibly diminish in numbers about November last; I then noticed that they were dying in large numbers. The condition of the feed on that station at the time was very good. The condition of stock was very good also. In fact, they sold some fat sheep about that time and they were the best that I saw in the Wilcannia district.
996. What is the condition of Tintinallogy station now as regards rabbits? I have reported the decrease at about 95 per cent. I would now classify the station as a thinly infested one.
997. In your opinion can this change be attributed to the starvation of the rabbits? I should say not.
998. Can it be attributed to the eating of bark? Well, that is a question which I can scarcely answer; I should think not.
999. Has there been any change in the habit of the rabbits with regard to the eating of bark that would account for that station, which was once densely infested, being now thinly infested? I do not think the eating of bark alone would account for the change.
1000. *Mr. Lascelles.*] Is there less or more scrub on Tintinallogy than on the other runs in your district? There is more open country on Tintinallogy than anywhere else, and less scrub than on the average run in my district.
1001. *The Chairman.*] Does this mortality prevail amongst the rabbits on Tintinallogy both in the open and thick country. It prevails on the whole of the run—on some isolated spots—sand hills on which rabbits were thick on my last inspection—more especially. My last general inspection was about the end of March last.
1002. Have you familiarized yourself with the details of Dr. Butcher's experiments? Yes. Dr. Butcher explained to me everything that I asked him. I was instructed at the commencement to watch the experiments he made when he obtained permission to keep live rabbits.

1003. Did you watch his experiments in placing healthy rabbits in a crate in which diseased rabbits had been previously kept? Yes. I have seen him put them in, but I had been on the station only a few days. I had to go around again. I have seen the rabbits put in and was informed that healthy rabbits were being put in diseased crates.

1004. Were these rabbits so bedded and fed as to exclude the idea of death from other causes? Yes; they were fed much better than wild rabbits running outside. They were fed from the garden.

1005. Did you see the conditions under which the yard experiments were conducted when diseased rabbits were turned in amongst healthy rabbits? Yes, I have seen them all together.

1006. Were those experiments so carried out as to exclude the possibility of death from starvation or unusual exposure? The rabbits were well fed, and sheltered, and watered.

1007. Did you witness any of the inoculation experiments at that time? Yes; I have seen inoculation by the syringe and the seton. I did not watch any of the experiments from beginning to end, because I had no chance.

1008. Did you obtain by your repeated visits a clear understanding of the results of the experiments carried out in the bend of the river? Yes.

1009. Will you describe shortly what results were obtained? Well, on my first inspection of the place I found that all the young rabbits died first. That inspection was made, I think, in October, shortly after the bend was fenced off. I was shown some aborted young that I was told were picked up in the bend by one of the camp men. The rabbits were then very thick in this bend. It was the most heavily infested place in my district. The water had been around it and the men were not able to get at it to work. I also saw a lot of dead rabbits lying about the fence. I inquired how they accounted for this and it was explained to me that they imagined the rabbits were brought from outside and that they were trying to make their way back again. These rabbits were ear-marked.

1010. What did you notice subsequently? That the rabbits decreased very much. In fact, the last time I was there I drove around the bend and only saw five or six where before there must have been between 20,000 and 30,000. The condition of the feed in the bend during the whole of this period was very good; it was not unusually dry. There was green feed there also, as much of the bend had been under water. On every occasion I made an examination of this bend the rabbits were not breeding, and have not bred anywhere in my district since about last September.

1011. Did the rabbits stop breeding at Tintinallogy earlier than in other parts of your district? No, I think not.

1012. Then the cessation of breeding was due to conditions prevalent generally through the district, and not to the occurrence of disease? It ceased through the whole district. Of course I am not in a position to say that it was not on account of disease at Tintinallogy; the feed has not been good enough since; the feed on this bend was not feed that rabbits would breed on; the rabbits only breed after rain.

1013. When was it that you found the aborted young? It must have been about October or November. They were shown to me as having been found in this bend. I think there were three of them; they belonged to the same litter; I did not see any others.

1014. Did you watch the experiments that were made on stock? Yes; I saw a sheep inoculated by a syringe containing blood taken from a diseased rabbit in one of the hutches. This sheep did not suffer; and on my next visit it appeared to be perfectly healthy; I could identify the animal. I was also shown marks on a horse that I was aware had been inoculated; the horse was an old one, but in very fair condition.

1015. Have you ever watched such experiments throughout the whole course? No; but I have seen the same horse and sheep on every visit, and they always appeared to be healthy. I saw guinea pigs living with rabbits that were diseased and that afterwards died. These guinea pigs kept healthy and fat.

1016. What was your general conclusion with regard to the causes of the great mortality amongst the rabbits on Tintinallogy? My conclusion was that some disease existed there which was fatal to rabbits; the rabbits started dying there while the feed was good, and before they died in other parts of my district; the feed was better on Tintinallogy than elsewhere, and yet the rabbits started dying there first.

1017. Do you know whether poison was laid at Tintinallogy which would account for any considerable portion of these deaths amongst rabbits? Some experiments were made with poisons, but they would not account for the death-rate all over the run; the poison experiments were made in fenced-off places.

1018. You were satisfied, then, that the general mortality throughout the run was not due to poison? Yes.

1019. And are you perfectly satisfied that the condition of the feed could not have caused this mortality? Yes; I am sure that the rabbits Dr. Butcher had were fed better than they could obtain outside. I am also satisfied that the mortality in the bend could not have been caused by conditions of feed.

1020. Could the disease at Tintinallogy be possibly attributed to the eating of bark? I should say not; because I saw disease there before any bark was eaten at all. I noticed eighteen months ago, at Mount Manara, that the rabbits were barking the mulga and sandal woods, and yet there was no unusual mortality amongst them.

1021. At Tintinallogy did the mortality prevail in the open as well as in the thick parts of the country? The rabbits had got under the shade of the trees in summer when dying. You will see more rabbits in the scrub than in the open country. In fact the death-rate was so great I recommended that the trappers should be discontinued, as they gave up a large number of skins, and were paid for them, which I would have to pass.

1022. Is there any special bark in the scrub at Tintinallogy that would account for this specially high death-rate? No; it is the same kind of scrub as on the adjoining runs, where mortality has not prevailed to the same extent.

1023. Has there been more marked traces on Tintinallogy of the mortality than on adjacent runs? Yes; until very recently.

1024. Has this recent increased mortality been general throughout, or is it merely on the Tintinallogy border? It has been general throughout; there is no feed.

1025. Has the prevalence of the rabbit plague in itself seriously diminished the carrying capacity of the runs in your district? Yes; very much so. My district is principally a scrubby country, and the scrub died on account of its having been barked by the rabbits.

1026. When scrub is barked in this way and dies off, does it recover itself? Well, we have had only about 18 months of it. The punta, mulga, and sandal-wood scrub are dying, but the leopard-wood tree is not dying; it seems to recover itself.

1027. Has the barking of the scrub increased rapidly? It increased very much in the last six or seven months, but the rabbits are now decreasing everywhere. They have only the bark to live on. The barking is not increasing now although the rabbits are living on the bark.
1028. This means that a large amount of scrub is being permanently spoiled? Yes.
1029. If this continues what will be the result? The country will be bare.
1030. Losing this scrub, could the country be used as a pastoral country at all? It could in good seasons.
1031. But I mean permanently? Well, the grass might come if the scrub were cleared off.
1032. Is it a fact that for some time the sheep have been largely dependent on scrub? Yes.
1033. Are you aware of any facts showing whether grass would or would not grow on this scrubby country after being cleared? Yes; miles of country have been cleared for the purpose of roads, and people do not use them, being sandy. There is no better grass anywhere than on them, in this scrubby country where the scrub has been cleared. I have known patches of this kind for two and a-half years.
1034. Over how many years does your experience of trapping extend? Well, I have known of trapping since I was a boy. I have had experience of clearing on a large scale for four years.
1035. What area have you been accustomed to allow for the operations of each trapper? About one man to every 5,000 acres. It would vary according to whether it was a thinly or thickly infested district, but the whole of my district has been very heavily infested lately.
1036. Did the cost of the operations of the trappers tend to increase during the latter part of the time that they were employed? Yes, very much, notwithstanding that during the last few years less was paid for scalps. While the trapping was going on the price increased very much up to the last. Of course the number of rabbits killed per man increased greatly. I do not think it was due to increased energy; they got just as many as they could at 6d.; the rabbits were far thicker at the end of their operations than at the beginning.
1037. That being so, do you think any good result was obtained by the operations of the trappers in your district? No; not any.
1038. Do you think that any evil results followed their operations? No; except that it was a lot of money thrown away.
1039. Did the operations of the trappers lead to the destruction in any large numbers of the natural enemies of the rabbits? Before trapping began we had large numbers of cats, but there were very few cats left when the trappers knocked off.
1040. Was there any diminution of the other enemies? Yes; the iguanas became very scarce; but the crows, hawks, and other birds remained about the same.
1041. Is it your opinion that the operations of the trappers tended to scatter the rabbits? Undoubtedly they spread the rabbits about.
1042. Would such disturbance prevent them from settling into colonies, and thus militate against operations by poisoning? Operations by poisoning would disturb the rabbits as much as trapping, probably. Rabbits are so general throughout the whole of the country now, that they may run around and pass on to another place.
1043. What is your general conclusion as to trapping as a means of destroying the rabbits? That it is far too expensive at any price per scalp.
1044. Under any circumstances, do you think it would be effective? Yes; it might be if the country was worth going to the expense; but it would cost probably £1 per acre to keep the rabbits down. If you could put on a man to every rabbit you would probably get rid of them. But trapping is of no practical use, taking into consideration the value of the country.
1045. Have you had much experience in poisoning? Yes; both in New Zealand and here. In the former place we used phosphorized grain very successfully; we used to lay the grain in the ordinary way around the burrows. We have found a better way of using phosphorized grain. Lascelles and Anderson's machine was very successful, but it is too expensive to be of any practical use here.
1046. What other poisons have you used? Strychnine and arsenic; we have killed a great many rabbits with strychnine-water. I think that in dry seasons strychnine poisoning is the method which should be adopted. I never tried arsenical water; I have used arsenic on chaff and bran, but not with such great success as the strychnine. It is very difficult to get enough poison on to the medium to kill rabbits with arsenic.
1047. Have you made experiments with poisoned bark and twigs, and other natural feed? Yes; and I watched the experiments on Teraweynia. I found where rabbits were strong that the arsenic would kill very few; but now that the rabbits are weak it is killing any number of them. With some experiments which we made we found that 3 grains of arsenic did not kill a rabbit; there was only one experiment made; the chemist in Wilcannia did it for us: I am certain we got what was said to be 3 grains; the chemist poured the stuff down the throat of the rabbit, which afterwards was killed by 134th part of a grain of strychnine. At Teraweynia I found that they only put 1½ grains of arsenic on 6 square inches of bark; the arsenic was dissolved in ammonia—20 lb. of arsenic and 45 oz. of ammonia; but I am not very sure of the proportions. My general conclusion with regard to the method at Teraweynia was that it was too expensive. In a particularly dry season it can be successfully used; but the system of eating a paddock down bare ruins the country. It will take three years for the paddocks to recover again, when the rabbits would be as thick as ever.
1048. *Mr. Quin.*] Where were these machines used which you say were too expensive? Over some country as Billilla, which is too poor. It only carries a sheep to 30 acres; and some would not carry a sheep to 1,000 acres in a season like this.
1049. *The Chairman.*] In your opinion there are certain districts of waste lands which require special treatment? Yes.
1050. Would it be cheaper to fence in this very bad land or thoroughly and repeatedly poison it? I do not think you could do it. It would be better to sink it altogether, if you could.
1051. But these lands are now sources of danger, and something must be done with them? If you could make rabbit-proof fencing it is far better to fence them in and allow the rabbits to have them entirely; that is, if you can make a fence that will keep them in. Except this or some disease—this is the only hope of this far western country.
1052. Have you had any experience in wire-netting? Yes; I saw it used in New Zealand, and also in the yards at Tintinallgy. I found that the rabbits in the yard would go over it; we put feed on one side of the fence, and discovered that they would go over to it. 1053.

1053. Did you notice the fence around the camp bend, shutting it off from the rest of the run? Yes. That was $1\frac{1}{2}$ in. mesh, lashed to the existing wire fence. I am not certain of the height, nor positive as to the character of the fence.

1054. Were you satisfied that the rabbits died on the camp side of that fence, having been stopped in their escape from it? The rabbits died on the camp side, but they were too weak and poor to go over it, having been diseased.

1055. What was the character of this fence over which you drove the rabbits? They were yards about 20 feet square. The fence was about 2 feet 6 inches out of the ground, and the rabbits ran across them for feed. We put the feed on one side and the rabbits on the other, and they jumped over. This fence was perpendicular. In fact the rabbits now run up the scrub. You see them up 10 and 15 feet high.

1056. Would the fact that rabbits passed over the fence in these little yards have any great application to the behaviour of the rabbits on a large run? No, I think not. Rabbits, unless they were specially trained, would not attempt to cross. I do not think they would do it naturally on a big run, and I think the fences would check them. At the same time fences in this back country would be in the way. A fatal disease is the only thing; and a fence would be in the way of its spreading.

1057. Apart from disease, do you not think a fence is necessary if the pest is to be successfully dealt with? I do not think the rabbit pest can be successfully dealt with except by disease. The country is too poor and no system of poisoning can be practically carried out. It is too expensive.

1058. Would the revenue from the land justify, in your opinion, the erection of wire-netting fences by the lessees? I do not think the lessees can afford to do it. Of course, in travelling around as rabbit inspectors do, we have a good chance of seeing what the country is like, and the returns from the stations.

1059. And what is your general conclusion? That the lessee cannot afford to fence. The country is valueless; paying the same rents as are paid now the lessees cannot fence.

1060. *Mr. Quin.*] Do you know the cost per 1,000 acres of using poisoned grain? No; I do not.

1061. If land owners were to abandon the present methods of dealing with the rabbits for several months, pending the results of investigations of disease, what would be the consequence? They are simply wasting money in doing work in an isolated way. It is of very little use, whether the method be poisoning or any other.

1062. *Mr. Lascelles.*] And yet you say the rabbits are being thinned down? Yes; they are decreasing now more than ever they did when they were being trapped. The work now being done is done in an experimental way by poisoning on most runs.

1063. *The Chairman.*] In your opinion the diminution of rabbits is not due to poison? No; but to the poverty of the feed and probably to some disease. I have been shown by Dr. Butcher what is said to be the Tintinology disease, and I have opened some hundreds of rabbits in other parts of the country, and the appearances of the organs are different.

John Andrew O'Flaherty called in and examined:—

1064. *The Chairman.*] What position do you hold? I am a rabbit inspector in charge of No. 5, Wilcannia district. The chief runs in my district are Momba, Caulpaulin, Nattalie, Grassmere, Gualta, Menamurtee, and Mootoowingee. I have been eight months in my district.

1065. Is your district thickly or thinly infested? I should call it moderately infested; parts of it near the river are thickly infested.

1066. Has the carrying capacity of any of the runs been seriously affected by the rabbits? I think so. Until last year I was overseer on the Lachlan, so I cannot say much about it. My work on the Lachlan was as overseer of a Government rabbit party. I have been occupied about two years and three months as overseer and inspector.

1067. In your trapping operations what area do you allow to each trapper? It is almost impossible to average, because we have trapped on stations requiring ten men to each 10-mile block. The conditions of runs are very different.

1068. What is your general opinion with regard to the system of trapping? Personally, I do not believe in it. It may have reduced the number of rabbits, but the rabbits are made to travel by it.

1069. But taking any moderately infested country with trapping executed in the ordinary way—granting that vast numbers of rabbits are killed—have you noticed a general diminution in your district? No.

1070. Do you think the scattering of the rabbits resulting from the operations of the rabbiters a real evil? Yes, I do.

1071. Did the cost of trapping operations in your district tend to increase last year? I think so.

1072. Did that occur notwithstanding that the price paid per head was lower at the end of the year than at the beginning? Yes; I think there were more rabbits caught.

1073. Why were more caught at the end than earlier? Because I think the men worked harder when the price was lower. It was not, I think, due to the fact that rabbits were more abundant.

1074. In your opinion, has any real good been obtained by all the outlay on the rabbiters? No, I do not think so.

1075. In your opinion could a system of rabbit parties ever be carried on in your district, so as to obtain substantially good results with trapping? No; I do not believe in trapping at any time as a means of extermination.

1076. Have you had much experience in the use of poisons? Well, within the last two months poison has been adopted in my district—phosphorized wheat, strychnine, and arsenic, have been the chief poisons used. My belief is that phosphorized wheat is the best.

1077. Have you found any special method of distribution best? I do not think there can be anything better than the patent machine used for the purpose. In one case I have found great success with the use of strychnine. The grain was steeped in strychnine, dissolved in vinegar, and very good results were obtained.

1078. Have you used the bisulphide of carbon? Yes; in the winter months I think it is most effective.

1079. Have you had any experience with the use of poisons applied to the natural food of rabbits? No.

1080. Have you had any experience with the use of rabbit-proof netting? I have seen it used around tanks or traps, and it has been most successful. I think the mesh is $1\frac{1}{2}$ inch, but I am not certain. It is the usual wire netting used; and this netting proved thoroughly effective, and the rabbits did not get out—so I have heard. If they do get out it is only in very exceptional cases. 1081.

1081. Have you visited Tintinallong at all? No, I have not. My district lies on this side of the river.
1082. Have the rabbits in your district been increasing in numbers? Recently they have decreased very much indeed. I do not know what to attribute this decrease to, but some suppose it is due to their eating the bark.
1083. Have you noticed the rabbits dying off both in open and thick country? Yes; more in the thick country. I first noticed it at Caulpaulin run—on the river on the 10th March. I have opened hundreds of them. The only thing I noticed was that the live rabbits were very weak and emaciated looking and gathered up. On opening the rabbit I invariably noticed that the liver was of a very dark colour, and not the same colour as the healthy rabbit. I looked carefully but cannot say that I saw any specks. The only other fact I noticed was that, there was no fluid whatever in the urinary bladder. Though I first noticed this mortality at Caulpaulin, I am of opinion, from what I have seen, and from opening the rabbits, that the deaths of rabbits in the back country are due to the same cause as the deaths at Caulpaulin.
1084. Did you see anything in your examination of these rabbits which you could fairly attribute to the eating of bark? No. The stomach was full, but I cannot say of what. I concluded it was bark from the way the trees were barked.
1085. Do you know anything about the mortality that has been prevalent amongst the rabbits on parts of Momba? Well, I cannot say that I do. I know the rabbits have been dying there; but I have not given any special attention to the matter.
1086. Generally, then, you have found that the rabbits have enormously decreased in numbers within the last two months? Yes; but I am uncertain as to the cause, except that the decrease has been by actual deaths. I think anything that is tried before wire-netting is adopted will be ineffective. Wire-netting is the foundation; and when it is done, methods of destruction will be effectual.
1087. Has breeding stopped in your district? Yes; the rabbits have not bred for certainly four or five months.
1088. Has this cessation of breeding been an extraordinary circumstance this year? Yes; I think it is owing to the want of green feed, and also to the emaciated condition of the rabbits.

John Lynden McMaugh called in and examined:—

1089. *The Chairman.*] What is your address? Cuthero Station, on the Darling, via Wentworth.
1090. You are a rabbit inspector? Yes; my district is No. 3. The chief runs in that district are Polia, Cuthero, Nctley, Buchleo, Burta, and Ophara. I have been in the district four years last November. It was only lightly infested with rabbits when I first took charge. On first coming here I was appointed to No. 16 district, but the districts have been altered since then. I have been in charge of No. 3 district for about two years; portions of it are now thickly infested. On other portions, of late, the rabbits have been dying very rapidly, and these portions are now thinly infested.
1091. In the thickly infested portions, has the carrying capacity of the runs been seriously affected? Not very seriously affected. It is only lately that the rabbits have become so numerous there.
1092. What has been the nature of the operations that you conducted? Up to the last four months we only used the ordinary rabbit-traps.
1093. What is your opinion as to the results of the trapping system? I do not consider it a sufficient means of coping with the rabbits at present.
1094. Do you think that the numbers of rabbits in the thickly infested portions of your district were sensibly diminished by the operations of the rabbiters? No; I do not.
1095. Do you think, then, that any good result was really obtained by the expenditure of a large amount of money in connection with the operations of the rabbiters? No; I do not think there has been any very good result. Of course they have been keeping the rabbits down to a certain extent, but they have kept on increasing in spite of every effort, and I hardly think any good result has been obtained. They have just been kept in abeyance for a time.
1096. Do you think that any evil result has come from the operations of the rabbiters? No; I think not.
1097. Do you think their work has tended to scatter the rabbits more widely? No; but of course I am only speaking now of my own district. We have had a very heavy influx of rabbits from South Australia, and I attribute to them, in a great measure, the difficulty our owners have had in keeping the rabbits down.
1098. Was there any special reason causing the rabbits to travel towards you? Yes. They were very numerous in South Australia, and had eaten the country very bare. They were then travelling on to Burta Run, and Mr. Armstrong erected 2 miles of wire-netting along the border in one particular place down the creek. I think the mesh was 1½ inches. There was afterwards a great number of rabbits dead on the South Australian side—hundreds of them lay dead all along the fence. I think this fence formed an effective barrier for this particular part. I have seen other netting around tanks at stations—on Cuthero, for instance. I know the gauge is that recommended by the New South Wales Government. This fence is effective in keeping the rabbits in. I have been told that occasionally odd rabbits get through it.
1099. Have you had any experience with the protection of gardens by wire-netting fences? Yes; I believe it is quite effective for that purpose—that is, the ordinary netting. Mr. Armstrong has poisoned rabbits by thousands. He had an enclosure around his garden, and adopted the system of laying poisoned herbage out of the garden around this fence. The rabbits were attracted inside by the green feed, and ate the poisoned herbage and died in hundreds. None of them ever got through into the garden. Of late, different methods of poisoning have been adopted by us. Mr. Armstrong's method seems to be the most effective. He boils vegetables for a short time in a strong solution of arsenic and sugar, and then strains the herbage, and lays it around the netting enclosure. The rabbits go in after the water, consume the poisoned herbage, and die in hundreds. Mr. Armstrong has cleared his run well with this; he also used sandalwood leaves, which the rabbits eat freely. This was during a rather dry time, when there was not much else for the rabbits to obtain. I have had no experience with disease in rabbits.
1100. Have the rabbits been dying in large numbers in your district during the last few months? Yes; there has been a sensible diminution in their numbers.
1101. Can you give any explanation of this fact? No; but my opinion is that it is due to want of water and green feed. I think they have eaten bark and it has had some ill effect upon them.

1102. Is the feed very scanty now? Yes. There is any quantity of saltbush, but rabbits do not seem to eat that. As for grass, there is none at all in the back country. The bushes are dying in my district in consequence of having been barked.
1103. Have you arrived at any general conclusion as to the best way of dealing with rabbits in your district? No; I cannot say that I have. I believe in the poisoning system, in wire-netting and trapping, and wire-netting at water-tanks.
1104. Would it be practicable to introduce boundary netting around the runs in your district? Yes; I think it would be. I would recommend it.
1105. Do you think poisoning operations would be permanently successful without the use of such netting? No; I do not think so—if you have anything like good seasons. The rabbits would multiply again, and come in from other parts.
1106. Then, generally, you would recommend that netting fences should be erected—that poisoning should be adopted along with trapping of rabbits at tanks? Yes.
1107. Do you think that these measures would be effective in exterminating rabbits? I do not know of anything that would be more effective.

Mark James Curry Tully called in and examined:—

1108. *The Chairman.* What is your office? I am inspector of stock for the sheep district of Wilcannia. Until last December this included all that country west of the Paroo down to the South Australian boundary, to the north point of Corona Station, about 100 miles north from here; then in an easterly direction across the Darling, nearly as far as Mount Manara; then across the Darling River, above Kallara, up to the Paroo, and to the Queensland boundary-line west of the Paroo. I have been in charge of that district nearly three years. At the end of last year the district was divided, and I have a smaller district now under my charge.
1109. You were, I believe, sent by Mr. Stanley to Tintinallogy to examine the experiments made by Dr. Butcher respecting the transmission of the so-called Tintinallogy disease to stock? Yes; I went there early in January. On my first visit, I had the stock yarded of which I had a description sent me by Mr. Stanley. I examined each animal separately and carefully. I was pointed out on the animals that were inoculated the spot of inoculation, which showed a slight mark. I saw that the animals corresponded with those described by Mr. Stanley, and was satisfied that they were the same. They appeared to be in perfectly good health, with no signs of disease of any kind.
1110. Did you personally see any experiments conducted on stock? No; no experiments were conducted in my presence. I merely had a list of the animals that had been treated, with instructions to watch those animals, and see whether any disease might develop itself. I stopped at Tintinallogy about two days at that time. I have been at Tintinallogy twice since. I was there on the 5th February, and again on the 18th March. I should have visited it before, but I was called to Sydney to give evidence before the Tanks and Wells Commission. I remained two days each time I visited Tintinallogy.
1111. You have not, then, seen any of the experiments continuously performed either on rabbits or on stock? No; I have not.
1112. During this February visit, what did you see? I had the stock again collected and examined them carefully, and saw that they were the same stock, by the description and marks, as I had at first examined. They all appeared to be perfectly healthy. The same remark applies to the third visit. When I examined them again they were in a healthy condition, and without any sign of disease of any kind.
1113. Did you see any of Dr. Butcher's experiments in progress either on rabbits in crates or in isolated yards? Yes; I had an opportunity of seeing all his experiments, as they were going on at the time.
1114. Were the rabbits under experiment, in your opinion, so housed, bedded, and fed as to put death from starvation or exposure out of the question? They appeared to be as well housed, bedded, and fed as could be wished for to keep animals in a healthy condition. They had an abundance of feed.
1115. Did you examine the camp bend experiments? Yes, on each of my visits. I did it for my own satisfaction, so as to have a knowledge of what was being done.
1116. Was the food there sufficiently abundant and green as to put death from starvation or from excessive dryness out of the question? On my first two visits the food was quite green; but on my last visit it was getting a little bad and rather dry, but not sufficiently to lead to the idea that the rabbits were dying from starvation, because stock were in the paddock at the time of my last visit.
1117. Were you able to form a general opinion about the available feed on Tintinallogy Run during your visits? I can only speak of the frontage portion of it. There was green feed there, because there had been water on the ground. This was during my first two visits. On my last visit the country was getting dry.
1118. Do you think that on this river frontage any great mortality amongst the rabbits could be attributed to starvation? I do not think so. I saw no great mortality on my first visit, and there was very little evidence of general mortality in the country that I passed through when going to Tintinallogy. I saw evidence of mortality in the camp bend on the first occasion, though there were very few dead rabbits to be seen lying about.
1119. What did you see on your second visit? I observed that there did not appear to be anything like the same number of live rabbits in the bend. There were carcasses under the lignum bushes and in the holes on the bank of the river that I particularly examined. I saw no appearances of disease on the first occasion until I got within two or three miles of Tintinallogy, although I passed along the river-frontage. I could see that something ailed the rabbits, and noticed that they were in very much lower condition than elsewhere, as if they could only run a short distance. On the first occasion I saw carcasses lying about some three miles distant from Tintinallogy. On my second visit I noticed a falling off in the condition of the rabbits, which were apparently ill from some cause a much greater distance up the river, a little more than nine miles from Tintinallogy. On one particular sandhill I noticed several dead rabbits, and the general body seemed to have numerous sickly ones amongst them.
1120. On your third visit, what did you see in the bend? There were very few rabbits there then. I reckon that the number had decreased about 50 to 75 per cent. There were a good many dead rabbits lying about, and though the country is full of lignum, I could see a great many. The live rabbits were all very weak, and all apparently sickly. The condition of the river frontage at the time was good, yet dry, and a little

little bare; but there was quite sufficient feed in the paddocks for the working stock. The condition of the rabbits along the frontage outside the enclosure appeared to be more or less sickly, and the numbers had decreased amazingly. The rabbits then appeared to be sickly for quite 20 miles up the river from Tintinallogy, the disease appearing to spread up the river as time went on. At that time certain of the rabbits were dying in the experimental yards. I asked that some of these should be killed, and one was killed, and another died in my presence. They were opened, and I examined them. I then requested that some of the strongest rabbits running in the bend should be shot. This was done. They were examined in my presence, and the same appearances were distinctly to be seen. I did not see what I considered to be one healthy rabbit in the bend at the time of my third visit.

1121. Are you familiar with the appearances of the organs in healthy rabbits? Yes; I have seen many of them.

1122. Tell the Commission the chief things you noticed in these diseased rabbits? Without looking for disease, I do not know that one would notice anything wrong except the emaciated condition of the rabbits. You would wonder why, in the midst of feed, they should be so emaciated. On closer examination certain of the internal glands appeared to be congested, with a darker colour than usual. These were the mesenteric glands, and what I was told were the supra-renal capsules.

1123. Did you notice anything in the liver? Yes; very minute white specks were to be seen in the livers of some, but all did not show them. I had an opportunity of seeing many of the rabbits opened, and examined perhaps ten or twelve in all. Some of them presented no appearance of disease in the liver, but many of them did show symptoms of the disease; these were little whitish specks.

1124. Could you satisfy yourself that in the bend and along the river frontage the mortality of the rabbits during your first two visits there was not due to starvation? I was quite satisfied that it could not have been due to starvation.

1125. On your second visit, was the condition of the feed such that you could fairly believe any great mortality amongst the rabbits was due to starvation pure and simple? Even on my third visit the condition of the feed was not such that I could conclude that the mortality was due to starvation.

1126. Did you watch the condition of things on any of the adjacent stations, as to the prevalence of the rabbit plague, so as to compare it with things at Tintinallogy? Not to compare it with Tintinallogy; but in a general way I took notice of the state of the rabbits on all stations in my district that I passed through.

1127. What was your general conclusion? That for several months after the disease appeared at Tintinallogy I saw no traces of it except at Tintinallogy. The rabbits were not dying off in the same way on any other station.

1128. Is it within your knowledge that at this time poisoning was being largely used on adjoining stations and not Tintinallogy? Yes; poisoning was largely used on Teraweynia at that time.

1129. And was the mortality there anything approaching that at Tintinallogy? No; I do not think it was.

1130. What was the general condition at Teraweynia—the part of it that you saw—as regards feed? The portion of it that I first saw poisoned was in very poor condition. It was entirely destitute of feed.

1131. And in this very poor destitute country, were the rabbits dying in anything approaching the degree which you noticed at Tintinallogy? No; they appeared to be dying only where the poison had been used.

1132. Did you see any great mortality on Teraweynia Station apart from the operation of poisoning? None whatever, though the feed was very good in some places and very bad in others.

1133. Is there anything further with regard to these experiments at Tintinallogy which you think would be of service to this Commission in its inquiry? I do not know of anything further. I distinctly noticed the spreading of what I considered to be disease amongst the rabbits from Tintinallogy.

1134. Do you think that this mortality amongst the rabbits at Tintinallogy could in the smallest degree be attributed to the eating of bark by the rabbit? I do not think so. I do not think the eating of bark has anything to do with the mortality of the rabbits.

1135. What reasons have you for that opinion? Because I have noticed the rabbits dying both in the country where they had eaten the bark, and where there was no bark to eat, and where their principal food was merely the ordinary bushes and grass. Of this fact I have clearly satisfied myself.

1136. Taking the country of which you have charge as a whole, has the carrying capacity been seriously affected by the rabbit invasion? In the more thickly infested parts it has been most seriously affected.

1137. Can you illustrate that in any way by reference to examples? On the south-east side of the Darling station-owners have had to sell off numbers of sheep, and have very little left to feed the remainder. Many complained that they would have had to sell these only that the rabbits have died off instead.

1138. Do you attribute the scarcity of feed distinctly to the rabbit plague, as distinct from the dryness of the season? I do not attribute the scarcity of feed to the rabbit invasion, though in a great measure it may have been due to it. The season has been very dry.

1139. What have you found on the north-west side of the Darling? The food is plentiful on all the north-west side.

1140. Yet a large portion of the north-west area is thickly infested? No; not nearly so thickly infested as the south-east. I would classify part of it as rather thickly infested, but some portions of the north-west side have not felt the full effects of the rabbit invasion.

1141. On the north-west side, is feed fairly abundant? Yes, in many places.

1142. What has been the rainfall in the district this season? In some parts they have had 1 inch, but scarcely an inch in the most of it.

1143. Yet the feed is fairly abundant, although the rabbits are not numerous? Yes, but the feed is gradually falling away.

1144. Are the rabbits producing any perceptible effect on the bushes by barking them? Yes, a very perceptible effect, by killing nearly half the best feeding-bushes in the country. You can see that wherever you go.

1145. What are the bushes that are suffering in this way? The sandal-wood, leopard-wood, emu bush, as it is called, the quondong bush, and several other edible bushes.

1146. Have you sufficient knowledge to say whether these bushes will recover after having been barked? I have not had sufficient experience, and there has not been time to judge since the barking, but apparently they are absolutely dead; and I do not believe they will ever recover, because the bark and the wood beneath have been eaten right into the sap.

1147. Have you noticed, when the scrub is being cleared away for roads, and when the roads have not been used, that grass springs up in the country so cleared? Yes; wherever there has been a clearance of the scrub some little grass springs up, but not sufficient in any case to compensate for the destruction of the scrub.

1148. You have watched for some years the effects of trapping? Yes, and my opinion as to the general result is that trapping is no check whatever upon the spread of the rabbit. Although bonuses were offered, large numbers of men put on, and thousands of rabbits killed, yet every month showed that the numbers were increasing.

1149. Have you had any experience yourself with regard to poisoning? No; I have had no experience either with poisons or with wire-netting fences.

David Brown called in and examined:—

1150. *The Chairman.*] What is your position? I am manager and part owner of Kallara Station, near Bourke. I have been resident on Kallara about eleven years. Kallara is situated on the western side of the Darling River, 100 miles above Wilcannia, and 120 miles below Bourke.

1151. When did the rabbits first make their appearance on Kallara? The first I saw was in 1883, but it would be difficult to say when they first became a nuisance on the run. I do not consider that they are thick enough now to be a curse to Kallara particularly.

1152. Have the surrounding properties become thickly infested? Yes; neighbouring properties have.

1153. Have special means been adopted on Kallara to prevent the rabbits becoming a plague? No special means. The work of trapping on Kallara has been avoided as much as possible.

1154. A certain amount of trapping was, I suppose, necessary? It was compulsory; I never considered it necessary.

1155. How many men were employed on Kallara, as a rule, in trapping? On the whole run, which embraces a million acres, from two to twelve men were employed in trapping from 1885 to 1887.

1156. Did any good come from the operations of the trappers, in your opinion? Absolutely none.

1157. Do you think any harm was done by the trappers, either in the way of positive mischief or by the prevention of good? I think good was prevented by confining us to a method which compelled us to produce the scalp.

1158. Do you think any positive evil resulted from the system of trapping? Yes, I do. My reason for that statement is that more bucks were caught than does, and there being a larger proportion of does left after trapping than bucks, this proportion was more favourable to an increase of the pest than if the natural proportion of the sexes had been allowed to remain. I was instructed by the first rabbit inspector I ever saw to set the traps at dung-heaps, and not at the burrows. His reason was that, the dung-heaps being removed from the burrows, the rabbits caught there would not frighten the others; while, if caught at the mouth of the burrow, the rabbit in the trap would frighten the others away. Much the larger proportion of the rabbits caught at the dung-heaps are bucks.

1159. Do you think that the trappers killed the natural enemies of the rabbits in any large numbers? They could not well avoid doing so.

1160. What would these natural enemies be? Iguanas and cats.

1161. Have you noticed any decided lessening in the number of cats about Kallara? No; I have not, because I had very few trappers employed.

1162. Have you known the number of cats to be seriously diminished on other stations? Not to my own knowledge.

1163. Do the operations of the trappers tend to scatter the rabbits all over the country? Most decidedly.

1164. Is a serious evil caused thereby, in your opinion? Yes, very serious. The same objection applies to the use of dogs, and with even greater force.

1165. In fact, hunting the rabbits with dogs would be even more objectionable in this respect? Yes.

1166. Have you used poisons largely in connection with the suppression of the rabbit trouble? Yes; during this year I have given it a trial. I have used phosphorised wheat only, distributed by Lascelles and Anderson's machine.

1167. What results have you obtained thereby? Very good results.

1168. Do you recommend that method for general adoption? Yes. The good results were not immediately apparent, but within a fortnight they were evident. A very large number of dead rabbits showed all over the country in which the poison had been used.

1169. Have you had any experience in poisoning the natural food of the rabbit—bark, twigs, &c.? None. In my opinion, unless the rabbits are very thick, they will not take the broken-off branches at all; the rabbits must be very thick and the feed bare.

1170. Have you had any experience in the use of wire-netting fences? No.

1171. Have you watched their use on other properties? I have only seen them around gardens. I think they are sufficient to keep the rabbit out.

1172. Is that the case even when the feed outside the garden is very bare? Yes.

1173. What fence have you found sufficient for this purpose? 1½-in. mesh, about 2 ft. 6 in. or 3 ft. out of the ground.

1174. Do you regard the difference between 2 ft. 6 in. and 3 ft. as of much moment? No.

1175. I believe you paid a visit to Tintinallogy? Yes, at the end of February, and remained there the better part of a day. I was appointed by the Wilcannia Pastoral Association to visit Tintinallogy and to publish what I saw. I went down through Murtie and Billilla, and through Tintinallogy to the station. The Billilla country was exceedingly bare, and the rabbits were there plentifully. On Tintinallogy the country was not quite so bare, but the rabbits were as plentiful. I noticed as we approached Tintinallogy particularly considerable numbers of dead rabbits on the road. We first noticed them above Wilcannia, and there were dead ones more or less from 15 miles above Wilcannia to Tintinallogy. I noticed as we got nearer Tintinallogy the number of dead rabbits became greater. I arrived there in the evening late, after dark, and in the morning I went down to what is known as the camp bend. After seeing the pens in which the rabbits were kept and the crates, and the different arrangements about the camp, we went through the bend. We caught a number of live rabbits there, some of which we killed and examined; and, in the absence of Dr. Butcher, we were shown by Mr. Reid the diseased appearances. These were similar

similar in every rabbit we examined, and most apparent in the rabbits that were thinnest. We did not open one rabbit in the bend in which these appearances were not more or less apparent. In opening the rabbit, with the tail towards you, if you turned the entrails towards your left, and examined the membranes which attach the bowels to the lower part of the stomach, there was an appearance of discoloration in patches, just over the spine, right in the little membrane. In many rabbits there was liquid in the cavity of the belly, and on the membrane there was an enlargement. In the enlargement there seemed to be a fluid matter of brown colour. Then I was shown another organ called the supra-renal capsule, and was told that in a healthy rabbit that ought to be nearly white and full. In many rabbits that I examined this organ was very much shrivelled and of a dark colour, and there was no fat in any of them; they were all more or less emaciated. On one or two of the livers we saw specks, but in the majority of cases the liver was apparently healthy.

1176. Were these the chief appearances that you saw? They were the only appearances that were universal; they were in every rabbit. After going back to the camp we took a turn down to the bends lower down the river. It struck me as curious that in these bends lower down, which were not fenced off, in which there had been fewer experiments, and which were open to the rabbits from the back country, there were fewer live rabbits and more dead ones than in the camp bend, which was fenced in for experiments. I should think there were twice as many dead rabbits in the outside bend as in the bend that was fenced in, and distinctly fewer live ones. We opened a number of the rabbits in these unfenced bends, and they all presented the same appearances. In the afternoon we took a turn out on the back portion of Tintinallogy, about 15 or 20 miles; the rabbits out there appeared to be in very much the same condition as on the frontage. There was a considerable number of dead rabbits about 5 or 6 miles from the river, and fewer the further you got away from the water. The next morning we left Tintinallogy and returned to Murtie, and all the way up the river it was evident that there was some cause which produced the same sort of wasting disease amongst the rabbits. On Murtie Station I suggested to Mr. Johnson that we should catch a few rabbits and take them in to Dr. Butcher, who was then in Wilcannia, so that we should be able to hear from him whether those appearances which we had been told were the disease were so or not. We caught twelve rabbits in a wire-netting trap that night, and selected three from them—one of the fattest and two of the poorest of those caught in the yard. We took them in, and Dr. Butcher agreed to examine them. He said he did not think these rabbits had the disease; that although they were poor, their poverty was perhaps caused by something else, and was not disease. When he examined the rabbits I saw the same symptoms exactly that were described to me as the morbid appearances, and he then said that they were affected with the same disease as he had been experimenting with at Tintinallogy.

1177. Did he test this disease by inoculation? I am not aware whether he tested it any further to establish its identity by inoculation or otherwise. The distance from Tintinallogy to Murtie is 57 to 60 miles. On Murtie we caught twelve rabbits and opened them, and we traced the same appearances in about half of them. The others were apparently healthy; throughout in good condition. Three or four weeks later I went down to Murtie again, and I examined a very large number of rabbits, and did not get a single one that did not clearly show the diseased appearances. The manager of the station, Mr. Johnson, who accompanied me to Tintinallogy, assured me that within that month 80 per cent. of the rabbits had died; that applies to the whole of Murtie—certainly to the whole of the frontage, and particularly to the southern or lower end—next Billilla. I have looked for these diseased appearances higher up the river, but I could not trace them. The rabbits there are very much scarcer than further west.

1178. In your opinion, then, have these diseased appearances anything to do with the scarcity or plentifulness of feed? I think that probably they have a close connection with the supply of feed, because where feed has become scarce, so also have the rabbits. Where the rabbits are very thick, and feed very scarce, there this disease appears; although the rabbits are thicker on the east side of the river than on the west in the neighbourhood of Kallara, they are not nearly so thick even on the east side as they are on Murtie, Billilla, and Tintinallogy.

1179. Is it your opinion that this disease has developed in consequence of the density of the rabbits and the scarcity of feed, and that, in all probability, it will disappear if the rabbits be somewhat thinned out and feed becomes again plentiful? I cannot state that, even as a matter of opinion, because I have had no means of forming one. It seems to me possible that a disease produced by bad feed conditions may be infectious, and that the infection from it may spread in spite of altered and better feeding conditions.

1180. Have you, on examination of this disease, been able to form an opinion as to whether it is a new disease, or whether it is some old disease that has prevailed occasionally? It is impossible to form any opinion on that subject, because an unprofessional eye could not detect any disease. But there is no difficulty for anyone of ordinary intelligence, on opening a rabbit that is diseased and a rabbit that is healthy, in at once recognizing the difference between the two, after it is pointed out.

1181. Did you see any of Dr. Butcher's experiments in progress at Tintinallogy? Yes; I saw all stages. I saw the rabbits in crates and yards. The conditions as to feed and bedding and covering were such as to put on one side all possibility of death being due to starvation or to exposure. The rabbits appeared to me to be as well cared for as if they had been domestic pets.

1182. Have you any personal knowledge of the experiments that were made on stock with a view of testing the transmissibility of this disease to stock? None.

1183. When you found the difference between the mortality of rabbits near Tintinallogy home station, and on parts more distant from Tintinallogy, did you notice any corresponding difference in the feed available for rabbits which might explain the difference in the mortality? I think not. It appeared to me that on Billilla feed was the worst, while on Tintinallogy the feed was not so poor as to cause sheep to be in a low condition. All the sheep I saw on Tintinallogy were in fair condition. I saw the sheep running in the camp bend, and they were penned in. I do not think there were rabbits running in the same pen. The sheep were said to have been inoculated.

1184. Did you pay any attention during your visit to the question whether this disease prevailing at Tintinallogy could be attributed to the rabbits eating bark? No. I had never seen the shrubs barked before as I noticed on that journey. The barking began on Murtie, and became more noticeable further down the river. The barking of all these shrubs is a new thing to me. I never saw rabbits thicker than during that journey. I had heard of the Tintinallogy disease for a considerable time previous to this visit. I saw a considerable number of dead rabbits on the road, although at that time the disease was only just noticeable

noticeable on Murtie. A month after that I travelled through Murtie, and the mortality was so great that the stench from some of the sand-hills was exceedingly bad. So that, within a few weeks of the disease becoming apparent on Murtie, a much greater effect had been produced than on Tintinallong with six months of experiments.

1185. *Mr. Lascelles.*] Did you satisfy yourself as to the cause of there being more deaths on the unfenced bend at Tintinallong than on the fenced land? I merely describe this as a remarkable fact and tried to find out the cause, but did not succeed. The only cause that struck me as probable was this; that the rabbits sick kept going to the river for water were prevented from getting to the camp bend, and were able to get to the river at the unfenced bend. Hence we found more live rabbits there.

1186. If the laws of the Colony allowed you to spread this disease would you take steps to have it spread over your run? I certainly would, because I look upon it as nature's remedy for the plethora of rabbits, and to refuse to use nature's remedy would, I think, be excessively foolish, particularly so as you cannot limit it by any effort on the part of the law. I remember that there was a somewhat similar disease amongst opossums. In 1881, I had occasion to travel from Louth to Cobar, through Nyngau, to Sydney. The first time I made that journey the opossums were very plentiful, dozens visible along every yard of the road. In fact every tree had its opossum. A few months later I made the same journey and I noticed that a few of the opossums were dead, and that others seemed very weak, while others still remained apparently healthy. Some months later I again made the same journey—this would be in 1882—when practically the opossums were all dead. There were none at all visible along the road. Since then I understand they have slowly increased; but there are very few indeed visible now compared with the numbers previous to 1881. The outward appearances were very much the same—staring coat, extreme poverty, and so on.

1187. *The Chairman.*] Did you notice whether opossums were affected with scabs on the skin or not? No; I did not.

1188. Have you seen any scab disease amongst rabbits? One or two rabbits that were caught on Murtie showed slight eruptions about the belly. It was a scab eruption and very slight, but I could not connect it in any way with the death of the rabbits. You may see similar eruptions on rabbits in good condition.

James Charles Wilkinson called in and examined:—

1189. *The Chairman.*] I believe you were superintending inspector of the Rabbit Department? Yes, for the whole Colony. I held that office for three years—from 1882 to 1885. I had not had previous experience in the Rabbit Department.

1190. In your opinion, has the general carrying capacity of stations been seriously injured by the rabbit trouble? That is a rather difficult question to answer. On some stations the carrying capacity would be diminished, but on others not.

1191. Do you think serious evil has been produced to the sheep-carrying power of the Colony of New South Wales by the rabbit plague? Most decidedly.

1192. Has the progress of that been rapid during the last two years? Yes. Although I have not had anything to do with the rabbits since March, 1885, I know, as inspector of stock, that the rabbits have been spreading and increasing.

1193. Have you noticed any great destruction of the edible bushes used by stock during the last few years? Since I came to the Silverton district, I know of one run where the bush is stripped of its bark for miles and miles by the rabbits. The bushes are dying, and of course they will be dead in another twelve months.

1194. Do you know whether bushes thus stripped of their bark will recover themselves? I do not. I have had thirty years experience of the country, and think no tree can possibly recover after it has been ring-barked.

1195. Does the stripping which the rabbits cause amount to ring-barking? Most decidedly, in many instances.

1196. Are large number of edible bushes suffering in this way? Yes.

1197. When these bushes are cleared away, as in the making of roads, does the grass grow up if the roads are not used? No; no grass grows up in this part of the world. If a tree is cut down, it is stripped by the rabbits immediately.

1198. I suppose you watched the operations of trapping parties in some general way over several years? Yes, and I wrote a book on the subject.

1199. What is your opinion with regard to the operations of trappers taken altogether? That is a very wide question; as a whole, the trappers did not try to exterminate. They simply trapped at one portion of an estate, and then moved on to another portion; and while they were absent the rabbits kept multiplying. I found the rabbits suddenly increasing—not decreasing—when I was Superintendent. I recommended that no more bonuses should be paid, as the increase in rabbits kept on.

1200. Have you had any experience in the use of wire-netting? No; only what I have seen others do with it. I saw Mr. Bertram, of Euston Station, employ it to enclose a paddock of medium size. He put the fence up in order that he might keep the frontage to the river clear from the rabbits. I do not think he was successful in this. I made a personal inspection to see whether he was or not. Mr. Bertram took all possible steps to destroy the rabbits on his property, and paid £95 per mile for putting up his fence.

Henry Prideaux Richardson called in and examined:—

1201. *The Chairman.*] You are I believe one of the rabbit inspectors of New South Wales? Yes. My district is No. 4, Menindie. The chief runs in my district are—Kincheega, Winterriga, Glenlyon, Cuttawarra, Topar, and Redan. I have been in the district since June, 1886. I had been in the Department previously, and had charge of Narrara run, in the Poonearric country, as a rabbit inspector. The district of which I am now in charge is thickly infested in portions, and in these the carrying capacity of the runs has been seriously affected.

1202. Has there been during the past few months any serious destruction of edible shrubs or bushes by barking, by the rabbits? Yes; very serious destruction indeed on some runs.

1203. Does your experience enable you to say whether the bushes barked in this way can possibly recover themselves? No; latterly I have noticed a great many of them dying. Any of them barked all the way around die; those only barked in part sometimes live.

1204.

1204. Have you watched whether the grass grows on the roads made through your district where the scrub has been removed, and where there has been no traffic? Yes, I should think it does; I have seen it on old roads.
1205. Does it grow to such an extent as to make up for the loss of the bushes? I could hardly say that; I should not think it would make up for the loss of the bushes; not in this country.
1206. You watched the operations of the trapping parties in your district for some time? Yes; and in other places as well, since 1882.
1207. In your opinion has any sensible effect been produced in diminishing the numbers of rabbits on thickly infested country by the operations of the trapping parties? Well, rabbits have diminished for a short time by numbers of trappers being kept on, but at the same time I never looked on trapping as a success, and I am now quite sure it is a failure.
1208. During the latter part of last year was there any marked increase in the numbers of rabbits killed by the trapping parties? Yes; there was. There was no increase in the amount of money paid during the last few months in consequence of the reduction of the bonuses; I think there was some reduction towards the end of the year. I am not certain that the number of rabbits killed and for which bonuses were paid, was not greater.
1209. Your general conclusion, then, is that trapping is a failure? Yes; I think so.
1210. Do you think it could under any circumstances be made a success in your district? No; I do not think so.
1211. Have you had any experience in poisoning rabbits? Yes, with phosphorized grain, wheat, oats, and barley. Some of these operations have been very successful indeed in my district, those with wheat and oats. We had used Lascelles & Anderson's grain distributors; I have not used any other persons. At Weinterriga they used poison on the branches of the emin bush, but I do not think the results were very good. The results were good until rain came.
1212. Have you had any experience in the use of wire-netting? Yes; around tanks for catching the rabbits. We used 4 ft. 2 in., and some 3 ft. 6 in. with 1½ in. mesh for this purpose. On one occasion, at Glenlyon, I saw a rabbit go right over the fence.
1213. Do you think that any number of rabbits could have escaped in this way without your knowledge? No; because I was watching the whole time. It is only in very exceptional cases that a rabbit can get over such a fence.
1214. Have you had any experience in connection with diseases in rabbits? No; but I have seen a number of rabbits that I thought were diseased on Cuttawarra, Topar, and in fact, all over my district.
1215. What were the characteristics of those rabbits that appeared to be diseased? They seemed to be very weak and poor, and the liver quite rotten, it would fall to pieces if you took hold of it. The liver is of very dark colour, and in odd ones you see a little blue streak.
1216. Did you see any yellowish white spots? No, I did not. I have noticed some of these animals with sores, and their legs seemed to have been singed as if they had run through the fire. From inside the sore goes up to the crutch.
1217. Is that disease now in existence? It was about ten days ago. It prevails extensively through the district, and has produced great mortality amongst the rabbits. On Glenlyon, in March last, the rabbits were so numerous that I wrote to the Department about it, and in April two men caught 15,100 rabbits in the wire-netting yards around the tanks. I passed through the run again in May and went all over it, and I do not think two men would catch 300 rabbits in a month.
1218. So the rabbits have practically been weeded out? Yes; on the Glenlyon Run they have. I noticed some to the west of Cuttawarra the last time I was there but once, and wrote to the Department about it. I noticed that the rabbits were dying very fast, and on my next visit I ascertained that where they formerly existed in thousands there are now hardly any at all.
1219. In this place was the available feed so scanty as to account for this great death-rate by reason of starvation? No. The feed was very dry, but there was plenty of it. There was an abundance of salt-bush and other dry feed.
1220. Have you known runs where the feed was just as scanty and dry, or in the same condition, and where the rabbits were not dying in this way? Yes; around one or two of the lakes near Menindie the feed is scanty and dry. I have noticed that on country far drier the rabbits do not die.
1221. Have you in your district in any year known runs where the feed was as dry or drier than on Glenlyon and yet the rabbits held their own and did not die in this way? Yes, I have.
1222. Do you think that this great mortality amongst the rabbits may possibly be attributed to their eating bark? No. I did think so at first but not now. They have died out so suddenly that it could not be possible for bark to have killed them in such numbers, and in so short a time. They had been eating bark for many months and yet in the early months they did not die in this way.

John Andrew O'Flaherty recalled and examined :—

1223. *The Chairman.*] What is it you wish to say? I desire to make a statement in amendment of my previous evidence. You asked me with regard to Momba Run whether the rabbits were dying out in greater numbers in one part more than in other parts, and I said no. On looking at my diary I find that the rabbits were dying out more rapidly on Tunanulgra Plains block, or what is called the White Cliffs paddock, more rapidly than elsewhere on the same run. I made no inquiries into the matter but I saw for myself.

Thomas Henry Elwin called in and examined :—

1224. *The Chairman.*] You are a rabbit inspector of New South Wales? Yes.

1225. What districts are you in charge of? I am in charge of district No. 8, Menindie, the chief runs of which are Albemarle, Tolarno, Moorara, and Pan Ban.

1226. How long have you been in charge? I have been in charge of this district for about two years.

1227. Is this district thickly or thinly infested with rabbits? It is very thickly infested and the carrying capacity of the runs has been very considerably affected thereby.

1228. Have the edible shrubs on which stock feed been destroyed in any great quantity? In places the shrubs are dying in acres.

1229.

1229. You have watched the operations of the trapping parties in your district during the time you have held office? Yes; closely.
1230. During the last year was there any marked increase in the number of rabbits killed? Yes; a considerable increase.
1231. Was the cost of the operations of the rabbit parties greater at the end than at the beginning of the year? Yes; I should say so, though towards the latter end the bonuses were considerably reduced.
1232. Is it a fact that the total amount expended was greater at the end of the year than at the beginning, notwithstanding the reduction of the bonus? Yes; I think it was. Many owners reduced their staff of rabbiters. My former remark applies to the time when the full complement of men was retained by the owners.
1233. What is your general opinion as to the results obtained from the work of the trappers? I did not favour the trapping system at all, nor do I think it tends to decrease the rabbits very much. A trapper will not remain long enough in one camp to do very effectual work.
1234. And when he moves to another camp the rabbits increase in the old one? Yes; and the trappers won't work there again until they do increase.
1235. In your district when the rabbit parties had finished their work and were paid off, were the rabbits more or less numerous than when they started? The rabbits were much more numerous at the last than when I took charge of the district.
1236. Have you had any experience in poisoning rabbits? Yes; considerable. I have employed all the known poisons, and that which I found most effective was strychnine. It mixes up with certain quantities of water, flour, and sugar, and then strychnine finely powdered is added to the mixtures; the poisonous solution thus formed is applied to any edible boughs and twigs by means of a small brush, and these twigs are placed where there are traces of rabbits. I have tried this, principally on Moorora, and found it very effective. I introduced it also at Albemarle, and Mr. Phelps, the manager, is well pleased with the result—so Mr. Curtayne, the financial manager, informs me. I have seen other methods of poisoning adopted. The next best is phosphorized wheat with Lascelle's distributor. That is effective, judging from the carcasses of dead rabbits found after its use.
1237. Is there any other special method that you can recommend as effective? Well at Albemarle they went in for Wynne and Yulle's method. I do not think the result was very favourable. The method was also tried on Tolarno, but the owners were not satisfied with it.
1238. Have you had any experience with wire-netting? Yes; with tank-traps, and I found netting fairly effective. I have seen Wreford and Smith's trap erected. I think it would be more useful on a long line or boundary fence than on a short sub-divisional line. I do not think it would be much use on an open tract of country; once they got in they would not possibly get out if it were properly erected.
1239. Have you had any experience in connection with the netting of any large areas of land? No; but I have seen a 2,500-acre netted paddock on Tolarno. At Albemarle the whole run is being fenced in—I think with $1\frac{1}{2}$ inch mesh. The results have yet to be seen. Sometimes a rabbit gets out through the fences around the tanks—they get in occasionally through the openings at the neck of the tank-trap. I have known rabbits to get over wire-netting also. I have seen them jump 2 ft. 6 in. wire-netting, scrambling over the top. We were after them on horseback, and one or two of them were closely pushed and jumped the fence. I have seen them, too, dig underneath a fence which was sunk 5 or 6 inches in the ground.
1240. Have you had any experience in connection with diseases in rabbits? No; I have examined lots of them that I found in an emaciated condition, but I have never been able to satisfy myself of the existence of disease.
1241. Have the rabbits during the last month or two been dying off in your district? Yes; in the back part of my district.
1242. To what do you attribute the death of all these rabbits? The best term that I can use is inanition—mere weakness, caused by the poisonous nature of bark, which they are compelled to eat.
1243. Has feed been so scanty as to account for the death of so many? Yes; they have had to take to the bark and the leaves of trees. The feed, too, during the last month was bad; in places there is no grass at all. I consider Tolarno is a very suitable place for experiments. This horse paddock which was offered to the Commission was thickly infested with rabbits, but they have been trapping and driving them out. At present I am not certain whether the paddock is thickly infested or not. I do not think it is, but the adjoining country is very thickly infested. St. Helena Island, Boola Boolka Lake, is also a suitable place for experiments.

George Urquhart called in and examined:—

1244. *The Chairman.*] I believe you are the manager of Mount Gipps Station? Yes; I have been on that station for about twenty years in one capacity or another. I first saw the rabbits on Mount Gipps about May, 1883, and it is now only moderately infested. The rabbits first became very numerous there about eight months ago.
1245. Have the rabbits as yet had much effect on the carrying capacity of the run? No, not as yet. They have not yet eaten many of the edible bushes used by stock.
1246. Was trapping carried on on the station on a large scale? Yes.
1247. What is your general opinion as to the results of the trapping system? It is of very little use, I think.
1248. I suppose large numbers of rabbits were destroyed? Yes.
1249. Did the number of rabbits tend to increase last year during trapping operations? Yes; they were increasing very fast.
1250. During the last two months have the rabbits been increasing or decreasing? Decreasing.
1251. To what do you attribute the decrease? They are dying off from some cause or other, but I do not know what is killing them. We have been poisoning them as well with phosphorized wheat, distributed by Lascelle's machine.
1252. Do you think they are dying in greater numbers than the bare and dry condition of the feed would account for? There is any amount of feed where they are dying in this way.
1253. Have you examined any of these rabbits to see whether you could find any disease amongst them? No, I have not. The grass is very dry on those parts where they are dying. I have also tried poisoned water, but it was not a success. I have not used wire-netting at all, and have had no experience with it.

1254. Do you think that the deaths of the rabbits in your district during recent months could be attributed to the eating of bark, or have they died where no bark has been eaten? Wherever I have seen dead rabbits the bushes are barked, and great numbers have died off, although not many bushes are barked.

1255. Did you find that the bushes were barked where the feed was dryest? Yes.

1256. Do you think you will have any chance of getting rid of the rabbits by poisoning, without fencing in the areas? I think we might keep them down by poisoning, though it will be constant trouble keeping the rabbits down that come from other parts. I think it would be better to make fencing the foundation of our operations. I believe the income from the run would justify me in having it fenced in, though I do not say that regarding the whole of the run.

John Binnie called in and examined :—

1257. *The Chairman.*] What are you? Manager of the Mundi Mundi Station, which is about 16 miles from Silverton, in a north-east direction. The area of the station is about 250,000 acres. I have been about three years at Mundi Mundi. When I went there first there was an abundance of rabbits, though they became thickest about two years ago.

1258. Have the rabbits as yet seriously affected the carrying capacity of the run? No.

1259. Has there been recently any great barking by the rabbits of the edible shrubs? Yes.

1260. Have you watched the operations of the trapping parties since you became manager? Yes. The numbers of rabbits killed by these parties greatly increased during last year, although we have reduced the bonuses. The increase in the number killed more than made up for the diminution in the bonuses. We employed in some parts of the year from twenty to seventy men, chiefly in shooting and trapping.

1261. What is your opinion in general as to the results obtained from the system of trapping? I do not think we are doing any good whatever.

1262. Do you think that under any conditions any real good could come from the system of trapping? No.

1263. Did you try poisoning on any large scale? Not at all. I have not tried wire netting, either.

1264. Have you any personal experience of diseases in rabbits? No.

1265. Has there been any marked reduction in the number of rabbits on your run lately? Yes. I think the deaths are due to the dry weather and the eating of bark and the want of water. The rabbits, I think, are dying from the poverty of the feed and the barking of the trees. It was the want of ordinary feed that led them to bark the trees. They had dry grass but they require sap in hot weather.

1266. Have you opened any of these rabbits to see what was the matter with them? No; I have not. All I know is that they have cleared off the run.

1267. Have you stopped the rabbit parties? No; we have some blacks on now.

1268. How are they engaged? Shooting and digging out.

1269. Do you propose to adopt any other measures? No; not at present.

The Commission adjourned.

TUESDAY, 29 MAY, 1888.

The Commission met at 2.30 p.m. at the office of the Commissioner of Crown Lands, Adelaide.

Present :—

Victoria : HARRY BROOKES ALLEN, Esq., M.D.

South Australia : EDWARD CHARLES STIRLING, Esq., M.D.

ALEXANDER STUART PATERSON, Esq., M.D.

In the absence of the President (Dr. MacLaurin), the Chair was taken by Dr. STIRLING.

Charles Jonas Valentine called in and examined :—

1270. *The Chairman.*] What are you? I am Chief Inspector of Stock for the Colony, and have been such for the past twenty-two years.

1271. During those twenty-two years, have you seen the rise and progress of the rabbit plague? Yes; I have seen it start, and have also seen it cleared out of some parts of the Colony completely, or as nearly as possible.

1272. Where did the rabbit plague first begin? It must have been about 1867 or 1868, but I don't know of any particular place. I think it was in 1871 or 1872 that they were brought under the Game Act. They were then very prevalent north of Kapunda, near the Burra and near Gawler—in the hills about. There were a few, but not in such large numbers. At one place the police prevented the people from shooting them. And on an island in the Coorong there were some rabbits that were very carefully looked after. It was looked upon as a good sporting-ground. In 1874 the rabbits became so numerous that they were struck out of the Game Act, and a movement was made to bring in a Bill to cause their destruction. Tasmania had taken some action in the same direction; and I reported to our Government at the same time on steps which had been taken there with regard to rabbit destruction. Then there came a series of years in which there was a great fight over the principles of the Rabbit Act. By this time the rabbits had increased marvellously. This was about 1876 or 1877, when the rabbits spread over the whole of the best part of the country northwards. The law passed about 1877 threw the onus of destruction upon the owners, and if they did not choose to take action the Government stepped in and put on rabbit parties at their expense. The consequence has been that the whole of the best pastoral land has been entirely cleared of rabbits, which had become very numerous on all the freehold properties about Booboorowie, Canowie, Anlaby, Kanoona, Mount Bryan, and others. The system adopted has completely cleared the country of them. This was by filling up the burrows and destroying the rabbits with the assistance of dogs and men. I do not think that poison was used to any great extent, but the bisulphide of carbon was used by the Government parties at a later date. By filling up the burrows, I mean that the burrows were closed up. I do not suppose there could be a much worse example of the rabbit-infested country than Anlaby, and now it would be very difficult to find a rabbit at all there. Since that time I think the rabbits made a move through the scrub. They were driven outside, and gradually worked their way out into the far country to the

the north-east. I have no doubt a large number of rabbits came here from the scrub country to the east of the Murray River, from the Colony of Victoria.

1273. What is the furthest northerly point that the rabbits now extend to? There have been plenty of them seen in the corner of South Australia near Queensland and New South Wales; also further north, and right away from here to the Darling country. They are also along our west coast, and we know that some of them are already in Queensland.

1274. You have spoken about rabbits dying off in some parts? Yes; the rabbits on the island in the Coorong died out completely, without any known cause. I hold the supposition that they were starved out—that they eat themselves out—and died. A great many also died near Tectulpa at the time that we had the horse disease. I do not know exactly what it was, or whether the rabbits became diseased from drinking the water which the horses had touched. I do not think that was the cause. They died in hundreds.

1275. Did the rabbits not die out also on Yorke's Peninsula in 1865? I do not remember any being on the southern portion of Yorke's Peninsula—in any number, until a later date. Afterwards, when they increased in numbers, they were destroyed by the usual means, and have not since increased to any extent.

1276. *Dr. Paterson.*] Do you mean to say that the rabbits died out completely in Tectulpa? They died in great numbers at one time, but not completely. I do not know what they died from, or whether they were starved. One of my men said he had broken the dead rabbits in two.

1277. Did you see this done? No. He told me he simply broke the back-bone. The liver was also enlarged, and the man thought they had some disease of the stomach.

1278. *The Chairman.*] What parts of South Australia are most infested at the present moment? I cannot say from present knowledge. I will send in this information later on.*

1279. Have you any information about the mortality of rabbits during the last two months? I have no personal information. I have heard that rabbits are now dying out in great numbers in this Colony.

1280. Can you give us any information as to how the carrying capacity of the different runs has been reduced by the rabbits? I could give the information, but I think it would be better I should do so in writing. [See Appendix.]

1281. Can you say whether these rabbits eat the trees and shrubs? I have seen the shrubs destroyed in some places out in the north-east; the bark was eaten off. The shrubs are acacias, so far as I could see—the mulga and the sandalwood. It is rather difficult to say whether the rabbits have destroyed the salt-bush, or whether it is the long dry weather that has done it. Rabbits do not thrive on salt-bush alone. The punta bush has also suffered.

1282. *Professor Allen.*] Do you know whether these bushes will recover after having the bark eaten off by rabbits? No; I do not, though I was anxious to make observations to discover whether they would or not. Many of our northern bushes recover themselves in a marvellous manner. The first time I saw the country in a drought I thought a great many of the bushes would never recover, but it was astonishing how they sprang up again.

1283. Have you ever noticed the grass and bushes recover after rabbits? Bushes recovered, but they were mallee, and of little service. The grass, too, will grow again where it has not been eaten thoroughly out; but I do not think the grass in that country makes up for the loss of the bushes.

1284. Do you know that the rabbits eat the mallee? I have been told so; but I do not know it of my own knowledge. They will eat anything rather than starve. If there is any green about they will eat it.

1285. We have heard that some rabbits died from constipation from eating the bark fibre? I have heard that, but I do not know how true it is.

1286. What has been the general effect of trapping parties? I do not think the rabbiters could have helped killing the natural enemies of the rabbits in cases. I have no knowledge that it has been done wilfully, though it is quite possible. They would not trouble themselves one way or the other, but if an animal came in their way they would kill it. There is not the slightest doubt that under the scalping system they would not kill the young ones and pregnant does, because for some time it was a profitable business, and they would be doing away with their own livelihood if they killed such.

1287. Have you had any special experience in poisons? No; but I know something of the use of carbon bisulphide. I have watched the use of rabbit-proof netting in certain places; but I have not taken more than a general notice to see what the result would be. I do not think there can be any doubt that 1½-in. mesh is good enough for all purposes. I have seen plenty of fencing 1½-in. mesh, and I do not think the rabbits will go through that in any large enclosure.

1288. Have you seen any of Professor Watson's rabbits? Yes; and I have tried the scab on the sheep that the Commissioners saw. I examined them last about a month ago, and they were then free. I feel quite positive that this rabbit scab is not communicable to sheep.

Samuel Graü Hübbe called in and examined:—

1289. *The Chairman.*] What is your position? I am Chief Inspector under the Vermin Destruction Acts and Government arbitrator for 1888 leases.

1290. How long have you held your present position? Since 1879. During that time I have been in the rabbit country, except during the last six or seven months.

1291. What have you observed in regard to the spread of rabbits? In 1879 I was employed in their destruction at Canowie, and in nine months we cleared that run. This was an estate, roughly speaking, of about 60,000 acres. I was then doing private work. At that time we had no chemicals, and the only method we adopted was digging the rabbits out. We did not employ dogs, because there were valuable stud sheep on that run. Afterwards we used bisulphide of carbon, and that run was cleared out at a cost to the estate of about £12,000, owing to the want of co-operation by some of our neighbours. I then went into the Government service, taking charge of the work of rabbit destruction.

1292. What were the infested portions of the country then? The western portion was from Anlaby, Coringa Camp Creek, Booboorowie, Canowie, Mount Bryen, and Gumbowie. At that time the rabbits were much further out than Gunbowie on the north. On the south they were at Point Sturt, on Lake

* Witness subsequently forwarded the following reply to the question:—On the country east of the Murray River, towards the Victorian boundary, in the dry north-eastern country, commencing at the edge of the farming districts up to the boundary of New South Wales; and in the western district near the coast.

Alexandria, and in the north-east about Narracoorte. On the west coast they were at Colton, Tabo, and Courtabie. They went out east from Cooringa and Kooromoolloo. That was about the furthest point, but you could trace the rabbits to the New South Wales border even in these days, when they were very limited.

1293. *Professor Allen*] Were there then any traces of the rabbits having come from the Victorian side then? No; but you could find traces from South Australia into the mallee country of Victoria. You would find them thickest where there was an oasis in the dense country. It is my impression that the rabbits went from South Australia into New South Wales, and rabbits, to my knowledge, were liberated at Coringa and Kallooloo, so that from these centres and others they spread out in an easterly direction towards New South Wales. I believe rabbits were also liberated on Narracoorte by settlers. From Glenclyg and along the border rabbits have come from Victoria, and have greatly increased in numbers here. In the north and on the west coast rabbits were again liberated and constituted fresh centres.

1294. *Dr. Paterson*] Do you know if the rabbits were liberated from centres in New South Wales to your knowledge, or have you heard that the same practice as prevailed here also existed there? I know that rabbits were liberated in 1874 in the Barrier Ranges in New South Wales, and at Campbell's Creek, on the Darling, and close to Menindie.

1295. *The Chairman*] You mean that they were introduced for purposes of starting the pest? Yes.

1296. What has been done since 1877-80? The Act under which we were working then was found to bear very heavily upon many of the people, who received notice to destroy the rabbits—I refer to the Act of 1879, which we are at present working under, with some modifications. The preceding Act provided that the Government were to destroy all rabbits existing on Crown Lands at their own cost; freeholders and lessees were also to destroy the pest at their own cost, and in the event of their failing to do so, the Government were entitled to go in and kill the rabbits at the expense of owners. That Act pressed very heavily on those who held large estates, especially those who held poor land, and they strenuously resisted the administration of the measure. In many cases they brought influence to bear to prevent entrance being made. This, of course, entirely nullified the effect of the work done on the adjoining land, which became again largely infested from the centres where the rabbits had not been destroyed.

1297. Were the Government always up to time in clearing their own lands? Yes; in every case the Crown Lands were cleared before the others; and had private owners worked in conjunction with the Government parties, the rabbit pest would have been reduced to a minimum.

1298. When you were in command of rabbit-extirpation parties, what means did you adopt in the early years? We principally relied upon the use of bisulphide of carbon. In the very beginning we only used picks and shovels to dig the rabbits out. We found the carbon very successful in deep alluvial burrows, where there was nothing to allow the fumes to escape. In other parts, where the rabbits do not burrow, we used phosphorized grain, arsenic, bran and chaff, and dry strychnine and bran and chaff. Cyanide of potassium, with bran and chaff, and various other poisons were used; and the trial had the effect of our retaining arsenic and phosphorised grain. In many cases the sheoak and cotton-bush, and other bushes in good seasons, were very successful when the poison was laid upon them. We used a large number of dogs—in fact, every possible means we could adopt we tried.

1299. Where did you first commence working? The first rabbit parties were sent to Point Sturt.

1300. What was the result? The result was that where we obtained co-operation from the settlers we were very successful, but where we did not obtain it we had the reverse of success. I may point out that in the hundreds of Yedualce, Bendleby, Uroonda, Euralba, Aladdie, in 1884, no country could have been more thickly infested than those hundreds were. It was exceedingly difficult country to clear on account of the rock and the dense undergrowth, and there were seven parties of five men each sent out into the country under a very good State inspector. In twelve months the whole of these hundreds were cleared, principally by the use of phosphorized grain, and bran and arsenic. We laid these very sparsely in fairly well-sheltered places, and away from the burrows. It is a mistake to put feed in any way near the burrows, because the rabbits run over it. We scattered the bran and chaff in very large quantities. The men were sent out as you might send out a line of skirmishers, and at the present time you could ride over the country for a week with a pack of dogs and you would not see a rabbit. This result was obtained by the farmers about there helping us in the work. The value of that country, approximately, it would be difficult to say, but it was sold at the upset price of £1 0s. 6d. per acre. This was an agricultural area settled principally by selectors who own from 640 to 1,000 acres each.

1301. *Dr. Paterson*] A large portion of this country was suitable for agricultural purposes? Some of it was also suitable for pastoral purposes. Nearly the whole of the ranges were covered with stunted scrub, such as stunted black oak and sandal-wood. Other portions of the ranges were covered with spinifex, which forms good shelter for rabbits. The plains were covered with saltbush and grass.

1302. *The Chairman*] While you were employed in this place, I presume other parties were working elsewhere? Yes; there were 65 Government parties in the field. Some of these parties met with success, but in no place did we meet with the success that we attained in the place I have mentioned, and that was obtained through co-operation by the settlers. I should like to say that the Act of 1879 was repealed, owing to the action of various persons who were not satisfied with the way it was worked. The vermin destruction of 1884 was then brought in, the main principle of which was payment for scalps. Any person who brought scalps or vermin, and made a declaration of the fact that they were destroyed upon certain lands, was paid at a schedule rate for different descriptions of vermin, including rabbits. The natural enemies of the rabbits were also included in this schedule. The effect of this Act was to introduce a class of people who relied solely upon the wages they could earn by destroying vermin of every description, and the most marked result was that large bodies of men went to the thickly infested districts, more especially where rabbits were said to exist, and commenced the work of destruction. They would remain there till the rabbits became, comparatively speaking, reduced in numbers; then they would go on to another place. This had the effect of driving the rabbits all over the country, to many places where they were never seen before—places which have since become thickly infested. In many cases I know that they were wilfully transported—taken out of thickly breeding spots and planted in new ground. Of this I have absolute proof. I have also absolute proof that rabbits were scalped alive and then allowed to go, in the hope that they would breed again.

1303. What was done with the young ones and the pregnant does? They were scalped; the scalps produced and the money claimed on them, although the rabbits were let loose. If the trappers found a pregnant female, they would scalp her and allow her to go; or, if they thought scalping would kill her, they would let her go unharmed, in order that she might breed. This practice prevails

prevails generally all over the country. I make the statement without any fear of contradiction that it prevailed all over the country in every direction. I attribute the spread of the pest therefore to the action instituted under the Vermin Destruction Act of 1884-85. The expenditure incurred under this Act was ultimately found to be so great that Parliament in 1885-86 repealed the measure.

1304. Do you attribute to this Act the destruction of the natural enemies of the rabbit? No; I do not think it had much effect, because the operations of the rabbit parties would destroy almost as many of the natural enemies of the rabbit as the scalpers. They generally destroyed eagles and iguanas, but unless they were actuated by special malice they would not go out of their way to kill the iguanas and lizards, which are great enemies to young rabbits. Though the iguana is very good eating, yet very few men like to eat it. The Vermin Act having been repealed, the Act of 1879 was reintroduced, and we worked under that until the Local Government Bill was passed in 1887, when the onus of rabbit destruction was entirely thrown on the local councils. The rabbits have increased considerably in many centres since the practice of scalping was discontinued, except in the northern district, where the country is exceedingly dry.

1305. Which are now the worst districts? The west coast, the south-east, and the north-east. I consider these the most badly infested places at the present time. From Koorunga to Silverton is the worst infested part of the Colony, and the country becomes more and more thickly infested the further you proceed eastward.

1306. What is being done now in the infested districts? Practically, nothing.

1307. *Professor Allen.*] Are you aware that there has been a large diminution of rabbits during the last two months? Yes; to some extent there has been in the hundreds of King, Tomlinson, and Rees.

1308. To what do you attribute that decrease? To drought.

1309. From your observation, do you think that any great amount of mortality could be attributed to the eating of bark, or do you attribute it directly to the drought? I think it is an outcome of the drought, because when the rabbits cannot get any feed containing more moisture than the bark they eat the bark. I have opened hundreds of these rabbits, and I have very rarely found this appearance of fibre. I do not think this enters into the element of their death.

1310. Have you made any recommendation to your Government in regard to the suppression of the rabbits in these thickly infested parts? I have suggested the desirability of erecting rabbit-proof fences. My idea was to fence off the pastoral from the agricultural country, as by doing so the rabbits from the pastoral country would be prevented from getting into agricultural areas, and so isolate the country where they are now to be found. My opinion is that if rabbit-proof fences were generally adopted the solution of the rabbit difficulty would be found.

1311. Have you any idea as to what mesh and height should be used? I think the fence erected on the border between South Australia and Victoria would be ample. It is 3 ft. 6 in.—6 in. in the ground and 3 ft. out—1½ in. mesh, with two barbed wires on top. This makes a dog-proof fence as well.

1312. You know what is known as the annually-leased country? Yes; and it was the specially infested nature of this country that led me to recommend rabbit-proof fencing.

1313. How do you deal with this poor pastoral country held on annual lease? After the erection of a main line of rabbit-proof fencing, I should cut the country up into blocks, and give it on long lease with favourable terms, with the distinct proviso that the vermin on the land should be destroyed by the lessee, and the fences kept in proper order. My recommendation, so far as the erection of Government fences, applies to the worst lands, but the divisional lines should be erected by the lessees, and the whole line kept in order by them.

1314. Would you absolutely prescribe the erection of such fence as a condition of the lease? Yes; and to enable them to do it I would allow the lessees to take the country up on lower rentals; but I would make it a *sine qua non* that the fences should be erected by the lessees, kept in repair, and the rabbits destroyed.

1315. *The Chairman.*] Have you considered the difficulty of fencing rough country and watercourses, especially parts that are subject to floods? Yes, I have considered that. It could be met in the same way as with the rabbit-proof fences that were erected east of the Murray on the cliffs for 16 miles. That line of fence crosses innumerable gullies and ravines that run into the river Murray. It was composed principally of pine pickets, set side by side. In places where the line crosses these ravines sluice-gates were left, and these were formed by swinging pickets on strong wires. Whatever flood matter was brought down by the floods swept through these sluice-gates, in some cases doing damage and in some cases not; but in all cases where damage was done it was repaired at very little cost by the boundary-rider who was in charge of the fence. I will send in specifications of this fence. I have found that this picket fence barred the progress of the rabbits, and I have received numbers of letters from settlers stating that these fences saved them from ruin.

1316. Do you feel satisfied that these methods are consistent with the poverty of the country? Unless some method that has proved effective is adopted the country will become entirely worthless, because the land adjoining, which is now occupied to advantage, will become infested. Before the rabbits came the annual lease country gave a very good return.

1317. *Professor Allen.*] Supposing that during this year and next the rabbits were to increase as last year on this annually-leased land, would serious permanent damage result? Undoubtedly.

1318. *The Chairman.*] That country is now particularly bare? Yes; the herbage has been destroyed principally by the rabbits. I think serious permanent damage will result, and also all over the country seriously infested, unless some proper measures are adopted.

1319. Do you think that the trees which are ring-barked die permanently? If they are completely ring-barked, both bushes and trees will die, but if there has been only a mere fluting of the bark and the tree not entirely ruined, it will recover.

1320. What height from the ground have you seen rabbits in trees? Twelve feet high. I was riding with a gentleman on Mr. Love's Mount Wedge Run, and my attention was directed by a movement in the sheoak. I looked up and said, "There's a rabbit in that tree." He said not; that it could not be a rabbit; it was impossible. I said I was sure it was a rabbit. I rode up to the tree, cut at the animal with my whip, and a rabbit jumped out of the tree. The rabbit was above my head, and I was sitting on a horse 15 hands high. It was a leaning stump, and I saw marks of the claws on the bark; the rabbit got there himself. I have seen rabbits while hunting in bushes get readily up five to six feet. I am not an expert in disease, and have not made any study of it.

John Miller called in and examined:—

1321. *The Chairman.*] What position do you hold? I reside at Merriton, and am a member of the Pastoral Board of South Australia.

1322. We understand you are anxious to make some communication to us? Yes. I have been engaged for three years in examining the pastoral leases expiring in 1888. Previous to that I had assisted in passing the Vermin Bill of 1884. While engaged in this work I saw a great deal of the rabbit-infested country. We have made it possible for the rabbits to live in this country by poisoning their natural enemies, by putting out baits for wild dogs, iguanas, &c. These made it impossible for rabbits to exist, because they had first to be protected on the West Coast. The poisoning that is going on to get rid of the wild dogs is wholly ineffective. I would also recommend the introduction of the domestic cat, which I think would be sufficient in conjunction with any disease that might be found suitable. The treatment which you adopt for dealing with the rabbits where they exist in large numbers you cannot extend out to the bounds of settlement of the rabbits, because the animals are more isolated and scattered. Where rabbits are scattered disease will not be communicable. I have had no practical experience with disease, but above all things I would protect the natural enemies of the rabbit, and I would prohibit their being either poisoned or trapped. I do not mean to say that you should not poison rabbits with grain, but I would prohibit poisoned baits that would be taken by carnivorous animals.

1323. As regards the question of fencing, have you made any recommendation as to the 1888 leases? I was asked by the Premier in 1885 to send him some notes, and I then recommended that a rabbit-proof fence should be put along the boundary. I intended to separate the agricultural from the pastoral districts. My experience of rabbit-proof fencing is that no rabbits will get through $1\frac{1}{2}$ inch mesh. The rabbits are said to run up the stays at the strainers and get over the wire-netting. I therefore have doubts about the fences as at present erected. I know one case where domestic cats were turned out and were killed by the rabbiters, which accounts for their non-success. On Flinders and Schlink Islands the only means used for the rabbit extirpation were cats, and they completely extirpated the pest. I used cats on the Lower Broughton in 1884, where dogs and men could not get at them, and the cats were completely successful.

The Commission then adjourned.

WEDNESDAY, 6 JUNE, 1888.

The Commission met at 10:30 a.m., at the Crown Lands Office, Melbourne.

Present:—

Victoria: HARRY BROOKES ALLEN, Esq., M.D.
ALFRED NAYLOR PEARSON, Esq.

Queensland: JOSEPH BANCROFT, Esq., M.D.

In the absence of the President (Dr. MacLaurin), the Chair was taken by Professor ALLEN.

Edward Micklethwaite Curr called in and examined:—

1324. *The Chairman.*] You are Chief Inspector of Stock for the Colony of Victoria? Yes.

1325. How long have you held that position? About twenty-five years.

1326. Have you studied the spread of the rabbit plague in Victoria? It is a subject that attracts me considerably. I have obtained a considerable amount of information, and thought it out in my own mind, but I have had nothing to do with the matter.

1327. Can you state briefly what was the general course of infesting Victorian lands by rabbits? Yes; about twenty-five years ago there were about half-a-dozen couples of rabbits imported here from England by Mr. Thomas Austin, of Barwon Park, who tried several times to acclimatize the rabbits and failed, though he eventually succeeded. These rabbits were preserved for some time, but eventually they spread all over the country in the order of things. I heard Mr. Austin's statement as one of the Acclimatization Society, and it was considered rather a feat at the time, nobody foreseeing the result.

1328. Are you aware whether rabbits have been intentionally let loose in Victoria? Not wild rabbits; I have heard of tame ones being let loose.

1329. Then, so far as you are aware, the wild rabbits throughout Victoria have come from the original stock imported by Mr. Austin? Yes.

1330. At about what time did the rabbit plague assume serious dimensions in Victoria? Well, I never heard much about them until about ten years back; before that I do not think they were very troublesome.

1331. What has been the general method of dealing with the pest? Poisoning and trapping, and filling up the burrows; these have been most successful, though most expensive.

1332. This would be on the rich southern lands? Yes; and in the western district.

1333. On these rich lands in the western district, have rabbit-proof fences been largely adopted? I believe so; but as I have not had occasion to make a tour for some years I cannot say so from personal observation.

1334. Are you aware whether any serious difficulty has been met with in coping with the rabbits on the rich western lands? I cannot say that I am.

1335. The principal difficulty, I presume, has been in connection with rocky mountain lands? Yes; it is on these poor rough lands and not on the good lands that the difficulty has arisen.

1336. Is it a fact that this was due to a want of co-operation by adjoining land owners? I cannot say that I personally know that; but I have no doubt that want of co-operation is one great difficulty in the way, and it is a difficulty which I think will never be got over.

1337. In what parts of the Colony have the pastoral lands been seriously affected in their carrying capacity by the rabbit plague? I should think chiefly in the western district, and around Geelong; but I have not had much personal experience.

1338. Have any official reports been made to you with regard to the diminution of the carrying capacity of the land? No; and they would not have been made to me in any case.

1339. Have you visited the mallee country lately? Not since the rabbits have become numerous there; it is about eight years ago since I was there.

1340. What recommendations would you be inclined to make as to the proper modes to adopt in connection with the rabbit difficulty? I do not think any useful result will be got by attempting to secure co-operation; the people will never be got to act together. The whole lot of rabbits have sprung from a-half dozen couples in one place, but you can never expect to get them down to that again. In spite of anything we can do there are likely to remain millions of rabbits in these colonies. When the Colony is cut up in farms, I suppose the rabbits will become as they now are in England and France. You ask me what measures I would propose for getting rid of the plague, or for reducing it. The first thing I would recommend is that the duties should be taken off fencing wire, and that fencing should be made as cheap as it is possible to make it; the law also should be such that neighbours will be obliged to pay their share of the cost of fencing between the two holdings.

1341. Do you, then, consider netting fences as essential to any effective scheme? I consider fencing is the only hope, and I do not think anything can be done without it. It gives resolute men and men of capital a chance of clearing their ground, and so you bring these men to the fore. Experience has shown that the rabbits can be kept down in a paddock of 10,000 acres as they are kept down in England, provided you do not allow it to be overrun from the outset; and hence I say, make netting fencing compulsory and also easy by taking off the duty that is imposed on the wire. I do not think that any Government would let it be supposed that they were adverse to the rabbits being got rid of, and yet they impose a tax upon the only means of disposing of the rabbits, which is netting.

1342. Do you know what is the cheapest form of netting? No; but I would like to mention this, that any establishment existing for the potting of rabbits and of sending them home should be compulsorily suppressed, for as long as you allow people to depend on the production of rabbits you may be sure rabbits will disseminated, whatever you do. This I consider to be a primary matter.

1343. Are you prepared to give any opinion in regard to the fencing in of Crown Lands from rabbits? Yes; I think it should be done.

1344. *Dr. Bancroft.*] Would you not go further and recommend that the Government should contribute to the cost of such fencing? No; I am a free-trader and would never recommend anything of the sort. I think the people should be quite well able to do their own business without any bonus.

1345. *Mr. Pearson.*] Would you not get a better return from the lands on lease if they were cleared of the rabbits? If there were no other means of doing it I think it would pay to give bonuses to get rid of them.

1346. *Dr. Bancroft.*] Would you give free railway carriage to the netting? There would not be much to be said against it. At the same time I do not much believe in these measures.

1347. *The Chairman.*] If large areas of poor land are to be dealt with can anything be hoped for unless the tenure is materially secure? Materially secure and materially long. I think a man must have an interest in his land, and some surety that he will be repaid for what he expends.

1348. Do you think the lessee should be secured against losing his run for some fixed period after he had dealt with the rabbits? Yes. As an inducement to such a man I think it should be said, "There is the country for you—you can have it so long, provided you do so and so."

1349. Are you prepared to make any specific recommendation as to the leases that should be given? No; I have never thought of this except in a general way.

1350. In the case of private or leasehold lands abutting on public lands, do you think the Government should pay its portion towards the erection of intermediate fences? Yes, I do.

1351. Allowing, then, that the erection of netting fences be made compulsory, what would be your next recommendation? It should be so arranged by law that anyone possessing land on any terms—rented or freehold—should be compelled to keep these animals in check. In the event of his not doing so, the Government should do it at his cost with a substantial fine as well. I think this would induce most people to set to work.

1352. *Dr. Bancroft.*] You would not compel a man to do this in any particular way? No; just the same as with scab. We do not say what is the remedy, but we punish a man if we find scab on his property.

1353. *The Chairman.*] Should this power be vested in the central Government or in local bodies? I believe it would be much better if vested in the Government. I do not think any result will ever be reached through the municipalities.

1354. Does your experience with scab and other diseases confirm you in that opinion? Yes, very strongly; I never had to do with municipalities, but from what I know of local bodies it is very hard to do any good with them.

1355. *Dr. Bancroft.*] By having one uniform course of procedure you have managed to stamp out the scab? Yes; and in a very short time and without much expense to anybody.

1356. *The Chairman.*] You think a central department should control all operations having reference to the extermination of rabbits? Yes, and the inspectors should be responsible to the central authority.

1357. Assuming that a certain amount of freedom of choice was allowed to owners of land, what plan of operations would you suggest as reliable? Well, I have not had sufficient personal experience to say.

1358. With the scab you proceeded from the extremity of the Colony and worked in towards the centre? Yes.

1359. *Mr. Pearson.*] You would not recommend a similar procedure with regard to the rabbits? No; because the circumstances are different. They are a different class of difficulties altogether.

1360. *The Chairman.*] What is your opinion as to the employment of any regular class of trappers? Well, that is a very difficult question. If you employ trappers then it becomes their trade and they live upon it. On the other hand they are more expert than others. Could the owner and his men do the work it would be preferable.

1361. Do you think that the mischief in the employment of trappers arises chiefly through their being paid for scalps? I should think it would have a good deal to do with it. When the rabbits begin to get low the trappers move on to where they are more numerous. Then while the trappers are away the district gets as thick as ever. Then if you employ men who are not expert at the work, the work will proceed much more slowly.

1362. Do you think the State should give any contributions to the expenses of rabbit parties? No; except to parties working on its own ground. It should act simply as a private owner or lessee acts with his own lands.

1363. Are you aware which are the best methods of poisoning? No.

1364.

1364. Generally speaking, is it your opinion that the pasture lands are suffering severely from the depredations of the rabbits? Yes, I think so.

1365. Are you aware whether the edible bushes on the mallee country are being destroyed? I have heard so.

1366. Can any reliable figures be obtained showing the diminution in the carrying power of the runs in this Colony? I have seen statements in the papers that certain runs that used to carry so many thousands now only carry so many hundreds. I think in one case, in the mallee country, the carrying power of a run had been reduced from 12,000 to 1,200 sheep. These figures are not obtainable in my Department, and I do not know whether the Rabbit Department has the information or not.

The Commission adjourned.

MONDAY, 15 OCTOBER, 1888.

The Commission met at 9:30 a.m., at the Crown Lands Office, Melbourne.

Present:—

<i>Victoria:</i>	HARRY BROOKES ALLEN, Esq., M.D. (in the Chair). ALFRED NAYLOR PEARSON, Esq.
<i>New Zealand:</i>	ALFRED DILLON BELL, Esq.
<i>South Australia:</i>	EDWARD CHARLES STIRLING, Esq., M.D. ALEXANDER STUART PATERSON, Esq., M.D.
<i>Queensland:</i>	HENRY TRYON, Esq.
<i>Tasmania:</i>	THOMAS ALFRED TABART, Esq.

James Ormond called in and examined:—

1367. *The Chairman.*] What is your address? 119, Collins-street, Melbourne.

1368. Where is your property situated? In the south-western corner of New South Wales near Wentworth.

1369. What area do you hold? About 800,000 acres. It is partly leasehold and partly freehold.

1370. Is the land of much the same value throughout, or is it of variable quality? It is very irregular.

1371. What is the average carrying capacity of your leasehold land? I should say about 12 acres to a sheep.

1372. Is your land very much infested? It has been—not so at present, but several years ago it was very much infested.

1373. When was it most thickly infested? About 1884 or 1885.

1374. To what do you attribute the decrease of infestments since? Partly destroying the rabbits, and largely to the drought, which existed for three or four years. I think it is very difficult to say to what extent the reduction is due either to one or to the other cause.

1375. What are the chief methods of destroying rabbits which you have adopted? During a long period, in which the work was done under Government supervision, it was almost entirely trapping. That was very expensive; and, in my own opinion, was a very costly method indeed.

1376. Was it effective? Well, it was only effective in a partial degree. It was very ineffective in a general sense.

1377. You mean that large numbers were killed but that the runs were not cleared at all? Yes; and never could have been cleared under that process.

1378. What process did you find most effective? Well, I think the process which we found most effective is Lascelles' machine.

1379. What poison do you use, chiefly? Phosphorized wheat, entirely. We tried strychnine and also arsenic.

1380. What was your general conclusion with regard to these three poisons? We found that the most inexpensive—phosphorized wheat—was the most efficient.

1381. You desire to give evidence before the Commission on certain distinct points? Yes. I had been under the impression that this Board had only examined a certain class of Crown tenants. I am possibly mistaken; and if so, I am only taking up your time. I did not think that you had examined tenants who hold excessively poor land; and it was more with regard to wire-netting fences that I wished to be examined than anything else.

1382. We have examined several other holders whose runs carry one sheep to 14 acres? Well, that is a class of country which I wanted to speak of. It is more against compulsory wire fencing of land of that character that I desired to give evidence.

1383. I believe you are prepared to make a statement as to the annual product of land such as is held by you? Yes. So far as my experience is concerned the annual product of such land as I hold has never paid expenses of working the station. I am prepared to go more into figures, if necessary; but this is the general result of my experience of over ten years.

1384. Why, then, is the land held? Because, having put money into it, I do not want to lose all. I am trying to recoup myself by good seasons; but as a matter of fact—I speak now for myself and for others—I have done nothing but lose money on the land, and I should be delighted to give it up if I could get one-half my money back. I am willing to sacrifice my improvements, on which I spent £50,000. I must admit I made a grievous error in making expensive improvements on such land—a thousand miles of fencing and a great number of tanks. I think these are mistakes; but I should like to get some of the money back, if possible.

1385. *Mr. Bell.*] Supposing you had not made mistakes—as you call them—would the land you hold, then, have paid you? Well, I doubt it. I know a great deal more now than I knew then. I went into this land when wool was 50 per cent. higher than it is now. Besides, I knew very little of the climate;

very little was known of it ten or fifteen years ago. The results of the first two or three years—the good prices for wool—encouraged me to incur these expenses to develop the station. Since then, between the very bad seasons, the droughts and the rabbits, these hopes have all been shattered to pieces, and it has been a series of losses, one after another, year by year. Even had I not gone to the expense I have gone to, I do not think I should have been able to make it pay; but still I should have saved a great deal that was expended on what is now practically useless, except for my own purposes. I have had for some considerable time one or two partners—practical men—who have been squatters all their lives, so that mine has not been an extravagantly-worked station. My partners are thoroughly intelligent squatters, who know their business; and they worked the station probably as well as any station could have been worked.

1386. Supposing that you had not had rabbits to contend with at all, would your land have paid you then? No; unfortunately the continuation of the drought destroyed all hope of that. As a matter of fact, I have not had a good year since 1881. That was a very good year. Last year was a good year, and this year is a very bad one. Like a great many other people, I was understocked in 1881, and I had not courage to buy. And the advantages of last year were not great in my case, nor in the cases of many other people. So that since 1881 we have not had a good year. I do not mean to say that the rabbits have not materially influenced the result, but on them should not be placed the whole responsibility.

1387. Then you desire this Commission to understand that your case is not an isolated one—that what you say applies to other people in the same district? Yes; I know that it is so. I am speaking for every other station in the same district. I have absolute knowledge of it.

1388. *The Chairman.*] What experience have you had in fencing against rabbits? None whatever. The only remark I want to make is that, so far as I am concerned, anything like compulsory wire fencing would make myself, and a good many others like me, throw up their stations and make our loss, or put them into the hands of the mortgagees, who would have to work them themselves. It would be utterly impossible to fence such areas as these in with wire-netting in the hope of making them profitable.

1389. *Dr. Stirling.*] Are you of opinion that the station would not stand the expense of it, or do you think wire-netting is in itself useless as a check on rabbits? I have not sufficient practical knowledge of the effects of wire-netting to give any evidence on that point.

1390. Then your contention is that the stations would not stand the cost of the netting whether the netting is any good or not? Yes; and I have no evidence to give whatever as to the value of wire-netting.

1391. That would apply to a case where a holder was compelled to put fences up; would you still be of the same opinion if the Government put the fence up and called on the holder merely to pay interest on the cost? That would not alter the circumstances; it is the strain of the extra expense that the station would not stand. In country like that—where, perhaps, there are 20 to 30 square miles of impenetrable scrub which is utterly useless for sheep, and is only a rabbit warren—to make any subdivision to keep them out of the enclosure, would be so ridiculously expensive that it could never pay.

1392. *Mr. Pearson.*] A boundary fence would not, then, be enough? That would not be of the slightest use. That would simply enclose rabbits that we could never destroy. We must fence off these parts of the mallee scrub which are no good, and which are merely breeding places for rabbits—where they live without burrowing.

1393. Have you had any attempts made in that district for the extirpation of this scrub, such as were made with the mallee scrub of Victoria? It is a totally different country. This is a loose, sandy soil, which, even if the scrub were taken off, would be utterly useless. We have often tried many miles of this and could not find holding places for water. There is nothing but sand, and you cannot find a place to put a water tank.

1394. *Mr. Tryon.*] Is not the number of rabbits greatly influenced by the influx of rabbits from South Australia? I am on the other side of the river, and therefore they do not affect my portion so much as the western side.

1395. *Mr. Pearson.*] What area of country do you suppose is of similar character to your station? A large portion of the resumed area of Lake Victoria station is of the same class. Take my neighbour, Mr. Cudmore,—I dare say he has got perhaps a couple of hundred thousand acres of that class of country. I would like to add that if we had not been so unfortunate in having a succession of droughty seasons the station might have paid me; but, with the conditions of the seasons and the rabbits, it has been a continual loss. I think had the seasons been fairly average ones I would have been able to save myself making losses.

1396. Are you speaking of fairly average seasons with yourself, or with the grazing areas all over the colonies? No; I speak only with respect to the Lower Darling country.

1397. Had you much experience of that country prior to your occupation of it? Yes; I have now the rainfall and climatic conditions so well before me that I am able to say that, in my opinion, with average seasons, such stations should pay.

1398. *The Chairman.*] What are the names of your stations? Tapio and Turlee.

1399. *Mr. Bell.*] Does what you say apply to both? Yes; they are only 40 miles apart, and are situated at the junction of the Murray with the Darling, on the eastern side of the Darling abutting on the Wentworth common.

1400. How much have you spent in rabbit destruction? I spent during the years 1884–85–86 a gross sum of £20,000 on rabbit destruction. I received as subsidy from the Government perhaps something equal to two-thirds of that amount.

1401. *Mr. Tryon.*] Has there been an unusual increase in the amount spent? In 1884–85 the sums were much larger than in 1883, but I may point out that the lowest amount spent in any year on rabbits was a great deal more than the rent came to. Before 1884, the year in which the new Bill came into effect, the rent of my run was £808.

1402. Had the Act relating to the mallee country in Victoria been in force, would it have had any effect on your position—would it have paid you to hold the station? No. I am not quite sure that I know enough about the Victorian Act to answer your question.

1403. Do I understand that you purchased the station, or did you take the country up in the first instance yourself? I took the country up in the first instance as a partner in a firm.

1404. Your opinion is that a barrier fence would have served no purpose, because when you arrived rabbits were already there? Yes. There must have been a horde of rabbits in New South Wales at the time. We had rabbits when we took up the station in 1871. We had them for years, and looked on the shooting of them as nice pastime, but they never increased much till 1881.

1405. What effect had the drought on the rabbits? It starves them, eventually.

1406. Do they acquire any special habits, owing to the drought, which hasten their destruction? Well, it is very difficult to say. A lot of them die, and the others do not breed very fast. I suppose they have only a certain class of feed, and when this is eaten up they have nothing to fall back on.

1407. Have you ever noticed that they eat any plants which might have a deleterious effect on them? I have no knowledge.

1408. Do you know that sheep thrive on plants which rabbits will not eat? Yes; generally scrub. Sheep eat the scrub, the bark of which has I believe a deleterious effect on rabbits, but of that I have no evidence.

1409. *The Chairman.*] Can you tell us anything about the relative amount of feed consumed by rabbits and by sheep? I can give you a little idea of what rabbits will eat in confinement; what a sheep will eat I suppose you know already. I have kept some rabbits in confinement during the last twelve months. A great many of us tried Professor Watson's scab disease. I got some rabbits affected with it twelve months ago, one of which I still have. I kept other wild rabbits in confinement with them and some of them got the disease, but it went very slowly. There is, however, one remarkable fact in connection with it. One of these wild rabbits had a litter of young after being in confinement for five or six months. Immediately we got the litter we moved them into another room, and in less than a month every one of these young ones had died.

1410. *Dr. Paterson.*] Do you attribute this to the condition of the mother? Yes; because the conditions under which the young ones were kept were as good as possible. There were four or five in the litter. Every one of these rabbits eat a good sized cabbage every day. We gave them as much as they could eat. They had 4 lb. or 5 lb. of oats per day amongst five—about 1 lb. of oats each.

1411. *Mr. Tryon.*] Have the rabbits permanently injured the carrying capacity of the runs by destroying the herbage? Whether they will permanently affect the run or not it is impossible to tell. The effect of a good rainfall in a country like that is something magical. No doubt the loss of the herbage must affect the runs considerably. A good deal of my salt-bush has been killed by them; though I should not like to say that it has been permanently killed.

1412. *The Chairman.*] Can you say that the destruction is due to the rabbits, or was it eaten down by sheep? I should say by both, but more particularly by the rabbits. No doubt both have affected it considerably.

The Commission adjourned.

SECTION III.

EVIDENCE given before the Executive Committee of the Royal Commission at Tintinallogy and Elsewhere.*

TINTINALLOGY.

MONDAY, 28 MAY, 1888.

Present:—

New South Wales: W. C. WILKINSON, Esq., M.D., M.P.
New Zealand: A. DILLON BELL, Esq.
Queensland: JOSEPH BANCROFT, Esq., M.D. (Chairman).
Tasmania: THOMAS A. TABART, Esq.

John Reid, manager and part owner of Tintinallogy Station, examined:—

To the Chairman: I have resided here four years, from July, 1884; there were rabbits here when I came. They were paying 2s. 6d. per scalp here then, and got some of this back from the New South Wales Government; I could not say how much was paid. Rabbits kept increasing till about January, 1888, when they began to die very fast; at present there are not as many as when I came; there has been no poisoning done, except some small experimental work in that way; we have trapped largely, paying at per scalp; latterly, 1½d. per scalp, before that, 2d; it was 1s. in November, 1884, when I took charge. Trapping was an utter failure; it ceased about 25th January, 1888. We tried strychnine last year, put on green feed, cabbages, &c.; not on twigs, I think; poisoning was not destructive enough. The increase was due to the rabbits coming from other places, not to natural increase; I have no doubt of that from the rapidity of the incursion; they came up the river and in from the back country. There was plenty of grass here before that; the rabbits barked the bushes even then when grass was plentiful; they are fondest of hop-bush; they also ate a lot of different bushes, including "old man salt bush" and lignum; they were dying fast before January, but very rapidly since. Before January I think the trappers were skinning rabbits dying from natural causes; I cannot, however, prove that; the skins were not kept for sale. Rabbits are still dying. To

* Taken by A. D. Bell, Esq., in the absence of the Secretary and shorthand writer, who was in attendance on the Commission at Silverton.

To Dr. Wilkinson : I first noticed the disease in the rabbits about August, 1887 ; Dr. Butcher was the first to notice it, and started some experiments, which have gone on ever since ; he first heard of odd ones being dead, then he caught some and tried experiments ; in any infested country we do find dead rabbits, but in this case more than usual.

To the Chairman : The reduction, I think, is by death, not by migration ; no one near here has said our rabbits have gone to them.

To Dr. Wilkinson : In one month we trapped 56,000 rabbits ; this was the largest month's work we ever did ; it did not reduce them perceptibly ; disease killed far more than 56,000 in a month ; I know this from riding along, and counting hundreds dead on a few acres.

To the Chairman : At this time there was plenty of feed for both sheep and rabbits.

To Mr. Tabart : I found dead rabbits all over the run. Wynne, Hudson, & Co. were our only neighbours poisoning them ; it was not possible for the dead rabbits found to be from there ; the nearest part of their run is 10 miles from the head station here, and we found dead rabbits 20 miles from there. I think rabbits will only go about a mile for food, but I am not sure. I first noticed barking being done about twelve months ago or more ; since then most of the country has been barked all over.

To Dr. Wilkinson : They will bark trees even when there is plenty of grass.

To Mr. Tabart : Barking, I think, has nothing to do with the mortality here.

To Dr. Wilkinson : On the runs further back from the river barking began twelve months earlier than with us ; rabbits are as thick there now as before ; by " far back," I mean outside our boundary.

To the Chairman : The rabbits bark equally summer and winter ; here they bark when there is plenty of feed.

To Mr. Tabart : Rabbits are spread by trapping, but in this case I cannot think they left our run, because if so, our neighbours would have had them thicker than ever.

To Dr. Wilkinson : The sheep did well here till 1st April last ; after that, they were a little pinched, till the rain came. In counting dead rabbits I would only count those with the fur on, not the skeletons.

To the Chairman : I cannot say how long fur would be noticed in dry weather ; not long, I think ; ants and other things destroy them. We had a plague of rats here, about the beginning of 1887, in a wave down the river ; they were not so numerous as the rabbits ; they burrow, and I think eat the grass ; it is the true rat, not the bandicoot.

To Dr. Wilkinson : The worst year for rabbits was 1887—the same year as the rats came. But for the rabbits we should have saved much more dry feed for this year, whereas now we pay £9 10s. for chaff. Horses can rub along all right in the horse paddocks on the dry natural grass if the rabbits had not eaten it.

To Mr. Tabart : The rats went away gradually ; they were not observed to die ; I think they went down the river ; we heard of them higher up a month before we got here.

To the Chairman : I have not much faith in wire netting ; this country is so loose and sandy that in hot winds in summer the net would be silted over in a few hours, and rabbits would walk over. I net my garden and yard with 1½-inch mesh, there being no sand close about here ; the drainage holes also, which are sometimes 20 to 30 yards long, would make roads under the netting.

To Mr. Bell : The Darling country, as a whole, is loose and sandy, as described ; I did not mean to refer only to this station.

To Mr. Tabart : I would use no larger mesh than 1½ inch ; I have seen a good large rabbit go through 1½ mesh—one that could live well by itself ; I don't consider 1½ rabbit proof ; it is too large. I would not erect netting unless compelled ; if I were compelled I would put up as cheap a one as I could, because I would not believe in its being rabbit proof anyhow.

To Dr. Wilkinson : I think 1½ inch would stop any rabbits, except those too small to live alone, if they got through ; a rabbit could get through 1½, however, and run away. I have seen them do it ; they would do it without being hunted, if they saw better feed the other side ; I would recommend 3½ feet out of the ground ; I don't think 3 feet out of the ground enough ; in fact, I believe they could climb any height ; I have seen them run up 3 ft. 6 in. netting like a cat.

To Mr. Tabart : This netting was perpendicular, without any bellying in it. I think netting worthless in this country ; that is my opinion, but many differ with me.

To Dr. Wilkinson : I have only seen them climb the netting in hurdle enclosures ; I have seen the marks where they have climbed trees, even 5 feet high. I never saw rabbits cross the river ; even when dry I have seen no trace of it, but I never looked particularly ; the bed when dry is sandy, not boggy. They will swim when hunted, but not otherwise. Ordinarily, I consider the Darling River rabbit proof. The natural enemies here are iguanas, hawks, native cat (this is very scarce), and tame cats, many of which have gone wild here ; we turn out as many as possible ; some come back, but not many ; they do not come back if half grown when turned out.

To Mr. Tabart : The rabbits here are so reduced in numbers now that I think the natural enemies can deal with them unless we are invaded again from elsewhere. The rabbits travel up the river always, not down ; I cannot account for that fact. The paddock we call " the bend " is fenced in and was very thickly infested ; its area is about 500 acres ; they began to die there shortly after Dr. Butcher began experimenting there. The bend is fenced in with 4-foot netting of 1½-inch mesh. Previous to Dr. Butcher putting diseased rabbits in there, all the rabbits were healthy ; I consider the extermination of the rabbits on this 500 acres was solely due to the introduction of disease by Dr. Butcher. There was splendid feed there, and has been ever since, up till the last month or six weeks ; there is plenty there even now ; it has never been short of rabbit feed since it was fenced in. The appearance of the disease among them was that they got very thin, their hair stood up, and they could not run away. I have not been often in " the bend " myself. The land was fenced rabbit-proof in all states of the river ; the netting was continued right out into the river itself, and staked there.

To Dr. Wilkinson : I never counted the dead rabbits in " the bend," but I saw lots of them lying about there. I do not know if a record was kept of the number of deaths there.

The question was here raised whether Dr. Ellis should be permitted to be present during the examination of witnesses. The Chairman ruled that examinations by the Committee must be conducted in private, and that Dr. Ellis could not be permitted to be present.

Examination continued,—

To the Chairman : Inoculated rabbits were put in "the bend."

To Dr. Wilkinson : Before this the rabbits had every appearance of being healthy ; if badly diseased I can pick them out by their appearance, as before described ; I never saw rabbits like these diseased ones before the disease came.

To Mr. Tabart : I consider the disease to be very infectious from rabbit to rabbit ; the young ones take it more quickly than the old ones, and die off sooner.

To Mr. Bell : I have had sheep running on the same country with these diseased rabbits ; the sheep were there when the rabbits were dying in large numbers—sheep of all kinds, all ages and sexes. I never saw any diseased sheep in that country, nor noticed any deaths of sheep ; the same is true about cattle and horses, and also about the kangaroos ; no disease or deaths were noticed among any of these animals ; I never took any steps to keep stock separate from the diseased rabbits ; I believe, from my experience that the disease is infectious among rabbits only.

To Mr. Tabart : The disease has extended into Billilla run, with the same fatal results ; it appeared on the part adjoining us, near the river, on the same bank ; not all over Billilla ; I believe the effect is from infected rabbits having gone there from here.

To Dr. Wilkinson : The disease showed in the most marked form near the river, but it went out back and is quite as bad there now, and kills just as fast.

To Chairman : The rabbits between this station and Menindie, so far as I know, have not the disease ; I have not been down there, and am not sure.

To Mr. Tabart : The weather has no effect one way or the other on this disease, nor the feed, nor the country.

To Dr. Wilkinson : On the other side of the river the station Weinterriga has the disease, on the back country ; it is better grassed than this, and less bush.

To Mr. Tabart : The disease is there twenty miles back from the river.

To Mr. Bell : Our sheep are in very fair condition now for the time of year. Between last January and this time they were much better than they are now ; in January they were in splendid condition ; since January we have sold 13,000 fat sheep off the run. They were fat, but were not sold as fat ; they were fat when inspected, in February. Where the rabbits were dying there is plenty of water ; most of the deaths took place where there was plenty of water. There were no stock but rabbits on the 500-acre bend when the experiments began ; there were sheep, horses, goats, and cattle put in the bend during Dr. Butcher's experiments with rabbits ; Mr. Stanley, V.S., of New South Wales, inoculated these stock there.

To Dr. Wilkinson : Some of the sheep were there three months ; there was plenty of feed for them there, and they kept in good condition ; no artificial food was given.

To Mr. Tabart : Tintinallogy is about 330 square miles in extent ; the deaths from disease have been all over it.

To Dr. Wilkinson : There are a few rabbits left here, but it would be a trouble to find any here now ; I will take you out to-morrow and show you any rabbits we can find. The disease has spread and cleared the run, and gone 10 or 12 miles into Billilla. The rabbits, as I have stated, travel north. The disease was first noticed here on Tintinallogy ; we have 40,000 sheep on it ; I don't think you will see any rabbits to speak of, alive or dead lately, till you get to the other side of Billilla station ; there is hardly a rabbit on the run ; you might ride 20 miles without seeing one, and before the disease you could hardly ride a mile without seeing a thousand. I can show you their dunghills still. I have observed the barking since twelve months ago.

To the Chairman : The "old man salt-bush" is a disadvantage on the run, no stock eat it, and it takes up a lot of ground. I don't think it would actually hurt stock if they ate it ; if really starved they do eat a little, but I never heard of fatal results. When the rabbits took to barking there was plenty of grass. The rabbits are dying all over the run, and the "old man" is only in patches here and there ; they die where there is none ; a good deal of the hop-bush close here has been barked by rabbits, and some is dead. We have no myall here.

To Dr. Wilkinson : In some places they bark the mulga, but not much so here ; they bark our leopard-trees. The rabbits have been eating "old man salt-bush" all over the Darling for years, without any deaths like this.

To Mr. Tabart : Trapping is an utter failure ; besides the other objections I have mentioned, the first thing the trappers kill is the natural enemies of the rabbit. I have said that in one month in 1887 I trapped 56,000 rabbits ; in 1888, from 1st January to present date, I have only expended £47 Gs. 2d. on rabbit destruction ; it was unnecessary for me to spend even that ; I only did it because I was forced by the Rabbit Act to keep some men on trapping.

Alexander Affleck examined:—

To the Chairman : I reside on and manage Weinterriga (G. and J. Riddoch's) on the northern bank of the Darling ; the area is 1,200 square miles ; I have been there twelve months. Rabbits, since I came, are much less numerous. We have been trapping to end of March, 1888, and since then have used phosphorized grain, also arsenic, and carbon bisulphide in the burrows. Trapping is not an effective means ; it is a great farce ; rabbits multiply fifty-fold during the trapping ; it is impossible to cope with rabbits by trapping. Last twelve months it cost us £12,000 on trapping ; we caught 1,042,000 rabbits. We have used phosphorized grain largely since the beginning of the year ; we tried wheat and oats ; wheat is good, but they will take oats. The result of the poisoning was very satisfactory ; I have counted 300 in a mile dead. I have no experience in any other methods of poisoning. I think disease is killing rabbits in Weinterriga, all over it. I do not know what disease ; where two months ago there were thousands, you can now see hardly any ; this is everywhere, except just on the river.

To Mr. Tabart : I first noticed it two months ago, when neighbours also noticed it ; I do not know where it came from or whether it began on Weinterriga or not ; I have stock all over the run where this disease is ; it has no effect whatever on stock.

To

To the Chairman : There are no young rabbits now on Weinterriga; during summer they breed very little; I have, of course, only twelve months' experience; there have been no young rabbits since the end of November. In October or November, 1887, one party of rabbiters got 9,000 young rabbits out of 10,000 total—that is, there were only 1,000 old to 9,000 young ones.

To Mr. Tabart : I have heard of disease being among rabbits on Tintinallogy; I have been over that run since, and have seen diseased rabbits there, and caught them; I consider the disease at Tintinallogy and at Weinterriga identical; the symptoms are precisely the same.

To the Chairman : I am not aware of diseased rabbits being taken from Tintinallogy elsewhere.

To Mr. Bell : The symptoms I mean are these: The rabbits fall away to skin and bone, and get very weak; I notice the liver is very black, and looks unhealthy; they get "roach-backed" and doubled up, and you can easily run them down.

To Mr. Tabart : I would not have the slightest hesitation in introducing this disease upon a run of my own; it is perfectly safe to stock.

To Dr. Wilkinson : When rabbits were on Weinterriga, far back, they were very numerous; about the same as on the east of the run; the feed was abundant there, and it is so still.

To Mr. Tabart : The country is open salt-bush country, with sand hills and scrub; rabbits have "rung" a good deal of the bush; not the salt-bush, which they do not touch, but leopard-wood, hop-bush, and others; in places they take the "old man;" in fact, in places, every bush that grows.

To Mr. Bell : The rate of progress of the disease on Weinterriga is such that I expect there will be no rabbits left there shortly.

To the Chairman : The wire netting we have put up keeps rabbits back; it is 3 ft. 6 in. high, 17 gauge, 1½ mesh.

To Mr. Tabart : We have 152,000 sheep on Weinterriga; even with that number of sheep at stake, I would not hesitate to introduce Tintinallogy disease if we had not already got it among our rabbits. When I was first on Weinterriga the bush was not destroyed by rabbits; I first noticed it about December, 1887; eating bush has, I think, had no effect on rabbits, nor has it, in my opinion, anything whatever to do with the outbreak.

To the Chairman : I never noticed any young rabbits dying, just as they were born, or later; I have seen none, as I said, dying at all till two months ago, except trapped ones.

To Mr. Tabart : Since disease came, we dismissed all trappers, but are still poisoning; there is plenty of water on our run; the rabbits are dying more thickly near the water than anywhere else.

To Mr. Bell : Our sheep are all in very good condition.

To Dr. Wilkinson : I don't consider our run heavily stocked at about one sheep to 8 acres; that is about what the country will stand.

To Mr. Bell : There is plenty of feed where rabbits are dying, and always has been.

To Mr. Tabart : They have died all over the run; where there were originally thousands, there were, in a month, hardly any left. They did not leave the run; they died on the run. I have never heard from neighbouring runholders that they have seen rabbits increase on these runs; on the contrary, they have seen them decrease, during the decrease on Weinterriga.

To the Chairman : The trapping extends the rabbits and spreads them over the country; if left to form colonies naturally, they are more easily killed; any means is better than trapping.

John James Phelps examined:—

To the Chairman : I am manager of Albemarle Station. It is about 740,000 acres; the average stock kept for the last ten years has been about 90,000 sheep; we have however 110,000 sheep on it now. I have been there twelve years; I first saw rabbits on the place about the end of 1882; I only saw one then; after that they kept increasing up to now. After 1882, we paid trappers weekly wages, besides scalp-money; rabbits being so scarce that they would not work without wages. In 1883, this cost £802; in 1884, £1,820; in 1885, £1,767; in 1886, £5,067; and in 1887, it cost £13,000.

To Dr. Wilkinson : The bonus system began about December, 1884, starting at 1s. each; in 1885, it decreased, and so up to now, the bonus now being 1d.; it stayed a long time at 6d.

To Mr. Tabart : During this time we employed only trappers. Trapping is the most ineffective means you can possibly adopt; it is a retail method, not in any way a wholesale one; I don't think it disperses rabbits much; trapping, in fact, has I think no effect either way; it is useless. Continuing the statement I have made of expenditure in former years, I may say that from the beginning of the present year, we have spent, on trapping, poisoning, driving, and yarding round tanks, about £2,300.

To the Chairman : We have no young rabbits now, but they will come very shortly; green feed starts them breeding; in former years there have always been young rabbits when the grass was green. The months or seasons have nothing to do with it; it depends on the presence or absence of green grass; there has been no green feed since last September till now, and consequently no young rabbits.

To Mr. Tabart : Ours is sandhill country with "old man" saltbush, and saltbush plain, with a good deal of mallee and pine; rabbits have been destroying the bush very extensively since about last August, when I first noticed odd bushes destroyed by them.

To Dr. Wilkinson : Sandalwood is the favourite, even better than leopard, which is a much scarcer tree than sandalwood; they have nearly denuded the "old man" saltbush; they have "ringed" all the mulga, of which we have not much altogether.

To Mr. Tabart : I have noticed disease among rabbits commencing about two years ago; it died out in a month or two, quickly; it showed as scabs on the skin; it was on scrubby country first, far away from the river; about 60 miles away. I do not think it has had much effect. The rabbits were very thick, and are now very thin; but it may be starvation that has done it.

To Dr. Wilkinson : There were no sheep on this country at the time.

To Mr. Tabart : I have been on Tintinallogy several times in this last twelve months. Since the disease there, the first time I came here was about last September; the rabbits were then as thick here as they could well be; I have not been there this year till to-day, but I only saw one rabbit to-day where previously you could see them in thousands wherever you looked. When I first came here I saw diseased rabbits

EXTERMINATION OF RABBITS IN AUSTRALASIA—EVIDENCE AT TINTINALLOGY. 111

rabbits, but only in the experiment "bend"; you could then see traces of disease on the skin. Since then it seems to have left the exteriors and gone to the interiors; the outward appearance is they fall away to skin and bone; I know of no other sign.

To Dr. Wilkinson: I saw very many rabbits so diseased, or showing those symptoms, in the open run, spread over it, just like those in the experimental bend. I have seen them at Albemarle, Henley, and Tintinallogy in the last few months; I saw such rabbits among the general lot. We sometimes drive 300 or 400 in a yard at once; the last rabbits we have been catching are all very poor and skinny.

To the Chairman: We employ six men to drive the rabbits into a yard with whips and dogs; in this way we took one day 900. That was our biggest drive; the least was about eighty; one can drive them a quarter of a mile, not farther; to attempt a longer drive is useless.

To Mr. Tabart: I have heard of Tintinallogy disease, but have heard of no loss of stock there. As manager of a large station I would not have the slightest scruple in introducing Tintinallogy disease into my flocks; I would be perfectly satisfied that the disease could not hurt my stock.

To Dr. Wilkinson: I have seen rabbits on Albemarle affected like those on Tintinallogy, but cannot speak positively that they were diseased; it might have been starvation. It was the same as at Tintinallogy; there were many more deaths than usual at that time; they began to die in large quantities last February, 1888.

To the Chairman: I never heard of diseased rabbits being carried from here (Tintinallogy) elsewhere. I am satisfied the rabbits have disappeared at Tintinallogy; I cannot explain why, without seeing the run. On Albemarle they disappeared largely; my present opinion is they disappeared from starvation, because there was nothing there for them to eat. The poor-conditioned rabbits we have on Albemarle are improving. On Albemarle, where the rabbits were dying in great numbers, there were sheep; these sheep fell away considerably in condition from absence of feed; the sheep fell away, and are falling away all over the run. This has been as bad as any year; there was only one year worse, namely, 1884; since the rabbits became thick, this is the worst year for feed we have had. I have not noticed that dead rabbits were thicker near water-holes, nor where food was specially abundant. I have seen these thin dead rabbits even where the first has been plentiful, but no dead sheep. If you overstock a paddock with sheep they will hunt all rabbits out of it. Theoretically, a notion occurs to me that you could dispose of the thick of them by overstocking successive paddocks over the whole country with sheep, and then netting it, but in practice such a plan might not work; I do not say I have thought it out thoroughly. I have not observed deaths among newly-born rabbits.

To Mr. Bell: I said I first saw rabbits disappear in large numbers in February last. We have not had much feed since last year. There was not any special falling off of feed in February, when I saw the rabbits begin to die in large numbers.

To Dr. Wilkinson: Since Christmas, 1887, we have had from 4½ to 8 inches of rain on our run, in various parts of it. Eight inches is our average yearly rainfall, and so this year we have in parts had a year's average rainfall in five months. But for the rabbits, therefore, this would have been a good year for feed; but, the rabbits being so plentiful, we have none. The rabbits have not bred since Christmas, the green feed having been taken—by the rabbits themselves—as soon as it grew.

To the Chairman: I have put up about 11 or 12 miles of wire-netting, and you could have nothing better to keep out rabbits; we have some 1½ and some 1¾ mesh, some 3½ and 3 feet high.

To Dr. Wilkinson: I think 1½ is as good as any, and 3 feet is high enough—that is, 2½ feet out of the ground and 6 inches buried; rabbits might be hunted over that, but I think they would not climb it otherwise; only very small rabbits could get through 1½ netting. On a place of my own, I would use 1½ and 3 feet high. I think sand would ultimately cover up wire-netting in this district, on the sandhills; it might happen in six months; not in twenty-four hours, certainly, and in some places it would never happen at all. I would think it even more likely that the sand would blow away from under the netting, leaving the netting above the level of the ground, that sometimes happens here with the fencing-posts, but it is not common. I don't think netting would be much use without sub-division.

To Mr. Tabart: I have not heard of any disease among rabbits below Albemarle. Rabbits, when they came first, all travelled north; but I think they are now stationary.

To Mr. Bell: In the case of the dying and dead rabbits on Albemarle, the liver I find is very much darker in colour than in the natural state, and very rotten; I observed this myself.

To Dr. Wilkinson: I found no well-conditioned rabbits like that.

To Mr. Bell: This did not alter my opinion, that they may have died of starvation; I should like to see more of the disease before I abandon that opinion.

To Dr. Wilkinson: In my experience in previous years, rabbits have bred noticeably from December to May, but this year I have not noticed any. This year I think there is some interference with the breeding; I attribute it to absence of green feed; they would breed all the year round if we had that; I have no doubt starvation is a large factor in making them thin, at Albemarle at any rate.

To Mr. Tabart: If sheep were thriving, and the rabbits had all disappeared on the same country, I would not then say the rabbits died from starvation.

Edward Hungerford Luttrell examined:—

To the Chairman: I have been assistant to Dr. Butcher for a time, at Tintinallogy station; I have been assisting him for the two months just past, and on another occasion before that. I am familiar with the condition of the rabbit question as affecting Tintinallogy. I first paid attention to rabbits here about four years ago, but had previous experience of them elsewhere; I noticed them gradually increasing up to December, 1887, notwithstanding the trapping, which did not seem to decrease them at all, though immense numbers were caught. They are decreasing now, however, since December, 1887; they began to die in December, and the mortality gradually increased. I was away from the end of December, 1887, to March, 1888, and on my return in the latter month, I could hardly see any rabbits where there were thousands before. I concluded from the look of the rabbits that they were dying from disease; I thought this from their emaciation and their general appearance. All ages and sorts died, young ones seemed to die very soon, and soon after the dying began no young ones were visible at all.

To

To Dr. Wilkinson : There were many dead young ones found, and plenty of nests deserted with the young ones in them—the mothers gone ; I dug out many myself and found the young ones dead in the nests ; they were quite young—"nest young"—say about a month old.

To the Chairman : Breeding ceased after the dying began ; I saw no young rabbits after that. The best breeding season for rabbits is from May to about October—all the winter, in fact ; I don't know that breeding depends on new grass. In the last year or two there has been more feed than there is just now ; the summer before last, I remember, rabbits were breeding all summer.

To Mr. Tabart : We shear here in August ; I saw the stock at shearing for a month or so, off and on ; the stock was thoroughly healthy. I took fat sheep away from here myself, last winter. I have seen nothing to cause me to suspect disease among the stock up to now ; I have been about among them, and seen them in the yards also, while the rabbits have been dying. I was on Tintinallogy when sheep were put in "the bend," and helped Mr. Butcher to inoculate them ; it had no effect on them ; I also helped to inoculate rabbits ; these rabbits died very soon ; they showed the effect in twenty-four hours. In my opinion the wholesale destruction of rabbits on Tintinallogy is due to disease. The state of the pasture all this time was very good, and the stock were fat ; from this, the natural inference would be that rabbits would also be fat. During this time, while grass was plentiful, I noticed rabbits were barking shrubs. I have seen the stock on Billilla Run ; they are perfectly healthy ; rabbits have died on part of that run from same cause, I believe, as on Tintinallogy ; rabbits were very thick there, and now there are hardly any. I cannot say if the disease in the rabbits is extending northward ; on Billilla, about 10 miles back from the Darling, rabbits seem healthy. Rabbits inoculated with this disease, have, to the best of my belief, been enlarged on different portions of Tintinallogy ; presumably from that, the extension of this disease is, I think, caused by infection. Since December, fat sheep have been sold off this run ; I forget exactly the number, I think about 13,000 ; these were all real good stores ; plenty of people would call them fat sheep. Fatality among sheep would not, I think, be caused by barking ; on the barked country back from this, on Terrawinia and Billilla, I saw no dead rabbits. I don't think they have migrated from Tintinallogy elsewhere.

To the Chairman : I cannot say if diseased rabbits have been carried from here to anywhere else.

To Mr. Tabart : I have never been on Weinterriga Run for twelve months ; Tintinallogy and Billilla are the only two places I have noticed the disease ; I have not been on any other for several months. To introduce this disease on a run where sheep were, I would not consider unsafe ; I would not have the slightest hesitation in introducing it on such a place.

To the Chairman : I never saw fat rabbits die with this disease ; all I have seen die are more or less wasted ; the young ones seemed to die very quick.

To Dr. Wilkinson : I should say, not long after they come out of the burrows.

To the Chairman : The rabbits that died in confinement were also equally emaciated ; I never saw any die in good condition. If a fat rabbit were inoculated, I hardly think it would die in good condition, they wasted away so quickly.

To Dr. Wilkinson : I have seen rabbits perfectly healthy and fat inoculated ; those rabbits always became rapidly thin and died ; I never saw any that withstood the inoculation ; I have seen four or five per day die in the crates ; scores of them altogether I have seen die so.

To Mr. Tabart : By placing rabbits in a certain particular hutch in the camp, which was considered infected, they always became infected and died. There were only two or three rabbits put in that hutch that did not take the disease. Previous to placing them in that hutch, they had not been inoculated in any way. They were caught and placed in the yards for four or five days to make sure they were healthy and unhurt before experiments were made on them.

To the Chairman : Some of these were tame rabbits ; by this I mean, rabbits that had been some time in hand ; the two white rabbits in the camp now, like all the others used, were caught wild on the run.

To Dr. Wilkinson : There were experiments made tending to show that, by a certain method of inoculation, rabbits could be protected from the disease ; they were given the disease in a very slight form by a certain method of inoculation, and, after that, they could not be made to take the disease by inoculation ; I do not know whether such rabbits were tried by being placed in the infected hutch.

To the Chairman : The confined rabbits never bred, I think ; some which were in young when caught had young ones in the hutches. The appearances I saw of the disease were, that they got watery about the eyes and nose ; the hair looked rough and set up, it did not fall off ; there was no scab, and no purging, though at first I saw a few here that had scabs on them ; when sick they neglected their food, whatever we gave them ; they had plenty of green feed as well as dry—cabbages and lucerne among other things. This neglect of food began about two days after inoculation ; the food at any rate, if they did eat it, did them no good.

To Mr. Tabart : The first two sheep inoculated were under observation for two months, and showed no sign of disease. The next lot were in while I was away ; they were a long time in "the bend," fenced in there with netting, where the rabbits were dying from disease, and were occasionally brought in and examined ; they showed no sign of disease ; they were afterwards turned on the run among the other sheep.

To Dr. Wilkinson : After inoculation, the inoculated rabbits were generally put in a hutch together, five or six being usually inoculated at a time ; I could not say if any rabbits were kept for a very long time in the experimental camp without being inoculated ; I think, however, that some were kept three or four weeks. We kept healthy rabbits in the yard a fortnight or more, at any rate ; I never noticed any of these healthy rabbits contract the disease spontaneously, without either being inoculated or being put in the infected hutch ; I remember, in fact, no single case of that kind.

To the Chairman : The rabbits used for the experiments were dug out of burrows on the run, or driven into V netting-yards ; they were taken where we thought they would be most healthy. They were then so thick that we could get twenty to thirty in a burrow ; they were shallow burrows mostly, running along close to the surface of the ground.

To Mr. Tabart : I find now, on the burrow country on Tintinallogy Run, that the burrows are silting up ; they show no signs of workings, and their condition demonstrates that no rabbits are there now ; I notice the same thing on parts of Billilla Run, where rabbits used to swarm in thousands.

ALBEMARLE STATION.

MONDAY, 28 MAY, 1888.

*Present:—**New South Wales:* W. C. WILKINSON, Esq., M.D., M.P.*New Zealand:* A. DILLON BELL, Esq.*Queensland:* JOSEPH BANCROFT, Esq., M.D. (Chairman).*Tasmania:* THOMAS A. TABART, Esq.

Nicholas Sadleir, general manager of Albemarle Station, examined:—

To the Chairman: I have been living in this neighbourhood for thirty years. I first occupied Billilla Station near here; I took that place up from the blacks in 1858. Rabbits first appeared here about four years ago, and kept increasing up to October, 1887; during this time they were regularly trapped and dogged; trapping still goes on, and we also use dogs, and poison. We pay the rabbiters 1d. per scalp. My instructions from the owner are to leave no stone unturned to destroy the rabbits. I think if we had not trapped so much we would have lost more feed; but as regards the number of rabbits we should have been in the same position now without any trapping at all as with all we have done. I think that for this reason—that if we had not trapped, rabbits would have increased more rapidly, and the present destructive conditions of disease would not have occurred. Of course I don't know whether it is disease or not, but something is killing the rabbits in a natural way. I would not favour leaving rabbits alone; we must destroy them to save our feed; I would not leave it to natural operations. My experience is that natural loss of rabbits never occurs until certain undesirable conditions occur on the run which it is our interest to avoid. There was no apparent decrease from trapping; wire-yarding, and traps round tanks did however, decrease them; the poisoning by strychnine was the most effective plan of all; it showed results; it cleared the rabbits off largely. No other means showed really important results.

To Dr. Wilkinson: I don't think trapping has tended to increase the rabbits. The trappers, I think, have worked faithfully enough; they don't breed rabbits, or deliberately increase them, I believe; but, of course, they will not catch young rabbits, unless you pay them well for it; you cannot blame them for that, I suppose.

To Mr. Tabart: I think trapping spreads and extends rabbits; that, I think, must be so, because it is only these last four years we have had rabbits here, whereas eighteen years ago there were rabbits on the Murray; they were as thick there then as they are here now. Rabbits did not seem to work up north at all till the last four or five years; when we heard of them 50 miles off here they were already here too; I attribute this quick spreading to the Murray people working so actively just at that time. The country came into the hands of new people from Victoria, who at once started to destroy the rabbits. Whatever disturbing influence you bring to bear on rabbits scatters them; trapping does this like other means, not pre-eminently so. I except the method of fumigation; that does not disturb, and, therefore, does not spread rabbits.

To Dr. Wilkinson: They warren here a good deal; a good number in the same warren some places; in others, few; it depends on the natural features of the country.

To Mr. Tabart: I see a great decrease lately in rabbits on Albemarle. I attribute this to want of proper food. The rabbits have died, but I don't think all that have disappeared have died; I do not see so many dead ones as would account for the great decrease; I know however that the holes are full of dead rabbits. I have heard rabbits have been dying in this district from disease, and I think those I have opened are not healthy; I think their stomachs and livers are diseased. I have lived on other rabbit country before this. I have heard of rabbits dying in Tasmania, at Ellenthorpe. I think they died there from bad food. The sheep on this run are all thoroughly healthy. I believe you can breed disease in sheep here as well as in rabbits, by putting them on the same country where the rabbits got unhealthy, and keeping them there. What I mean is this, if you keep sheep on certain food continuously they breed a fatal disease; I think under such circumstances they die from anthrax. They die like that from the description I have heard of anthrax. I don't consider phosphorus poisoning any good here, and I think therefore, that distributing-machines for such purposes are useless; I have used them, and followed regularly on their tracks, and that is my conclusion; We have more sheep on this run now than we had in 1887—only 3,000 or 4,000 more; the sheep are healthy, and the rabbits are dying; and I would not be able to infer from this that the sheep have starved the rabbits. I think the rabbits are dying because they are eating scrub. The past twelve months has been as good a season as we ever had on the Darling—an unusually heavy rainfall floods, in fact. Four and a half rabbits will eat as much as a sheep; this was ascertained by careful experiments made at Tintinalloy. Ever since rabbits became appreciable in number no stock have done really well.

To the Chairman: Rabbits breed in winter, from April in average seasons, and breed on till the grass gets dry, ordinarily till October or November, but in a drooping season they may breed all the summer. There was a heavy rainfall in December last year, and the rabbits started making nests, but I have no record of any young being found in them; many nests were dug out, without any young ones being found; actual nests—does' nests—I am talking of, not mere burrows. The instinct of bringing forth the young and preparing for them was manifested, yet no young seemed to come.

To Dr. Wilkinson: Lately, though I have seen no young ones, I have found does in young.

To Mr. Tabart: The external appearance of the affected rabbits is that they are emaciated and cannot run; when you see their internal organs, you can easily see that such rabbits could not run, the organs are so congested. I have experience in wire-netting, but have not made comparisons much. We use 3 feet 6 inch netting—sometimes it is 1½ and sometimes 1½ inch mesh; I think 1½ sufficient; young rabbits can get through it, but I do not think they do; I consider 1½ safe enough. My cultivation paddock, so fenced, kept all rabbits out; I am using now 42-inch netting, some 1½ and some 1½ inch mesh; I consider them about equally good; I have made no comparison as regards height, having never used or had any experience with 36-inch net. We intend netting the entire run by paddocks successively, lifting the

the netting from the cleared ground behind us, and advancing it further on. Subdivision is essential to dealing with rabbits by wire-netting; if ring-fenced only, such an area as this, 75,000 acres, could not be effectively dealt with—in fact it would be pure waste of money; the smaller the paddocks the better. If it were proved that what is destroying rabbits on Tintinallogy is an infectious disease, I would not fear introducing it here; we have it, in fact; I believe, however, it is produced by the food.

To the Chairman: A very similar disease to the present one—in fact, identical, so far as I can observe—has displayed itself on this station during the summer in previous years; but as those seasons were unusually good, and the feed abundant, it did not last long, and the rabbits seemed to get quite healthy again. I think the food being abundant keeps the disease away. At the present time, since the rain a fortnight ago, the rabbits are becoming more active and getting quite strong; they cannot be caught so easily now as before; before the rain the dogs could catch forty to fifty in a day, whereas now, by the time they have caught two, they are exhausted by the run.

ADELAIDE.

FRIDAY, 1 JUNE, 1888.

Present:—

New South Wales: W. C. WILKINSON, Esq., M.D., M.P.

New Zealand: A. DILLON BELL, Esq.

Queensland: JOSEPH BANCROFT, Esq., M.D. (Chairman).

Tasmania: THOMAS A. TABART, Esq.

Frederick Langloh Parker examined:—

To the Chairman: I have had experience at Darling (Block D) in 1878, when rabbits first appeared; since then on borders of South Australia and New South Wales; the station is called Buckalow, and contains 388,000 acres. I have seen rabbits dying in May, 1888, on Buckalow, for the first time; I was there in November, 1887, when the country was swarming with rabbits. In May I saw very few alive, but hundreds dead everywhere; those left were so reduced that they could be caught with the greatest ease. I never saw this before on the Darling, or anywhere, nor have I heard of it before. There were sheep on Buckalow. In 1881, when I bought, there were no rabbits there; I inspected it in June, 1881, and found no rabbits there; rabbits began to appear there in 1883, and constantly increased, in a regular wave, up to November, 1887. Buckalow is now comparatively clear; men could not make wages at 2s. 6d. a scalp, yet the Government threatens to summons us unless we put on men at once. The few remaining rabbits are weak—one out of five is fairly strong, four out of five are miserable weak crawling objects; I could discover no disease, but a wasting away; I know of no diseased rabbits having been brought there; I have heard reports that some have been brought on to neighbouring stations.

To Mr. Tabart: The feed is (where sheep have been running) very bad—very much reduced; but a few miles from water it is very good, the sheep mostly keeping near the water.

To the Chairman: Rabbits are more about the water than far out. I inspected the back part of the run, which was well supplied with food; there were rabbits there, but not so many as near water. The deaths are as numerous on good feed country as elsewhere. Rabbits are also caught in bushes sometimes, and so killed.

To Mr. Tabart: There is a good deal of bush on my country. Rabbits eat the bush a great deal—in fact, up to 9 feet high; sheep eat the same bushes, but do not bark them as rabbits do. The sheep are in fair store condition there; the only deaths are the usual ones of old sheep—the usual percentage only—and some deaths occur from the unusual distance they have to travel for water; I don't think it possible for sheep to starve rabbits; rabbits, on the contrary, will starve sheep.

To Mr. Bell: I noticed rabbits barking trees two years ago, and did not know what was doing it; it was not so extensive as now; I noticed no rabbits dying then. The shrubs being barked then were just the same as are being barked now.

To Mr. Tabart: I believe the cause of death is disease; the symptoms seem the same as Dr. Butcher describes about his diseased rabbits at Tintinallogy. Tintinallogy run is about 100 to 120 miles away from mine; my stock are not suffering from any disease. Knowing what I do of it, I would not hesitate, if this is a disease, to introduce it among my stock—not in the slightest degree, though I have valuable stud flocks there. I am satisfied that my country cannot be cleared by present known means without dividing into small paddocks with wire-netting.

To the Chairman: On the Darling (Block D Station) rabbits were not so thick as at Buckalow; there are some there now.

To Mr. Tabart: I had trappers on Buckalow. In November, 1887, they were killing 100 a day each, at 3d. a-piece; in 1883 I gave 2s. 6d., then 2s., and downwards to 6d., 3d., and 2d. per scalp. According to the boundary-riders on Buckalow, the rabbits there are beginning to breed again; for certain reasons, this statement may be received with caution, still, it may be correct. Rabbits do not breed in the dry season.

SECTION IV.

EVIDENCE concerning the mortality among Rabbits in the Wairarapa District (N.Z.), given by Mr. Coleman Phillips before Dr. Wilkinson and Mr. Dillon Bell, Members of the Commission.

GENERAL STATEMENT MADE BY MR. COLEMAN PHILLIPS.

IN 1883-4, finding that our poisoning operations with phosphorized grain were not successful in coping with the difficulty, I determined upon calling my neighbours together to devise some further measure of relief. The neighbouring runholders met and agreed to form a voluntary association for the district. We agreed upon simultaneous poisoning during the winter months, and subsequently upon turning out the natural enemy—chiefly the ferret. The runholders of the district sent me application for some 1,200 ferrets, but one runholder preferred to obtain some stoats and weasels. I think that gentleman obtained some 300 of these animals from England.

It was at my earnest wish that the turning out of these animals was assayed as a general experiment. Previously three of us had been breeding and turning out the ferret, and two or three of us the cat. We found that cats did good work, which they still continue.

Being empowered to proceed I began the purchase of all the ferrets obtainable, and distributed them as freely as I could amongst the runholders. I could not at first obtain many—not more than 100—but these were kept to breed from. Subsequently more were obtained. There may have been turned out up to 1887 some 600 ferrets, 300 stoats and weasels, and 300 cats. We had, of course, all been using dogs in hunting. I should think that some 400 dogs were used; perhaps more. The South Wairarapa district contains over a million acres.

In 1886 signs of disease appeared amongst the rabbits, but little notice was taken of it. Some were affected with bladder-worm, some with liver rot, and some were scabby. Early in 1886 I had noticed that my rabbit's dogs were looking mangy, and mere skeletons. I told the man that he should keep his dogs in better condition. His reply was "that the dogs were so badly infested with worms from constantly feeding upon raw rabbit that he could not keep them in better condition." My reply was that I had noticed a neighbour's pack of dogs looking in much better condition, and that I would inquire into the reason. Upon inquiry I learnt that these dogs were given areca-nut to expel the worms. I consequently insisted upon my dogs getting this medicine also. To this accident I attribute the great subsequent spread of the disease around and upon my run.

In 1887 the combined operations of simultaneous and proper poisoning operations, the turning out of the cat, ferret, stoat, and weasel, and the spread of disease, produced a remarkable effect upon the pest. The rabbits disappeared like magic. We could scarcely credit the great fact that the pest had been conquered. In three years our operations had succeeded; and as I write now, towards the latter end of 1888, the fact remains that the South Wairarapa district is the first large district in the Australasian colonies which has succeeded in conquering the pest.

It may be said from the above facts that the natural enemy did the work and not the disease. There is a great conflict of opinion among the runholders themselves in the district about this. Some think that the simultaneous and proper poisoning operations did the work. Others that the ferrets did it. Others that there was some other cause, *perhaps* the disease. Few joined with me in thinking that the disease was the *summum bonum*, combined with the natural enemy and the poisoning operations; that one depends upon the other, but all require to be used.

I pointed out that under disjointed poisoning operations poisoning was of no avail whatever. Year after year we had been poisoning and I had personally sent home about a quarter of a million skins. One of my neighbours had sent almost that number from his run in one year. And it will be seen from the last report (1888) of the Chief Rabbit Inspector for New Zealand, that from the South Island of the colony some twelve million skins were sent away last year as the result of poisoning operations, *and that the rabbits were still as bad as ever*. At the present time we do not send away a single bale of skins from South Wairarapa. Surely, then, it cannot be said that poison is effectual.

As to the natural enemy. Many of the rabbiters say that the ferret does little good. They are delicate and die off quickly in bad years. They are not an animal strictly of the *fera natura* (wild nature), like the stoat and weasel. Nor do they kill for the mere sake of killing. I know for a fact that ferrets and rabbits often occupied the same warren when the pest was at its height. In my opinion the ferret eats a certain number of the young ones, but its chief duty is to kill by its intestinal worms, which infect the grass and so kill off. The great use of the ferret is that it is an admirable distributor of worms. That it sometimes dies off rapidly is its highest recommendation to us in Australia. For it is of no use to us in large numbers, when it *has* cleared away the pest in any district. I would rather be constantly turning out a few ferrets upon say 20,000 acres of land, than have to be sweeping off a swarm of ferrets. Not that it would be at all difficult to clear that 20,000 acres of ferrets. That could be done by trapping in about a month with one man. But then there would be the danger to the neighbouring lands. I have no wish to infest the lands of Australia with a worse animal pest than the rabbit.

I scarcely like entering upon the scientific side of this question. My opinion is that we shall get little help from the men of science. I say this with all respect, but I think I have good reason for saying so. Professor Thomas, one of the most able biologists in the colonies, I believe, visited the Wairarapa and failed completely to see the beauty of nature's working—this conquest of a pest by means of a worm. His visit occupied ten days, and his reports contain scarcely a word touching the excreta of the ferret or cat. Sir James Hector, on the contrary ascribes to this disease its full credit. That gentleman very properly instances the fact that the great North American Continent is kept free from a rabbit pest by means of this very disease. M. Pasteur takes no notice of the disease, but wishes to use chicken-cholera
The

The question arises, then, as to whether there is not a higher law than the minute investigations of scientists, which may result one way and may result another; whether the disease that swept off the rabbits upon Tintinallong run, the rabbits in South Wairarapa, the cats near the Darling River, the rabbits in Green Island in Otago, and in one district in Tasmania, may not be one and the same; whether the Commission itself has been right, I make bold to say, in taking the course it has done in its investigations; whether it should not have taken a wider view.

And what is that view? The honorable members of the Commission must pardon me if I speak confidently, perhaps too much so. My excuse is that I occupy the curious position of having passed through and conquered the pest, and that I can now look back and think in the widest sense of the forces which have been at work. Let me suggest the widest view from a map of the earth. Let me point to the great continents of North and South America, Europe, Asia, and Africa. Is there any rabbit pest in any of those places? We hear of none excepting in North America. There at the present moment, the rabbit is crossing the frozen Snake river into Oregon in millions. But what does Sir James Hector say? That every few years these rabbits are swept off by this very disease which I am now attempting to describe.

Again in A.D. 1 the inhabitants of the Balearic Isles in the Mediterranean petitioned the Emperor Augustus for relief against a plague of rabbits, and the emperor sent two legions of the army to repress it. Some persons had doubtless introduced a few rabbits into these insular places, and there was no natural enemy to check their increase.

Again in the 15th century after Prince Henry of Portugal had discovered the islands lying off the western African coast, and sent colonists there, and sheep and goats, and doubtless rabbits, the inhabitants complained of a plague of rabbits. Here, again, an insular speck of land cut off from the inroad of the natural enemy.

So in New Zealand and Tasmania and Australia. We introduce the rabbit, but how have we introduced the natural enemy? Scarcely at all. Practically only in the South Wairarapa district of the North Island, at my earnest suggestion, and what has been the result? The rabbit has disappeared there. It really matters not very much whether the natural enemy actually eat up the rabbits or whether their excreta diseased them. I say, from what I saw, that the latter is the highest good. The fact remains that the rabbits disappeared which they did not do under the poisoning operations.

Has, then, this honorable Commission been right in the narrow course of view it has hitherto adopted, in this total neglect of historical precedent?

I may not be justified in thus venturing to criticise the work of the Commission. But I cannot help pointing out the value of historical precedent in such a question as this. The Balearic Isles, the Islands off the coast of Western Africa; Tasmania, New Zealand and Australia, were and are insular lands separated from the main continents. Rabbits were liberated in those islands and they soon multiplied and became a pest. They would not have become a pest had the natural enemy been liberated with them. On the great continents history is silent as regards any pest, save that Sir James Hector states that from his experience in North America, the jack rabbit does assume the pest form there. (A great distinction exists between the rabbit as a mere animal, and the rabbit as a pest. It is the pest form only with which I am now dealing.) But what follows? Owing to the existence of the wolf, fox, wild cat, prairie dog, other dogs, ferrets, stoats, weasels &c., &c., in North America, the pest is every few years swept away, and the land is strewn with millions of the dead rabbits. So virulent appears the bladder-fluke or worm-disease there, when it does break out, that few rabbits are left alive. Sir James Hector says indeed that his party were almost starving in consequence of their having relied upon catching rabbits for food. I fancy that the rabbits were only reduced to the "minimum of safety." Nature does not entirely exterminate. As a mere animal, the rabbit is useful to man. Sufficient rabbits will escape any disease and breed up afresh.

The question follows, how is the pest cleared off—how comes the land to be strewn with the bodies of the dead? In my opinion the answer is simple. It is a mere repetition of the history of the fluke in sheep. The land becomes thoroughly infected with the eggs of the bladder-worm. For as the rabbit increases in numbers, so do the natural enemies increase theirs, and congregate, and by their excreta thoroughly infect the land. Then some favourable season comes, like the seasons favourable to sheep fluke, and the rabbits die by the million. In England, quite of late years, the sheep have died off by millions. To understand the bladder-worm the Commission should also understand the history of the sheep fluke.

One corollary and one only follows: That the natural enemy *slays by its excreta, and not by directly killing its prey.* I regard the economic arrangement as beautiful in the extreme. Furred and hairy animals are of use to man; therefore they are here. But the majority of these very animals are the living machines which distribute the worm that sweeps off others of them. I would therefore advise station-owners in Australia at once to recognize this great principle. To give their sheep and cattle dogs, where there are no packs of rabbit dogs, raw rabbit to eat, and nothing but raw rabbit. Soon the dogs will become full of worms from constantly living upon this one food. Then, when they get thin and mangy looking, let two monthly doses of areca-nut be given them. This will cause large portions of the worm to be excreted, and the dogs will become sleek again. Their ordinary work will not at all be interfered with, but in all the damp spots of the continent, where these dogs visit, there will the segments of the tape worm be deposited, and millions of eggs will quickly infest the grass. I would rather that small packs of rabbit dogs were used by station holders for this purpose, than their sheep dogs interfered with. But it is essential to spread the worm as quickly as possible.

Areca-nut is a cheap medicine, a shilling's worth goes a long way. We use it in my district, use it as follows:—Take as much as will lie on the point of a sheath knife to half an inch back, mix this up with some butter, spread the butter over some small pieces of mutton and give these to the dogs. Unfasten the dogs next day and take them immediately to any damp lands. Hold them there for a little while and then examine their excreta. Fine long thin segments of the worm will be found wrapped round and round the lumps. Each of these segments, and there may be 50 to 100 in each long thin piece, contains a male and female organ, which stocks the segment with from 1,000 to 2,000 eggs. Each segment separates itself and possesses the independent power of wriggling into the grass, there dying (much after the manner of the female spider and its eggs), the eggs becoming liberated and washed all about by the rain. The rabbit comes along, eats the grass, and the eggs find their proper host, and form the bladders. But the dogs must be allowed to become thin before the areca-nut is administered, for if it is expelled too quickly, the segments of
the

the worm are immature and not properly stocked with eggs. The dogs should be fed upon raw rabbit for a year at least, until they do get thin and mangy looking. The bladder upon the rabbit which I gave Sir James Hector, and which is now at Rodd Island, has increased very much since I caught it, but it does not appear to be in so vital a part as others we have caught, or that rabbit must have died. The disease is often most hideous. I have seen the bladder come between the hind legs, and not a sign of the genital organs left. That rabbit naturally soon died. I have again seen it internal, upon the ribs or diaphragm, pressing the heart, liver, and lungs out of all shape. That rabbit soon died. The bladder appears to come anywhere, but wherever it appears there it grows into a hideous sore. I should think that the rabbit upon Rodd Island would soon begin to dwindle away and die. For that bladder, even upon a safe part of the body, where none of the internal organs are affected, as it is, must naturally sap the vitality of the animal. When the rabbit disappeared, my men noticed many dead animals upon the run, which were not killed by poison, gun, or dogs. They were usually mere skeletons, and many rabbits were caught mere skeletons, not having the strength to get away from the dogs. I will of course send over some more of my rabbits, but I have so few left, and it is so difficult to get specimens of the disease, when a run is clear and the minimum of safety reached, that your honorable Commission must not expect good results from me. It would be better to ask the New Zealand Government to forward some for experiment from one of the newly-diseased runs on the South Island.

I mean by this, from some of the runs in the South Island where the disease is beginning to show itself. For I have been distributing my diseased rabbits and dogs about, and people are beginning to adopt the measures I have been urging them for nearly two years to adopt. Ferrets, stoats, and weasels, are to be turned out, and the dogs will get doses of arca-nut. I indeed began confining fluked rabbits for my own experiment about a year ago; but so many persons asked me for specimens, that I gave them away. Now, all that I can do is to catch what rabbits I can off the known fluked portions of the run and send them over, bladder or no bladder. These should be killed. Small bladders, the beginning of the disease, will be found in perhaps half of them. But it takes some months to develop, and death of course will depend on the locality of the bladder. We know the fluked spots of the run, which always appear fluked.

And I desire to say that I have never claimed that this disease will effect a hasty sweeping off, or sudden extermination of the pest. It appears rather to be slow, but effectual. It may only be intermittent, as Sir James Hector says, but it appears certain in its work. The way to properly test it would be this. To let me take a million acres of the worst infested land in the settled districts of Australia. Let me there adopt exactly the same measures as I adopted in my own district, and in three or four years the result would be certain.

The landowners would, I suppose, carry out, as well as they could, the regulations I would suggest which would not be one-fifth as expensive to them as their present system of poisoning. To let me have also a million acres of the worst infested Crown lands, and the Government to carry out the measures there that I would suggest.

As to poison. Poison is quite ineffectual. It is an annual waste of money.

As to rabbit-netting. I cannot help saying that rabbit-netting is a most expensive remedy in any shape or form. I once thought that New South Wales might be netted in with advantage, because I was unaware of the fact that the rabbits had crossed the borders. But now they are across the borders, rabbit-netting can be abandoned as a mere waste of money in Australia. The province of Canterbury in New Zealand is trying to net itself in. It will not succeed; but it has already spent some £60,000 towards the fence. The 30,000 ferrets which the Government have advertised for and will turn out shortly there at a cost of about £15,000, will be of more effectual good than a dozen such fences. (This advertisement upon the part of the New Zealand Government is an entire concession to my plan and process of reasoning and an admission that past measures have been futile.)

Not that the ferret is the proper animal for the Government to turn out in New Zealand, but it will still do the good I say. The ferret is too delicate for the snowy lands of the South Island and dies off too quickly. The stoat, the weasel, and the polecat are the proper animals to get for snowy lands. In Australia I should think the ferret would answer, but stoats and weasels may have to be tried. Nature especially changes the ferret into the stoat so that it may follow the rabbit even to the poles. The jack rabbit is found far north in Behring's Straits.

But this offer to clear a given tract of country in a certain time brings me to this important feature that certain principles of action must be accepted and adopted. I will briefly refer to what I deem these principles to be:—

1. The recognition of the fact that settled districts must be treated differently to unsettled Crown districts.
2. That the rabbit has two forms. (1.) The animal form useful to man. (2.) The pest form.
3. The recognition of the minimum of safety maxim above referred to. That is, that the rabbit cannot be totally exterminated.
4. In settled districts the recognition of the principle of voluntary suppression—to let the district suffer until the settlers take measures for their own relief.
5. The principle of voluntary combination amongst settlers.
6. Rigid inspection either by Government or local officials.
7. Trapping to be made a penal offence.
8. The inutility of rabbit-netting. Nature did not use rabbit-netting to keep down the rabbit pest upon the great continents. It ought perhaps to have done so, but it preferred otherwise.

I should like also to have permission to send over a box of half-a-dozen ferrets immediately, and for the Commission to turn out those animals in the worst infested land and note the result. I remember the Hon. G. M. Waterhouse turning out half-a-dozen ferrets, in my district so far back as 1877-8 and it was surprising how the little animals increased and multiplied.

I think also that a certain number of bladder-wormed rabbits should be got over from New Zealand and fed to the dogs, say at 50 miles distances, in badly infested places, so as to start the disease fairly, in case it does not break out by itself. When once started it will always remain. Rose, writing in 1837, states that the Norfolk warreners in England prick the bladders, expel the seed eggs, and then send the rabbits to market. This shows that the disease has been constant in England for centuries, and proves another thing: that it is not at all harmful to man, else we should have heard of many cases of hydrophobia in England.

England from eating these rabbits. In Australia, owing to the constant eating of mutton many cases of hydatids have occurred and are still in the hospitals. I think it will be better for people not to eat fluked rabbits, but the disease has not been found harmful in England.

In saying that I should like to adopt my plan of suppression upon two separate million acres of land, it is because I have more faith in my proved past measures of relief, than in observations to be taken at Rodd Island. Of course, I wish the course of the disease to be thoroughly investigated at Rodd Island. The scientific gentlemen in charge there may indeed be enabled to suggest a more virulent form of action for the disease and a quicker method of propagation. Professor Thomas told me he thought he might effect that, but that scientist is so much engaged in other duties that he could only give about ten days, as I have stated above, to investigate this important matter. This was not sufficient, and proper observations can therefore be taken at Rodd Island, if it is possible, to obtain the same conditions there as upon a wider area. Wolves, foxes, dogs, cats, ferrets, stoats and weasels are living machines for spreading the disease naturally over a wide area like M. Pasteur wishes to spread disease artificially. Then animals go where man rarely, if ever, goes.

And I would say this, also, with all respect—that I have never believed in M. Pasteur's remedy, as it is opposed to historical precedent. Nature has not kept the great continents free from rabbit pests by chicken-cholera, but by the natural enemy spreading this very bladder-worm I speak about. Chicken-cholera must fail, like the poison remedy, in *ineffectuality*. It will be found useful, but not effectual. But the natural enemy is effectual at once and for ever, for it will place Australia in the same condition as the great continents. It will be found that many rabbits will become proof against chicken-cholera, as I found many rabbits proof against poisoned grain, and the pest will then always be springing up again. Nor is there any *nidus* in the Australasian colonies yet for the proper spread of such diseases as cholera, pleuro-pneumonia, and the like. These diseases start but they soon die out. They will not die out so quickly a century or two hence. Chicken-cholera can however be tried as a process of rabbit extermination, but it must be regarded as an entirely new remedy and therefore a dangerous one. I don't think that it will prove effectual, but I am not opposed to its being tried. Let the experiment be tried, just as M. Pasteur directs, upon a large scale, at a distance from or side by side with my own plan. I have no fear as to the ultimate triumph of the natural enemy. Yet, I would rather that M. Pasteur was compensated for his work, and the experiment not tried, as I am convinced that it will end in failure. Australia must be placed under the same conditions as the other lands of the earth, and one of these conditions is not chicken-cholera for rabbit pest suppression.

In the Wairarapa district and in other parts of New Zealand we have had what we thought were visitations of chicken-cholera amongst the fowls. The hen-roosts were devastated. But *all* the animals were not killed in any one particular fowl-house. Some old rooster or hen would resist and laugh at the disease. So will the rabbit. But the animals I mention are nature's machines for always laying fresh supplies of worm disease in places where man does not go. In Central Australia and in south western New Zealand there are, I believe, 250 different kinds of tape-worms fatal to various animals, *ex. gra.*:—The lung worm in our hoggets, trichinosis in pigs.

With respect to the disease being made more virulent—I would ask the Commission to abandon this idea of virulence, and to oppose the general wish that a hasty clearance is advisable—poison is a hasty form of clearance but it is not effectual. I rather like the slow way; the bladder-worm has worked with me. Of course, it is only natural that people wish a hasty clearance, but the more haste in this matter the less speed.

Let no man give up his run in consequence of this rabbit pest, as men did in New Zealand. Let him only be careful what remedies he applies. It is the application of the remedy which saves or ruins him. The grass is not ruined, although eaten almost out of sight. It comes again, when the pest has been conquered, better than ever. One of the most pleasant sights I know is the grass waving upon plain and hill-side after the pest has passed away.

And I would digress for a moment to consider the difference of climate and population conditions here, and to point out that the excess of population often leads to rabbit pests. There is more danger now of rabbit pests upon the great continents than there was when population was scarce. This results from the natural enemy, especially wolves, foxes, &c., being cleared off, and the rabbit left to increase and multiply unchecked, except by men going out hunting. Per contra, Australia has an extremely scattered population; but there no natural enemy has yet been introduced. I say this now owing to the observation often made to me that Australia is different from the great continents.

I think upon the 1,000,000 acres of badly-infested Crown lands allotted to me for clearance—if it should be—I should like to try stoats and weasels, and watch the results there. But generally for Australia I think the ferret and the bladder-worm disease sufficient. I have no wish for more virulence than what I have seen; but if it is wanted, the meer-kat and ard-wolf can be introduced. These animals partake of the fox and wolf tribe. But, as a man whose living depends upon sheep, I should prefer not to introduce these animals; to use nothing, indeed, but the ferret, which does no harm to anything but rabbits, rats, and mice, and can most easily be trapped off if so desired. Fowl-roosts suffer, perhaps, from an occasional visit; but settlers would have to be warned to protect their fowl-houses. I made my fowls roost all about upon different trees, and, strange to say, I have never had any fowls killed. As to the mongoose, I have my doubts about that animal, too.

Ferrets do not eat babies or lambs, or diminish the production of eggs. These are some of the cries that will be raised against them.

A list of measures of relief would have to be drafted for the voluntary guidance of settlers; but this list should not be allowed to be pleaded against the penal clauses of the Rabbit Acts. I think I can furnish such a list. But I must say that I have never yet met with a rabbit inspector in New Zealand competent to express a proper opinion. Such officer's duty is best confined to the mere fact of whether there are or not rabbits upon any particular place.

As to droughts—droughts will be found most useful in diminishing the number of rabbits; but droughts will not exterminate the pest. In New Zealand, in summer time, I always found that the rabbits left the hills and came down to the wet and damp places. It is, therefore, fortunate that it is these very damp places which first become infected with bladder-worm, and the rabbits then carry the disease back to the dry lands when rain comes.

Care must be taken to check the preservation of rabbits in Australia. The thing should be nipped in the bud. In New Zealand (in the Kaikouras) one settler is preserving and tinning the rabbits which he traps, and consequently traps off the ground vermin his neighbours turn out. The settler employs some 200 men in the work; and democratic members of Parliament point to this and say that it is better than sheep-breeding, where no men are employed. Of course, this one preserving staff benefits, and all the neighbourhood suffers.

I wish, of course, that all my statements should be rigidly investigated, and those rejected which cannot be fairly supported. Some are certain to be wrong. No scientific man even can tell us the proper remedies to pursue. How much more can I? My evidence may perhaps be of use in lifting the question out of the grooves of science. This honorable Commission will cull the best measures to adopt from all plans. Yet should it not hastily dismiss mine as being local to my district; for I claim that it is world-wide, and that Australia must inexorably be brought within its action.

I should be glad to know how the foxes have progressed which were turned out a few years ago in Victoria. I believe great pains must be taken in following these animals up and watching the effect of their excreta upon the rabbit.

There may be some native animals in Australia fitted to spread the bladder-worm about. This point will also require investigation.

I would, of course, recommend every runholder in Australia troubled with rabbits not to wait for Government action, but each to buy and breed a few ferrets and let them loose; to go on poisoning just the same, and to keep a book of the number of skins daily gathered and rabbits killed. The Governments of South Australia, Queensland, Victoria, and New South Wales to each start a breeding establishment and turn out what ferrets they can. (I can easily send over some of my old hands or neighbours' hands thoroughly used to ferret-breeding. It will be necessary to get men used to the work, and then the breeding is quite easy). But I should like to take a run through the badly infested country first, and then suggest where these animals should be liberated upon the Crown lands. I should like them liberated near water; for the ferret is a thirsty creature. It must get blood or water. I shall be happy to describe my ferret-breeding house if the Commission wishes to know of it. I will also send over copies of the proceedings of our voluntary association in 1883-4-5 for attachment to this evidence.

I regret that the full Commission does not happen to be sitting, so that I might be fully cross-examined. A full cross-examination would bring out many matters that I may now overlook.

The question of sheep-fluke should also be investigated. Sheep grow strong and fat under the fluke, and they are then sent to the market. But if they once begin to fall away there is no saving them. It is, or was, a penal offence in England to fatten sheep for the market by fluking them. The course of the bladder-fluke disease appears much the same to my mind as that of the sheep-fluke disease.

Settlers will find that ferrets will vastly reduce the plague of rats and mice in Australia.

No difficulty will be experienced by keeping small rabbit-packs of dogs. It will be best to let the men own their own dogs; but swapping or changing dogs should on no account be allowed amongst them. I do not like using the sheep dogs as worm distributors. They would do it, of course; but then they have their own work to do, and shepherds don't like their dogs interfered with.

There appears to be fair reason for thinking that the bladder-worm disease which sweeps off the rabbits periodically in North America is a more virulent form of the disease than I had at Dry River. It may be the tape-worm of the wolf or wild cat. Inquiry should at once be made from the United States and Canadian Governments concerning this.

Sir James Hector did not think, when I called his attention to the disease, that the tame dog or cat could distribute it; that the wild dog or cat, wolf or fox, would be required. I could only point to the state of my run for proof that the tame dog and cat could distribute it.

A curious thing happened directly I called public attention to the disease, and the matter became known. Many settlers who had been badly afflicted with the pest declared that they knew of the disease long before I did; that it was upon their runs, and they had thought little of it. Chiefly that such rabbits had been wounded only by gun shot; hence the bladders. But as to its clearing off the rabbits, that was absurd. I always notice that those people who said this had *got through their rabbit difficulty* and had reached the *safety* stage. The poison, the ferret, and the disease had worked the cure unknown to the very people whose lands had been cleared. I instance the case of the Taratahi in the Wairarapa—well known to my neighbours.

In sending over what diseased rabbits I can, I would rather that the Commission requested the Government of New Zealand to forward them on by steamer from Wellington, as I reside some 60 miles from Wellington, and wild rabbits require to be properly looked after *in transitu*.

Whether a confined experiment with the disease will work out well I cannot say. Fluke and bladder-worm require to pass through two or three stages, and one of these stages may be wanting in confinement. But it may not be. The Commission would confer a vast public good by allowing me to try the experiment I wish to try upon these two separate blocks of country; any one else can try it that the Commission wishes, but I doubt whether they will have my experience.

With regard to the present state of large estates in England and Scotland it appears to be somewhat as follows:—Rabbits, polecats, stoats, weasels exist side by side upon the same estate, and have so existed for a thousand years past. Trap off the ground vermin, as it is called, and the rabbits soon increase in numbers. A natural balance of prey upon prey appears to be attained in England and the rabbit does not assume the pest form except where there is no ground vermin. As to stoats and weasels, farmers like to see one or two about their barns, as they keep the rats away from their stacks. Other people immediately they see them kill them off as vicious. Ferrets do not exist widely in number at all. Weasels are vicious. I am not disposed to introduce weasels if it can be avoided. But the stoat might be introduced. I would prefer to work first with the ferret and then the stoat.

I should like to see the evidence that has been printed, as it will prove useful to me. This evidence upon my part is written in Sydney, and I have not been able consequently to refer to my own papers.

I have little wish to be regarded as an enthusiast. I feel certain that the remedy I now propose will eventually be adapted. It will clear any piece of country just as it cleared my district. Practically the North Island of New Zealand is now free from a rabbit pest.

The

The question is of vast importance for Australia. The Commission has barely begun its labours. The experiments with M. Pasteur's remedy has, I am afraid, been only waste of time, but it is nothing but right that these experiments should have been made. I should like to visit Tintinallong run and inquire into Messrs. Butcher and Ellis' disease and see wherein it differed from mine. At present I can but regard it as a mere local outbreak of disease which died out in consequence of the natural enemy not being there to carry it on and propagate it.

To my mind there is little doubt that a wide and statesmanlike view of this rabbit question will have to be taken, and Australia placed under the same conditions as the four great continents. Had Australia been joined on to Asia by as narrow a strip of land as joins Africa there would never have been a rabbit pest here. That narrow strip of land would allow the passage of the rabbit and the natural enemy, and long since nature would have worked out its own cure.

I cannot refrain from stating here that little reliance can be placed upon the views of local rabbit inspectors. These gentlemen necessarily take a narrow view of the question. They are useful for rigid observation purposes only. The question is far wider than their ken. I well remember how my efforts were sneered at in 1884-5-6 by foolish inspectors. But it is pleasant to be able to say now that I cleared my district in spite of them, and kept good friends with them, too. The New Zealand Government is now going to follow my plans in the South Island; five years have, however, been thrown away there. I would recommend this honorable Commission to read the last report (1888) of the Chief Rabbit Inspector for New Zealand. A more lamentable display of inefficiency I think upon the part of nine-tenths of the rabbit inspectors cannot well be imagined. But we purpose altering all this, and in five years from this there will be no pest of rabbits in the South Island of New Zealand. I am sorry to say what I do say with regard to these gentlemen, but it will be well for Australia not to make the mistake, which we fell into in New Zealand, of relying upon their judgment. At the present moment, as I write, they are allowing the use of traps all over the Colony, which alone is a sufficient excuse for my speaking so strongly as I do.

Sydney, October.

COLEMAN PHILLIPS.

ADDENDUM to the evidence of Mr. Coleman Phillips.

Before leaving Sydney I wish to append to this evidence one or two points that I have overlooked:—

Firstly,—I wish to emphasize my opinion that it is very desirable for the Australasian Governments to continue the scientific investigations at Rodd Island. The rabbit pest is only in its infancy as yet in Australia. We, who have had ten years' experience of it in New Zealand, alone can tell what it means, and of its danger. I personally never took the proper and minute observations I should have taken with regard to many things I wished information about. Had I done so I should simply have had to neglect all my other work, and I could not do that. The New Zealand Government too never made those observations either, and that colony has suffered to the extent of hundreds of thousands of pounds annually in consequence of that neglect. I may perhaps be allowed to give a couple of instances of loss. Upon a neighbour's run of 20,000 acres in the North Island, which now carries nearly 20,000 sheep, during the years of the height of the rabbit pest not 5,000 were carried. In the South Island (Lake Wanaka, I believe) the steamer used to take down about 5,000 bales of wool annually from that one district before the rabbits appeared, six or seven years ago. Last year the steamer took down 300 bales; this means a loss of at least £60,000 annually to that one little district.

The observations made by Professor Thomas were altogether too hasty and incomplete. An establishment of some kind is, therefore, absolutely necessary to make, and to continue to make, for years to come, these observations and experiments which any private individual can hardly be expected to go through, without sacrificing all his other work. No matter what the cost may be, I strongly urge upon the Australian Governments the absolute necessity of keeping up such an establishment, sharing in the expense, and, for the sake of the landowners, trying every experiment which may be deemed feasible and worthy of trying. If, for no other thing, the Rodd Island experiments may have saved the Colony from the wrongful application of M. Pasteur's remedies.

I have omitted, also, to mention hawks as a natural enemy to the rabbit. In the Wairarapa, the hawks increased very fast as the rabbit increased, and they killed off large numbers of young and weak rabbits. One of my neighbours indeed thinks the hawks almost cleared her run. They certainly did a fair amount of good, and no harm, that I could see, to the stock. We had an idea, too, that those birds carried the bladder-worm about. Birds of the captive order may, perhaps, do so: eagles and the like. I should recommend landowners troubled with rabbits to get a few hawks. They will soon increase, and when the pest is conquered they can easily be cleared off from the settled districts. In Central Australia they will, with the ferret, be always doing a certain amount of good.

As to clearing them off. I have caught as many as four hawks within an hour, by tying a piece of meat to the fall of an ordinary gin trap, and placing the trap upon the top of a post near my house; fastening the trap with a piece of chain to the post.

I should therefore like the excreta of all Australian birds or animals feeding upon the rabbit examined, in order to see whether the bladder-worm and the diseases which we found incident thereto (liver rot, &c.) may not be propagated by this means also. It may be that the ferret and hawk does good only by eating off the young rabbit, and that it takes the dog and cat (to which can certainly be added the fox in Australia) to propagate the disease. We certainly always called the eggs in the bladders dog worm eggs. The hawk may consequently not carry the worm. Sir James Hector told me that only the wolf, the lynx, the fox, and the wild dog could distribute the worm. I think I convinced him and Professor Thomas that the tame dog also carried the disease. Other things may therefore also carry it. I think the cat does, and eagles may. That is why I should have liked to have known more concerning the reason so many cats died lately in one district of Victoria or New South Wales. Carrying the worm about may prove too exhausting for the cat; but that doesn't matter, providing a certain amount of good is effected.

The pity really is that we did not more closely investigate the disease in New Zealand; but, as I have said, the pest was actually conquered in my district before I called attention to the matter. In giving this evidence, therefore, I can only state the broad features of clearance which I wish applied to Australia. I cannot say for certain whether the ferret, stoat, weasel, cat, or hawk carried the disease or not; but I know for certain that the dog did. And if the dog did the good with us, surely it will do the

same

OF RABBITS IN AUSTRALASIA—MORTALITY AMONG RABBITS, WAIRARAPA (N.Z.) 121

same good in Australia. Poison swept off swarms of old rabbits. Ferrets, stoats, weasels, cats, and hawks swept off swarms of young rabbits, and then the disease attacked what rabbits remained behind. That we all know now. Thus was the rabbit pest conquered in South Wairarapa.

I hope I shall be accorded permission to clear the piece of land I ask leave to clear in Australia. I can assure the honorable Commission of this: That my remedies did no harm to stock in New Zealand, and they will do no harm in Australia. They are simply nature's remedy—(excepting the poisoning)—slow in action, but effectual in the end. And should they be applied in Australia, as I think they must be—should they do the good that I say they will do—and should it be found that all my statements are not scientifically correct, still I shall rest content with having been able to do some little good in directing the minds of my fellow landowners towards the proper method of cure. One can but do but little good to one's fellows in this life. Each of us can but do his best.

COLEMAN PHILLIPS.

MONDAY, 29 OCTOBER, 1888.

Present:—

New South Wales: WILLIAM CAMAC WILKINSON, Esq., M.D., M.P.

New Zealand: ALFRED DILLON BELL, Esq.

Coleman Phillips called in and examined:—

1. *The Chairman.*] Did you make any observations to prove the existence of bladder-fluke in large numbers of the rabbits that died during the epidemic? We made many and constant experiments.
2. What did you find? That three out of five of the rabbits were infested with bladder-fluke; but only in certain parts of the run.
3. Have you any idea how many observations were made—did you examine thousands of rabbits? There were not thousands of rabbits to examine.
4. Then you only began to examine rabbits when they were being all cleared off? When they disappeared we began to examine into the causes of disappearance.
5. And can you say about how many you examined? I should say 100. I gave away more than 100.
6. And you found 60 per cent. of these diseased? It was only diseased rabbits that were brought into me for examination.
7. And what were the evidences of disease? Sometimes none; not the slightest evidence of disease until the rabbit was killed. The rabbits were brought in from a portion of the run which we knew was thoroughly "fluked," and we expected to find the disease there.
8. You examined about 100 rabbits? Yes; or perhaps more; and in 60 per cent. of these we found bladder-fluke. Sixty per cent. of all rabbits caught on my run are now suffering from bladder-fluke; but of course we do not catch many.
9. Have they shown any tendency to increase again? They would if they were not watched. If we did not turn out ferrets occasionally there is no doubt the rabbits would get up again. The ferrets die off and go to other places, or are trapped in the neighbouring districts; so that we have to turn out others in their place.
10. You do not know what sort of tape-worm is in the dog and in the rabbit? Yes. Professor Thomas told me the precise name, but I forget it now. I should know the name if you mentioned it.
11. Is it the *canurus*? Yes; that is the name.
12. You are of opinion that ferrets, cats, stoats, and dogs, are the means of this particular tape-worm which produce bladder-fluke in rabbits? Yes.
13. Well, Professor Thomas' experiments show that the dog is certainly the host of this worm, but have you any evidence to show that the cat or the ferret may also be the host of this particular tape-worm? Yes; the cats upon the run are almost skeletons, and the ferrets, too. A great many of them get like dogs that are fed on raw rabbit. They are mangy, weak skeletons; and I believe also these animals are full of worms.
14. But have you ever proved it? Well, no; I have not proved it. I think that ferrets and cats should be got and examined at Rodd Island.
15. *Mr. Bell.*] The scheme that you have brought forward rests principally upon the distribution of the germs of a particular tape-worm (which in one stage is bladder-fluke in rabbits) by the natural enemy—that is to say, by ferrets, stoats, weasels, cats, as well as dogs? Yes.
16. Then you are aware the truth of that statement must necessarily rest upon the question whether these particular natural enemies harbour the parasite which in one of its stages is bladder-worm in rabbits? Yes.
17. Then upon what does your belief rest that these natural enemies act as hosts of this parasite at all? Well, that we have seen the worms exist in dogs. And because it exists in the dog I am enabled to assume that it also exists in the ferret, stoat, weasel, and cat.
18. Yes; we admit it exists in dogs—Professor Thomas' experiments prove that. But Professor Thomas' experiments, so far as they go, negative the presumption that the other animals named harbour the parasite at all. Do you disagree with that? I think dogs are sufficient to spread the disease themselves. If you use sufficient dogs you can spread the disease. I really have very little faith in Professor Thomas' experiments, so far.
19. *Dr. Wilkinson.*] But he has proved what you maintain? But he has not proved what I wish.
20. *Mr. Bell.*] Your scheme involves—to use your own language—a very large dependence on the spreading of this bladder-fluke, not by dogs, but by other animals? Yes; by ferrets. And I believe that the ferret is full of worms at times.
21. *Dr. Wilkinson.*] Did you always believe that? Yes; since I commenced reading on the subject.
22. It is a wonder, then, that you did not look for yourself? I certainly ought to have killed and dissected one or two.
23. Professor Thomas states in his report:—"I found that the rabbiters were unconsciously doing their best to prevent the spread of the disease. Noticing that their dogs were infected with tape-worms, they periodically

periodically gave them medicine to expel the worm. This may in part account for the much smaller percentage observed by me." You think on the other hand that this very action of the rabbiters tended to spread the disease? Yes; by expelling the worms and the eggs in greater numbers. In reply to that I would say that after eighteen months use of the areca-nut Professor Thomas sent to me for one of my dogs infected with tape-worms. I had been in the habit of giving it regular doses of areca-nut and the worms came out regularly.

24. *Mr. Bell.*] In your view, dosing with areca-nut tends to expel a portion but not the whole of the tape-worm? Yes; I would not turn out a single ferret in Australia if a sufficient number of dogs could be used; but still I think the ferret is far preferable to the dog. Dogs are such enemies to sheep and ferrets are not. The dogs sometimes go wild amongst the sheep.

25. Why do you prefer the ferret? Solely because it is not dangerous to sheep.

26. *Dr. Wilkinson.*] But you will admit that a ferret is no use unless it can be proved that it harbours this particular tape-worm? Yes; they are useful. Besides they are an important factor in killing young rabbits, though they do not kill the old ones.

27. *Mr. Bell.*] You expressly state in your evidence that the natural enemy is of value by virtue of spreading the bladder-worm in much greater proportion than by any direct means. And you then say that you greatly prefer the ferret to turn out, though you admit you are quite unable to say whether the ferret spreads the worm or not? I believe it does.

28. But you have no grounds for making that statement? No. Where the ferret especially comes in—besides the spread of disease—is that, after poisoning (which kills the old rabbits), the ferrets then come in and eat the young ones. Then the disease attacks the old ones again.

29. *Dr. Wilkinson.*] In your written statement, I notice that you seem to lay particular stress upon the use of ferrets? Yes; but dogs would still require to be used. I should like to see sheep dogs used.

30. But you think the introduction of a large number of ferrets is a most important step for the destruction of the natural enemy of the rabbit, the bladder-worm? I wish to make this as an assertion. On the central lands of Australia some disease is wanted—periodically acting of itself, to clear off the rabbits, as cleared off on other parts of the earth, before they become a pest. If you turn out a sufficient number of ferrets to go through the whole of Central Australia they will keep the rabbits in check. This is on the same principle, and I will be very sorry if I cannot prove it.

31. *Mr. Bell.*] You are aware that Mr. Bullen's run in New Zealand was understood to have been cleared by the turning out of a large number of ferrets? Yes; it was cleared once by turning ferrets out, but the rabbits have come there again.

32. When it was cleared, was the work done in your opinion by the outbreak of the bladder-fluke? No. Bladder-fluke never appeared there that I am aware of.

33. Your opinion is that by turning out ferrets rabbits can be cleared off, without bringing in the question of bladder-fluke at all; but would not the rabbits be liable to reappear unless they were kept down? Yes; but unless the bladder worm disease appears the ferrets are not effectual.

34. But I understood you to say that ferrets were effectual in this case? I meant to say totally effectual. They may be effectual for a time, but not permanently.

35. You ask to be allowed to clear a million acres of infested country in Australia? Yes; under the Colonial Secretary and the officers of the Government.

36. *Dr. Wilkinson.*] I do not think that is possible. [No answer.]

37. *Mr. Bell.*] You rely largely in all your conclusions upon what you call historical precedents? Yes.

38. Now what evidence have you that bladder-worm was at work in any of the historical instances which you cite? North America and England.

39. But what evidence have you that bladder-worm was at work in these cases? Rose, and Sir James Hector.

40. You know that Professor Thomas differs with you in these conclusions? Yes.

41. And on this point you differ with Professor Thomas? Yes.

42. In your evidence you express dissatisfaction generally with Professor Thomas' work? Yes.

43. Professor Thomas apportions what he thinks is the greatest share in the disappearance of the rabbits to poison, disease, and other means of destruction? Yes.

44. What fault, then, do you find with that apportionment; do you think he allows too much weight to poisons and other means and too little to the bladder-fluke? Yes. I would say that poison is good, ferrets are good, and disease is good; but one depends upon the other. Disease is the finishing off of the work of the others. I think that Professor Thomas did not take sufficient time for his investigation. This is my reason for being dissatisfied.

45. Are you a candidate for the reward offered by the New South Wales Government? Yes.

46. Do you think that a ferret in killing a rabbit is likely to eat portions of the flesh of the rabbit which is infested with the bladder-worm? Yes; it eats everything to the back bone—save that in poisoning operation, I do not think it eats the intestines.

47. Does it eat the dead rabbit at all? Yes.

48. You express positive disbelief in any disease which works quickly? I do.

49. What ground have you for a disbelief in the existence of any possible disease which might work as an epizootic amongst rabbits? Nature rarely works quickly, and drastic measures appear to be avoided.

50. These are the only grounds upon which you disbelieve in other diseases than your own? Yes.

51. Are you quite sure that ferrets do not hurt lambs? Quite sure.

52. Like everybody that has tried it you hold strong opinions against trapping? Yes. I think it must be made a penal offence.

53. Now will you tell us why? Simply that it destroys the natural enemies.

54. Do you think that trapping has any tendency to spread rabbits? I think it preserves the rabbits.

55. Are you willing to procure rabbits suffering from this disease to be taken to Rodd Island and used for purposes of experiment, so that the life history of the bladder-worm may be traced out, and it may be decided what carnivorous form acts as hosts for this parasite? Quite willing; and I will send over what rabbits I can get that may be affected with the disease.

56. You condemn the investigations at Rodd Island, but in the case of your own disease, you think we ought to investigate it? I do not condemn that; I said that they were necessary. And while I think it is necessary to investigate my disease, it would be better to allow it to be tried on a large scale.

57. You will observe, however, that if tried on a large scale, by turning out dogs, stoats, weasels, and cats together, that the particular point required to be cleared up would not be decided, because such an experiment would not determine what particular animal carried the parasite? Yes.

58. Do you recognize that a mixed experiment of that kind is insufficient to determine the point? I think both experiments would be good; and I think both are necessary. There is an idea in New South Wales that the rabbits will die out of themselves; but people need not buoy themselves up with that fallacious hope, for I still watch my rabbits jealously. It would be well to have a return from every large owner of the cost of rabbit suppression. The Colony will soon find out how much poorer it is annually thereby, as rabbit suppression is a totally unproductive expenditure. Just as the natural enemy becomes spread about, so will this annual loss be reduced.

SECTION V.

STATEMENT made in lieu of Evidence, by Mr. E. H. Lascelles, a Member of the Commission.

My first practical experience with rabbits was in 1878, when I purchased the Lake Corrong station, in the mallee district of Victoria. It was then mid-summer, and a very dry season. What rabbits were to be seen were in poor condition, and I had the idea that in so dry and waterless a country they could never take possession of it. Up to then the rabbits in the mallee had not been much talked about, the settlers keeping the matter quiet in the hope that buyers for their runs might be found. Their first start was in Morton Plains Station, on the edge of the mallee, where a few couple had been obtained from the westward about 1866; but it was not until 1876 that they began to affect the carrying capacity of that run, from which time they gradually spread throughout the mallee country, the good season in 1878 giving them a great start. Owing to the runs being held under annual licenses, expiring in 1880 (at same time open to free selection) no united action was taken for their destruction. The urgent state of the case was repeatedly brought under the notice of the Government, but no legislation was forthcoming, the consequence being that in 1879 one run after another was abandoned. The first to be forfeited and put to public tender, with all the previous lessee's improvements given in, was the Lake Hindmarsh run, which, up to 1878, paid £705 per annum for rent. By tender it brought £36 per annum. Other runs brought similarly low prices. When the leases expired in 1880, it was thought certain there would be legislation; but the Government, being strongly anti-squatting, were afraid to deal with it, and merely renewed the existing Act for a year. This state of things went on until October, 1883, when the "Mallee Pastoral Leases Act" was passed giving absolute tenure for one-half the country for twenty years, and five years' tenure for the other half. Each existing lessee was entitled to the lease of one block, and the remaining blocks were put to auction, rental being fixed at a minimum of 2s. 6d. per square mile, or if over fifteen sheep to the square mile were carried, 2d. per head was paid for the first five years, 4d. for next, and 6d. for the last ten years. For those going to auction very small sums in the shape of premiums were received, and the country fell almost entirely back into the hands of previous tenants; so that, in endeavouring to find new tenants, valuable time was wasted, with the still greater disadvantage that the new ones coming in being mostly unaware of the difficulties to be encountered, and being without necessary conveniences and plant to carry on work, practically did nothing towards the destruction of wild dogs and rabbits. This, to a large extent, paralyzed the action of other lessees; and it was not until 1885, when the Government agreed to erect a netting fence between the pastoral blocks and mallee allotments, and also gave compensation at end of leases for netting fences, that any show was made in bringing the mallee country again into profitable occupation. Since that time large areas have been netted, and these are now carrying sheep at large, dogs being practically exterminated and rabbits reduced to a minimum.

Having followed the course of legislation, I will now state my experience in destruction of rabbits. In 1879 I laid phosphorized wheat with good results, but, owing to their being no tenure, the work could not be systematically carried out, and as the neighbours were doing nothing, I had to follow suit. It may be said that practically nothing was done from 1879 until the beginning of 1884; but in 1882—owing to the rabbits having increased beyond the capacity of the country to carry them, or it may be from disease—they died off in millions. If tenure had then been settled, and netting fences erected, there is no doubt they would have been easily kept in check, but there were enough left to breed up, and when the Mallee Act was finally passed at the latter end of 1883, they were almost as numerous as ever. In the summer of 1884, I started laying phosphorized grain, chaff, and arsenic, with good results; still with the then mode of merely scattering it in heaps amongst brushwood or near burrows, no extent of country could be got over, and merely the best patches were treated. When the green grass came, very little execution was done by poison, and resort was had during the winter to trappers. At first this promised well—rabbit skins were a good price—the Shire Councils gave a bonus for scalps—so the cost was not great. Still at the end of the year, it was found that, although thinned near the favourite camps, the men had no sooner gone to another place, than they were as thick as ever. During 1884, I started a rabbit and dog proof fence, to enclose 31,000 acres, being, I believe, the first large enclosure for such a purpose. The fence consisted of about 24 miles of stubbs and 6 miles of wire-netting. Although the cost came nearly to £100 per mile, I was at once satisfied that the erection of wire-netting fencing was the best means of ensuring finality in both rabbit and dog destruction, and from thence forward my constant endeavour was to induce my fellow settlers and the Government to recognize this.

In the summer of 1885, I again tried poisoning, and seeing a paragraph in some newspaper that it was a good plan to lay the grain in a plough furrow, I tried this with great success, but thinking it involved a deal of unnecessary labour, I hit upon the idea of attaching a scarifier to the axle of a spring cart, and laying the grain in the scratch, which proved quite as effective as the large furrow. My neighbour, Mr. Andrew Anderson, paying me a visit shortly after. He suggested a hopper in the cart and pipe leading from it, to convey the grain to the furrow, which he put into effect. Ultimately, more improvements were added, making

making the present "Lascelles and Anderson Patent Rabbit Poison Distributor," which is so far, I have found, the best means of dealing with rabbits, especially during the summer months. When green grass is plentiful, rabbits require to be very thickly congregated for poison to be much taken. During this winter, I have found wheat poisoned with strychnine—2 oz. to 50 lb.—with the addition of a stick of phosphorous, gave good results; there is no doubt it is a good plan to vary the poisons, chaff and arsenic being often better eaten than wheat. I have felt for some time that the mode of mixing the wheat by the Raymond Phosphorizer could be improved upon; it involved a large amount of labour, careful watching to see that it was well mixed, danger of bush-fires from small lumps being undissolved, and, when too much water was used, the wheat would clog when going through the hopper. At the close of last summer, I came to an arrangement with Messrs. Felton, Grimwade, & Co. to allow me to mix wheat under their patent process, the principle of which is that the phosphorous is dissolved by its cheapest natural solvent—bisulphide of carbon—then mixed with ordinary bookbinder's paste in a "cherry" churn, the paste being revolved with the wheat in an iron cylinder, each grain being coated with the poisoned paste.

My manager reports unmistakably in favour of the new method, so much so that I have put aside the Raymond Phosphorizer and now prepare all my wheat by the Felton, Grimwade, & Co. process.

On the more open country in the winter months I use bisulphide of carbon, but this is too expensive to go over a large tract of country; ploughing out burrows on open sandhills is also a good plan.

When the Mallee Act was passed, wild dogs, from the pastoral point of view, were considered as the greatest evil, and to deal with these and also rabbits, by means of poisoned water, the various tanks were either stubbed or netted. Summer thunder-storms prevented the work being carried out in 1884, but in 1885 the tanks were closed, and particularly in salt-bush country great execution followed. *Vide* a letter of mine to the *Argus* dated 17th January, 1885, showing that at two tanks I had skinned in two nights 1470 rabbits. Where scrub surrounded tanks, the results were not good; showing that where bark is to be had, rabbits can exist without water. During the last two or three seasons there has been so much outside water in swamps and claypans, that there has been no chance to close the tanks during the heat of summer, and when the nights are long and cool I have found very little good is done by having water shut off.

The result of our experience in the mallee country is that rabbits can be kept within reasonable limits by present known means, but except at an enormous cost they cannot be exterminated. Each year there will be the recurring expense of a good systematic poisoning.

In certain descriptions of country where rabbits are not thick, I am a believer in dogs and traps for the winter months, but the latter should only be used by reliable station hands and not professional rabbiters.

My trip through the most heavily rabbit infested country of New South Wales convinces me that the country I passed through is fast drifting into the same state as the mallee country did in Victoria, and with the experience gained there, it seems madness not to introduce remedial legislation. In its present condition there is no chance of the country being taken up under homestead leases, and in any case on the same principle as the old saying that, "horses should not be changed when crossing a ford," it would be a grave mistake to put new tenants on rabbit-infested country. In its transition state, nothing would be done and even when possession was taken, it must be some time before the swing of the work could be got into. The advent of the rabbit has completely put a stop to the squatting tenure. Annual leases and destruction of rabbits cannot possibly go hand in hand. State subsidy is a snare, and nine-tenths of the money so expended might as well be flung into the sea. The goal to be reached can only be attained by the falling on the part of the lessee that if he is successful he will reap the benefit of his labours.

Resumptions of runs must be gradual and certain fixed notice be given—say of at least three years, and then only for limited portions, say not more than a sixth of a run at a time, so that the lessee with some years before him of the balance, would not neglect keeping rabbits down on the resumed piece. If there is no chance of the resumed areas being required, what is the object of keeping a lessee in suspense? The portion of the country that is soon likely to be wanted for settlement should be netted off, and when that is taken up, give notice for other areas, netting them in the same manner. Under present conditions the lessee who does the most to keep rabbits down, has, as his reward, the certainty that his run will be the first to go.

It will be urged that my views are those of a squatter, and that they are formed from self-interest. I can only say that in giving expression to them I have endeavoured to reconcile the three interests to be considered, viz.,—Those of the existing lessees, the homestead lessees, and the State. I have no interest direct or indirect in New South Wales squatting, and I am only actuated by a desire to see the country profitably occupied. If it is not so, it goes without saying that the greatest loser will ultimately be the State.

RABBIT DESTRUCTION.

Sir,

To the Editor of the *Argus*.

As further details in connection with rabbit destruction by poisoned water may be of interest to your readers, I now give these, and also other views on the subject.

For some years I have thought that in dry and comparatively waterless country like the mallee, water would prove the means whereby it could be ridded of rabbits as well as dogs. From personal observation I saw that immense numbers of the former watered at the tanks, and having had occasion during the last few years to travel over a large area of the country, I also noticed that in the summer months there were few rabbits—and these very weak—any distance from water, except about dry beds of lakes where green rushes, thistles, &c., supplied a certain amount of moisture.

When the Government passed their Mallee Bill, giving fixed tenure for a term of years, I lost no time in erecting rabbit and dog-proof fencing round my tanks, but I found that to insure a thorough trial it was necessary to make a similar fence round Lake Corrong and Yarrock Swamp, and covering together about 6,000 acres. I therefore decided on enclosing 30,000 acres, which would take in both sheets of water, and I also endeavoured to get the Murray frontage and Lake Hindmarsh lessees to similarly fence off their water, but to no avail. The timber being suitable and handy to the line of fence, I contracted for 23 miles pine stubb fencing at a cost of £64 per mile, but the contractor, before getting half through, failed to complete, and I had to carry out the unfinished portion by day labour at a cost of about £75 per mile. The remaining six miles either ran across plains or through poor timber, and on this portion I erected wire-netting

netting 3 feet 6 inches high, 16 gauge, 1½-inch mesh, let into the ground about 4 inches, and with a thick-set barbed wire about 4 inches above netting. Extra precautions must be taken with fencing around tanks both for rabbits and dogs, and I have put three barbed wires in place of the one wire round the paddock. On the completion of the fencing no animal can obtain water in any portion of my runs outside the stubb fence, but owing to an inch of rain last month, all surface water had not quite dried up over the Corrong run, when I left there last week, and it was only on Tyrrell Downs and back country adjoining there that the gates at tanks could be closed. Previous to this, 6 gallon galvanized iron troughs sunk level with the ground had been kept filled with good water, in a small sheep-proof enclosure alongside the main gate; these were poisoned with strychnine dissolved by putting into a clear bottle an ounce of strychnine with about a third of a pint of acetic acid; the latter can be obtained extra strong, when a much less quantity will suffice. It can easily be seen if the grains of strychnine are dissolved the mixture thus formed will poison 12 gallons of water.

At the two tanks, where it was known most rabbits were in the habit of watering, men were put in to skin the dead rabbits, the result in two nights being 1,470 all gathered within 100 yards of each tank. At the six other tanks the rabbits were not gathered, but the numbers varied from about 20 to 150 each night; in addition I had four arsenic troughs in other parts of the run, around each of these there were a few dead rabbits, but more scattered about; the action of the poison being slower may have enabled them to get back to their burrows, but with strychnine they were completely piled round each trough.

The wild dogs have been so thinned out at Tyrrell Downs, that although sheep are running at large, very few tracks have been seen for some time, so none were got, but at one trough of strychnine water in the back country at Lake Corrong, six were obtained in one night.

I think the results already obtained should cause each Vermin Board to use every effort to have all tanks and dams within their respective districts made dog and rabbit-proof. The Minister of Lands fully recognizes the importance of this, and at once signified his intention of affording the Boards every assistance; these will meet on the 30th inst.

No doubt the Tyrrell Downs run is a specially suitable place for the experiment of poisoned water, being principally open salt bush country, and therefore the feed all of a saline nature. Taking this into consideration it would be a mistake to discontinue laying poisoned chaff and grain, but at any rate, it may be claimed for water, that it is another known method of destroying the vermin, and if they are not got rid of during this summer, I intend making small tanks, of thirty yards each, on every square mile of country habited by rabbits. These would be logged over with a sloping side for rabbits to drink at. A simultaneous closing of these during midsummer and laying poisoned water would mean almost total extermination, as there can be little doubt, that if within a moderate distance of water, all rabbits will drink. When the mallee country was first occupied by rabbits they could stand a dry summer better than now, as the bark of dogwood, hop bush and other scrubs afforded some moisture, but these they have almost entirely killed out, and the necessity for water thus becomes greater.

Looking at the requirements of the Colony as a whole, I am certain that the crection of rabbit-proof wire-netting fencing will prove the greatest factor in getting rid of the pest. And I submit that it would be a wise step on the part of the Government if they at once offered a bonus of £1,000 for say the first 250 miles manufactured here. If this is done, I would undertake to start a company for the purpose. The duty of 27½ per cent. should be abolished. It is an industry which can stand on its own legs, being quite enough protected by the high freights and other charges on the manufactured article; thus, I imported five miles, gauge, &c., as above, costing £34 per mile in England, landed here the cost was £70 per mile. No doubt being wanted quickly extra steamer freight added almost £10 per mile. I believe such netting could be made here for £45, and at such a price a large demand would be created.

One great advantage in having even a portion of a run made rabbit proof, is that before January, the outside portion can be heavily stocked and grass eaten off, the inside portion being held in reserve when rabbits on the former can more readily be poisoned.

Yours, &c.,

EDWARD H. LASCELLES,

Chairman, North Eastern Vermin Board.

Geelong, 19th January, 1885.

SECTION VI.

MINUTES of Proceedings of the Experiment Committee.

FRIDAY, 27 APRIL, 1888.

The Committee met at 10:30 a.m.

Present :—

New South Wales : W. CAMAC WILKINSON, Esq., M.D., M.P.

EDWARD QUIN, Esq.

Victoria : A. N. PEARSON, Esq.

New Zealand : A. DILLON BELL, Esq.

Queensland : JOSEPH BANCROFT, Esq., M.D.

After waiting until 11 o'clock,—

Mr. BELL moved, "That Dr. Wilkinson be appointed Chairman of this Committee."

Mr. PEARSON seconded. The motion was carried.

Subsequently Dr. MacLaurin, President of the Commission, entered the room and occupied the chair.

Dr. WILKINSON mentioned that he had seen Professor Threlfall on 26th instant, and that gentleman had stated the Physical Laboratory at the University would not be ready for three or four weeks.

After

After deliberation,—

Mr. BELL moved, "That Dr. MacLaurin and Dr. Wilkinson, M.P., with their consent, be a Committee with full power to arrange the headquarters of Dr. Katz's scientific work, and with power also to require at any time the attendance and assistance of members of the Committee; further, that Messrs. Pearson and Quin be a Committee to ascertain whether any suitable house is available near Sydney—both Committees to report as early as possible."

Mr. QUIN seconded. The motion was carried.

A letter was received from the Under Secretary for Mines, in reply to an application by the Committee for a site for an experimental station, stating, as regards Shark Island, that stock were expected shortly which would have to be placed there; and as to the Randwick Quarantine Ground, that rabbits could escape from the enclosure at that place.

The Committee adjourned until 11 o'clock on the following day.

SATURDAY, 28 APRIL, 1888.

The Committee met at 11 a.m.

Present:—

<i>New South Wales:</i>	W. CAMAC WILKINSON, Esq., M.D., M.P. (Chairman).
	EDWARD QUIN, Esq.
<i>Victoria:</i>	A. N. PEARSON, Esq.
<i>New Zealand:</i>	A. DILLON BELL, Esq.
<i>Queensland:</i>	JOSEPH BANCROFT, Esq., M.D.

Dr. WILKINSON having been called away on business, the Chair was taken by Dr. BANCROFT.

Mr. A. BRUCE, Chief Inspector of Stock, was examined, and gave certain information regarding Shark Island, Clark Island, the Quarantine Ground at Randwick, and Railway grounds near Newton, which had severally been mentioned as places whereon experiments with disease might be conducted.

A letter was directed to be forwarded to the Secretary for Mines, asking that the Randwick Grounds and a portion of the buildings thereon should be placed at the disposal of the Committee.

Mr. PEARSON handed in certain papers and plans of enclosures necessary for the carrying on of experiments.

Mr. QUIN moved, "That a sum of money (£10) be placed in the hands of the Secretary for the purposes of petty cash."

Mr. BELL seconded. The motion was carried.

Dr. WILKINSON moved, "That Dr. Bancroft be asked to write a short account of the investigations undertaken by the Commission at Dr. Ellis' house, to be included in the Report of the Proceedings of the Commission."

Mr. BELL seconded. The motion was carried.

The Committee adjourned to Monday, at 10:30 a.m.

MONDAY, 30 APRIL, 1888.

The Committee met at 10:30 a.m.

Present:—

<i>New South Wales:</i>	W. CAMAC WILKINSON, Esq., M.D., M.P. (Chairman).
	EDWARD QUIN, Esq.
<i>Victoria:</i>	A. N. PEARSON, Esq.
<i>New Zealand:</i>	A. DILLON BELL, Esq.
<i>Queensland:</i>	JOSEPH BANCROFT, Esq., M.D.

A letter was received from Mr. P. Marceau, Adelaide University, stating that most of the rabbits of Professor Watson affected with *sarcoptes cuniculi* had been distributed to stock owners, to whom Professor Watson had transferred all his rights in the disease. It would be difficult, therefore, to obtain the six required by the Commission at a month's notice.

It was ordered that the writer be informed the Commission would meet in Adelaide, about 23rd May next, and it was hoped that some rabbits would be in a fit state at that time for experiments.

A letter was received from the Under Secretary for Lands, stating that the netting in use for the barrier fence between New South Wales and South Australia was only 42 inches wide, whereas the wire recommended by the Commission was 48 inches.

It was ordered that the writer be informed the recommendation was made under a misconception; also that the Committee hope the Government will afford the use of a portion of the wire from that parcel, should it be found necessary to fence any portion of land for experiments.

A letter from Mr. James Tyson, junior, offering the use of Tupra Station, near Hay, for experiments was read. Mr. Quin also handed in similar letters from Mr. N. Sadleir, of Launceston, offering Victoria Lake Station on the Albemarle Run, Darling River; and from John H. Patterson, of Orange, offering Tolgol Station.

Ordered, that Mr. Tyson's offer be acknowledged.

It was ordered that the Tasmanian Government should be communicated with, to ascertain whether it would be possible to collect in vacuum tubes some of the blood of the fowls affected with the disease amongst fowls in that colony, and reported to be chicken-cholera.

It was further ordered that the New Zealand Government be requested to obtain from Professor Thomas a full account of the diseases which he had found in rabbits in the course of his investigations.

The Committee adjourned to 10 a.m. on the following day.

TUESDAY,

TUESDAY, 1 MAY, 1888.

The Committee met at 10 a.m.

Present :—

New South Wales : W. CAMAC WILKINSON, Esq., M.D., M.P. (Chairman).
EDWARD QUIN, Esq.
Victoria : A. N. PEARSON, Esq.
Queensland : JOSEPH BANCROFT, Esq., M.D.

Correspondence was received from the Under Secretary for Lands relative to remuneration to members of the Commission and to Secretary and shorthand writer.

It was ordered that the following reply be sent to the Minister :—“ It seems that the representatives of the various Colonies look to their respective Governments for reimbursement of their expenses, but the Commission does not know whether or not there will be any further settlement in this matter between the Governments of this and the various Colonies. Naturally, it is understood that the New South Wales Government will make the necessary provision for their own representatives.”

Dr. BANCROFT handed in a paper on fowl-cholera at Mount Grey Downs, New Zealand, by W. H. Symes, Esq., M.D.

Dr. BANCROFT moved, “ That the paper be printed and included in the report of the proceedings of the Commission.

Mr. PEARSON seconded. The motion was carried.*

Dr. BANCROFT moved, “ That letter No. 647 be printed in the report of the Commission.”

Mr. QUIN seconded. The motion was carried.

Mr. PEARSON moved, “ That a communication be forwarded to the Government of New Zealand, with a view of obtaining from Dr. Symes, or some other suitable gentleman in New Zealand, some of the blood and secretions of the fowls said to be now attacked by fowl-cholera in the neighbourhood of Canterbury; the blood and secretions to be forwarded in vacuum tubes; and further, that a short account of the observations be also furnished to the Commission.”

Mr. QUIN seconded. The motion was carried.

The Secretary was instructed to forward to the Minister for Lands a list of the animals to be included in permit.

Dr. BANCROFT moved, “ That the books referred to in Leuckart giving an account of an infectious influenza in rabbits, be obtained for the Commission through Mr. Bruck, Castlereagh-street, and that the appended extract from Leuckart's work ‘ Parasites,’ be incorporated in the Report of the Commission.”

Mr. PEARSON seconded. The motion was carried.†

Dr. KATZ handed in a schedule of articles required in the laboratory, and an estimate of cost of same, amounting to £80.

The list was approved of.

Mr. PEARSON proposed a motion having reference to the immediate occupation of a site at Summer Hill as an experimental ground.

Mr. QUIN seconded the motion.

Dr. BANCROFT and the CHAIRMAN having spoken, it was decided to visit the ground.

The Committee adjourned to 10.30 a.m. on the following day.

WEDNESDAY, 2 MAY, 1888.

The Committee met at 10.30 a.m.

Present :—

New South Wales : W. CAMAC WILKINSON, Esq., M.D., M.P. (Chairman).
EDWARD QUIN, Esq.
Victoria : A. N. PEARSON, Esq.
Queensland : JOSEPH BANCROFT, Esq., M.D.

In reply to certain correspondence from the Lands Department it was ordered that the Under Secretary for Lands be informed that M. Pasteur's representatives required permission to inoculate only rabbits and fowls in their preliminary experiments at the laboratory of the Board of Health.

Another letter was read from the Under Secretary for Lands, stating that all the correspondence having reference to the introduction of diseases amongst rabbits had been forwarded to the Commission.

A further letter from the Under Secretary for Lands was read, stating that thirty-two rabbits had been sent to the Quarantine Reserve at Randwick, and that one hundred others would be obtained, as requested by the Commission.

Dr. BANCROFT moved, “ That a record of visits to various places, for the purpose of obtaining suitable premises and grounds for experiments, be prepared by the Secretary for insertion in the Minutes of the Proceedings of the Committee.”

Mr. PEARSON seconded. The motion was carried.

Dr. BANCROFT moved, “ That the expenses of the Executive Committee be defrayed by the various Governments represented on the Commission in a proportion to be fixed by the said Governments.”

Mr. PEARSON seconded. The motion was carried.

It was ordered that this resolution be transmitted to the Government of New South Wales.

The Committee then proceeded to interview the Hon. the Secretary for Lands in reference to premises for experimental purposes.

The Committee adjourned to 10 a.m. the following day.

THURSDAY,

* See Section XII of this Report.

† See Appendix 9.

THURSDAY, 3 MAY, 1888.

The Committee met at 10 a.m.

Present :—

New South Wales : W. CAMAC WILKINSON, Esq., M.D., M.P. (Chairman).
EDWARD QUIN, Esq.
Victoria : A. N. PEARSON, Esq.
Queensland : JOSEPH BANCROFT, Esq., M.D.

A telegram was read from Dr. John Nicholson, of Benalla, Victoria, stating that a fowl diarrhoea epidemic had broken out there, and asking if a portion of the intestines would be of use to the Commission.

Ordered, that Dr. Nicholson be thanked for his offer, and that he be asked to forward fresh blood from the heart of diseased fowls in vacuum tubes, together with an account of the symptoms and *post-mortem* appearances.

A letter was received from the Under Secretary for Mines asking for detailed statement of experiments to be made, and how they were to be conducted, information that was necessary before acceding to the Committee's request that the Quarantine Reserve at Randwick might be granted for experiments.

The Committee decided to interview the Hon. the Secretary for Mines on the subject.

The Committee adjourned until 10 a.m. on the following day.

FRIDAY, 4 MAY, 1888.

The Committee met at 10 a.m.

Present :—

New South Wales : W. CAMAC WILKINSON, Esq., M.D., M.P. (Chairman).
EDWARD QUIN, Esq.
Victoria : A. N. PEARSON, Esq.
Queensland : JOSEPH BANCROFT, Esq., M.D.

Messrs. QUIN and PEARSON reported that they had visited Rodd Island, which was proposed to be set apart by the Secretary for Lands for the use of Committee as an experimental station.

Mr. PEARSON moved, "That Rodd Island be obtained for purposes of experiments."

Mr. QUIN seconded. The motion was carried.

The Secretary was directed to forward same to the Secretary for Lands, and to ask that instructions be given the proper authorities for the erection of buildings, to be approved by the Committee.

It was ordered that Dr. Katz be empowered to employ a first assistant at the rate of £16 per month, with board and residence.

Mr. QUIN moved, "That a recommendation be made to the Minister for Lands that Mr. Mahon be paid at the rate of £500 per year for his services in connection with the Commission."

Dr. BANCROFT seconded. The motion was carried.

The Committee then adjourned.

TUESDAY, 8 MAY, 1888.

The Committee met at 10.30 a.m.

Present :—

New South Wales : W. CAMAC WILKINSON, Esq., M.D., M.P., (Chairman).
New Zealand : A. DILLON BELL, Esq.

A letter was read from Dr. Frank Hinds stating that the preliminary experiments were finished and asking when the Committee would be ready to examine M. Pasteur's scheme.

Ordered, that Dr. Frank Hinds be informed that the Committee hope to be ready to begin experiments with M. Pasteur's scheme within a week; also that a list of experiments be forwarded, and Dr. Hinds be asked to suggest any others.

It was ordered that the parcel received from Dr. Nicholson, of Benalla, and report on fowl disease, be handed to Dr. Katz.

Approval was given to the action of the Secretary in summoning, on the previous day, the following witnesses, whose names had been submitted by Mr. Quin:—Mr. David Brown, Kallara; Dr. Herbert Butcher, Wilcannia; Mr. Alexander Bell, Langawirra; Mr. George Urquhart, Silverton; the Manager, Mundi Mundi Station, Silverton; the Manager, Corona Station, Silverton; Mr. W. Horne, Adelaide Club, Adelaide.

The Committee then adjourned.

MONDAY,

MONDAY, 14 MAY, 1888.

The Committee met at 10:30 a.m.

Present :—

New South Wales : W. CAMAC WILKINSON, Esq., M.D., M.P. (Chairman).
Victoria : A. N. PEARSON, Esq.
New Zealand : A. DILLON BELL, Esq.
Queensland : JOSEPH BANCROFT, Esq., M.D.

A letter was read from Dr. Hinds, Dr. Germont, and M. Loir, dated 10 May, declining to accept any participation in the investigations directed by the Commission to be carried out; and stating that they were prepared to practically demonstrate that M. Pasteur's method was at once efficacious, practical, and without danger to domestic animals.

The Secretary was directed to communicate with M. Pasteur's representatives and request their attendance at 2:30 p.m.

Dr. Hinds, Dr. Germont, and M. Loir accordingly attended, and after deliberating with these gentlemen the Committee discussed the following motion, moved by Mr. BELL, and seconded by Dr. BANCROFT, "That as soon as the preparations at Rodd Island are in a sufficiently forward state, the representatives of M. Pasteur be requested to perform their experiments upon the island with the facilities which we will provide, it being understood that the expert appointed by the Commission shall have full information from the experimenters from time to time with regard to the progress of the experiments, and full access thereto at all times."

The motion was agreed to.

Mr. BELL moved, "That the representatives of M. Pasteur be requested to furnish the Committee, as soon as possible, with a list of the experiments of demonstration which they propose to carry out."

Dr. BANCROFT seconded. The motion was agreed to.

The Committee then adjourned.

MONDAY, 11 JUNE, 1888.

The Committee met at 11 a.m.

Present :—

Queensland : JOSEPH BANCROFT, Esq., M.D. (in the Chair).
Victoria : A. N. PEARSON, Esq.,
New Zealand : A. DILLON BELL, Esq.

Mr. PEARSON moved, "That the Colonial Architect be requested to conduct gas on to Rodd Island from the mainland by means of a main pipe laid under water, and that such work be executed as quickly as possible."

Mr. BELL seconded. The motion was carried.

Mr. PEARSON moved, "That Dr. Katz be authorized to take immediate steps for procuring the requirements for Rodd Island, a list of which he had submitted."

Mr. BELL seconded. The motion was carried.

The Committee then adjourned.

TUESDAY, 12 JUNE, 1888.

The Committee met at 11 a.m.

Present :—

Victoria : A. N. PEARSON, Esq. (in the Chair).
New Zealand : A. DILLON BELL, Esq.
Queensland : JOSEPH BANCROFT, Esq., M.D.

And subsequently :

New South Wales : W. CAMAC WILKINSON, Esq., M.D., M.P. (Chairman).

Dr. Hinds, Dr. Germont, and M. Loir, the representatives of M. Pasteur, were accorded an interview by appointment.

The Chairman (Mr. Pearson) : Have you read the account (p. 26, of the Board of Health Papers) of the mixed experiment made by M. Pasteur?

Dr. Germont : Yes.

The Chairman : Are you acquainted with the account of the experiment made on diseased and healthy rabbits being put in the same enclosure?

Dr. Germont : Yes.

The Chairman : Have you any objection to the same experiments being made for the satisfaction of the Committee?

Dr. Germont : We have been sent by M. Pasteur to make determined experiments with a plan exactly traced for us, and that we cannot change without authorization.

The Chairman : Will you allow us to make experiments on the contagious nature of fowl-cholera of rabbits inoculated by you?

Dr. Germont : Yes, after the end of experiments made by us.

The Chairman : After having proved that chicken-cholera kills rabbits, will you allow us to make experiments showing the contagious character of that disease amongst rabbits, before we make experiments in a place not enclosed, as you proposed in your letter of the 14th of May?

Dr. Germont : Yes, if it is to be at the end of our experiments. Have you any special reasons to wish us to make those experiments before the end of all ours?

Mr. Bell : Yes, we have many—first, we would not be authorized to incur expenses for buying cattle, &c., unless we are sure that the disease is contagious; second, unless the disease is proved to be contagious amongst rabbits, then since it is certainly deadly to fowls and perhaps other birds, we should not be justified in spreading the disease broadcast in the open country.

Dr. Germont : When Mr. Abigail, with the approbation of the Government, proposed a prize for the best method of destroying rabbits, he fixed the conditions and programme of the prize. When M. Pasteur studied this programme he authorized us to make a demonstration of the efficacy of chicken-cholera to destroy the rabbit pest. Sir Daniel Cooper sent a despatch to M. Pasteur asking him for a supply of microbes and instructions how to use them, and invited M. Pasteur to send us out at once. We have come for that purpose here. If you wish to modify the programme, we cannot on our own account, without authorization from him, alter the instructions which we have received. And we cannot either help you with the scientific researches which we are looking forward to. In fact, so far you have not given us a declaration that the programme sent by Mr. Abigail is of no value in your eyes, but we are not allowed to follow any other programme.

The Chairman : Is this the proclamation (producing *Gazette* notice dated 31st August, 1887), you refer to?

Dr. Germont : Yes.

The Committee adjourned to 2:30 p.m.

On resuming, the chair was taken by A. N. PEARSON, Esq.; also present, A. D. BELL, Esq. Dr. WILKINSON, M.P., attended.

The Chairman : In your last answer you referred to this proclamation. That proclamation requires that the approval of the Board appointed by this Government should be given to any scheme that may be proposed?

Dr. Germont : After experimenting for 12 months.

The Chairman : And we only assume that before our approval can be given such tests as are necessary to convince us of the efficacy and safety of it should be applied. One test that we consider necessary is that a number of (say half-a-dozen) rabbits, which have been fed on microbe-infected food, should be allowed to go amongst a number of other rabbits which have not been so fed. That we consider is a necessary test. If that test be not applied and reliance be placed alone upon direct feeding of the whole of the rabbits with microbe-infected food, we should have no grounds to decide that this was a new process at all. It would be merely the old process of direct poisoning.

Dr. Germont : What is the first experiment you intend to perform?

The Chairman : The first experiment we propose to perform is to take a number of rabbits that have been fed on microbe-charged food and to place these in an enclosure with healthy rabbits.

Dr. Germont : What is your second experiment?

The Chairman : The second experiment is very similar to the one which you propose, except that whereas in your experiment it appears that the animals fed with microbe-charged food would be kept separate, while we desire that they should be allowed to mix together, and that a certain number of birds should be allowed to fly about in the enclosure with the animals. We do this to ascertain the effect of the natural transmission of the microbes from one animal to another by means of their droppings.

Dr. Germont : For what purpose do you wish to have birds put in that paddock?

Mr. Bell : To see whether contagion will spread from rabbits to birds. You have said that after you have performed your own experiments, as laid down in your letter, you will make experiments demonstrating the contagiousness of fowl-cholera?

Dr. Germont : No; we will give you the microbes to do it yourselves.

Mr. Bell : You have already authority from M. Pasteur to give us your microbes or your infected rabbits for our own experiments.

Dr. Germont : We have authority to hand you these microbes, but not for a specific purpose, after our experiments are concluded.

Mr. Bell : But you will not do so till you have made your own demonstrations as laid down in your letter of 14th May?

Dr. Germont : No; the reason is that we do not want criticism on our experiments before they are concluded. The newspapers have already received communications as to our first experiment, for instance, whether our microbes were alive or dead.

Mr. Bell : Our desire is that we should receive your microbes or infected rabbits after the completion of your experiment number one, and before proceeding to numbers two and three. Our reason for that is that unless contagion experiments are successful it is useless and unnecessary waste of time and money to perform your experiments numbers two and three at all. Moreover, we could on no account allow fowl-cholera to be introduced into the open country unless we are first satisfied by experiments in the enclosure as to the disease really spreading from rabbit to rabbit. After this explanation will you now allow contagion experiments, either by yourselves or by us, to follow immediately upon your experiment number one, and before numbers two and three?

Dr. Germont : We cannot for the present. We cannot even answer it; and, therefore, we cannot give you the microbes for the present. If you will wait, we will write to M. Pasteur for new instructions, but if you cannot wait it is impossible for us to make experiments without authorization.

After discussion it was decided that the Committee would recommend Dr. Germont to send a cablegram requesting the authority of M. Pasteur for performing such experiments as the Commission desired, the message to be mutually agreed on.

Mr. BELL moved, "That the following message be sent by letter or telegram to the members of the Commission:—'Have you any objection that the restriction to the use of Butcher's disease of rabbits be removed?'"

Dr.

Dr. BANCROFT seconded. The motion was carried.

Mr. BELL moved, "That a special requisition be sent to the Under Secretary for Lands for furniture required for immediate use on Rodd Island."

Mr. PEARSON seconded. The motion was carried.

The Committee adjourned to 10:30 a.m. on the following day.

WEDNESDAY, 13 JUNE 1888.

The Committee met at 11 a.m.

Present :—

<i>Queensland</i> :	JOSEPH BANCROFT, M.D. Esq., (in the Chair.)
<i>Victoria</i> :	A. N. PEARSON, Esq.
<i>New Zealand</i> :	A. DILLON BELL, Esq.

The representatives of M. Pasteur (Dr. Hinds, Dr. Germont, and M. Loir), were again in attendance and, after discussion, it was agreed to recommend the Government to despatch the following cablegram :—

"Cablegram. 13 June, 1888. Pasteur, Paris.—Commission ne peut laisser faire nos expériences sur une large échelle avant que la contagion de lapin à lapin ait été démontrée. Même après cela elle ne peut nous promettre d'avance de nous autoriser à faire l'expérience sur une large échelle. Autorisez-vous expérience de contagion suivante : Mêler cinq lapins infectés dans une cage avec vingt lapins sains et observer les résultats pendant six jours. Commission aussi demande lapins infectés pour expériences particulières.—GERMONT."

The Committee then waited upon the Under Secretary for Lands, who arranged to despatch the cablegram.

Inquiry was made as to a telegram authorized to be despatched by the Secretary on the journey from Melbourne to Adelaide, which conveyed a request to the Under Secretary for Lands to receive from Sir James Hector, on his arrival in Sydney, and to convey to Dr. Katz, certain chicken-cholera material from New Zealand. The Secretary stated that the message had been duly despatched by him.

Mr. BELL moved, "That Dr. Katz be instructed to take charge of, examine, and report as to the condition of the chicken-cholera material brought over from New Zealand by Sir James Hector."

Mr. PEARSON seconded. The motion was agreed to.

The Committee adjourned to 2 p.m. on the following day.

THURSDAY, 14 JUNE, 1888.

The Committee met at 3 p.m.

Present :—

<i>New South Wales</i> :	W. CAMAC WILKINSON, Esq., M.D., M.P. (Chairman).
<i>Victoria</i> :	A. N. PEARSON, Esq.
<i>New Zealand</i> :	A. DILLON BELL, Esq.

The Secretary was instructed to forward the following telegram to each member of the Commission, on the motion of Mr. BELL, seconded by Mr. PEARSON :—

"Commission meet Tuesday, 19 June, 2:30. If Pasteur accedes to our request, contagion experiments begin Wednesday morning. If Pasteur refuses, Commission meet consider situation."

The Committee adjourned to 10:30 a.m. on the following day.

FRIDAY, 15 JUNE, 1888.

The Committee met at 10:30 a.m.

Present :—

<i>New South Wales</i> :	W. CAMAC WILKINSON, Esq., M.D., M.P. (Chairman).
<i>Victoria</i> :	A. N. PEARSON, Esq.
<i>New Zealand</i> :	A. DILLON BELL, Esq.
<i>Queensland</i> :	JOSEPH BANCROFT, Esq., M.D.

It was decided to appoint Frederick Bell as cook at the experimental station at Rodd Island, at a salary of 30s. per week, with a bonus of 5s. if he should prove suitable, the appointment to date from this day.

Mr. PEARSON moved, "That the Committee have no objection to the removal of any restrictions placed upon experiments conducted by Drs. Butcher and Ellis, provided that they undertake to conduct such experiments only with the so-called Tintinology disease in certain places to be specified by the Commission; that this resolution be conveyed to the Hon. the Secretary for Lands; that Drs. Butcher and Ellis' letter be acknowledged, and they be informed that the Committee have communicated their views to the Hon. the Secretary for Lands."

Mr. BELL seconded. The motion was agreed to.

The Committee adjourned to 10:30 a.m. on the following day.

SATURDAY,

SATURDAY, 16 JUNE, 1888.

The Committee met at 10.30 a.m.

Present :—

New South Wales : W. CAMAC WILKINSON, Esq., M.D., M.P. (Chairman).
Victoria : A. N. PEARSON, Esq.
New Zealand : A. DILLON BELL, Esq.
Queensland : JOSEPH BANCROFT, Esq., M.D.

The following was received from Dr. Germont, one of the representatives of M. Pasteur :—

“Copie du télégramme envoyé à M. Germont par M. Pasteur, le 16 Juin 1888 :—‘Contagion notable dans terriers. Faites expérience demandée sur terre foulée, un mètre surface. Attendre pour donner microbes du lapin mort; mais donner dessin cultures paraffé (1) par membres.—(Signed)—PASTEUR.’”

(1) Ce mot est écrit sur l'original “parapse,” ce qui n'a aucun sens.—Pour copie conforme : DR. GERMONT. Le 16 Juin 1888.

Translation of the telegram (by Dr. Germont) :—“Contagion great in the burrows. Make experiments demanded on solid ground of a square meter. Wait before giving microbes of dead rabbits. But give drawing of the organisms of the cultivations, to be signed by the members.—(Signed)—PASTEUR.”

Experiments proposed :—Five rabbits, which have received a feed sprinkled with microbes of chicken-cholera, will be put with fifteen healthy rabbits in an enclosure one meter square on solid ground.

Explanation of the despatch :—

We will give proof to the Commission that for each of our experiments we use the same microbe and same cultivations; and for this purpose the expert named by the Commission shall examine, with microscopic preparations of our cultures, and make drawings of the microbes which he shall sign as a guarantee of their correctness.

The representatives of M. Pasteur having attended, the following questions were then put and answered :—

The Chairman : If the experiment described in the telegram to M. Pasteur is successful, have you any objection to make yourselves, or allow the expert of the Commission to make, further experiments to prove that contagion takes place under less favourable conditions than those of the experiment above mentioned; say, in artificial burrows, or in a larger space, or with fewer rabbits?

Dr. Germont : You have sent a special despatch to M. Pasteur, who has made a direct reply. We cannot modify the instructions which he has given us. It was useless, otherwise, to ask M. Pasteur for instructions. Our position now is the same as before. We can only make the experiments which we are authorized to make.

Mr. Bell : Are you willing to make the experiment authorized by M. Pasteur, not only once (which would be of no value) but several times over; each experiment under identical conditions—for instance, to place in each of six enclosures two infected rabbits and five healthy rabbits. Each enclosure to contain 2 square metres?

Dr. Germont : No; we refuse to do that.

The representatives of M. Pasteur then withdrew.

Mr. BELL moved, “That the representatives of M. Pasteur be requested to make their contagion experiments as authorized by M. Pasteur in his telegram received this day, and that such experiments should begin on Rodd Island on Monday.”

Dr. BANCROFT seconded. The motion was agreed to.

Mr. Pearson had left the room before the adoption of the motion.

It was decided to employ F. Ambrose at a salary of 25s. per week, with 5s. per week additional should he prove suitable.

The Committee adjourned to 10.30 a.m. on the following Monday.

MONDAY, 18 JUNE, 1888.

The Committee met at 10.30 a.m.

Present :—

New South Wales : W. CAMAC WILKINSON, Esq., M.D., M.P. (Chairman).
Victoria : A. N. PEARSON, Esq.
New Zealand : A. DILLON BELL, Esq.
Queensland : JOSEPH BANCROFT, Esq., M.D.

The Committee deliberated and adjourned to 2.30 p.m. on the following day.

TUESDAY,

TUESDAY, 19 JUNE, 1888.

The Committee met at 2:30 p.m.

Present :—

New South Wales : W. CAMAC WILKINSON, Esq., M.D., M.P. (Chairman).
Victoria : A. N. PEARSON, Esq.
New Zealand : A. DILLON BELL, Esq.
Queensland : JOSEPH BANCROFT, Esq., M.D.

The Committee deliberated and adjourned to 2:30 p.m. the following day.

WEDNESDAY, 20 JUNE, 1888.

The Committee met at 2:30 p.m.

Present :—

New South Wales : W. CAMAC WILKINSON, Esq., M.D., M.P. (Chairman).
Victoria : A. N. PEARSON, Esq.
Queensland : JOSEPH BANCROFT, Esq., M.D.

Also present :—

South Australia : A. S. PATERSON, Esq., M.D.
 E. C. STIRLING, Esq., M.D.
Victoria : E. H. LASCELLES, Esq.

The Committee deliberated and adjourned.

SECTION VII.

REPORT of the Experiment Committee.

At our first meeting steps were taken to secure a suitable place for the conduct of the laboratory experiments, a list of which had been drawn up by the Commission. For this purpose Dr. Bancroft and Dr. Wilkinson decided to visit the University, in order to find out whether the physical laboratory, which Professor Threlfall had offered to the Commission for this work, would be a suitable place. The building and surrounding grounds were inspected, but inasmuch as the building was not likely to be ready for some weeks, the idea of undertaking the work in this laboratory was abandoned.

Mr. Pearson and Mr. Quin at the same time made inquiries about suitable quarters in the neighbourhood of Sydney, and agreed to recommend that a certain house with suitable grounds should be inspected at Summerhill. During the next few days we visited Clark Island, Shark Island, and the late Baron Macleay's laboratory at Watson's Bay, accompanied by Mr. Oliver, the Under Secretary for Lands, and Mr. Bruce, the Chief Inspector of Stock. Clark Island was considered to be too rocky for the purpose, and we found that the late Baron Macleay's laboratory had been converted into a private house. Shark Island was considered to be in every way suitable, but was not available, being the chief place for the quarantining of imported stock. Later on we visited the quarantine station at Randwick, which had been suggested to us by Mr. Bruce, but as we found that this station was next to a very valuable poultry farm, we thought it unwise to select this ground as the site for experiments with fowl-cholera.

As no suitable place yet offered itself, Mr. Pearson strongly advised that a certain house at Summerhill should be inspected. Here we might have leased a small paddock a short way from the house. The great objection to choosing a house placed in a populated neighbourhood became apparent upon further inquiry. We learned that if a petition signed by the residents had been presented to the Board of Health, it would have had the effect of putting an end to all experimental work.

At this stage, therefore, we decided that, in order to run no risk of molestation, it would be best to obtain some piece of Crown Land at a convenient distance from any centre of population. With this object in view we proceeded to interview the Hon. the Secretary for Lands (Mr. Garrett). In Mr. Garrett's absence we saw the Under Secretary (Mr. Oliver), and urged upon him the necessity of the Government placing at our disposal some unoccupied land belonging to the Crown. We even suggested that Shark Island should be given to us for our experimental work. Mr. Oliver advised us to visit the Honorable the Secretary for Mines (Mr. Abigail), under whose control Shark Island is; and accompanied by Mr. Oliver, we accordingly did so. Mr. Abigail said he could not comply with our request in regard to Shark Island; but instructed the Inspector of Stock to find out whether the Crown land bordering Sirius Cove could not be secured for us. The next day, with Mr. Bruce, we visited this spot, and found it very suitable for our work. On the day following this visit, accompanied by Mr. Coles, of the Colonial Architect's Office, we visited this site, in order to arrange for necessary buildings. But no sooner was this done, and it became known that we thought of carrying on our work at this place, than objections were raised to our plan by the Board of Health.

After

134 ROYAL COMMISSION OF INQUIRY INTO SCHEMES FOR THE EXTERMINATION

After some further communication with the Department for Lands, Rodd Island was definitely selected as the site for the experimental station. Mr. Coles visited the island, and no time was lost by him in clearing it and erecting thereupon the necessary buildings. Acting under our instructions, Mr. Coles entered into the work of planning and erecting the necessary buildings and enclosure, with an energy that left nothing to be desired. The plans and general arrangements were drawn up chiefly by Mr. Pearson and Mr. Coles, the fuller details of which are furnished by Mr. Pearson for the information of the Commission.*

Meanwhile Mr. Pasteur's representatives had been carrying on their work in the laboratory of the Board of Health, and, on Tuesday, 8th May, we were informed by letter that these preliminary experiments, with a view to test the virulence of the microbes of chicken-cholera, were completed, and M. Pasteur's representatives were ready to put the scheme of M. Pasteur upon its trial. We informed Dr. Hinds that Rodd Island would probably be ready in a week or two for experimental work, and forwarded to M. Pasteur's representatives the schedule of experiments prescribed by the Commission. At the same time we asked Dr. Hinds whether M. Pasteur's representatives desired to supplement this schedule by any suggestions of their own.

In answer to our communication we received a letter signed by all the representatives of M. Pasteur:—

To the President of the Commission for the Destruction of Rabbits.

Sir,

Union Club, Sydney, 10 May, 1888.

We beg to acknowledge the receipt of the letter, dated 8th May, from the Committee, informing us that it will shortly be ready to commence experiments of its own upon the method proposed by M. Pasteur for the destruction of rabbits in Australia, and of the list of investigations which it is intended to pursue.

We are unable to accept any participation in these investigations.

M. Pasteur has instructed us to make certain experiments having for their object—strictly in accordance with the conditions for the reward published by the New South Wales Government—the demonstration that his method is at once efficacious, practical, and without danger to the domestic animals mentioned in the note of the Government.

This demonstration we are prepared to make; but we cannot take any part in the proceedings of the Committee, when it seeks to pursue scientific investigations foreign to the purely practical question upon which it is going to decide.

When the Commission is willing to examine the method of M. Pasteur, we shall be at their disposal to make, ourselves, in the presence of the Commission, the necessary experiments.

We have, &c.,

D. GERMONT.
FRANK HINDS.
A. LOIR.

This letter received our careful consideration on Monday, 14th May. The attitude adopted by M. Pasteur's representatives seemed to us so serious, and so difficult to understand, after their statements to the Commission, that we decided to call them before us without further delay, in order to hear their own explanation of the contents of this letter. We made an appointment to meet them the same Monday at 2:30 p.m., when M. Pasteur's representatives were in attendance. We expressly asked them to explain why, after having accepted the proposals and arrangements made by the Commission, they stated in their letter that they were "unable to accept any participation in these investigations." We produced in their presence, and read, the report of the proceedings of the Commission, in which they stated they would perform, in conjunction with Dr. Katz, the experiments prescribed by the Commission. They did not hesitate to repudiate any such agreement, stating at the same time that they had no idea that such an arrangement had been accepted for them by Dr. Hinds. They argued that they had come to Sydney on the strength of representations made to M. Pasteur by the Agent-General for New South Wales, for the express purpose of performing a definite series of experiments drawn up for them by M. Pasteur himself, and that, as agents for M. Pasteur, they had only power and authority to carry out this definite series of experiments. They could not deviate in the least from M. Pasteur's set plan. They therefore could not undertake any other experiments than those expressly prescribed by M. Pasteur. Further, they refused to give us any microbes of fowl-cholera until they had completed the programme of experiments that M. Pasteur had authorized them to perform. This was their attitude, and we could do no more than ask them to furnish us with a list of the experiments which M. Pasteur had set down for their guidance. We had no power to modify in the least the programme of experiments arranged by the Commission.

While, however, we accepted no responsibility in the experiments arranged by M. Pasteur himself to test the efficacy and safety of his method, we considered it only reasonable to allow M. Pasteur's agents to carry out their preliminary experiments. We did this more readily because M. Pasteur's agents declined to hand over their microbes to the Commission until these preliminary experiments had been completed. We did not see that any harm—beyond, indeed, a loss of time—could come from allowing M. Pasteur's agents to superadd to our intended experimental work any separate experiments which they might have been instructed by M. Pasteur to perform. We wished, in fact, to allow them to put their own case in their own way. Without, therefore, in any way altering our intention to perform the schedule of experiments prescribed by the Commission after M. Pasteur's should be finished, and desiring to treat M. Pasteur with every consideration, we asked M. Pasteur's representatives to furnish us with a list of the experiments they intended to perform. On the day after this interview took place the members of the Committee had to leave Sydney to attend the prearranged meetings of the full Commission at Melbourne and Adelaide. It thus happened that the reply of M. Pasteur's representatives, furnishing their list of proposed experiments, was not delivered to us until we had left Sydney, and it was not possible to consider this furnished list until we reassembled in Sydney on 11th June.

This letter and list of experiments are here appended, and special attention is directed to the terms and conditions of the experiments:—

To the President of the Committee for Rabbit Destruction,—

Sir,

"The Albany," Bligh-street, Sydney, 14 May, 1888.

We have the honor to lay before you, in accordance with your request, a list of the experiments which M. Pasteur has instructed us to make before you for the purpose of demonstrating—

- (1) The efficacy of the disease which he has proposed for the destruction of rabbits;
- (2) The immunity which is enjoyed by domestic animals with regard to the agent of this disease.

I.

* See Section VIII of the Report, page 136.

I. Experiments showing the rapidity and certainty of the action of chicken-cholera :

Three sets of rabbits of ten each will be taken.

- (a) The first ten will have a single feed of green grass, over which a culture of microbes has been sprinkled, given to them.
- (b) The second ten will have a single feed of chaff, sprinkled in the same manner.
- (c) The third ten will have a single feed of oats, treated as above.

II. Experiments showing the immunity of domestic animals to the microbe of chicken-cholera. The following animals will be the subjects of these experiments :—Two sheep, two cows, two lambs, two calves, two horses, two pigs, two goats, and two dogs.

A culture containing the microbes of chicken-cholera will be sprinkled over one of the feeds which each animal will receive daily for six days. These animals will be watched for ten days after the last feed.

When the Committee is satisfied that the disease is not dangerous to domestic animals, we will make a third experiment—really the only one which is at the same time practical and demonstrative. It consists in testing the method upon an area, enclosed with rabbit-proof fencing, in a part of the country infested with rabbits. At the conclusion of each experiment a statement of its nature and result will be drawn up, either by us or by the expert nominated by the Government and signed by both parties.

We have, &c.,

D. GERMONT,
FRANK HINDS,
A. LOIR.

It will be seen that experiments (1) and (2) detailed in Dr. Hinds' letter, although quite insufficient and inconclusive, whatever their results might be, were such as we might fairly allow to proceed, reserving, of course, to ourselves the right to impose, after their conclusion, the further tests which obviously suggest themselves as necessary, and which were in fact provided for in the schedule of experiments already prescribed by the Commission. But experiment (3), that is, the proposed experiment in the open country, is on quite a different footing. Besides the fact that the nature of this proposed experiment was in no way defined, it was impossible to allow its performance until we should first have satisfied ourselves that by the introduction of fowl-cholera into the country there was a real and substantial chance of exterminating the rabbits.

It has not yet been proved that true fowl-cholera exists in this country, so that its introduction would clearly be an undesirable innovation, and could only be recommended—if recommended at all—on the distinct ground that it would, in some way, cause much more good than harm.

M. Pasteur's proposed experiments (1) and (2)—even supposing their results were successful in highest degree—were so loose, and so wanting in scientific accuracy with regard to the points especially requiring demonstration, that they could not reasonably be held to justify us in allowing free dissemination of fowl-cholera in the open country.

On our return to Sydney a further interview with M. Pasteur's representatives was at once arranged, and every possible effort was patiently made to impress upon them the unsatisfactory nature of their proposed "demonstration," and the primary necessity of satisfying the Committee, among other matters, of the spread of fowl-cholera from rabbit to rabbit before any introduction of the disease into the open country would be permitted.* M. Pasteur's representatives, however, for reasons already mentioned, positively refused to make any further experiments with fowl-cholera until they had gone right through with experiments (1), (2), and (3) in full accordance with the instructions received from M. Pasteur. They also refused to hand over to us either their microbe cultures, or any part of them, or any rabbits affected therewith or the bodies of any rabbits that had died from fowl-cholera, until the conclusion of their own experiments, including the so-called demonstration in the open country. In other words, they refused either to demonstrate with any scientific precision the spread of the disease from rabbit to rabbit or to enable us to do it. They only offered to perform a series of experiments, so inadequate and inconclusive as to be of little value; and indeed designed, as it would appear, either to avoid any risk of failure or to prevent the possibility of detecting failure if it should occur. On becoming convinced that experiments (3) in the open country would not be permitted until some proof was given of the likelihood of the spread of chicken-cholera from rabbit to rabbit, M. Pasteur's agents at our suggestion agreed to ask further instructions from M. Pasteur on this most important point. M. Pasteur's representatives were, in their judgment, so tied down to the exact instructions of M. Pasteur that they refused to take any further action until they had asked leave from M. Pasteur to make the "demonstration" we required. It was therefore decided that a cablegram should be sent directly to M. Pasteur asking permission for his agents to make an experiment showing the contagion of this disease among rabbits, and asking also that cultivations of microbes of chicken-cholera should be given to the Commission for the purpose of supplementing the experiments of his own representatives.

We therefore recommended the Government to despatch the following cable message to M. Pasteur in the name of Dr. Germont which was accordingly done :—"Pasteur, Paris.—Cablegram, 16 Juin 1888.—Commission ne peut laisser faire vos expériences sur une large échelle avant que la contagion de lapin à lapin ait été démontrée—même après cela elle ne peut vous promettre d'avance de nous autoriser à faire l'expérience sur une large échelle. Autorisez-vous expérience de contagion suivante :—Mêler cinq lapins infectés dans une cage avec vingt lapins sains, et observer les résultats pendant six jours? Commission aussi demande lapins infectés pour expériences particulières."

Translation.—"Pasteur, Paris.—The Commission cannot allow your experiment to be made on a large scale before contagion from rabbit to rabbit has been proved. Even after that it cannot promise beforehand to make experiments on a large scale. Do you authorize the following experiment in contagion :—To mix five infected rabbits in a cage with twenty healthy rabbits, and observe the results for six days? The Commission also asks for infected rabbits for special experiment."

M. Pasteur agreed to a contagion experiment being performed, but under such conditions that we held the experiment to be of little practical value.

The cablegram from M. Pasteur with regard to the contagion experiment and the conditions prescribed by him together with the explanation of his own agents is here appended.

Translation.—"Contagion great in the burrows. Make experiments demanded on solid ground of a square metre. Wait before giving microbes of dead rabbits, but give drawing of the organisms of the cultivations to be signed by the members."

"Experiments proposed :—Five rabbits, which have received a feed sprinkled with microbes of chicken-cholera, will be put in with fifteen healthy rabbits in an enclosure 1 metre square on solid ground."

"Explanation

* A full account of this interview will be found in the Minutes of the proceedings of the Committee.

"Explanation of the despatch :—We will give proof to the Commission that for each of our experiments we use the same microbe and same cultivations; and for this purpose the expert named by the Commission shall examine with microscope preparations of our cultures and make drawings, which he shall sign as a guarantee of their correctness."

We had a further interview with M. Pasteur's representatives, and the final question put by our Chairman, and the answer of Mr. Pasteur's representatives thereto here follow, and speak for themselves :—

The Chairman asked, "If the experiment described in telegram to M. Pasteur is successful have you any objection to make yourselves, or allow the expert of the Commission to make, further experiments to prove that contagion takes place under less favourable conditions than those of experiment above mentioned (say) in artificial burrows, or in a larger space, or with fewer rabbits?"

To this Dr. Germont replied, "You have sent a special despatch to M. Pasteur, who has made a direct reply. We cannot modify the instructions which he has given us. It was useless otherwise to ask M. Pasteur for instructions. Our position now is the same as before. We can only make the experiments which we are authorized to make."

The same question, asked by Mr. Bell, and Dr. Germont's reply here follows :—

Mr. Bell then asked, "Are you willing to make the experiment authorized by M. Pasteur, not only once (which would be of no value), but several times over; each experiment under identical conditions; for instance, to place in each of six enclosures two infected rabbits and five healthy rabbits; each enclosure to contain 2 square metres?"

Dr. Germont replied, "No; we refuse to do that."

With the exception of Mr. Pearson we thought it best to allow them to undertake this contagion experiment at their earliest convenience on Rodd Island, pending any further action of the full Commission.

It is important to observe M. Pasteur orders his representatives to wait before they hand over their microbes to the Commission for the purpose of experiment.

We now desire briefly to summarize our negotiations with M. Pasteur's representatives since the sending of the first cable message to M. Pasteur. M. Pasteur agrees to a contagion experiment being made, but he stipulates it be made by putting twenty-five (25) rabbits, five (5) of them sick with fowl-cholera, into an enclosure a yard square, and keeping them there six (6) days. He refuses to allow the Commission to have any microbes for any experiments of their own, but offers them instead some "drawings" of the organisms. We felt that our only duty was to leave all further action in the hands of the full Commission. Throughout our negotiations we have striven with the utmost patience to find some common basis of experiment upon which the Commission and M. Pasteur's representatives could act in harmony. The outcome of these negotiations is that M. Pasteur's representatives have obtained permission to give the "demonstrations" of contagion above described. This permission is coupled with a refusal to hand over to the Commission any microbes for experiments of their own. We need hardly add that the conditions of the experiments are such that whatever the result may be the experiment is of little value for testing the spread of chicken-cholera from rabbit to rabbit; in other words, of testing the efficacy of M. Pasteur's scheme. It will now be for the Commission to take up the matter at this point and deal with it. Before the Commission we shall be prepared to make our suggestions as to the course to be pursued.*

July 3, 1888.

W. CAMAC WILKINSON.

SECTION VIII.

DESCRIPTION of the Laboratory Buildings at Rodd Island.

In accordance with the recommendation of the Commission efforts were made in the first instance to obtain a suburban house, with water and gas laid on, having about an acre of land attached, and containing a sufficient number of rooms to provide accommodation for the laboratory, and for the chief expert, his assistant, cook and handy man. It was intended, had this arrangement been carried out, to have done little more in the way of building than to simply enclose a piece of land about 100 feet square; surround and roof this with fly-proof wire gauze, and construct, in open connection therewith, a large shelter shed with stalls and pens. Messrs. Sheerin and Hennessy, architects, of Pitt-street, in response to private inquiries from Mr. Pearson, furnished drawings of such an enclosure, and also a rough estimate of the cost. They estimated that the enclosure and shed, closed in with rat proof wire netting, would cost about £300. If the enclosure were covered with mosquito proof wire gauze the cost would amount to £600. The wire gauze would, however, they estimated, be saleable afterwards for about £150; the net cost being therefore reduced to about £450. Messrs. Sheerin and Hennessy stated that if the work were placed in their hands, they would put up the enclosure and shed, and also fit up the laboratory rooms with gas and water connections, cupboards, tables, and so on, within a week.

In consequence, however, of the final decision of the Government authorities to place Rodd Island at the service of the Commission for the purpose of laboratory experiments it became necessary to make much more extensive building arrangements.

Rodd Island, situated in Long Cove, opposite the Callan Park Lunatic Asylum, contains, above high-water mark, about 1½ acres, roughly speaking, but of this only about half an acre is suitable for building purposes, the rest being either too rocky or too steep to be of any use without reclamation or levelling. When the island was placed at the service of the Commission it was unoccupied, and covered with scrub. It is now covered on every available spot with a collection of buildings, which present an interesting appearance, and which it is hoped will, after they have served their immediate purpose, become permanently useful for bacteriological work and the investigation of stock diseases. The

* The substance of this Report, together with the correspondence referred to in it, was submitted to the Commission at a meeting on 21st June, when it was unanimously agreed that the experiments proposed by the representatives of Mr. Pasteur were not satisfactory. (See the Minutes of the Proceedings of the Commission on page 30.)

The buildings consist of a large enclosure covered in with wire gauze, and connected with a shed containing stalls and pens, an aviary, a laboratory containing four rooms, a dwelling-house containing six rooms and a kitchen, with servants' quarters. Water-tanks have been fixed in convenient places, and a wharf constructed, with a road leading therefrom. The general arrangement of the buildings is shown in the accompanying sketch plan.

The enclosure and shed cover nearly a quarter of an acre of ground, thus affording room for horses, cattle, sheep, pigs, birds, &c., to move about amongst one another in an easy and natural manner. There are also artificial burrows constructed for rabbits. Thus it will be possible not only to perform isolated feeding experiments with microbe-charged food, but also to conduct, on a small scale, a general experiment in which the animals shall be placed under conditions similar to those of the open country. By allowing the birds and beasts to mix freely together an almost infinite number of transmissions of the microbes from one animal to another may be obtained. The conditions of the test in this enclosure will be more stringent than in the open country, on account of the confinement of the animals within such a limited area; and if no serious outbreak of disease should occur within the enclosure, there will be good grounds for concluding that none is likely to occur outside.

The object of the wire gauze is to keep away birds and insects, which, by flying to and fro, might carry infectious matter with them. The wire gauze rests upon wire netting of 4-inch mesh, which in its turn rests upon a number of wire ropes, stretched right across, over the ridge beam and the side posts, after the manner of a tent. A barbed wire fence inside the enclosure protects the gauze from injury by the larger animals. The entrances to the enclosure are double, so that the outer door may be closed before the inner one is opened. The shed is constructed of corrugated iron, with a brick basement. The drainage from the stalls will run into a gauze-covered tank, containing disinfecting material. All ventilating openings are covered with wire gauze.

Artificial burrows, which it is believed were first used by Mr. Pearson, in Victoria, for experiments on poisoning rabbits, are very simply constructed, as shown in the diagrams which are appended to this report. [See Diagrams at end of Appendices.]

It will be seen that they are simply small winding trenches cut in the surface of the ground, covered over with boards and then with loose material. The boards are made in short lengths so that the burrows may be easily opened when required. The entrances to the burrows are made as natural in appearance as possible. When wild rabbits have no other cover they go into these burrows quite readily.

The laboratory contains a large general working-room, with tables, sink, shelves, incubator stands, gas and water connections; a microscopic room, with a south-east aspect so as to be as much protected as possible from the daily variations of temperature; a storeroom for apparatus, &c.; and a wash-house with sink, copper boiler, and a furnace for burning dead carcasses and infected matter. The gas is supplied in cylinders from the railway works at Redfern; from the cylinders it is passed in a small gasometer with constant pressure, and to which is attached an automatic tap, which shuts off or turns on according as the gasometer rises or falls. It was at one time thought that it would be possible to conduct the gas from the mainland by a main pipe laid under the water; but the difficulty of preventing an accumulation of water in the bend of the main caused this idea to be abandoned.* The laboratory as well as the house and kitchen are constructed of corrugated iron, the walls being double and packed with sawdust.

The house contains three bed-rooms, a bath-room, a large dining-room, and a large library and office room. The kitchen quarters are commodious. The cook's room adjoins the kitchen; but it is arranged that the handy man, who will attend to the stables, will sleep in a tent. There are several water-tanks, and there is sufficient roofing on the island to give an abundant water supply.

An aviary, 16 feet square, half enclosed and roofed in, and half open, is provided to accommodate birds before they are put into the experimental enclosure. Arrangements will probably be made for accommodating the larger animals, previous to their being experimented upon, on the Callan Park Asylum reserve; and the smaller animals will be kept in hutches.

The whole of the above buildings have been put up in less than two months, the work having been carried out with admirable expedition by the Colonial Architect's Department. The sum spent upon the work is said to amount to over £2,500, the work having been specially costly owing to the water carriage. Over forty men were at one time employed on the island.

[See sketch plan of Rodd Island and diagrams I to VII.]

SECTION IX.

REPORT by Dr. Katz on the Rabbit brought from New Zealand by Sir James Hector†.

Sir,

Rodd Island, 19 November, 1888.

Referring to your letter, dated 16th instant, and received by me yesterday, I have to report that the rabbit, brought from New Zealand by Sir James Hector, and transferred to Rodd Island on the 16th June last, has so far not been made the subject of experiments. All that I can state is, that it is still alive. The tumour which it showed, on arrival, at the left side of the body, over the ribs, has enlarged since. The shape of this tumour, which is firm, elastic on touch, and covered with dense hair in like manner as the body throughout, is a semi-oval, the longer axis of which is parallel to the vertebral column. Its dimensions at the base are at present, 10 centim. (4 inches) in length, and 8 centim. ($3\frac{1}{8}$ inches) in width. In other respects the rabbit appears in a normal condition. * * *

H. Mahon, Esq., Secretary Rabbit Commission.

I am, &c.,

OSCAR KATZ.
SECTION

* The supply of gas by means of cylinders having on trial proved inconvenient, this arrangement was eventually replaced by a gasolene generator.

† This is the rabbit suffering from bladder-worm disease, referred to in Mr. Coleman Phillips' evidence at the top of page 117.

SECTION X.

REPORT on the experiments carried out by M. Pasteur's representatives (M. Loir, Drs. Germont and Hinds), with a view to demonstrating the efficacy and safety of the introduction of the microbes of chicken-cholera as a means for the extermination of Rabbits in Australasia.

THESE experiments of demonstration took place at Rodd Island, near Sydney, and lasted from 7th July till 4th August, 1888.

As a detailed account of the arrangement of these experiments, of the results they yielded, and of other noteworthy facts is given in the attached Appendices A-F, I need only confine myself here to summarising their main contents.

One portion of the experiments was, as stated above, devoted to showing the efficacy of the microbes of chicken-cholera, both as regards their power to kill rabbits by feeding them on infected food, and the contagiousness of the fatal disease which they set up in rabbits.

With reference to the first point, namely, that the microbes under discussion are fatal to rabbits when administered to them along with food, I am perfectly satisfied, taking into consideration not only the result of the experiment recorded in Appendix A, but also the results of experiments made for the purpose of controlling the virulence of the microbes given to domestic animals. (*Vide* below.) The quantity of infected broth as added to food (cabbage leaves, turnip leaves, carrot tops, green barley, chaff, oats) ranged from 1 ccm. to about 3 ccm.* for each rabbit;† the time which it took until death, from twenty to forty hours. I may here at once point out, although I shall mention it again later on, that death did not always follow after infected food had been placed in the boxes in which the animals were confined. The number used for each experiment of such a nature amounted to from two to ten specimens. Part of such lots always died in consequence of infection; and the reason for the survival of the other part—now and then, as may be seen in Appendices A and D, all of the same experiment died—may be found by assuming that they perhaps did not partake of the infected meal at all (especially when the animals were confined in one and the same box, and not in separate compartments); or, possibly, that they ate only a slight portion of the infected broth, not sufficient to infect; or, lastly, that perhaps this infected broth had become dry, and in this way lost its virulence, when it was eaten by the surviving rabbits. Whatever the cause of such occurrences may have been, such rabbits were not proof against infection by the micro-organisms in question, because they ultimately succumbed after being fed again. (*Vide Appendix E.*)

For demonstrating the presence of the *bacteria* of chicken-cholera in the dead subjects, M. Pasteur's delegates made use of a Zeiss' microscope placed at their disposal; but although the use of homogeneous immersion objectives and of my aniline dyes was offered to them, they contented themselves with demonstrating preparations of fresh blood from the heart by means of Zeiss' F (dry objective, Oc. I and II). In all such preparations micro-organisms were seen not unlike those of chicken-cholera. A demonstration, however, of such a description could hardly have been convincing by itself had it not been aided by the appearance at the *post-mortem* examinations of certain organs and tissues (*e.g.*, lungs, pleura, pericardium), which each time exhibited certain pathological changes met with in rabbits dead of that particular disease, and also by the results of occasional inoculations into healthy rabbits from blood of those which died of the disease.

I feel certain that the microbes of chicken-cholera were present in each of the cases in which a *post-mortem* examination was made, and that they must be looked upon as the cause of the death of the animals under consideration. It stands to reason that the same took place with regard to all those which died under the same conditions and after the same treatment, but on which a *post-mortem* examination was not made.

As to the second point, namely, that the fatal disease set up by the microbes in rabbits, either by inoculation or by feeding, should be contagious among them, two sets of experiments were conducted:

First.—*Five* rabbits were inoculated‡ with about two drops each of a broth-culture of the microbe, and thereafter placed in an enclosure of 1 square metre area with *twenty* other healthy rabbits. They were kept under observation for a period of *seven* days. The *five* inoculated ones died within fourteen and a half hours; of the remaining *twenty* not inoculated ones *five* died within seventy-one hours, and from that time until the conclusion of the experiment no more died.

This experiment does not admit of any inference being drawn from it as to its practical value, because not one of the dead rabbits of any of the descriptions which were left in the enclosure to the last was subjected to an examination.

Out of *twenty-five* control rabbits (*vide Appendix B*) *three* died within five days and five hours; an examination of these did not take place either.

Secondly.—*Five* rabbits in one box were given some cabbage leaves infected with five ccm. of a broth-culture of the microbe, and two and a half hours afterwards placed in an enclosure of one square metre area with *twenty* healthy rabbits. (*Vide Appendix C.*) They were kept under observation for a period of *ten* days. Within this period *eleven* in all died; among them *three* (specially marked) of the *five* to which infected food had been given, while *one* of the latter survived. (*Vide Appendix E, Series III, conf. also above.*) Whether the *ffth*, which it had been forgotten to specially mark, as forming one of the originally infected ones, was among the dead ones or not could not be decided. This

* One cubic centimetre is equal to sixteen minims; one minim is generally considered as equal to one drop.

† All the rabbits used in the experiments here were wild rabbits from Carrathool, near Hay, N.S.W.

‡ Inoculation means here always subcutaneous application.

This experiment, unsatisfactory as it was as regards its arrangement, can, therefore, hardly be utilized for drawing any exact conclusions as to its practical value. All that I can state in reference to the result of this experiment is that on examination of *three* dead rabbits which were not specially marked, that is to say, which had not been given infected food [with the exception possibly of one (*vide* above)], the result as to presence of micro-organisms and pathological changes were the same as usual. Of the *four* original ones (specially marked) not one was examined, but there is no room for doubt that they died in consequence of their having eaten the microbes, since two other rabbits fed the same day on infected food under the same conditions (*Appendix D*) could be shown to have died of the disease.

A control experiment on twenty-five rabbits was not made.

The other portion of the experiments, as stated in the heading, tended to show the safety of the introduction of the microbes of chicken-cholera. It was to be demonstrated that a number of useful animals were immune from becoming infected with such microbes.

These animals consisted of an old horse, a cow (with calf at foot), a sheep (young merino ewe), a goat (in kid), a pig (young sow), and a young dog (half-bred collie). All these animals, with the exception of the calf, which was not experimented upon at all, were given once a day for a period of *five* days varying quantities of broth-cultures of the bacterium of chicken-cholera in or on various articles of food, as may be seen in *Appendix D*. Then came a resting period of *five* days, at the end of which all the animals, with the exception again of the calf, were fed once more on very much larger quantities than before of infected broth in or on food. From that date they were kept under observation for *six* more days, according to the programme, but in reality for *twelve* days up to date (August 7).

The result was a favorable one. At no time did any of the above animals show signs of illness; they presented always normal appearances.

Of course, control experiments on rabbits were made each time when infected food was given to the above domestic animals (*Vide Appendix D*). Of these control rabbits, which always numbered more than one at a time, part often survived, an occurrence already commented upon in the foregoing lines.

The mere fact of this occurrence is no doubt sufficient to render the ultimate result less transparent than it would have been if all the control rabbits had died; but still I incline to the opinion that the microbes of chicken-cholera applied in the way described are harmless to domestic animals of the above description.

Rodd Island, 7 August, 1888.

OSCAR KATZ.

To the Chairman Experiment Committee Rabbit Commission.

I beg to forward the following account of the experiments performed by M. Pasteur's agents, under the supervision of Dr. Katz, and agree fully with the general tenor of Dr. Katz's remarks and inferences.

W. CAMAC WILKINSON,

August 18, 1888.

Chairman Experiment Committee, Rabbit Commission.

APPENDICES.

A, B, and C.—Details of experiments intended to demonstrate the efficacy of the disease.

D.—Details of experiments intended to demonstrate the safety of the disease, viz., the immunity of certain domestic animals.

E.—Details of further experiments upon rabbits surviving from previous experiments.

F.—Explanation of the diagrams accompanying this Report.

Appendix A.

DETAILS of experiment intended to demonstrate the efficacy of the Disease.

July 7th—*Three* rabbits were placed in one box (Diag. I, c.) and fed at 3 p.m., upon cabbage leaves and carrot tops sprinkled with about 10 ccm. of a broth-culture of the microbe of chicken-cholera.

Annotation.—Most of the infected food was eaten by 10 p.m. on the 7th, and by 11 p.m. the pieces of leaves, &c., not eaten, were trodden flat on the bottom of the box and partly covered with droppings. The next day food was given to them as usual.

Result.—

July 8th—*One* died between 8:30 p.m. and 9:45 p.m., or in 29½ to 30½ hours after being fed.

July 8th and 9th—*One* more died between 11 p.m. of 8th and 4:5 a.m. of 9th, or in 32 to 37 hours after being fed.

July 9th—*One* more died between 4:5 a.m. and 7:10 a.m., or in 37 to 40 hours after being fed.

On examination the presence of micro-organisms morphologically similar to those of chicken-cholera was demonstrated in fresh preparations of blood from each of the three. (Zeiss F.)

Appendix B.

DETAILS of experiment intended to demonstrate the efficacy of the Disease.

July 7th—*Five* rabbits were inoculated at 2:45 p.m., with about two drops each of a broth-culture of the microbe of chicken-cholera, and placed immediately thereafter in a box 1 metre square (Diag. I, a), containing twenty other fresh rabbits.

Annotation.—The box referred to consisted of a four-sided wooden enclosure 1 metre square, having for its bottom the paved floor of a stable stall (Diag. I, 1), and for its top a covering of rabbit-proof wire netting.

Conditions as to treatment.—All the rabbits to be fed twice a day; the carcasses of dead rabbits to be left in the box until the conclusion of the experiment.

Result.—

July 7th—*One* died between 10:40 p.m. and 11:15 p.m., or 8 to 8½ hours

July 8th—*Two* more died between midnight and 2:15 a.m., or 9 to 11 hours

Two more died between 2:15 a.m. and 5:20 a.m., or 11½ to 14½ hours

(The above *five* were the inoculated rabbits.)

July 9th—*One* more died between 11 p.m. of 8th and 4:5 a.m. of 9th, or 32 to 37

hours

One more died between 1:45 p.m. and 3:50 p.m., or 46½ to 48½ hours

One more died between 8:25 p.m. and 9:45 p.m., or 53 to 54½ hours

July 10th—*One* more died between 10:15 a.m. and noon, or 67 to 68½ hours

One more died between noon and 1:45 p.m., or 68½ to 70½ hours

Annotation.—On the 11th July it was noted that the carcasses of rabbits previously dead were covered with dry lucerne stalks left over after feeding. It was observed at the same time that the bottom of the control experiment box (*v. below*) was partly covered with lucerne stalks also. On the 12th July it was observed that very little food was left at the bottom of either box.

July

140 ROYAL COMMISSION OF INQUIRY INTO SCHEMES FOR THE EXTERMINATION

July 14th—

*Conclusion of the experiment—*At 4 p.m. the experiment was concluded, and the *fifteen* surviving rabbits were liberated from the box.*Annotation—*An examination of the dead rabbits did not take place.*Control experiment—*July 7th—*Twenty-five* rabbits were placed in a box 1 metre square (Diag. I, *b*) similar in every respect to that described above.*Conditions as to treatment—*To be kept under exactly the same conditions as the other twenty-five rabbits.*Result—*July 9th, 10th—*One* died between 10.45 p.m. of 9th and 7.15 a.m. of 10th.*Annotation—*The skin on the nose of this rabbit had been removed by injury on the 7th July.July 11th—*One* more died between 9 a.m. and 11 a.m.July 12th—*One* more died between 7.40 p.m. and 8 p.m.July 14th—At 4 p.m. the experiment being concluded, the *twenty-two* surviving rabbits were removed from the box*Annotation—*An examination of the dead rabbits did not take place.

Weather during the course of the experiments referred to in Appendices A and B. Fine weather prevailed during the course of the experiments until the evening of the 13th July, when one or two heavy showers fell. From then until midday of the 14th (when the experiments were concluded) the weather was again fine, the air being cool but dry.

Appendix C.

DETAILS of experiment intended to show the efficacy of the disease :—

July 17th—*Five* rabbits were fed, at 1.30 p.m., upon cabbage-leaves sprinkled with 5 ccm. of a broth-culture of the microbe of chicken-cholera. At 4 p.m. these five rabbits (having finished their meal of infected food) were placed in a box 1 metre square (Diag. III, *a*) amongst twenty other fresh rabbits.

Annotations—(a) Four out of the five fed upon infected food were ear-marked with a "fork" taken out of the tip of the off ear just before being placed in the box amongst the other rabbits. The first of the five was inadvertently placed in the box without being specially marked.

(b) The box referred to consisted again of a four-sided wooden enclosure 1 metre square, having for its bottom the paved floor of a stable stall (Diag. III, 6), and for its top a covering of rabbit-proof wire netting.

*Conditions as to treatment—*All rabbits in the box to be fed twice a day, and the carcasses of any that die to be left in the box until the conclusion of the experiment.

*Result—*July 18th—*One* of those fed upon infected food (and ear-marked) found dead at 5 p.m.July 19th—*Two* more of those fed upon infected food (and ear-marked) found dead at 9 a.m.July 23rd—*Two* more found dead at 5 p.m.*Three* more found dead at 8.30 p.m.July 24th—*One* more found dead at 9 a.m.On examination of *three*, out of the six last dead, the presence of micro-organisms morphologically similar to those of chicken-cholera was demonstrated in fresh preparations of blood. (Zeiss F.)

Two fresh rabbits, confined in separate boxes, were inoculated at 4.30 p.m. on the 24th with blood from two out of the three examined as above. They were found dead at 9.30 a.m. (July 25th), and, on examination, the presence of micro-organisms morphologically similar to those of chicken-cholera, was demonstrated, as in previous examinations. (Zeiss F.) *One* rabbit was inoculated, at 1 p.m. on the 25th, with blood from one of these two, and was found dead at 9 a.m. on the 26th. On examination the presence of micro-organisms was demonstrated, as in previous examinations. (Zeiss F.)

July 25th—*Two* more found dead at 9.30 a.m.

July 27th—

*Conclusion of the experiment—*At 4 p.m. the experiment was concluded, and the *fourteen* surviving rabbits were liberated.

*Annotation—*One of these fourteen rabbits was observed to be one of the four ear-marked, as noted in Annotation (a) (17th July) above. It was still alive on the 1st August, when it was treated as may be seen in the notes upon the experiment of that date. (Appendix E, series III.)

*Control experiment—**Vide* control experiment of the same date (17th July). (Appendix D, below.)

Appendix D.

DETAILS of experiments intended to demonstrate the safety of the disease, viz., the immunity of certain domestic animals :—

The following animals were experimented upon :—

An old horse, placed in one of the stable stalls. (Diag. III, 5.)

A cow (with calf at foot), also in one of the stable stalls. (Diag. III, 2.)

A sheep (six-tooth merino ewe), placed in a wire-netting division of the main enclosure. (Diag. III, 7.)

A goat (a female, in kid), placed in a similar division of the main enclosure. (Diag. III, 8.)

A pig (a young sow), placed in a similar division of the main enclosure. (Diag. III, 9.)

A dog (a young half-bred collie), chained to a post (Diag. III, 10^c), and provided with a box-kennel. (Diag. III, 10.)

Annotations—(a) On no occasion was the above-mentioned calf experimented upon. (b) In other respects, all the animals were kept under normal conditions during the course of the experiments.

July 17th, 1 p.m.—

The horse }
The cow } was fed upon a small portion of moistened pollard mixed with { 5 ccm. of a broth-culture of the microbe
The pig } of chicken-cholera.

The sheep }
The goat } was fed upon a handful of green barley, sprinkled with..... 5 ccm. of the same culture.

The dog was fed upon about $\frac{1}{4}$ of a pint of milk, mixed with 5 ccm. of the same culture.*Control experiment—**Two* rabbits (in one box) were fed upon cabbage leaves sprinkled with 3 ccm. of the same culture.

*Result—*The *two* rabbits were found dead at 2 p.m. on the 18th, and, on examination, micro-organisms morphologically similar to those of chicken-cholera, were demonstrated as in previous examinations. (Zeiss F.)

*Annotation—*In this and all succeeding control experiments the rabbits were kept in boxes placed in a space denoted by β . Diag. III.

July 18th—The several animals, fed yesterday upon infected food, presented normal appearances.

At noon—

The horse }
The cow } was fed upon similar food to that given yesterday (July 17th), mixed with the same quantity (5 ccm.)
The goat } of a broth-culture of the microbe of chicken-cholera.
The pig }
The dog }

The sheep was fed upon dry lucerne, sprinkled with 5 ccm. of the same culture.

*Control experiment—**Six* rabbits (in one box) were fed upon cabbage-leaves, sprinkled with 6 ccm. of the same culture.*Result—*

OF RABBITS IN AUSTRALASIA—REPORT ON M. PASTEUR'S EXPERIMENTS. 141

Result—

Three were found dead at 9 a.m. on the 20th. On examination the presence of micro-organisms was demonstrated (in each case) as in previous examinations. (Zeiss F.)

*Annotation—*The other three rabbits were still alive on the 26th July, when they were further treated, as may be seen in the notes on the experiment of that date. (Appendix E, series I.)

July 19th—The several animals again presented normal appearances.

At 11:30 a.m.—

The horse
The cow
The sheep
The goat
The pig
The dog

was fed upon similar food to that given yesterday (18th), mixed with the same quantity (5 ccm.) of a broth-culture of the microbe of chicken-cholera.

*Annotation—*The pig left uneaten a small portion of the infected food given to it.

Control experiments—

July 19th—(a) Three rabbits, in one box, were fed upon about a handful of green barley, sprinkled with 6 ccm. of the same culture.

Result—

One was found dead at 9 a.m. on the 21st, and on examination the presence of micro-organisms was demonstrated as in previous examinations. (Zeiss F.)

*Annotation—*The other two rabbits were still alive on the 26th July, when they were treated as may be seen in the notes upon the experiment of that date. (Appendix E, series I.)

July 19th—(b) One rabbit was inoculated with about 5 drops of the same culture.

Result—

The rabbit was found dead at 9 a.m. on the 20th, and on examination the presence of micro-organisms was demonstrated as in previous examinations. (Zeiss F.)

July 20th—The several animals again presented normal appearances.

At 3:30 p.m.—

The horse
The cow
The goat
The pig

was fed upon a small portion of moistened pollard mixed with $\left. \begin{array}{l} 17 \text{ ccm.} \\ 10 \text{ ccm.} \\ 5 \text{ ccm.} \\ 5 \text{ ccm.} \end{array} \right\}$ of a broth-culture of the microbe of chicken-cholera.

The sheep was fed upon dry lucerne sprinkled with 17½ ccm. of the same culture.

The dog was fed on about ¼ of a pint of milk mixed with 5 ccm. of the same culture.

*Annotation—*At 4:15 p.m. the sheep had eaten a part only of the food given to it, and it was not until 5:30 p.m. that it had finished all but a few stalks of the lucerne.

Control experiment—

July 20th—Six rabbits (in separate compartments of one box) were fed upon turnip leaves sprinkled with 1½ ccm. of the same culture for each rabbit.

*Annotation—*Three of the six were observed to have finished their meal of infected food at 5:30 p.m., and were then fed upon uninfected food. The other three, not having finished their infected food, were left unfed until the morning (21st), when practically all the meal given on the previous afternoon was finished.

Result—

July 21st—Three were found dead at 3 p.m.; one more found dead at 5:30 p.m.

July 22nd—One more found dead at 11:30 a.m.

On examination of four of the above five, the presence of micro-organisms was demonstrated as in previous examinations. (Zeiss F.)

One fresh rabbit was inoculated at 11:30 a.m. on the 22nd, with blood from one of the four examined. It was found dead at 8 a.m. on the 23rd, and on examination the presence of micro-organisms was demonstrated, as in previous examinations. (Zeiss F.)

*Annotation—*The other rabbit was still alive on the 26th July, when it was treated as may be seen in the notes on the experiment of that date. (Appendix E, series I.)

July 21st—All the animals at the time of feeding again presented normal appearances.

At 4 p.m.—

The horse
The cow
The goat
The pig

was fed upon a small portion of moistened pollard mixed with $\left. \begin{array}{l} 15 \text{ ccm.} \\ 15 \text{ ccm.} \\ 25 \text{ ccm.} \\ 15 \text{ ccm.} \end{array} \right\}$ of a broth-culture of the microbe of chicken-cholera.

The sheep was fed upon some dry oats and chaff mixed with 25 ccm. of the same culture.

The dog was fed upon about ¼ of a pint of milk mixed with 12 ccm. of the same culture.

*Annotation—*The sheep did not finish its meal at once, but had done so at 4:30 p.m.

Control experiments—

July 21st (a)—Three rabbits (confined in separate compartments) were fed upon dry oats chaff, sprinkled with 1½ ccm. of the same culture for each rabbit.

Result—

July 22nd—One was found dead at 4:45 p.m. P.M.—The appearance of the organs was similar to that as observed in rabbits dead of chicken-cholera.

One fresh rabbit was inoculated at 5:30 p.m. on the 22nd, with blood from the above. It was found dead at 8 a.m. on the 23rd, and on examination the presence of micro-organisms was demonstrated as in previous examinations. (Zeiss F.)

July 23rd—One more found dead at 5 p.m.

*Annotation—*The third rabbit was still alive on the 25th, when it escaped from its box during the night. It was found on the 26th in the stable-drain and killed.

July 21st (b)—Three rabbits (also in separate compartments) were fed upon dry oats sprinkled with 1½ ccm. of the same culture for each rabbit.

Result—

July 23rd—One was found dead at 8 a.m. On examination on the 24th the presence of micro-organisms was demonstrated as in previous examinations. (Zeiss F.)

*Annotation—*The other two were still alive on the 26th July, when they were treated as may be seen in the notes on experiment of that date. (Appendix E, series I.)

July 21st to 26th—

From 3:30 p.m. on the 21st to 3:30 p.m. on the 26th July, all the domestic animals presented normal appearances. Between the times named infected food was not given to them.

July 26th, at 3:30 p.m.—

The horse
The cow
The sheep
The goat
The pig

was fed upon a small portion of moistened pollard mixed with $\left. \begin{array}{l} 45 \text{ ccm.} \\ 65 \text{ ccm.} \\ 80 \text{ ccm.} \\ 45 \text{ ccm.} \\ 45 \text{ ccm.} \end{array} \right\}$ of a broth-culture of the microbe of chicken-cholera.

The dog was fed upon about ¼ of a pint of milk mixed with 50 ccm. of the same culture.

*Annotation—*The sheep and pig each received a smaller portion of food than usual in the morning, thereby causing them to finish their meal of infected food more quickly.

Control—

142 ROYAL COMMISSION OF INQUIRY INTO SCHEMES FOR THE EXTERMINATION

Control experiment—

July 26th—*Ten* rabbits were fed in one box (without separate compartments) upon green barley sprinkled with 15 ccm. of the same culture as above.

*Annotation—*These ten rabbits had not been fed as usual in the morning, thereby causing them to finish their meal of infected food more quickly.

Result—

July 27th—*Two* were found dead at 9 a.m., and *one* more at 2 p.m. On examination of two of the three the presence of micro-organisms was demonstrated as in previous examinations. (Zeiss F.) *Three* more found dead at 5.30 p.m.

July 28th—The remaining *four* found dead at 9.30 a.m. On examination of one of the seven last dead the presence of micro-organisms was demonstrated as in previous examinations. (Zeiss F.)

August 1st—

Conclusion of experiment—

From 3.30 p.m. on the 26th July to 2.30 p.m. on the 1st August all the domestic animals under observation presented normal appearances. At the latter date and hour the time for keeping the animals under observation expired.

*Annotation—*At 5 p.m. on the 29th July the goat was observed to have broken into the sheep's pen. The goat was left therein until the conclusion of the experiment, the sheep being placed in the pen previously occupied by the goat. It may also be noted here that (with the above exception) the animals remained, during the whole period in which they were under observation, in the respective enclosures in which they were originally placed.

Weather during the course of the experiments referred to in Appendices C and D: Fine weather prevailed from the 17th to the night of the 27th July, when heavy rain fell. Showers continued to fall during the morning of the 28th; the weather then cleared up until the night of the 29th, when the atmosphere became very damp, with a dense fog lasting until 9 a.m. on the 30th. From the 30th to the conclusion of the experiments the weather was generally fine and cool, with more or less of a westerly wind.

Appendix E.

DETAILS of further experiments upon rabbits surviving from previous experiments:—

SERIES I.

July 26th, 2.30 p.m.—

The rabbits remaining alive from previous control experiments, viz.:—

From control experiment of 18th July (v. page 141),	<i>three</i>	}
" " 19th July (v. page 141),	<i>two</i>	
" " 20th July (v. page 141),	<i>one</i>	
" " 21st July (v. page 141),	<i>two</i>	

in all eight, were placed in one box (without separate compartments) and fed upon green barley sprinkled with 12 ccm. of the same culture as used in feeding the domestic animals on infected food this date. (*Vide* Appendix D, page 3.)

*Annotation—*These eight rabbits had not been fed as usual in the morning, thereby causing them to finish their meal of infected food more quickly.

Result—

July 27th—*Two* were found dead at 5.30 p.m.

July 28th—*Two* more found dead at 9.30 a.m.

On examination of *one* of the four the presence of micro-organisms was demonstrated as in previous examinations. (Zeiss F.)

July 29th—*One* more found dead at 4 p.m. On examination (on the 30th) the presence of micro-organisms was demonstrated as in previous examinations. (Zeiss F.)

*Annotation—*The three remaining rabbits were still alive on the 1st August, when they were treated as may be seen in the notes upon experiments referred to in Series II and IV of this Appendix (E).

Control experiment—

Vide control experiment to feeding of domestic animals on infected food this date. (Appendix D, above.)

SERIES II.

August 1st, 2.30 p.m.—

Two of the three surviving rabbits from the feeding experiments of 26th July (*vide* series I of this App.) were fed (in separate compartments of one box) upon green barley sprinkled with 2 ccm. of a broth-culture of the microbe of chicken-cholera for each rabbit.

Result—

August 2nd—*One* found dead at 9.30 a.m. On examination the presence of micro-organisms was demonstrated as in previous examinations. (Zeiss F.)

August 3rd—The *other* found dead at 8 a.m.

*Annotation—*The third of the surviving three from experiment of 26th July (series I of this App.), escaped from confinement on the 1st August. On the 2nd August it was found again and treated as may be seen in the notes upon the experiments of that date. (Series IV of this Appendix.)

SERIES III.

August 1st, 2.30 p.m.—

The surviving *one* of the four rabbits fed on infected food on the 17th July, and *ear-marked* before being put in the square metre box with the twenty healthy rabbits, was fed upon green barley sprinkled with 2 ccm. of the same culture as used in experiment of Series II of this Appendix.

Result—

August 2nd—It was found dead at 9.30 a.m. On examination the presence of micro-organisms was demonstrated as in previous examinations. (Zeiss F.)

SERIES II AND III.

Control experiment—

Two rabbits were fed (in separate compartments of one box) upon green barley, sprinkled in each case with $1\frac{1}{2}$ ccm. of the same culture as used in the experiments of the series named.

Result—

August 2nd—*One* was found dead at 9.30 a.m. On examination the presence of micro-organisms was demonstrated as in previous examinations. (Zeiss F.) The *other* was found dead at 5.30 p.m.

SERIES IV.

August 2nd, 4 p.m.—

The remaining *one* of the three rabbits surviving from the experiment of 26th July (*vide* Annotation, Series II of this Appendix), was fed upon green barley sprinkled with 2 ccm. of a broth-culture of the microbe of chicken-cholera.

Result—

August 3rd—It was found dead at 2 p.m. On examination (on the 4th) the presence of micro-organisms was demonstrated as in previous examinations. (Zeiss F.)

*Control experiment—**One* rabbit was fed upon green barley sprinkled with 2 ccm. of the same culture.

*Result—*August 3rd—It was found dead at 8.30 a.m. On examination (on the 4th) the presence of micro-organisms was demonstrated as in previous examinations. (Zeiss F.)

Appendix F.

Appendix F.

EXPLANATION of Diagrams I, II, and III, referred to in this Report :—

Diagram I is a sketch of the stable in plane section.

The stable is a galvanized-iron building, one storey-high, containing six paved stalls and an open space (unpaved) between the stalls and the beginning of the roofed-in wire gauze enclosure, as sketched in Diagram III. There is a one-brick wall running round the three inside walls of the stable enclosure, to a height of from 2 to 3 feet from the ground.

1 to 6 represent ordinary paved stable stalls.

a and *b* are referred to particularly in Appendix B.*c* is referred to particularly in Appendix A.*d* represents a drain in front of the stalls, running across the whole width of the stable, and emptying outside into a tank.*e, e* represents a porch-entrance to the stable, having double doors.*f* represents a temporary fence of wire and wire-netting, erected to prevent the calf (or any other animal that might get loose) passing from the stable to the main enclosure and *vice versa*.*Diagram II* shows the height of the divisions between the stable stalls, and also a vertical section of the stable, on a scale of 5 feet to the inch.*Diagram III* is a sketch of the stable and main enclosure (on half the scale of Diagrams I and II).*Stable*—The description of the stable, as given above, applies to this diagram also, except in the following respects :—*a* is referred to particularly in Appendix C.*β* The space occupied by the various control experiment boxes referred to in the several Appendices.*Enclosures 7, 8, and 9* represent the pens of wire-netting erected for the temporary accommodation of the sheep, goat, and pig respectively.*10* represents the kennel for the dog, and*10'* represents the post to which the dog was chained.*g* represents the outside wall of the main enclosure.*h* represents an inside protecting fence of posts and barbed wire.*k* represents the direct entrance to the main enclosure (double doors).*l, l* represent posts supporting the wire-gauze roof of the enclosure.

SECTION XI.

EXPERIMENTS with microbes of chicken-cholera, conducted by Dr. Katz,
Chief Expert to the Commission.PROGRESS REPORT (No. I.) ON EXPERIMENTS WITH THE MICROBES OF
CHICKEN-CHOLERA.

Rodd Island, 21 September, 1888.

To the Chairman, Experiment Committee, Rabbit Commission,—

BEFORE proceeding to report on the various experiments conducted by me, during the period mentioned below, with the microbes of chicken-cholera on wild Australian rabbits, I must say a few words as to the material used for the carrying out of these experiments.

On August 4th, 1888, I took—with permission of M. Loir, who was then concluding his experiments of demonstration on behalf of M. Pasteur (*vide* report thereon)—some blood from the heart of a rabbit that had died after having been fed on food infected* with a broth-culture of the microbe of chicken-cholera, and transferred this blood to two test-tubes containing a specially prepared infusion of rabbit flesh.

This infusion was prepared in the following way :—The lean flesh of a few well-nourished, thoroughly healthy wild rabbits was finely minced up and mixed with double the quantity (in weight) of distilled water in a spacious glass jar. It was then allowed to stand, in a cool room, for twenty-four hours, during which period it was stirred up from time to time. The mixture was then filtered and pressed through strong cheese-cloth into clean glass flasks, which, after having been filled to about two-thirds of their capacity, were exposed to steam of 100° C.† (212° F.), produced in a copper cylinder (steam steriliser) for about three-quarters of an hour. Immediately after that the contents of the flasks were filtered through fine filtering paper. The precipitated albuminous substances having thus been removed, the filtrate, representing in the flasks a clear light-yellowish liquid, was rendered slightly alkaline by means of a 20 per cent. watery solution of pure anhydrous carbonate of soda, which was obtained by heating pure bicarbonate of soda. The liquid was then retransferred to the steam cylinder for some time, filtered again, distributed into test tubes in quantities of about 10 ccm.‡ (for tubes of 25-30 ccm. capacity), and about 20 ccm. (for tubes of 50-60 ccm. capacity), and sterilised.

The nutrient gelatine alluded to in this report was thus prepared :—Six parts of extra fine gelatine were, in proportion, dissolved in a hundred parts of the original rabbit-flesh infusion, after it had been steamed and filtered (*vide* above.) This mixture was then rendered slightly alkaline as before, $\frac{1}{2}$ per cent. chloride of sodium added to it, and afterwards placed in the steam cylinder for about twenty minutes. It was then filtered, distributed in test tubes, and sterilised.

On this occasion I will remark once for all that the manipulations necessary for the obtaining and successful continuation of pure cultures of the micro-organism under consideration, were guided by antiseptic precautions; that the cotton-wool stoppered glass tubes intending to contain the nourishing soils were sterilised by dry heat; and finally, that the nourishing media, before being used, were thoroughly tested for their sterility.

From the cultures obtained another growth, in similar broth, was secured; from this culture a rabbit was inoculated, which, after death, furnished the material for further cultivations (Aug. 10). A small platinum-loop full of heart-blood of this rabbit was mixed with gelatine, liquefied at between 30° and 40° C., and from this gelatine two successive attenuations in two more tubes with liquefied gelatine were prepared. The gelatine, still liquid in all three tubes, was made to solidify, by means of cold water (according to the "roll-method"), along the inner walls of the tubes, when, after a few days incubation at a temperature of between 20° and 23° C., the third tube was found to answer best for further cultures, as there was only a limited number of points of growth, or "colonies," derived from germs deposited at different spots in or on the layer of gelatine.

One

* In every case where the word *infected* is used it denotes fed or mixed with material competent to produce the disease—"chicken-cholera."† 1° C. = ($\frac{9}{5}$ Fahr.)+32. 15° C. (c.g.) = (15 × $\frac{9}{5}$ F.)+32.

‡ One cubic centimetre (ccm.) is equal to sixteen minims; one minim is generally considered as equal to one drop

144 ROYAL COMMISSION OF INQUIRY INTO SCHEMES FOR THE EXTERMINATION

One of these "colonies" formed the material from which pure cultures in successive generations, as used in the undermentioned experiments, were obtained. I may, however, mention that pure cultures may be obtained directly from fresh virulent* rabbit blood, which—as direct observations have shown—contains, as a rule, only the microbes under consideration.

The identity of these microbes with the microbes of chicken-cholera was undoubted, as shown by testing their morphological and physiological properties. Besides, the microbes came, indirectly, from Pasteur's laboratory, and this alone should be regarded as a sufficient guarantee of such an identity.†

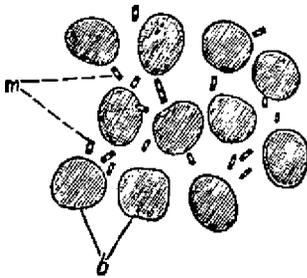

Fig. 1.

Blood of a rabbit dead of "Chicken-cholera."

methylene blue.
× 1000 (approximately).

In order to avoid repetitions, I may state beforehand that the broth-cultures alluded to in the various experiments were always such as had been in a thermostat for two days at temperatures having their maximum at 37° C., their minimum at 33° C. They were taken out of the thermostat immediately before the experiments commenced. Before infecting rabbits with such cultures along with food, I took the precaution to starve them to some slight extent, thereby causing them to eat their infected food speedily. (For further particulars see Appendices.) The same practice was followed with regard to uninfected rabbits used in the artificial burrow experiments (Appendix A). The culture was spread on about as much food as was required by the respective rabbits for one meal.

The way in which the culture was administered along with food (fresh cabbage leaves, with one exception, when green barley was used) was as follows: At the bottom of an ordinary soup-plate a layer of the green food was placed, and sprinkled with one ccm. of culture, by means of a glass pipette, which had been drawn out into a fine tube in the gas-flame. This layer was then covered with another layer, which in case only 1 ccm. of culture was employed, was at once pressed down on the former by means of two flat wooden sticks, the whole repeatedly manipulated and given to the rabbit on a wooden board, on the surface of which there was a fresh leaf, not sprinkled. In case 2 ccm. of culture were to be given to the rabbit, the abovementioned second layer was sprinkled with the second ccm., then covered with another layer, and the whole pressed together. In case 2½ ccm. were to be administered, the third-mentioned layer was sprinkled with the ½ ccm., and so on. The result of all these arrangements was that the infective material adhered firmly to the food, and that, consequently, danger of the infected broth becoming detached from the latter while the animal was eating was reduced to a minimum.

By feeding the different animals to be infected in separate compartments, the arrangement of the experiments was naturally more exact than it would have been if two or more had been fed together.

With a view to ascertaining whether or not infection occurs among healthy rabbits exposed to rabbits which had been infected with the virus of chicken-cholera, three sets of experiments were conducted namely,—

I.—In artificial burrows.

II.—In hutches—wooden bottomed and wire-netting bottomed.

III.—In boxes or hutches in which rabbits had died of the disease ("chicken-cholera").

As a detailed description of the arrangement of these experiments, of the results they yielded, and of other noteworthy facts, is put together in the attached Appendices A–C, I may well abstain here from entering into repetitions, and may at once proceed to give a summary. Before that, however, I will state that all the rabbits used in the course of the above three sets of experiments were wild rabbits from near Hay, New South Wales, and, unless mentioned otherwise in the reports, full-grown animals.

I will now sum up the main results of the above experiments, and the inferences that may be drawn from them.

1. Australian rabbits are, to judge from a number of experiments conducted, highly susceptible to infection by the virulent microbe of chicken-cholera through their digestive organs. Of twenty-seven rabbits in all infected, each with a small portion of a virulent broth-culture (2½–1 ccm.), or of virulent blood (one case), twenty-five succumbed in from 19 to 48 hours from the time the infected food had been given to them (most of them were found dead after 20–24 hours), but as it took some time (in some cases more, in others less) before the respective animals had finished their infected meal, they died from the effects of such a meal in less time than that noted. Of the remaining two (fed with 1 ccm. of virulent culture for each) of those twenty-seven rabbits one died of some other cause (*vide* Appendix B, series I, pages 151, 152), the other did not die at all until it was infected again, seven days later, with 2 ccm. of a virulent broth-culture (*vide* Appendix B, series II, page 153), when it succumbed to "chicken-cholera" about 25½ hours after being fed.

From these exceptions it would follow that the quantity of virulent culture should not be too small, in other words, should be larger than 1 ccm., in order to secure infection without fail. On the other hand it remains yet to be seen whether Australian rabbits may be rendered immune, or, in other words, whether and in what way they may be able to withstand infection, under any shape, by the microbes under consideration. (For a case of immunity in a tame rabbit, *vide* Appendix D, series II, page 154).

Inoculation

* The word *virulent*, wherever it occurs in the report, is used in the sense of non-weakened, non-attenuated.

† About the bacteria of Koch's rabbit-septicaemia *vide* footnote, p. 147.

Inoculation, *i.e.*, subcutaneous application, of minute portions of virulent cultures of the microbe (blood of dead rabbits, or artificial cultures), caused the death of sixteen wild rabbits thus experimented upon in from 7½ to about 15 hours, as actually observed (found dead up to 18½ hours after inoculation).

2. The disease set up by the microbes in rabbits is a most acute septicaemia. The incubation occupies most of the time until death, the actual disease being only of comparatively very short duration. The death occurs under clonic cramps and dyspnoea.

3. The cause of death in all the rabbits referred to left no doubt as to its being due to the action of the virulent microbes.

This was proved—

(a) *By the course and symptoms of the disease (paragraph 2 above).*

As regards the body temperature during the course of the disease, I shall give particulars in the next report.

(b) *By the autopsy.*

Of the organs which were invariably found to offer characteristic changes, must in the first instance be mentioned the *lungs*. These always proved to be discoloured; they were very voluminous due to an emphysematous hæmorrhagic œdema involving their entire substance. Their surface presented a shining, mottled or tessellated appearance (corresponding to the hæmorrhages).

The *spleen*, which showed a bluish or bluish-red colour, was more or less hyperæmic.

In the *peritoneal, pleural, and pericardial* cavities existed serous, sometimes hæmorrhagic exudations.

The *bladder* was usually empty, only occasionally distended with urine, which, in the majority of the cases examined, appeared highly (yellow) coloured, with a considerable amount of corpuscular matter distributed in it.

The *intestines* were more or less hyperæmic, containing normal-looking feed material in abundance; the *rectum* showed in almost every case normal faecal balls. Hæmorrhages in the intestines did not come under observation.

Now and then there was a serous discharge from the *nostrils*, and froth round them, and round the mouth.

(In cases of inoculation, the seat of inoculation was slightly œdematous).

(c) *By direct examination of the blood.*

The blood was derived from the right ventricle of the heart, stained on cover-glasses with Loeffler's alkaline methylene blue, and examined with homogeneous immersion objectives. It invariably showed the characteristic bacteria of chicken-cholera (*vide* Fig. 1, page 144).

(d) *By artificial cultures.*

Cultures in rabbit-broth, in or on nutrient gelatine, and on nutrient agar-agar presented typical appearances.

(e) *By experiments on rabbits.*

Introduction into healthy rabbits, of both artificial cultures and blood of infected animals, succeeded invariably in reproducing the disease. [For one exception (*tame rabbit*) *vide* Appendix D, series II, page 154].

4. A transmission of the disease from infected rabbits to healthy rabbits in *artificial burrows*, such as were used in the experiments and under the conditions recorded in Appendix A, did not take place in any case. Of the *eight* infected rabbits, *six* (or 75 per cent.) died outside the burrows, *two* (or 25 per cent.) inside.* The result, that of the *sixteen* fresh rabbits† in the same burrows and enclosures not one succumbed to infection by "chicken-cholera," can scarcely be surprising when we see that the disease runs a most acute and rapid course, appearing as it does in the form of a pure septicaemia, and as a rule, unaccompanied by any liquid, simply-diarrhœal or hæmorrhagic evacuations.‡ I may, however, point out that this is not always the case, as may be exemplified by the result of the *post-mortem* examination of an infected pregnant doe, which showed abortion of part of the foetuses accompanied by severe hæmorrhages from the vulva.¶ [*Vide* Appendix B, series I, hutch VI, page 152.] Another, but altogether different case, is that of a rabbit infected with the virus of chicken-cholera (2½ ccm. of culture), and taken from one of the burrows after having been three days in it. [*Vide* Appendix A, page 150; diag. VI (c).] The contents of the rectum of this rabbit were not in the shape of faecal balls as usually observed in healthy rabbits as well as in infected ones, but soft, without any visible traces of blood. A small quantity of this faecal matter, collected under proper precautions so as not to injure any blood-vessel, was inoculated into a healthy rabbit which died of veritable septicaemia (chicken-cholera), after 23½ hours. [*Vide* Appendix D, series III (a), page 155. Another rabbit, however, which had been given to eat on cabbage leaves a larger portion of this faecal matter remained alive (*l. c.*) The urine usually passed in the case of rabbits infected with the virus of chicken-cholera, and when still in the bladder, found to be free from blood—is not infectious, if I am permitted to draw this inference from the result of one experiment. Two rabbits were inoculated, each with about ½ ccm. (2 minims) of such urine. The one was found dead in its box after somewhat less than two days, but infection with the microbes, as accounting for this occurrence, was altogether out of question. The other rabbit remained alive. [*Vide* Appendix D, series III (b), page 155.]

5. Without further proof we may not, it appears, conclude that the negative results as to the transmissibility of the disease, fairly deducible from these experiments in artificial burrows, would hold good also when infected rabbits were placed amongst those living under perfectly natural conditions in their own warrens. Rabbits dead of the disease may, as a rule, become the source of infection for healthy rabbits in the same or, perhaps, in neighbouring warrens only when their carcasses have broken up by some means or other, so that the virulent blood, or the various organs containing it, may have a chance of becoming exposed, and in this way gain access somehow or other to wounds or to the digestive organs of healthy animals. This, of course, is more or less a supposition, in support of which I am unable as yet to adduce any decisive experiment. At all events I venture to suggest that a repetition of those experiments, only performed under more natural conditions—say in the open—may yield other, possibly more favourable results. These, of course, would be greatly influenced by climate, soil, vegetation, and last but not least, by such factors as carrion-feeding animals capable of disseminating the virus.

I do not know whether I am justified in assuming that rabbits infected with the microbes of chicken-cholera will in the majority die outside their burrows, when in the open, as has been the case with infected rabbits placed in artificial burrows (*vide* above). If this were so—and the chances are in favour of the supposition—the carcasses of the dead rabbits would be more accessible to the agency of factors such as noted above.

The possibility of a successive infection in the open would also seem to be favoured by the fact that the virus of chicken-cholera preserves its infecting power in conjunction with other bacteria in putrefying or putrid substances for a considerable time.§ I have made some experiments with virulent rabbit

* Their carcasses were left untouched for three clear days after death.

† These rabbits, unless they died before, were left in the burrow enclosures for seven days from the beginning.

‡ In this and other ways the disease is altogether different from that in poultry.

§ Pregnant females were not among the *eight* infected rabbits in the artificial burrows.

§ *Vide* Kitt. Wert und Unwert der Schutzimpfungen gegen Tierseuchen. Berlin, 1886; p. 65.

rabbit blood. Nineteen days after having been derived from the rabbit, during which time it was allowed to putrefy, it was still able to kill a vigorous rabbit in less than seventeen hours; the autopsy showed infection by "chicken-cholera." [*Vide* Appendix D, Series III. (c.), page 155.] These experiments will be continued.*

6. A transmission of the disease from infected rabbits to healthy rabbits in *wooden hutches*, (according to the arrangement described in Appendix B), was successful in so far that of *twenty* rabbits placed with *ten* (half the number) infected rabbits (in different hutches, but always in the proportion of *one* infected to *two* uninfected), *four* (or 20 per cent.) died in consequence of infection by the virus of chicken-cholera in from two days sixteen hours to four days seven hours (*vide* Appendix B, pages 163—165) after being put in the hutches.

In what particular way these fatal results (by transmission of the infection) were brought about, I am unable to decide until all excretions and secretions of infected rabbits have been submitted to a whole series of tests, with a view to ascertaining their virulence or otherwise.

What I may, however, state is, that—

- (a). Here, as well as in the artificial burrow experiments, the feeding of the rabbits after they (infected and uninfected) had been placed in the hutches, was so managed that contamination from outside was excluded.
- (b). The droppings in the hutches did not exhibit anything indicating the presence of hæmorrhages.
- (c). The uninfected rabbits were not observed to gnaw at the carcasses of the dead (infected) ones which were left in the hutches for three clear days.

7. A transmission of the disease to fresh rabbits which were placed in hutches or boxes 10 minutes, 2½ hours, and 13–14 hours after rabbits, dead of infection, had been removed therefrom, did not take place in any of the *five* single experiments made. *Four* of the rabbits died within 4½ and 7 days, of some other cause, the *fifth* was still alive after 8 days.

8. The results of these hutches-experiments, arranged and conducted in the way described, show that transmission of the disease from rabbit to rabbit is possible. Transmission in the open may occur where analogous conditions obtain, but the chances in this case will probably be less favourable than those adduced above.

9. Taking everything into consideration it would seem advisable to have further experiments conducted on a larger scale under quite natural conditions, provided other considerations admit of the use of "chicken-cholera" as a means for the destruction of rabbits.

Before concluding this Report, I would draw attention to an article in the "Centralblatt für Bakteriologie und Parasitenkunde," Band IV, No. 6, August 4th, 1888, by Dr. N. Gamaleia, Vice-director of the Bacteriological Station in Odessa, namely,—

"Contribution to the Etiology of Chicken-cholera, together with some Notes on the question of Protective Vaccination."†

I think the article important enough to entitle me to give it in literal translation.

"Twice already, during a hot summer, I have met in carcasses of pigeons killed by poisoning through non-pathogenic bacteria, with bacteria which occur spontaneously, so to say, and which, by successive transmissions through pigeons, attain such a degree of virulence, that a single drop of heart-blood from the dead pigeon is able, by means of subcutaneous application, to kill the next pigeon within a few hours. The carcasses showed the appearances of the most acute septicæmia, no reaction at the seat of inoculation, hyperæmia of the intestinal canal, and a large number of bacteria in the blood.

"These bacteria appeared in the shape of fine rods, their centres staining only with difficulty. They resembled altogether the bacteria of chicken-cholera, both by their form and their growth in broth, in gelatine, and in agar-agar.

"It was not until lately that I had the opportunity of conducting further investigations into the nature and the origin of these unwelcome aggressors. It was to be ascertained, as we had not any chicken-cholera in our laboratory at the time: Can they be identified with the bacteria of chicken-cholera? Are the latter, therefore, to be regarded as being dispersed in Nature, possessed of the faculty of putting in an appearance without specific infection?

"In the literature there are some hints at such a behaviour of the microbes of chicken-cholera.

"Thus, Toussaint, for instance, gives it as his opinion that chicken-cholera is septicæmia, which can be called into existence by various putrid substances. His works to this effect are, however, of little importance, because he evidently confounds chicken-cholera with the vibrio-septicæmia.‡

"Marchiafava and Celli, in spite of numerous experiments, were not able to produce chicken-cholera by means of putrid or purulent substances ||

"Experiments by Kitt also yielded negative results. Nevertheless he supposed—supported by spontaneous occurrences of chicken-cholera, which, for instance, made its appearance in consequence of feeding on putrid flesh or dipterous larvæ—that the chicken-cholera microbe, which has a far range of distribution, may happen to get into a wound of a fowl, and thus give rise to an epidemic.

"Such suppositions, however, are hardly compatible with the biological properties of the bacteria of chicken-cholera. For a general saprophytic distribution of the microbes of chicken-cholera in the dead nature is not at all in harmony with their liability to perish when acted upon by dryness, light, and air.

"I have hit upon the following explanation:—Influenced by poisoning, the organism of the pigeon lost its power to withstand the attacking bacteria from the intestinal canal, and in this way the latter gained the upper hand in the blood. Or, in other words: I thought the bacteria of chicken-cholera to be constant parasites in the normal intestinal canal of a bird.

"For the solving of this question the following experiments were undertaken:—

I.

"On 30/V a healthy pigeon was killed (the remaining pigeons of the same lot did not manifest any traces of sickness later on). The contents of the stomach, of the small intestines, and of the rectum were, mixed with sterilised broth, introduced subcutaneously into a fresh rabbit. "On

* After twenty-two days it killed a vigorous rabbit in from fifty-one to fifty-four hours after inoculation; the autopsy showed the same result. After twenty-six days the blood had lost its virulence, as is evidenced by a rabbit surviving inoculation (after seven days) Oct. 1.

† Zur Aetologie der Hühnercholera. Nebst einigen Bemerkungen über die Schutzimpfungsfrage.

‡ Toussaint, L'identité de la septicémie expérimentale aigüe et du cholera des poules. (Compt. Rend. T. XCI, 1880; p. 301.)

§ S. Kitt's Wert und Unwert der Schutzimpfungen, p. 63.

"On 31/V the rabbit succumbed. The autopsy showed a gelatinous œdema at the place of inoculation. The intestines were filled with liquid contents; the spleen was cherry-brown. In the heart-blood was a considerable number of fine rods, which perfectly resembled the bacteria of chicken-cholera. With this blood another rabbit was inoculated, and agar-agar, gelatine, and broth sown.

"This rabbit was found dead on the morning of 1/VI. At the seat of inoculation was a gelatinous œdema; the spleen was faintly hyperæmic. Numerous bacteria of chicken-cholera occurred in the heart-blood, from which cultures were prepared and a fresh rabbit inoculated.

"This rabbit died at night, 2/VI. At the place of inoculation was a small hæmorrhagic œdema, and the same bacteria occurred in the blood of the heart. With this blood, also, a rabbit and a pigeon were inoculated.

"Both animals succumbed on 3/VI. The rabbit exhibited the familiar appearances. The pigeon had the spleen very hyperæmic and soft, and the intestines filled with a liquid, impregnated with blood. In the blood of the heart were the same bacteria as in the previous cases. With this blood two pigeons were inoculated, and gelatine, agar-agar, and broth sown.

"On 4/VI, at night, the pigeons succumbed. In the first there was hæmorrhagic coagulum at the seat of inoculation,* a hyperæmic and soft spleen, hyperæmia of small intestines, and many bacteria in the heart-blood.

"The other pigeon showed hæmorrhages in the intestines, and diarrhœa, a very soft and dark spleen, and very many bacteria in the blood. This was inoculated into two pigeons.

"On 5/VI, towards morning, both were dead. The autopsy of both of them yielded the same result.

"I may add that all the dead pigeons exhibited altogether typical symptoms of the disease—spread-out plumage, drowsiness, diarrhœa. Cultures from blood of the above-mentioned manifested all the features of the cultures of the microbe of chicken-cholera—a faint turbidity of the broth, a drop-like growth on gelatine, a white layer on agar-agar, failure of growth in beer-wort.

"A complete proof of the identity of the bacteria found by me with those of chicken-cholera will be given below.

II.

"On 3/VI a healthy pigeon was killed and dissected, and the contents of the intestines inoculated (subcutaneously) into a *Ziesel*.† On 4/VI the animal succumbed. The place of inoculation, the intestines, and the spleen did not differ much from the normal appearance; in the blood was found a rather inconsiderable number of bacteria. With these a fresh *Ziesel* was infected.

"On 5/VI, at night, it succumbed. At the place of inoculation was a granular inflammation, accompanied by purulence in the centre; there was a hyperæmic spleen, and in the heart-blood a number of typical bacteria of chicken-cholera. This blood was inoculated into a pigeon, which died on 26/V (?)‡, exhibiting the spleen strongly hyperæmic and soft, and the intestines filled with liquid hæmorrhagic contents. In blood from the heart were found the typical bacteria of chicken-cholera. With this blood again, a pigeon was infected, which died on 27/V. (P)§ at night. Hyperæmia of intestines and spleen, typical bacteria in the heart-blood, from which broth, gelatine, and agar-agar were sown. In each case characteristic cultures of the microbe were obtained.

"The result of these two series of experiments shows that the intestinal canal of healthy pigeons contains bacteria, which are identical with the microbes of chicken-cholera in all their morphological as well as physiological characteristics examined. As, however, the bacteria of rabbit-septicæmia resemble altogether the bacteria of chicken-cholera, I have had to prove, in order to complete my argumentation, that my bacteria possess also the specific property of the chicken-cholera microbes, a property discovered by M. Pasteur, namely, that under certain conditions they confer immunity against chicken-cholera.§

"I may be permitted to note something about the conditions necessary for the vaccinations, in so far as they have been made clear by my investigations into protective vaccinations.

"I showed by means of direct experiments on more than 300 sheep, that vaccinations against anthrax bestow a lasting and never-failing immunity when their effect manifests itself by an increased but not long-continued fever (about 2° C. above the normal).¶

"The significance of this *vaccinal fever* is also cleared up by direct researches. It consists in the fact that, during its duration, there takes place a multiplication of the vaccines, as well as a destruction of the same in the interior organs.** From this would seem to follow that the vaccinal fever is indispensable also with regard to other protective vaccinations.††

"The following experiment justifies this presupposition as regards chicken-cholera.

III.

Protective Vaccination.

"On 24/V, the heart-blood of a pigeon (I series) was mixed with broth, and, in the portion of $\frac{1}{4}$ ccm. inoculated under the skin of the wing of a fresh fowl. The fowl remained somewhat languid on the following day, but soon recovered. On 27/V the heart blood of a pigeon (inoculated the day before with a culture that had been obtained from the I series—the pigeon died at night) was mixed with broth, and, in the portion of $\frac{1}{2}$ ccm. inoculated into the pectoral muscle of the same fowl. This time the fowl evidently became sick; it had bad appetite for two days, the evacuations were somewhat thin and liquid, but it recovered again. "On

* "Repeatedly I have found, at the place of inoculation, these changes which Kitt considers as characteristic of cholera in pigeons. Thus, a pigeon was inoculated, 24/VI, with a culture of my bacteria. At night it succumbed, showing, besides the typical features, at the place of inoculation yellow, subcutaneous, and inter-muscular formations."

† A rodent (*Spermophilus citellus* (L.) Wagler), very common in certain parts of Europe. (O.K.)

‡ Should probably be 6/VI. (O.K.)

§ Should probably be 7/VI. (O.K.)

¶ So far as I am aware experiments in this direction with the microbes of (Koch's) rabbit-septicæmia, have not yet been conducted or at least published. It is premature, in my opinion, to say that the two microbes differ from one another on account of the one (the microbe of chicken-cholera) being shown to possess the faculty alluded to, and the other (the microbe of rabbit-septicæmia) not yet being shown to possess it or not. (O.K.)

** "Vide my accounts in the 'Agricultural Society,' Odessa, January and May, 1888."

†† "Sur la destruction des microbes dans les organismes fébricitants (Ann. de l'Inst. Pasteur. Mai 1888)."

‡‡ "Save rabies, where the same effect is caused in another way. 'Vide 'Sur la vaccination préventive de la rage.' (Ann. de l'Inst. Pasteur. Mai 1887)."

"On 2/VI the heart-blood of a pigeon (inoculated the day before with a culture that had been obtained from the I series—the pigeon died at night) was mixed with broth, and, in the portion of a full cem. inoculated into the pectoral muscle of the same fowl. The fowl did not become sick at all.

Control by the virus of chicken-cholera.

"On 5/VI a culture of the virus of chicken-cholera, sent to me from Pasteur's laboratory, was inoculated into a fresh fowl, which died on 7/VI, at night. Its heart-blood containing typical bacteria of chicken-cholera, was, in the same portion (1 cem.) inoculated into the pectoral muscles of the preserved fowl as well as the control fowl.

"The control fowl perished the following night, of typical chicken-cholera, as was proved by the course of the sickness, by the *post-mortem* examination, by microscopical examination, and by cultures, whereas the preserved fowl did not manifest the least signs of illness and remained well up to date."

In explanation of these facts, Dr. Gamaleia furnishes a table of temperatures* recorded during the course of the experiments at the first and second vaccinations, at the control by the same and by M. Pasteur's virus. The first vaccination was followed on the second day by an increase in the temperature of the fowl of 1.7° C. (from 42° to 43.7°); the second vaccination by an increase of 1.5° C. (from 41.7° to 43.2°). The control inoculation by the same and Pasteur's virus did not produce any essential change in the temperature of the preserved fowl, whereas the control fowl inoculated with Pasteur's virus, showed on the second day an increase in the temperature of 2° C. (from 42° to 44°) before it died, somewhat later.

"From this it follows that in regard to chicken-cholera, as well as anthrax, the vaccinal fever is an indispensable and sufficient condition for producing immunity.

"Returning to our main object, we are allowed to draw the conclusion that our chicken-cholera bacteria, which were obtained from the intestines of a healthy pigeon, protect not only against repeated infection by themselves, but also in regard to the undoubted bacteria of chicken-cholera from Pasteur's laboratory.

"Therefore our bacteria are in every respect identical with the genuine chicken-cholera bacteria, or in other words: *The chicken-cholera bacteria must be regarded as constant parasites of the intestinal canal of pigeons, perhaps also of other birds*, in a similar manner as the septic-vibrio is an inmate of mammals (Pasteur). Therefore I propose to strike out the altogether inappropriate designation "bacteria of chicken-cholera" to replace it by a scientific name "bird septicæmia" and to assign the microbes to the genus *coccobacillus*, with the species name *avicidus*.

"The explanation for *coccobacillus avicidus* being found in the intestines of a bird without doing any harm, is given by the form existing there *not* being virulent enough, and being able to produce a disease only in susceptible animals—rabbit and Ziesel. Repeatedly I inoculated the contents of the intestines of pigeons into other pigeons, but not once did these inoculations bring about a deadly infection (chicken-cholera).

"Usually they did not call forth any perceptible disturbances in the organism of the animals, and caused only in exceptional cases an increase in the temperature, drowsiness, and diarrhoeal evacuations, in which the typical *coccobacilli avicidi* could be recognised.

"This fact of the presence of non-virulent *coccobacilli avicidi* in the normal intestines of birds furnishes an easy and practical method for preparing their vaccine. For this it is sufficient to proceed in such a way as has been described in the first series of experiments, in which, for this very reason, have been given all details. By way of transmission through rabbits there is obtained a virus of such a strength that, by injection of one cem. into the pectoral muscle, it kills pigeons the next day, and fowls the fourth to fifth day. This virus may be used for vaccinating fowls according to the process explained by me in the third series of experiments.

"Then a most important question presents itself: under what conditions do the *coccobacilli avicidi*, harmless to their host, attain their dreaded epidemic virulence?

"In my experiments quoted at the beginning of this paper, the cause of such an increase was poisoning by potato *bacilli* and Naples *bacilli*. In those cases the occurrence of chicken-cholera may be explained, (1) By a general poisoning, by means of chemical products of the vital activity of non-pathogenic bacteria; (2) By gastro-enteritis, which can be produced by those bacteria; (3) By the removal from the intestinal canal of all mesoderm phagocytes, which must be engaged in the digesting of large quantities of the introduced saprophytes.

"Although, for the present, I cannot adduce in support of this presupposition any decisive experiments, I am inclined to adopt it in the face of the negative results yielded in regard to the first two points (artificial gastro-enteritis or poisoning), and I may be permitted to sum up as follows:—

"Microbes of chicken-cholera inhabit, in slightly virulent varieties, the normal intestinal canal of birds, and must be assigned to the entosaprophytes which are facultative parasites.

"Protective vaccinations against chicken-cholera are subject to the general principle of vaccinal fever."

Odessa, June, 1888.

The results obtained in the foregoing experiments by Dr. Gamaleia are interesting enough to recommend inquiries being made with a view to ascertaining whether similar results may be obtained with reference to birds on Australian soil. It would seem advisable to try the effect on rabbits (and not only on birds) of the inoculation (or otherwise) of the contents of the intestinal canal, not only of birds that have died under suspicious circumstances, but also of perfectly healthy birds. In this connection I may just as well mention an experiment, which, however, yielded a negative result. On September 13th, 1888, I received a dead young chicken sent from Mr. Jindsay Thompson, in Burwood. (The mortality amongst chickens there has been very great, according to information). It was kept in an ice-chest till September 14th, when (1) a microscopical examination of heart-blood was made, (2) a half-grown rabbit was inoculated at 11.30 a.m. with a portion of the contents of the intestines. Results: (1) micro-organisms resembling those of chicken-cholera absent, and (2) the rabbit died on September 15th, between 11 a.m. and 12.30 p.m., but on examination there was no proof of its having succumbed to infection by the microbe of chicken-cholera. (Another half-grown rabbit was inoculated with blood from the same chicken and died, also on the 15th September, between 9.20 a.m. and 11 a.m.; result of *post-mortem* examination also negative.)

REPORT

* The normal temperature of fowls fluctuates, according to his inquiries, between 41.5° and 42.5° C. (O.K.)

REPORT ON MISCELLANEOUS EXPERIMENTS WITH THE MICROBES OF CHICKEN-CHOLERA.

In Appendix D will be found details of miscellaneous experiments on—

- I. Hares.
- II. Tame rabbits.
- III. Wild rabbits.
 - (a) With fecal matter from an infected rabbit.
 - (b) With urine from an infected rabbit.
 - (c) With virulent blood allowed to putrefy.
- IV. On ferrets.

ad I. Hares are very liable to take the disease both by feeding and by inoculation.

ad II. One tame Angora rabbit was found to be proof against inoculation with a virulent culture of the bacterium of chicken-cholera after having been fed three successive times with $1\frac{1}{2}$ ccm., 3 ccm., and $4\frac{1}{2}$ ccm. of a virulent culture of this bacterium. This is, to my knowledge, the first recorded case of a rabbit having proved immune against inoculation, let this immunity be a natural or an acquired one. Although I cannot furnish any absolute proof, I am inclined to adopt the latter alternative. It is intended to inoculate this rabbit once more, this time with virulent blood, as soon as the healing of the abscess, which has formed at the place of inoculation, is completed.

ad III. These experiments and their results have already been alluded to in the summary of the first report (pages 145, 146).

- (a) The fecal matter of an infected rabbit was not able to infect a fresh rabbit by feeding with a small portion of this matter, whereas inoculation with a minute quantity into another rabbit caused the animal to succumb to "chicken-cholera."
- (b) Urine of infected rabbits is not infective (one experiment).
- (c) Blood containing the microbes and allowed to putrefy, retains its virulence for some considerable time.

ad IV. Ferrets are not liable to take "chicken-cholera," either by being inoculated or by feeding.

OSCAR KATZ.

APPENDICES.

A.—Details of experiments with the microbes of chicken-cholera on rabbits in artificial burrows.

B.—Details of experiments with the microbes of chicken-cholera on rabbits in hutches.

C.—Details of experiments on rabbits placed in boxes or hutches in which rabbits had died of infection by the microbes of chicken-cholera.

D.—Details of miscellaneous experiments with the microbes of chicken-cholera:—

Series I.—On hares.

Series II.—On tame rabbits.

Series III.—On wild rabbits—

- (a) With fecal matter from an infected rabbit.
- (b) With urine from an infected rabbit.
- (c) With virulent blood, allowed to putrefy.

Series IV.—On ferrets.

E.—Explanation of Diagrams IV to VII, referred to in this Report.

Appendix A.

DETAILS of Experiments with the Microbes of Chicken-cholera on Rabbits in Artificial Burrows.

THE following is a short description of the burrows made use of in the experiments under consideration:—

From the loose sandy ground-surface of the roofed-in wire-gauze enclosure* (Diag. IV), hereinafter referred to as "the main enclosure," a small trench was taken out, as nearly as possible 5 inches deep and $4\frac{1}{2}$ inches wide. The trench was then covered with boards wide enough to prevent soil falling into it, the boards being thereafter covered with the soil taken out of the trench. Here and there the bottom of the burrows was directly formed of solid rock (hard sandstone), of which Rodd Island (where all experiments were conducted) is built up. The soil was quite dry when the burrows were made, and remained so, in the burrows, during the whole course of the experiments.

There were three burrows, each one being surrounded, at some distance, by a wire-netting fence preventing the rabbits therein from mixing with the rabbits in the other burrows. One of these three, however,—

Burrow A (Diag. V), was divided into three subdivisions (separated from one another by wire-netting), viz.,—

Subdivision AA,	containing in all about	16'	of burrow
" BB,	" "	16'	6" of burrow
" CC,	" "	13'	6" "

The other two, viz.,—

Burrow B (Diag. VI), containing in all about 58' of burrow, and

Burrow C (Diag. VII), " " 70' "

were without subdivisions.

The experiments were begun on

August 28, at 11 a.m., when *eight* rabbits were fed,† in separate compartments, upon cabbage leaves infected with $2\frac{1}{2}$ ccm. (for *each* rabbit) of a virulent broth-culture of the microbe of chicken-cholera, of the 4th generation.‡

Annotations:

- (a) These *eight* rabbits had been marked, before being fed on infected food, with a special mark for each rabbit, so that each one could be subsequently identified when in the burrow enclosures.
- (b) The *eight* rabbits had only received a small quantity of food on the night of the 27th, and were not given any on the morning of the 28th August until fed upon the infected food.
- (c) At 1 p.m. *five* of these rabbits had finished eating the portions of infected food given to them, whilst *three* had only about half finished their portions. At 3 p.m. all of the *eight* had finished their meal.
- (d) The hutches in which the *eight* rabbits were fed upon infected food were placed in such a position as to prevent the sun from shining into them.
- (e) The *eight* rabbits were selected as being especially vigorous and healthy.

At the same time,

Sixteen healthy-looking rabbits were fed, in separate compartments, on as nearly as possible the same quantity of *uninfected* cabbage leaves as given to the *eight* fed upon infected leaves.

Annotations

* A description of this enclosure may be found on reference to section VIII. of the Report, p. 136, and to section X., Appendix F, on page 143, and Diagram III at end of Appendices.

† For control experiments, *vide* below.

‡ The history of this culture is as follows:—Colony from virulent blood of a rabbit, fed on culture, 29/VIII, 1888, = I generation; gelatine stick-culture, 14/VIII, = II generation; broth-culture, 23/VIII, = III generation; broth-culture, 29/VIII, = IV generation.

150 ROYAL COMMISSION OF INQUIRY INTO SCHEMES FOR THE EXTERMINATION

Annotations :

- (a) These sixteen rabbits had only received a small quantity of food on the night of the 27th, and were not given any on the morning of the 28th August until being fed as above described.
- (b) At 3 p.m. only three of the sixteen had finished eating all the leaves given to them, but all the others had eaten more or less of their portions.

At 3.20 p.m.,

The eight rabbits fed upon infected food were, with the sixteen fed upon uninfected food, distributed into the burrow enclosures as follows :—

To Burrow Enclosure A :

- To Subdivision AA. One infected and two (full-grown) uninfected.
 BB. One infected and two (full-grown) uninfected.
 CC. One infected and two uninfected (one full-grown and one half-grown).

To Burrow Enclosure B :

Two infected and four uninfected (two full-grown and two half-grown).

To Burrow Enclosure C :*

Three infected and six uninfected (four full-grown and two half-grown).

Annotations :

- (a) At 3.45 p.m. all the twenty-four rabbits had found their way inside the burrows in their respective enclosures.
- (b) The rabbits referred to in these experiments were fed twice a day upon green food (barley and cabbage-leaves).

Control Experiments :(a) *Feeding :*

Aug. 28th, at 11 a.m.,

Two vigorous rabbits were fed (in separate compartments) under the same conditions as the eight infected distributed into the burrow enclosures. They remained in the compartments in which they were fed, and were given food as usual until death.

Results :

Aug. 29th.—One was found dead at 7 a.m. (i.e., about 20 hours after being fed). P.M., *Positive*.†

The other was found dead at 9 p.m., having died between 8 p.m. and that time (i.e., between 33 and 34 hours after being fed.) P.M., *Positive*.

A rabbit inoculated (at noon on the 29th August) with two small platinum loops full ($=\frac{1}{25}\frac{1}{4}$ ccm.) of heart-blood from the rabbit found dead at 7 a.m., died between midnight, 29th, and 1 a.m., 30th August, (i.e., between 12 and 13 hours after being inoculated). P.M., *Positive*.

(b) *Inoculation :*

Aug. 28th, at noon,

Two rabbits (one full-grown and one half-grown) were inoculated with a small quantity each of the same culture.

Results :

Aug. 28th.—One (half-grown) found dead at 7.45 p.m. (i.e., about 7½ hours after being inoculated). P.M., *Positive*.

Aug. 29th.—The other (full-grown) found dead at 7 a.m. P.M., *Positive*.

Results of Burrow Experiments :

Burrow Enclosure A. (Diag. II),

Subdivision AA. One infected to two uninfected.

Aug. 29th.—Infected one found dead at 7 a.m.‡ (i.e., about 20 hours after being fed), lying right in the mouth of the burrow at (a). P.M., *Positive*.||

Annotation : The head of this rabbit was partly under the board-covering at the mouth of the burrow, so that, in entering and leaving the burrow, the two uninfected rabbits must, each time, have passed immediately over the dead body.

Sept. 1st.—The burrow was uncovered at 5.15 p.m., when the two uninfected were found alive. (The carcass of the infected one was removed and the burrow re-covered immediately).

Sept. 4th.—The burrow was again uncovered at 3.30 p.m., when the two uninfected were found alive and removed from the enclosure.

Subdivision BB. (One infected to two uninfected.)

Aug. 29th.—Infected one found dead at 7 a.m. (i.e. about 20 hours after being fed), about 3 feet from the mouth of the burrow, at (a). P.M., *Positive*.

Sept. 1st.—The burrow was uncovered at 5 p.m., when one of the two uninfected was found dead inside the burrow, at (b). P.M., *Negative*. The other uninfected was still alive. (The carcasses of the two dead rabbits were removed and the burrow re-covered immediately.)

Sept. 4th.—The burrow was uncovered again at 3.30 p.m., when the other uninfected rabbit was found dead inside the burrow, at (c). P.M., *Negative*.

Annotation.—At 3.45 p.m. on the 29th August, it was observed that the two surviving rabbits in subdivision AA had burrowed a hole at the end of the right branch of their burrow (which, as may be seen on reference to Diag. II, extended beneath the subdivision fence into subdivision BB), and had thus made communication between the two subdivisions possible. At 4.30 p.m., however, it was observed that two rabbits were outside the burrow in subdivision AA, and two outside the burrow in subdivision BB, and as they bore the marks showing that they belonged respectively to the enclosure in which they were then seen, the hole at the end of the burrow was closed up.

Subdivision CC. One infected to two uninfected.

August 29th to September 1st. Infected one not seen outside the burrow.

Sept. 1st.—The burrow was uncovered at 4.45 p.m., when the infected rabbit was found dead inside the burrow, at (a). P.M., *Positive*. The two uninfected were found alive. (The carcass of the infected rabbit was removed and the burrow re-covered immediately).

Sept. 4th.—The burrow was again uncovered at 3.30 p.m., when the two uninfected were found alive, and removed from the enclosure.

Burrow enclosure B (Diag. III). Two infected to four uninfected.

Aug. 29th.—One infected found dead at 7 a.m. (i.e. about 20 hours after being fed) lying about 9 feet from the mouth of the burrow, at (a). P.M., *Positive*.

Aug. 30th.—One uninfected (full-grown) found dead at 4.45 p.m., about 3 feet from the dead body of the infected one, at (b). (This rabbit was removed from the enclosure immediately.) P.M., *Negative*.

Sept. 1st.—The burrow was uncovered at 4.15 p.m., when the other infected rabbit was found dead inside the burrow, at (c). P.M., *Positive*. One uninfected (half-grown) was also found dead inside the burrow, at (d). P.M., *Negative*. The carcasses of the two last-mentioned rabbits were removed and the burrow re-covered immediately.

Sept. 4th.—At 3.30 p.m. the burrow was again uncovered, when the two remaining uninfected were found alive and removed from the enclosure.

Burrow enclosure C. (Diag. IV.) Three infected to six uninfected.

Aug. 29th.—One infected found dead at 7 a.m. (i.e., about 20 hours after being fed), about 6 feet from the mouth of the burrow, at (a). P.M., *Positive*. Another infected was observed to die at 7.10 a.m. (i.e. 20½ hours after being fed), at (b). It rushed out of the burrow against the wire-netting opposite the burrow's mouth, fell over on its side, struggling convulsively on the ground; the muscles of the neck contracting and expanding, and drawing the head spasmodically backwards and forwards three or four times. It died in about 15 seconds from the time it emerged from the burrow, lying about a foot from the mouth with its head towards the burrow and its body in a line with the entrance thereto. P.M., *Positive*.

* For notes on the *Weather* and *Temperature* during the course of the experiments recorded in this Appendix, vide p. 151.

† Each time when death was due to infection caused by the microbes of chicken-cholera, the result of P.M. examination is noted as *Positive*; when death was due to causes other than infection by these microbes the result of P.M. examination is noted as *Negative*.

‡ Whenever infected rabbits referred to in these burrow experiments died, they were allowed to remain untouched for three clear days.

|| As will be seen P.M. examinations were made on all rabbits from the burrows so as not to leave the slightest doubt as to the cause of their death.

- Another infected found dead at 12:45 p.m. (i.e., about 25½ hours after being fed), about 6 feet from the mouth of the burrow at (c). P.M., *Positive*.
- Sept. 1st.—One uninfected (half-grown) found dead inside the burrow at 4 p.m., at (d). P.M., *Negative*. The burrow was uncovered at 4 p.m., when the five other uninfected were found alive. (The carcasses of the dead rabbits were removed and the burrow re-covered immediately).
- Sept. 4th.—Another uninfected (full-grown) was found dead at 7:15 a.m., in a side opening of the burrow, apparently jammed between the board-covering and the earth at the side of the burrow, at (e). P.M., *Negative*. At 3:30 p.m. the burrow was again uncovered, when the four remaining uninfected were found alive and were removed from the enclosure.

Notes on the *Weather* during the course of the experiments:—

- Aug. 28th.—Bright and calm all day.
- Aug. 29th.—Morning dull; strong southerly gale all day; night calm.
- Aug. 30th.—Calm and fine all day.
- Aug. 31st.—Calm and fine all day.
- Sept. 1st.—Morning dull, air damp, with light showers; afternoon light rain; evening calm and fine.
- Sept. 2nd.—Bright and calm.
- Sept. 3rd.—Bright, with light southerly breeze blowing.
- Sept. 4th.—Calm, sky overcast, air damp.

Notes on the *Temperature*, underground and in air (shaded), taken at the times stated during the course of the experiments:—
To ascertain, approximately, the temperature in the artificial burrows a small trench was dug out in the main enclosure (close to burrow enclosure C) corresponding in depth and width to the size of the burrow trench. In this trench a thermometer was placed, having its bulb lightly covered with some of the loose earth at the bottom of the trench. This was then covered with a board similar to the boards over the burrows, this board being completely covered with loose earth. To ascertain the temperature in the shade a thermometer was suspended from a post in the centre of the main enclosure, and, by means of boards, completely shaded from the sun. The temperatures are given in the centigrade scale.*

Underground.					In air (shaded.)				
August 28th			7:45 p.m. 30°		August 28th			4 p.m. 19°	7:45 p.m. 17½°
29th	7 a.m. 15½°	12:45 p.m. 15½°	5 p.m. 16½°	11:15 p.m. 15½°	29th	7 a.m. 13½°	12:45 p.m. 16°	5 p.m. 16½°	11:15 p.m. 14½°

APPENDIX B.

DETAILS of experiments with the microbes of chicken-cholera on rabbits in hutches:—

First Series.

The following is a short description and enumeration of the hutches used in the undernoted experiments. All the hutches were placed in the main enclosure. (Diag. IV.)

Hutches I, II, and III were made of boards with closely fitting wooden-bottoms, and with a hinged door of rabbit-proof wire-netting in front of each hutch. Each hutch measured in the clear inside 23" x 18" x 18" in depth, height, and width respectively.

Hutches IV, V, and VI were of the same size and material as hutches I, II, and III, save that each had a rabbit-proof wire-netting bottom, which rested on the ground so that the netting touched the loose soil of the main enclosure.

Hutch VII was a wooden-bottomed four-sided wooden enclosure, 2 feet deep, covering an area of one square metre, and having for its top a covering of rabbit-proof wire-netting.

Hutch VIII resembled hutch VII in all respects, save that it had a rabbit-proof wire-netting bottom, which rested on the ground of the main enclosure, and was lightly covered with loose earth.

Annotations:

- The six first mentioned hutches were placed (in the main enclosure) in such a way that the sun was completely prevented from shining into them.
- The two last mentioned hutches were the same enclosures (with the addition of a wooden and wire bottom respectively) as were used in, and are referred to in the report upon the experiments conducted by M. Pasteur's representatives.
- For weather and temperature during the course of the experiments recorded in this Appendix, *vide* page 153.

The experiments were begun on

September 3rd, when, between 11:45 a.m. and noon, eight rabbits (specially marked) were fed (in separate compartments) upon cabbage leaves infected with 2½ ccm. for each rabbit of a virulent broth-culture of the microbe of the fourth generation.†

At noon, two rabbits (also specially marked) were fed in separate compartments, upon cabbage leaves infected with 1 ccm. of the same culture (for each rabbit).

Annotations:

- These ten rabbits had not been fed on the night of the 2nd or on the morning of the 3rd September until the infected food was given to them.
- At 3 p.m. all but one of the ten had finished eating their portions of infected food. This one had only eaten about half its portion when it was removed from its compartment.
- The ten rabbits were selected as being especially vigorous and healthy.

Between 3:15 p.m. and 3:30 p.m., the ten infected rabbits were, with twenty uninfected rabbits, distributed into the hutches (described above), as follows:—

- Hutch I. { One infected (1 ccm.) to
 { Two uninfected (one full-grown, one half-grown).
- Hutch II. { One infected (2½ ccm.) to
 { Two uninfected (one full-grown, one half-grown).

Annotation: The infected one had only eaten half its portion of infected food when it was removed, from the compartment in which it had been fed, to this hutch.

* 1° C. = (9° Fahr.) + 32. 15° C. (e.g.) = (15 × 9° F.) + 32.

† The history of this culture is as follows:—Colony from virulent blood of a rabbit (fed on culture) 10/VIII 88=I generation; gelatine stick culture 14/VIII=II generation; gelatine stick culture 18/VIII=III generation; broth culture 1/IX=IV generation.

Hutch III.	{ One infected (2½ ccm.) to Two uninfected (full-grown).
Hutch IV.	{ One infected (1 ccm.) to Two uninfected (one full-grown, one nearly full-grown).
Hutch V.	{ One infected (2½ ccm.) to Two uninfected (full-grown).
Hutch VI.	{ One infected (2½ ccm.) to Two uninfected (full-grown).
Hutch VII.	{ Two infected (2½ ccm.) to Four uninfected (two full-grown, two half-grown).
Hutch VIII.	{ Two infected (2½ ccm.) to Four uninfected (two full-grown, two half-grown).

Annotation: The rabbits referred to in these experiments were fed twice a day on green barley.

Control experiments:

- (a) A vigorous rabbit was fed upon cabbage leaves infected with 2½ ccm. of the same culture as used in feeding the eight rabbits referred to above, and was kept under the same conditions.

Result:

Sept. 4th. It was found dead at 2:40 p.m., having died between noon and that time, (*i.e.*, between 24 and 26½ hours after being fed.) P.M., *Positive*.

- (b) A vigorous rabbit was fed upon cabbage leaves infected with 1 ccm. of the same culture, and kept under the same conditions as (a) above.

Result:

Sept. 4th. It was found dead at 2:40 p.m., having died between noon and that time, (*i.e.*, between 24 and 26½ hours after being fed.) P.M., *Positive*.

Results of the experiments in hutches:

Hutch I. One infected to two uninfected.

Sept. 6th. The infected one was found dead at 7:15 a.m., and was removed from the box at 10 a.m. on the 9th Sept.* P.M., *Negative*.

Sept. 10th. One uninfected (full-grown) was found dead at 9 a.m. P.M., *Negative*.

Sept. 10th. The other uninfected (half-grown) being alive at 4 p.m. (when the experiment was concluded) was removed from the hutch at that time.

Hutch II. One infected to two uninfected.

Sept. 4th. The infected one was found dead at 7:15 a.m. (*i.e.*, about 19½ hours after being fed), and was removed from the hutch at 10 a.m., on the 7th Sept. P.M., *Positive*.

Sept. 9th. One uninfected (half-grown) was found dead at 7:30 a.m. P.M., *Negative*.

Sept. 9th. The other uninfected (full-grown) was found dead at 10:50 p.m. P.M., *Negative*.

Hutch III. One infected to two uninfected.

Sept. 4th. The infected one was found dead at 7:15 a.m. (*i.e.*, about 19½ hours after being fed), and was removed from the hutch at 3 p.m., on the 7th September. P.M., *Positive*.

Sept. 7th. One uninfected (full-grown) was found dead at 10:20 p.m. (*i.e.*, about 4 days and 7 hours after being placed in the hutch), and was removed from the hutch at once. P.M., *Positive*.

Sept. 8th. The other uninfected (half-grown) was found dead at noon. P.M., *Negative*.

Hutch IV. One infected to two uninfected.

Sept. 9th. One uninfected (half-grown) was found dead at 7:30 a.m. P.M., *Negative*.

Sept. 10th. The infected and the other uninfected being alive at 10:45 a.m., were removed from the hutch at that time. (For notes on the further treatment of these two rabbits, *vide* second series below, page 153).

Hutch V.—One infected to two uninfected.

Sept. 4th.—The infected one was found dead at 7:15 a.m. (*i.e.*, about 19½ hours after being fed), and was removed from the hutch at 3 p.m. on the 7th Sept. P.M., *Positive*.

Sept. 6th.—One uninfected (nearly full-grown) was found dead at 2:30 p.m. (*i.e.*, just about three days after being placed in the hutch), and was removed from the hutch at 3:30 p.m. P.M., *Positive*.

Sept. 7th.—The other uninfected (full-grown) was found dead at 12:15 p.m. (*i.e.*, about 3 days and 21 hours after being placed in the hutch). P.M., *Positive*.

Annotations:—

(a) A broth-culture was prepared from a minute quantity of the heart blood of this rabbit.

(b) A rabbit inoculated with ½ ccm. of this culture at 11:30 a.m. on the 10th Sept. was found dead at 7:50 p.m. the same evening (*i.e.*, a little more than 8 hours after being inoculated). [*Vide* Appendix D, Series IV, page 156.] P.M., *Positive*.

(c) A rabbit inoculated with ⅓ ccm. of heart-blood from the last-mentioned rabbit at 12:50 p.m. on the 11th Sept. was found dead at 7:30 a.m. the next morning (*i.e.*, about 18½ hours after being inoculated). [*Vide* Appendix D, Series IV (b) (i), page 156.] P.M., *Positive*.

Hutch VI.—One infected to two uninfected.

Sept. 4th.—The infected one was found dead at 3 p.m., having died between 2:50 p.m. and that time (*i.e.*, between 23½ and 24 hours after being fed). It was removed from the hutch at 3 p.m. on the 7th Sept. P.M., *Positive*.

Sept. 6th.—One uninfected (a vigorous pregnant female, in the end of the first or beginning of the second week of gestation) was found dead at 7:15 a.m. (*i.e.*, about 2 days and 16 hours after being placed in the hutch), and was removed from the hutch at 10 a.m. P.M., *Positive*.

Sept. 10th.—The other uninfected being still alive at 4 p.m. (when the experiment was concluded) was removed from the hutch at that time.

Hutch VII.—Two infected to four uninfected.

Sept. 4th.—One infected was observed to die at 3 p.m. (*i.e.*, 27 hours after being fed), and was removed from the hutch at 3 p.m. on the 7th Sept. P.M., *Positive*.

Sept. 5th.—The other infected was found dead at 7 a.m. (*i.e.*, about 43 hours after being fed), and was removed from the hutch at noon on the 8th Sept. P.M., *Positive*.

Sept. 7th.—One uninfected (full-grown) was found dead at 7:30 a.m. P.M., *Negative*.

Another uninfected (full-grown) was found dead at 5 p.m. P.M., *Negative*.

Sept. 9th.—Another uninfected (half-grown) was found dead at 7:15 a.m. P.M., *Negative*.

Sept. 10th.—The other uninfected being still alive at 4 p.m. (when the experiment was concluded) was removed from the hutch at that time.

Hutch VIII.—Two infected to four uninfected.

Sept. 4th.—One infected was found dead at 7:15 a.m. (*i.e.*, about 19½ hours after being fed), and was removed from the hutch at 3 p.m. on the 7th Sept. P.M., *Positive*.

Sept. 5th.—The other infected was found dead at 12:15 p.m., having died between 11 a.m. and that time (*i.e.*, between 47 and 48½ hours after being fed). It was removed from the hutch at noon on the 8th Sept. P.M., *Positive*.

Sept. 7th.—One uninfected (full-grown) was found dead at 9 a.m. P.M., *Negative*.

Sept. 10th.—Another uninfected (half-grown) was found dead at 10:30 a.m. P.M., *Negative*.

The other two uninfected being still alive at 4 p.m., (when the experiment was concluded) were removed from the hutch at that time.

Second

* Wherever infected rabbits, referred to in these hutches experiments died, they were allowed to remain untouched for three clear days.

Second Series.

THE two experiments, in which two rabbits were infected, each with 1 ccm. of a culture of the microbe, and placed with two uninfected rabbits for each of them into hutches I and IV, respectively, having failed altogether (*vide* above), two other experiments were carried out. The two hutches used for this purpose were hutches III and V (*vide* above), which had been disinfected by means of boiling hot water and allowed to dry. They may be designated as hutches IX (wooden-bottomed) and X (wire-bottomed).

Sept. 10th, at 11:45 a.m.,—

A rabbit (the surviving uninfected specimen from hutch IV, *vide* pages 151, 152) was fed upon green barley infected with 1 ccm. of a virulent broth-culture of the microbe of the first generation.

Annotation: This culture was derived directly from blood of a rabbit that had died on Sept. 7th, in hutch V, about four days after having been exposed to an infected rabbit in the same hutch (conf. *Annot.* to result of hutch V, above).

Having finished eating its portion of infected food at 12:30 p.m., it was placed, at 4 p.m., in hutch IX, with two uninfected rabbits (one full-grown, one half-grown) that had survived from the artificial burrow experiments.*

Annotation: The infected rabbit had not been fed in the morning.

Hutch IX. One infected to two uninfected.

Result:

Sept. 11th.—The infected one was found dead at 9:10 a.m., having died between 8:30 a.m. and that time, (*i.e.*, between 20½ and 20¾ hours after being fed). It was removed from the hutch at 9:30 a.m., on the 14th Sept. P.M., Positive.

One uninfected (half-grown) was found dead at 11 a.m. P.M., Negative.

Sept. 17th. The other uninfected being still alive at 5 p.m. (when the experiment was concluded) was removed from the hutch at that time.

Sept. 10th, at 11:45 a.m.

A rabbit (the surviving infected from hutch IV (1 ccm. of culture) *vide* pages 151, 152) was fed upon green barley infected with 2 ccm. of the same culture as used in feeding the rabbit placed in hutch IX. Having finished eating its portion of infected food, at 12:30 p.m., it was placed, at 4 p.m., with two uninfected (one full-grown, one half-grown), that had survived from the artificial burrow experiments, in

Hutch X. One infected to two uninfected.

Result:

Sept. 11th. The infected one was found dead at 1:15 p.m. (*i.e.*, about 25½ hours after being fed), and was removed from the hutch at 10 a.m. on the 13th Sept. P.M., Positive.

Sept. 12th. One uninfected (half-grown) was found dead at 11:15 a.m. P.M., Negative.

Sept. 13th. The other uninfected (full-grown) was found dead at 7:30 a.m. P.M., Negative.

NOTES on the Weather during the course of these experiments:—

Sept. 3rd.—Bright and calm all day.

Sept. 4th.—Morning, calm, sky overcast, air damp. Afternoon and evening—calm and fine, air dry.

Sept. 5th.—Fine, with strong easterly wind in afternoon.

Sept. 6th.—Fine until 5 p.m., when light rain fell for about an hour. Heavy rain set in about 6 p.m., lasting an hour or so; after that the night was fine.

Sept. 7th.—Fine morning. Afternoon showery, with southerly wind. Evening calm and fine.

Sept. 8th.—Calm and fine all day.

Sept. 9th.—Fine morning; at midday a few light showers fell, lasting off and on for two hours or so; thereafter calm and fine.

Sept. 10th.—Calm and fine.

Sept. 11th.—Early morning, fine; thunder-shower and downpour of rain from 9:30 a.m. to about 2 p.m.; light rain fell till about 3 p.m.; thereafter calm and fine.

Sept. 12th and 13th.—Calm and fine.

Sept. 14th.—Morning, dense fog, air very damp till about 10 a.m.; thereafter calm and bright.

Sept. 15th, 16th, and 17th.—Calm and fine.

NOTES on the Temperature (in the shade) taken during the course of the experiments. The temperatures are given in the centigrade scale.

September 3rd.	7 a.m. 7°	1:45 p.m. 16¼°	6 p.m. 13¼°	10:30 p.m. 10¼°	September 11th.	7:15 a.m. 10¾°	2 p.m. 12¼°	5 p.m. 11¾°	10:15 p.m. 12°
4th.	7:15 a.m. 16°	1:30 p.m. 18°	5 p.m. 14¼°	9:30 p.m. 10¼°	12th.	7:30 a.m. 9¼°	1:45 p.m. 16¼°	Midnight. 14¼°
5th.	7 a.m. 7¼°	1 p.m. 20°	5:30 p.m. 16°	10:15 p.m. 12¼°	13th.	7:30 a.m. 9°	1 p.m. 21¾°	5 p.m. 16¾°	10 p.m. 12¼°

APPENDIX C.

DETAILS of Experiments on Rabbits placed in Boxes or Hutches in which Rabbits had died of Infection by the Microbes of Chicken-cholera.

(a) August 29th, at 9:30 a.m.,—

A rabbit was placed in a box† in which two rabbits, that had been inoculated with a portion of a virulent broth-culture of the microbe, were found dead at 7:45 p.m. on the 28th and 7 a.m. on the 29th August respectively, and from which they were removed immediately thereafter.

Annotations: (a) The inoculated rabbits referred to were control animals to the burrow experiments (*vide* Appendix A, page 150).

(b) In this box there was a considerable amount of normal-looking faeces when the healthy rabbit was put in, and a large portion of the (uninfected) food given to the two inoculated rabbits on the evening of the 28th August.

Result:

September 6th.—It was still alive at noon (*i.e.*, after about eight days), and was then removed from the box. (b)

* These rabbits had to be taken from want of fresh rabbits at the time.

† The boxes or hutches alluded to in this Appendix were placed (in the main enclosure) in such a way that their insides were almost completely sheltered from the rays of the sun. For temperature and weather during the experiments noted in these Appendices, *vide* Appendix A, pages 151 and 153.

154 ROYAL COMMISSION OF INQUIRY INTO SCHEMES FOR THE EXTERMINATION

(b) August 29th, at 9.30 a.m.,—

A half-grown rabbit was placed in a hutch in which a rabbit, that had been *fed* on the 28th upon cabbage leaves infected with 2½ ccm. of a virulent broth-culture of the microbe, was found dead at 7 a.m. on the 29th August, and from which it was removed immediately thereafter.

Annotations: (a) The infected rabbit referred to was control to the burrow experiments (*vide* Appendix A page 150).

(b) In this hutch there was only a small quantity of normal-looking faeces, but part of the hutch floor was damp with urine. All food left over by the rabbit fed on infected food was removed from the hutch before the healthy rabbit was placed therein.

Result:

September 3rd.—It was found dead at 7 a.m. P.M., *Negative*.

(c) August 30th, at 10.15 a.m.,—

A half-grown rabbit was placed in a hutch in which a rabbit, that had been *fed* on the 28th upon cabbage leaves infected with 2½ ccm. of a virulent broth-culture of the microbe, was found dead at 9 p.m. on the 29th August, and from which it was removed immediately thereafter.

Annotations: (a) The infected rabbit referred to was control to the burrow experiments (*vide* Appendix A, page 150).

(b) In this hutch there was a considerable quantity of normal-looking faeces, and part of the hutch floor was damp with urine. All the infected food had been eaten by the rabbit fed thereon on the 28th August, but some of the (uninfected) food given it on the night of the 29th was still in the hutch when the healthy rabbit was placed therein.

Result:

September 6th.—It was found dead at 7.15 a.m. P.M., *Negative*.

(d) September 4th, at 2.50 p.m.,—

A half-grown rabbit was placed in a hutch in which a rabbit, that had been *fed* on the 3rd upon cabbage leaves infected with 1 ccm. of a virulent broth-culture of the microbe, was found dead at 2.40 p.m. on the 4th September, and from which it was removed immediately thereafter.

Annotations: (a) The infected rabbit referred to was control to the experiments in hutches (*vide* Appendix B, p. 152).

(b) What has been said in *Annotation* (b) to 30th August, with reference to amount and appearance of faeces and food in the hutch, applies also to this experiment.

Result:

September 9th.—It was found dead at 9.15 a.m. P.M., *Negative*.

(e) September 4th, at 2.50 p.m.,—

A young rabbit was placed in a hutch in which a rabbit, that had been *fed* on the 3rd upon cabbage leaves infected with 2½ ccm. of a virulent broth-culture of the microbe, was found dead at 2.40 p.m. on the 4th September, and from which it was removed immediately thereafter.

Annotations: (a) The infected rabbit referred to was control to the experiments in hutches (*vide* Appendix B, page 152).

(b) What has been said in *Annotation* (b) to 30th August, with reference to amount and appearance of faeces and food in the hutch, applies also to this experiment.

Result:

September 9th.—It was found dead at 9.15 a.m. P.M., *Negative*.

APPENDIX D.

DETAILS of Miscellaneous Experiments with the Microbes of Chicken-cholera.

Series I.

Experiments on hares:—*

(i) Aug. 11th.—At 3.30 p.m.

A hare was *inoculated* with five small platinum-loops full (about $\frac{1}{5}$ ccm.) of virulent blood from a rabbit that had died after inoculation with a small quantity of a virulent broth-culture of the microbe.

Control:—A control rabbit (full-grown) was found dead at 9 a.m. on the 12th Aug. P.M., *Positive*.

Result:

Aug. 12th.—The hare was found dead at 9 a.m. (*i.e.*, about 17½ hours after being inoculated). P.M., *Positive*.

(ii) Aug. 11th.—At 4 p.m.

A hare was *fed* upon a few cabbage leaves infected, by means of a platinum-loop, with about $\frac{1}{4}$ ccm. of blood from the same infected rabbit from which blood was taken for the inoculation of a hare this date [*vide* (i) above]. It was not until 10 p.m. (*i.e.*, six hours after the infected food had been placed in the box) that the hare was observed to have eaten all the infected food given to it.

Control:—A control rabbit, which had finished eating its portion of infected food shortly after the food was placed in its box, was found dead at 8.30 p.m. on the 12th Aug., having died between 5.30 p.m. and that time (*i.e.*, between 25½ and 28½ hours after being fed). P.M., *Positive*.

Result:

Aug. 16th.—The hare was still alive at 11.30 a.m. (*i.e.*, about 8 days after the feeding referred to above).

(iii) Aug. 16th.—At 11.30 a.m.

(a) The same hare was *fed* upon cabbage leaves infected with 1½ ccm. of a virulent broth-culture of the microbe.

(b) Another hare (which had survived from inoculation with some dried blood taken by Dr. Bancroft, of Brisbane, Qu., from a hare that had died in captivity) was *fed* upon cabbage leaves infected with 1½ ccm. of the same culture.

Control:—(a) Of two control rabbits, large vigorous animals (both *tame*†), *fed* together in the same box upon food infected with 3 ccm. of the same culture, one (a long-haired black specimen) was found dead at 8.45 p.m. on the 18th Aug. (*i.e.*, about 57½ hours after being fed). P.M., *Positive*.

The other (a long-haired albino) was still alive on the 20th Aug. (For further treatment of this particular rabbit *vide* Series II of this Appendix.)

(b) A control rabbit (a *tame* long-haired albino) *inoculated* with a small quantity of the same culture was found dead at 8 a.m. on the 17th Aug. (*i.e.*, about 20½ hours after being inoculated).

Results:

Aug. 17th.—Both hares were found dead at 8 a.m. (*i.e.*, about 20½ hours after being fed). P.M. (in each case), *Positive*.

Series II.

Experiments on tame rabbits:

(a) Aug. 16th, at 11.30 a.m.

A tame rabbit (full-grown long-haired albino) was *fed*, together with another tame rabbit, upon cabbage leaves infected with 3 ccm. (*i.e.*, 1½ ccm. for each rabbit) of a virulent broth-culture of the microbe. [This experiment has already been mentioned in the foregoing Series I. (iii.) *Control*, when it was stated that the latter rabbit was found dead at 8.45 p.m. on the 18th Aug.]

Result:

Aug. 20th.—It was still alive at 9.30 a.m.

(b)

* The hares mentioned in these experiments were among five full-grown hares received from the country, through Mr. H. C. Taylor, of the Rabbit Branch of the Lands Department.

† The tame rabbits mentioned in this report were received at Redd Island in June last, having been sent (according to information) from Adelaide, S.A., by Professor Watson.

(b) Aug. 20th, at 9:30 a.m.

It was fed upon cabbage leaves infected with 3 ccm. of a virulent broth-culture of the microbe of the third generation.

Control:

- (i) A control rabbit (fed under the same conditions as the tame rabbit) was found dead at 8 a.m. on the 21st Aug. (*i.e.*, about 22½ hours after being fed). P.M., *Positive*.
 (ii) Another control rabbit (half-grown), fed upon food infected with only half of the portion of culture (*viz.*, 1½ ccm.), was found dead at 8 a.m. on the 21st Aug. (*i.e.*, about 22½ hours after being fed). P.M., *Positive*.

Result:

Aug. 25th.—It was still alive at 10:30 a.m.

(c) Aug. 25th, at 10:30 a.m.

It was fed upon cabbage leaves infected with 4½ ccm. of a virulent broth-culture of the microbe, of the third generation.

Control: A vigorous (Tasmanian) rabbit was observed to die at 8:30 a.m. on the 26th Aug. (*i.e.*, 22 hours after being fed). P.M., *Positive*.

Result:

Sept. 1st.—It was still alive at 4 p.m.

(d) Sept 1st, at 4 p.m.

It was inoculated with ½ ccm. (2 minims) of a virulent broth-culture of the microbe, taken directly from the blood of a rabbit dead after feeding with that microbe.

Control: A control rabbit was found dead at 8 a.m. on the 2nd Sept. (*i.e.*, about 16 hours after being inoculated). P.M., *Positive*.

Result:

It remained alive, but at the seat of inoculation was formed a large abscess, which was at first closed, but which was found to be opening five days after inoculation, discharging a sticky, yellowish, inodorous pus.

A platinum-loop full of this pus was inoculated into a rabbit at 12:45 p.m. on the 10th Sept. This animal was found dead at 7:30 a.m. on the 13th Sept., but the P.M. examination yielded a negative result, so far as infection by the virus in question was concerned.

The abscess began to heal, showing at the bottom a dry crust, but up to date (21st Sept.) the healing process is not yet complete.*

Series III.

Experiments on wild rabbits:

(a) With Faecal matter from an infected rabbit.†

(i) Inoculation:

Sept. 2nd. At 11:35 a.m.

A rabbit was inoculated with a small portion (one platinum-loop full) of the soft green contents taken from the rectum of a rabbit dead about four days.

Annotations: (a) This last mentioned rabbit died in consequence of infection in burrow enclosure B. [*Vide* Appendix A; Diag. VI (c)].

(b) The faecal matter was obtained from the rectum by means of a glass tube carefully introduced into the anus.

Result:

Sept. 3rd.—It was observed to die at 10:50 a.m., (*i. e.*, 23½ hours after being inoculated). P. M., *Positive*.

(ii) Feeding:

Sept. 3rd. At 8:15 p.m.,

A half-grown rabbit was fed upon cabbage leaves infected with about ½ ccm. of the same faecal matter, kept moist meanwhile under a bell-jar.

Annotation: This rabbit had not received any food since 9 a.m. on the same day; at 10 p.m. it had eaten all the infected food given to it.

Result:

Sept. 10th.—It was still alive at 10:45 a.m. (*i. e.* about 4½ days after being fed), and was then removed from its hutch.

(b) With Urine from an infected rabbit.

Sept. 11th. At 1:30 p.m.

Two rabbits were inoculated with about ½ ccm. each of urine taken from a rabbit dead of infection by the virus of chicken-cholera (after inoculation with ½ ccm. of culture).

Annotation: The bladder of this (infected) rabbit was much distended. The urine, in which was a large amount of corpuscular matter, presented a peculiar amber-yellow appearance. The urine used for inoculation was obtained by means of sucking a small portion into a fine glass tube through a wide hole made into the lifted and stretched vortex of the bladder by means of a heated glass rod.

Results:

Sept. 13th.—One was found dead at 7:30 a.m., P.M., *Negative*.

Sept. 15th.—The other was still alive at 9:30 a.m., when it was removed from its box.

(c) With virulent blood, allowed to putrefy.

At the examination, on the 2nd September, of a rabbit about four days after its death in one of the burrows [Appendix A, Burrow Enclosure B (c); the same rabbit mentioned in (b) of this Series], the coagulated blood of the right ventricle of the heart was removed and placed in a small clean glass (flask), which was stoppered and put aside in the laboratory. On microscopical examination on the date mentioned, only the microbes of chicken-cholera were present.

(i) September 3rd, at 11:30 a.m.—

A half-grown rabbit inoculated with a small platinum-loop full of this blood (not yet putrid) was found dead at 7 a.m. on the 3rd September (*i.e.*, about 19½ hours after being inoculated). P.M., *Positive*.

(ii) September 10th, at 5 p.m.—

A rabbit inoculated with about the same quantity of the blood (now putrid) was found dead at 8:25 a.m. on the 11th September, having died between 7:15 a.m. and that time (*i.e.*, between 14¼ and 15½ hours after being inoculated). P.M., *Positive*.

(iii) September 17th, at 2:10 p.m.—

A rabbit inoculated with about the same quantity of the blood (putrid) was found dead at 7:40 a.m. on the 18th September (*i.e.*, about 17½ hours after being inoculated). P.M., *Positive*.

(iv) September 20th, at 10:40 a.m.—

A rabbit inoculated with about the same quantity of the blood (putrid) was still alive (midnight, 21st September).‡

(v) September 24th, at 11:10 a.m.—

A rabbit inoculated with about the same quantity of blood was still alive after seven days (October 1st).

Series

* For further history of this rabbit see Chief Expert's Report (No. 2) pp. 160-161.

† For further experiments with faecal matter see page 161.

‡ It was found dead at 5 p.m. on the 22nd September, having died between 1:50 p.m. and that time, *i.e.*, between 51 and 54 hours after inoculation). P.M., *Positive*.

156 ROYAL COMMISSION OF INQUIRY INTO SCHEMES FOR THE EXTERMINATION

Series IV.

Experiments on ferrets :—*

(a) Inoculation.

(i) With culture.

September 10th, at 11:30 a.m.—

Two ferrets (one male, one female) were inoculated with $\frac{1}{2}$ ccm. of a virulent broth-culture of the microbe of chicken-cholera obtained directly from blood of a rabbit that had died of chicken-cholera (by transmitted infection in Hutch V—*vide* Appendix B, page 152).

Control: A control rabbit was found dead at 7:50 p.m. the same day (*i.e.*, about 8 $\frac{1}{2}$ hours after being inoculated) P.M., *Positive*.

Results:

September 11th to 20th.—On being fed at 9 a.m. on the 11th September, the two ferrets appeared dull and feverish. Both drank water freely before touching the meat or porridge and milk given to them, and when they took up the pieces of meat did not tear at them ravenously, as was their wont before being inoculated. So they remained for some time. The seat of inoculation showed some special reaction, which in one (the female) subsided gradually (up to date), while the condition of the other (male) became worse and worse, till it succumbed on the 18th September.

P.M.—Extensive gangrene round the seat of inoculation; organs abnormal; absence of any micro-organisms in preparations from heart-blood and spleen.

Amputation: A rabbit inoculated with a small quantity of heart-blood from this ferret died during the night in consequence of some injuries accidentally received in its hutch.

(ii) With blood.

Sept. 11th.—At 12:50 p.m.

Two ferrets (one male, one female) were inoculated *each* with five platinum-loops full (= $\frac{1}{2}$ ccm.) of heart-blood from a rabbit that had died of "chicken-cholera" (inoculation).

Control:—A control rabbit was found dead at 7:30 a.m. on the 12th Sept. (*i.e.*, about 18 $\frac{1}{2}$ hours after being inoculated). P.M., *Positive*.

Results:

Sept. 11th to 20th.—The seat of inoculation did not show any special reaction. The two ferrets appeared somewhat sluggish at first, but very soon afterwards behaved as before.

(b) Feeding:

(i) Sept. 12th.—

Three ferrets (one male, two females) were fed together upon 30 grammes (= about 1.07 oz) of virulent liver taken from a rabbit newly dead of "chicken-cholera" (inoculation).

Results:

Sept. 11th to 20th.—The ferrets did not appear to show any reaction whatever.

(ii) Sept. 18th.—

Two ferrets (one male, one female) were fed together upon 45 grammes (= about 1.6 oz) of virulent liver from a rabbit newly dead of "chicken-cholera" (inoculation).

Results:

Sept. 18th to 20th.—The ferrets did not appear to show any reaction.†

APPENDIX E.

EXPLANATION of Diagrams IV to VII referred to in this Report.

Diagram IV is a sketch of the main enclosure and part of the shed (with regard to the construction of which full particulars have been already given in section VIII. of the Report, pp. 136, 137, and in section X, Appendix F, page 143, and Diagram III at end of Appendices. The diagram shows (approximately) the relative sizes and positions in the main enclosure of,

A (AA, BB, CC), B, C, which represent the wire-netting enclosures encircling the artificial burrows referred to particularly in Appendix A

l.l.l.l. represent posts supporting the wire-gauze roof of the main enclosure.

Diagrams V, VI, VII show (approximately), on a scale of 5 feet to the inch the respective artificial burrows within the wire-netting enclosures referred to above. The small letters (*a, b, c, &c.*) show, approximately, the position of the rabbits as they died in the respective burrows or enclosures: the bodies of the rabbits being represented by two cross lines (+) in the case of rabbits dead of "chicken-cholera," and by a plain line (—) in the case of rabbits that died from other causes.

Diagram V shows also a sketch of a vertical section of the artificial burrows. This sketch applies also to the burrows figured in Diagrams VI and VII.

PROGRESS REPORT (No. II.) ON EXPERIMENTS WITH THE MICROBES OF CHICKEN-CHOLERA.

To the Chairman, Experiment Committee, Rabbit Commission,—

Rodd Island, 2 November, 1888.

I BEG to report as follows:—

A. Infecting Rabbits in successive series of twenty generations.

It being from a practical point of view—in case the microbes of chicken-cholera were to be employed as a means for the destruction of rabbits in Australasia—a matter of some importance to know whether these microbes, by passing through the bodies of rabbits in a number of continuous generations, become altered in their degree of virulence or not, the Experiment Committee of this Commission decided that such an experiment, with a view to obtaining the required information, should be made, extending to the number of twenty successive transmissions from rabbit to rabbit.

Let us suppose the virus under consideration is endowed with the faculty of becoming more virulent, or, in other words, of attaining a greater poisoning strength in its action on rabbits, by means of such successive transmissions, the consequence will naturally be that, under the same conditions, the period of incubation and actual disease, or the whole period from infection to death, becomes shorter, until a certain stationary point is reached; this period must, on the other hand, provided the conditions be the same, become longer, or infection with subsequent death may not follow at all, if there should be any decrease or attenuation of the virulence of the microbe. Should the latter preserve its degree of virulence uniformly from the first rabbit to the last, it stands to reason that the above period will remain about the same throughout, provided again the conditions be the same. The

* The ferrets referred to in these experiments were sent to the Rabbit Commission by the Government of New Zealand, and were received at Rodd Island on the 31st August.

† The ferrets continued to be in good health (October 1st).

The experiment was carried out in the following manner:—A healthy pigeon was inoculated October 3rd, with a small quantity of the surface growth of a virulent stick-culture of the microbe of chicken-cholera (fourth generation, 32 days old). Not long after the death of this pigeon, which died of typical chicken-cholera within about twenty hours, two rabbits* were inoculated each with five platinum loopsful, equal to $\frac{1}{4}$ ccm., † of heart-blood from this pigeon. The blood of the *first* rabbit that died, or that was found dead, furnished the material for inoculation in like manner into two further rabbits; with the blood again of the *first* of these dead, two other rabbits were inoculated, and so on till the number of forty rabbits, or twenty generations, were arrived at, when the experiment was concluded.

Before directing your attention to the table of results of the experiments given below (Table I, page 162), I wish to state the following:—The rabbits used were, if not specially noted to the contrary, full-grown animals of normal appearance. If at the *post-mortem* examinations anything abnormal was found, it will be remarked in the table below. The rabbits for this experiment were taken irrespectively of the sex. From practical reasons it was not possible to employ either males or females from the beginning to the end.

Immediately after the inoculations the rabbits were placed in spacious clean hutches, separately, and food was given to them as usual. They were also, all of them, sheltered from rain and sun in like manner.

The blood used for the inoculations was in each case derived from the right *atrium* of the heart, near the *venae cavae*. The quantity of blood derived was pretty uniformly the same each time, viz., $\frac{1}{4}$ ccm. (*vide* above).

The time of inoculation of each new series lay within about *two* hours from the moment the first of the preceding series died. In cases where such rabbits were found dead, instead of being observed to die, the body-temperature then taken yielded a cue as to the approximate time when death occurred.

The seat of inoculation was always a corresponding area on the left side of the belly. After having shorn this area, a small fold of the skin, where there was no blood-vessel running, was cut across by means of a small pair of scissors. The wound thus produced was made the entrance into a small subcutaneous pouch, where the inoculation-material was easily and safely deposited by means of the platinum loop.

The quantity of bacteria thus inoculated into the different rabbits was, comparatively speaking, a limited one. The direct microscopical examination of uniformly obtained and stained samples of heart-blood of all the rabbits shortly after their death succeeded in showing only moderate numbers of individual bacteria.

In four cases I have tried to determine approximately the number administered, namely, in Inoculation Series X, XV, XIX, and XX, [Nos. 19, 29, 37, and 39 (*vide* table below)]. About 10 ccm. of 6 per cent. rabbit-broth-peptone-gelatine in a test-tube were liquefied, so as to have a temperature of between 30° and 40° C., mixed with one platinum loop full (one-fifth of the quantity for inoculation) of the heart-blood, and made to solidify, by means of iced water, in a homogeneous layer along the inner walls of the test-tubes (Esmarch's method). After having been in a thermostat at a suitable temperature for three or four days, the coating of gelatine in the tubes presented innumerable, as it seemed, whitish points of growth or colonies, the number of which, however, could without difficulty be calculated by counting the number of colonies at, usually, ten different spots each of the area of one-sixteenth of a square cm., area cut out of a piece of black paper. The total number of colonies which were calculated as being contained in the four tubes amounted to 67,023, 71,887, 65,367, 48,593, *i.e.*, in the mean, 63,368. This figure multiplied by five yields 316,840, and, if we are permitted to make use of this average number, we may well say that the quantity of microbes transmitted into the rabbits along with blood was not very far off this number. We are, however, well justified in taking it somewhat higher, from the fact that a portion of the bacteria in the blood are occurring in twos, which will not be easily separated by mixing with gelatine, in which, on beginning to multiply, they will give rise to but one colony.

This relative scarcity of the micro-organisms of chicken-cholera in the heart-blood of rabbits *newly* dead, stood in a sharp contrast to the relative abundance of these microbes in samples of the same blood taken from rabbits *which had been left* where they died untouched (say) for *twelve, twenty-four, thirty-six, or more* hours. In each case where such a comparison was made—for that purpose one portion of the rabbits as used for the inoculations were examined soon after their death, and the other corresponding portion at some time after their death; but also on other occasions, when I had an opportunity of thus comparing, I could not fail to be struck with the disparity of the heart-blood alluded to.

On the other hand it was repeatedly noticed that the capillary-blood derived from cut surfaces of the liver, soon after the death of rabbits, contained incomparably more numerous bacteria than the heart-blood derived from the same subject and at the same time.

I must add that all the samples for microscopical examination were derived in like quantities, and spread and stained on cover-glasses in like fashion. From this it is evident that in rabbits dead of "chicken-cholera," at the time of death or shortly after it, the blood of the heart and main vessels carries only a relatively small number of the bacteria, and that their relatively plentiful occurrence there some such time after death as noted above, can only be declared by their having multiplied there after the death of their hosts.

The table, the arrangement of which will, I think, be easily understood, contains the results of this experiment. I may at once remark that, for the sake of convenience, those rabbits which as having died first were used for the successive inoculations of the different series (column one) are designated uniformly by the first (odd) number (column two) of each series:—

[See Table I, page 162.]

In looking over the figures in this table, we cannot help arriving at the conclusion that by transmitting the virus of chicken-cholera from rabbit to rabbit to the extent of twenty generations, neither an increase nor a decrease in its virulence is attained—that, rather, its virulence does not exhibit any striking differences throughout the whole series. It is true that in four cases out of the forty the figures regarding time of death are a little lower than usual (Nos. 1, 21, 29, 33), that in three other cases they are somewhat higher (Nos. 4, 14, 28), and that in one case (No. 34) the figure is very high. But these exceptions may be declared to arise from certain individual properties of the rabbits employed. It was, as a matter of fact, not possible to take exclusively only such rabbits as were like one another in every respect (age, size, weight, sex, and health). That

* The rabbits used in this and other experiments recorded in this Report were, with one exception when special notice will be given, wild rabbits from Carrathool, near Hay, N.S.W.

† One cubic centimetre (ccm.) is equal to sixteen minims.

‡ 1° C. = (2° Fahr.) + 32; 15° C. (e.g.) = (15 × $\frac{9}{5}$ F) + 32.

§ 2.515 cm. = 1 inch.

That the rabbit No. 34, Series XVII—a light-grey female, with a white streak running longitudinally from the back of the head over the middle of the head down to the under side of the neck (mammary glands fully developed, containing milk)—did not succumb until two days after inoculation, which had been performed in the usual manner, is very remarkable. Seeing it outlive the first day, I thought of having hit upon another, but somewhat different, example of immunity in rabbits (*vide* page 154, Appendix D, series II). The *post-mortem* examination later on left no doubt as to its having died of "chicken-cholera." I may, however, mention that the seat of inoculation differed from that in all rabbits inoculated, in so far as there was a yellowish-white membranous formation adhering to the under surface of the cutis, of about the size of a sixpence. This appearance was not unlike that which is noticed at the seat of inoculation with the virus of chicken-cholera in the case of fowls and pigeons; but while the substance of the yellowish subcutaneous masses forming after inoculation in fowls and pigeons are found to be crowded with chicken-cholera bacteria, in the corresponding case of the rabbit these bacteria were exceedingly scarce.

The next table (II), page 163, contains the results of inoculations into fowls and pigeons with heart blood from the first-mentioned rabbits as used in the Inoculation Series, V, X, XV, XX of Table I. In reference to the first case which I denoted as inoculated from Inoculation Series I, I must state that, as the date, 16th October, implies, that particular rabbit was not exactly the first dead of the first generation as followed directly by the others; but this experiment was added later on, when, on 14th October, a pigeon was inoculated with a small quantity of the surface-growth of a gelatine stick-culture of the microbe (fifth generation, 17 days old), and after the death of the pigeon which died between 14 h. 15 m. and 17 h. 5 m., a rabbit was inoculated (15th October), in pretty much the same way as the two of the first series in Table I. From this rabbit, which died between 12 h. 30 m. and 15 h. 45 m., the fowl and pigeon of series I of the following table were inoculated. Therefore, I call Series No. I simply inoculated from Inoculation Series I. The conditions under which the five series were inoculated were, on the whole, corresponding to those stated for the rabbits (Table I); the seat of inoculation was an area under the skin which covers the pectoral muscle.

[See Table II, page 163.]

As evidenced by the data obtained and put together in this table, the virulence of the microbes of chicken-cholera neither increases nor decreases, perceptibly, in fowls and pigeons inoculated with virus descending from rabbits of the first, fifth, tenth, fifteenth, or twentieth Inoculation Series. The hours which it required to kill either fowls or pigeons did not show any considerable difference in either the one or the other case, so that we may say here, as we did before, that the degree of virulence was at the end of the experiment practically the same as at the beginning.

Notes on the Body Temperatures of Rabbits inoculated with the microbes of chicken-cholera.

In connection with the experiment conducted with a view to determining the degree of virulence of the bacteria of chicken-cholera, when made to pass through the bodies of rabbits in twenty generations of two rabbits for each, I have been able to make a series of observations regarding the body-temperatures of such rabbits.*

In a number of cases the temperature was taken, at intervals, from the time of inoculation (immediately before it) until death (immediately after it); in several instances only up to some time before death.

These observations are put together in a table.

[See Table III, page 164.]

From the data given in this table we may reasonably conclude that—

1. As *a priori* intelligible, the septicæmia which is the result of transmitting virulent chicken-cholera bacteria into rabbits, is associated with a gradual increase in the body-temperature, which in its maximum was found to differ from the initial temperature by 2.5° C. in one case (No. 8), by 1.95° C. in another (No. 2), by 1.9° C. in a third (No. 7), by 1.8° C. in two others (Nos. 10 and 16), while in the remaining cases the difference was less.
2. This maximum, as a rule, is noticed some little time before death.

The difference between the initial body-temperatures (taken immediately before inoculation) and the ultimate body-temperatures (taken immediately after death) may also be seen, in the majority of cases, as noted in the aforementioned table. Apart from these I can offer several examples where only initial and ultimate temperatures were taken. All the examples that may thus be utilized number nineteen. The following are the figures as compared with one another in the different instances:—

40.0 — 39.6 : 39.2 — 39.67 : 39.6 — 40.6 : 39.3 — 41.0 :
 38.9 — 39.6 : 39.1 — 40.2 : 39.2 — 39.15 : 39.4 — 40.0 :
 39.05 — 39.45 : 38.85 — 40.0 : 39.1 — 40.9 : 39.8 — 39.6 :
 39.8 — 41.25 : 39.0 — 39.9 : 38.8 — 39.65 : 39.9 — 41.7 :
 39.8 — 40.2 : 39.6 — 41.2 : 40.0 — 38.4 :

In fifteen cases, then, out of nineteen the body-temperature was found to be higher at the end than at the beginning. Taking the mean out of each of these two series of fifteen observations, we arrive at the figures 39.3—40.355; the difference is thus 1.055° C. In four cases out of the above nineteen the end temperature was lower than the beginning. Taking, again, the mean out of each of the two series of four observations, we obtain the figures 39.75—39.19, that is a difference of .56° C. in favour of the initial temperature.

From this, therefore, we may deduce that, as a rule, the ultimate body-temperature is higher than the initial by about 1° C. on the average.

I may add the initial temperatures of eleven more cases, without any corresponding end temperature. They were 39.9, 39.85, 40.2, 40.0, 39.45, 39.3, 40.1, 39.4, 38.7, 39.0, 39.6. The end temperature in one case, without any initial temperature taken, was 41.25. †

Although

* The observations were made by means of an efficacious clinical thermometer which, after having been oiled with *ol. amygd. dulc.*, was introduced into the nares to the length of between six and seven centimètres.

† Note on the Respiration.—The breathing shortly before death is very much accelerated. In one instance, two minutes before death, I have found it to be forty-six to $\frac{1}{2}$ minute; in another instance, ten minutes before death, forty-four to $\frac{1}{2}$ minute.

OF RABBITS IN AUSTRALASIA—CHIEF EXPERT'S REPORT (NO. II). 159

Although the temperatures which the air showed during the course of the experiments recorded above (Table I) may be regarded as having only a secondary meaning in the judgment upon the results obtained, it is just as well to give a number of figures as they were noted.* They show here and there marked differences:—

October 4th.	1.35 p.m. 25°	3.35 p.m. 25½°	5.35 p.m. 22½°	7.35 p.m. 20°	9.40 p.m. 18½°			
" 5th.	2.10 p.m. 21°	4.10 p.m. 19½°	6.45 p.m. 17½°	8.55 p.m. 16°	11 p.m. 14½°

B. Experiments on Indigenous Birds.

In the Table given below (IV, a, b, c) are put together seriatim the results of experiments with the microbes of chicken-cholera on a number of indigenous birds. These consisted of:—

- (1.) Two wekas, or Maori- or wood-hens (*Ocydromus australis*, Sparrm.). *Habitat*: South Island of N.Z.
- (2.) Two magpies (*Gymnorhina tibicen*, Lath.). *Hab.*: Q., N.S.W., V., S.A.
- (3.) Two laughing-jackasses (*Dacelo gigas*, Bodd.). *Hab.*: Q., N.S.W., V.
- (4.) Two butcher-birds (*Cyathicus torquatus*, Lath.). *Hab.*: Q., N.S.W., V., S.A.
- (5.) One blue-jay (*Graculus melanops*, Lath.). *Hab.*: Austral. (and New Guinea).
- (6.) Two gallahs, or rose-breasted cockatoos (*Cacatua roseicapilla*, Vieill.). *Hab.*: Austral.
- (7.) Two wonga-pigeons (*Leucosarcia picata*, Lath.). *Hab.*: Q., N.S.W., V.
- (8.) One bronze-wing pigeon (*Phaps chalcoptera*, Lath.). *Hab.*: Austral.
- (9.) Two common swamp-quail (*Synoicus australis*, Lath.). *Hab.*: Austral.†

[See Table IV, (a), (b), (c), pages 165, 166.]

From the results thus far obtained we see that the virus of chicken-cholera, derived as it was in the shape of blood from rabbits which died in consequence of infection by that virus, proved, when caused to gain entrance into the digestive organs in the noted quantities, fatal to the magpies, butcher-birds, and blue-jay (which are principally animal feeders), to the wonga- and bronze-wing pigeons, to the gallahs and quail (which are all of them vegetable feeders). One of the wonga-pigeons, however, and one of the quail, did not succumb until after having been fed a second time on somewhat larger portions of the virus than before. One of the gallahs, although surviving two experiments by feeding, perished quickly in consequence of inoculation, thus manifesting its ready susceptibility to inoculated "chicken-cholera."

Of two laughing jackasses (true animal-feeders) one died after the first experiment (feeding), but not of chicken-cholera, as shown by the result of the *post-mortem* examination. The other survived feeding on virulent material for two successive times; but when inoculated later on it succumbed, we are entitled to say, to this disease, in so far as evidenced by the occurrence of numerous bacteria of chicken-cholera in the blood, by their successful cultivation and inoculation into a healthy rabbit, which died as usual. The appearance of the organs was less characteristic than is usually the case with birds dead of the disease.

Two wekas (animal-feeders), of which one was once fed and twice inoculated, the other twice fed and once inoculated, remained alive. Whether their insusceptibility in this case arose from the fact of their having been possibly treated preventively, or whether birds of this description are naturally immune against chicken-cholera in any shape of application, can only be decided by further experiments.

That

* These figures are also put down in connection with certain statements as to the relative quantity of bacteria in the blood of rabbits some time after their death of "chicken-cholera," *vide* above.

† All the specimens of birds mentioned were obtained, in an apparently good condition, from a dealer at the Sydney markets, on the 8th October. On the Island they were kept in spackus, airy boxes so as to be protected from any injurious effects of the weather. During the course of the experiments they were regularly fed on suitable feed material. However, when they were to be experimented upon (in case of feeding only) they were slightly starved beforehand, and their boxes emptied of all food except water.

That with regard to all the representatives of indigenous birds which, experimented upon, died, the cause of death must be regarded as due to chicken-cholera, as briefly noted in the quoted table by "P.M., Positive" (with the exception of one laughing-jackass, where the *post-mortem* was negative) was, I think, conclusively demonstrated by the presence, usually in immense numbers, of the typical bacteria in the blood; by cultivation of such material in suitable media, when they gave rise to typical cultures; and by the positive results of occasional inoculations of blood into normal rabbits. Besides, the appearance of the organs was nearly always such as to bear a close resemblance to that in the case of fowls and pigeons which succumb to the disease.

Certain results obtained in the foregoing experiments would seem to lead to the belief that indigenous birds, as exemplified by a few instances, may not always necessarily become affected or killed by taking up, along with food, certain small or minute quantities of the microbes, derived, we had better add, directly from the bodies of rabbits newly dead of chicken-cholera. On the other hand, inoculation with the virus taken from the same source may be looked upon as a far more dangerous, although naturally a more rarely occurring, mode of infection for such birds. Further below I shall mention a corresponding case in common pigeons.

How far there is danger for all the useful indigenous birds to take up the disease (chicken-cholera), should it be introduced into the country, cannot be precisely defined from the results of the above experiments. That such a danger, however slight it may be, does exist if the disease was wilfully spread and reared in the open, cannot be denied by the unbiassed mind; and that, even admitting that in the first instance only a minute fraction of wild birds may be carried off by the disease—an occurrence which in itself would be of little importance—these few birds, travelling as they may perhaps after having become infected, may transmit the germs hither and thither, ready to be taken up again by susceptible birds of the same or some other description.

C. Miscellaneous Experiments.

(i) The following table (V, a, b, c, d) contains the results of some experiments on fowls and pigeons, whence it will be seen that one fowl (hen) proved insusceptible to taking chicken-cholera by feeding on a small portion of virulent material from a dead rabbit, while after a second feeding on a considerably larger portion it died, unfortunately, soon afterwards of some cause other than chicken-cholera. (The result of the *post-mortem* examination is denoted as *negative* in the table). Another fowl (rooster) was fed three consecutive times on successively always larger portions of virulent material (taken from rabbits) without harm to its health. Later on it was inoculated, but it remained alive.

The immunity in this instance was possibly due to the animal having been subjected to three previous and successive feeding experiments, which may have acted as a preventative. I say, they may; we are not warranted in adopting this view as the only correct one, since we are informed of instances in which fowls have withstood inoculation with virulent microbes of chicken-cholera from the very first (Salmon). On the other hand, two common pigeons, which were repeatedly fed (the one twice, the other three times) on infected food, succumbed promptly to the effects of inoculation later on, thus showing that they had not been rendered proof by the previous treatments. However, in the judgment of these results it should be borne in mind that, as the pigeons were too slow in eating (*vide* table), the previous treatments (feeding) cannot be regarded as exact. (The results of the *post-mortem* examinations in the table are simply denoted as *positive*.)

The virulence of the material used for the above experiments was out of question, although special control-experiments (on rabbits) were not made each time.

[See Table V, (a), (b), (c), (d), page 167.]

(ii) In my previous Report (Progress Report No. I, Appendix D, Series II, pp. 154, 155) I drew attention to a tame Angora-rabbit (albino), which was found to be insusceptible to "chicken-cholera" on inoculation, which had been preceded by feeding at intervals on successively increasing quantities of virulent cultures of the microbes of chicken-cholera (three times). Consequent on the inoculation it reacted as already stated, with a large abscess at the place where the virulent broth-culture ($\frac{1}{8}$ ccm. = 2 minims) had been injected. This was on the 1st September.

On 10th October, when the abscess had completely healed, the rabbit received on a corresponding spot on the other side of the belly $\frac{1}{8}$ ccm. (= 2 minims) of fresh virulent heart-blood from a rabbit out of the series of experiments as recorded in Table I (Series X, No. 19).

Controls:

The two rabbits from Series XI, Table I, which died in 14 h. 21 m., and between 7 h. 20 m. and 9 h. 20 m. after inoculation, respectively. (Quantity for inoculation only $\frac{1}{10}$ ccm.)

The fowl and the pigeon from Series III, Table II, which died between 20 h. 15 m. and 21 h. 40 m., and between 14 h. 15 m. and 20 h. after inoculation, respectively. (Quantity for inoculation the same as before.)

Result:

It remained alive, although it reacted by the formation of an abscess, and a higher body-temperature for some time after inoculation.

Remarks on Body Temperatures, &c. :—

Oct. 10th.—At time of inoculation (noon) 40.4°C.
5.55 p.m. 41.0°
10.15 p.m. 41.2

Oct. 11th.—11 a.m. 40.47
3.30 p.m. 40.2
10.10 p.m. 40.86

On the morning of this day its appetite did not appear to be so keen as usual. The seat of inoculation began to show reaction by inflammation.

Oct. 12th.—3.15 p.m. 40.6
Oct. 13th.—1.15 p.m. 40.05

Oct. 18th.—A distinct closed abscess, elastic to the touch, pink at surface, and of pear-shape.

Oct. 19th.—Abscess, still closed, measures 30 mm.* in length (from apex to base), 23 mm. across the widest part—raised about 12 mm. above the level of the adjoining portions of the skin of the belly.

Oct. 22nd.—Abscess still closed, but apparently smaller.

Oct.

* 25.15 mm. = 1 inch.

OF RABBITS IN AUSTRALASIA—CHIEF EXPERT'S REPORT (NO. II). 161

Oct. 26th.—Pus was derived from the abscess by pressing. It was very thick, tenacious, and inodorous. The microscopical examination of preparations of a sample of this pus coloured with methylene-blue solution did not disclose any chicken-cholera bacteria. At the same time some blood, unmixed with pus, was obtained from the abscess at another place, and inoculated in the quantity of a platinum-loop full into a half-grown rabbit. This rabbit was found dead about nine hours afterwards, but "chicken-cholera" was not the cause of death. A half-grown rabbit was inoculated (Oct. 27th) with a similar platinum-loop full of blood from the latter. It was found dead the following day, but the P.M. was again negative so far as "chicken-cholera" was concerned.

Nov. 2nd.—Abscess considerably reduced. Rabbit appears quite normal.*

(iii) Addendum to experiments of feeding rabbits on faecal matter from rabbit dead of "chicken cholera" by feeding.

In the previous Report (Appendix Series III, (ii), page 155), I recorded such an experiment with negative result. Since that time I have made a similar experiment yielding, likewise, a negative result.

On October 15th at 11.5 a.m., two half-grown rabbits (in one hutch) were fed upon cabbage leaves, to which had been added about 5 ccm. of a mixture, consisting half of a portion of the contents of the caecum from a young rabbit [control (b) to the feeding of indigenous birds], dead of "chicken-cholera," and half of a 0.6 per cent. sterile salt-solution.

- Annotations:* (a) These two rabbits had been removed from their hutch before feeding time on the morning of the 15th, and did not receive any food until at above time.
 (b) They had eaten all but a few small pieces of the cabbage leaves by 12.30 p.m., and had eaten all by 2 p.m.
 (c) The matter in the caecum was derived by carefully cutting the latter open to some length with a hot scalpel, and collecting that matter directly in a sterile test-tube.

Results:

Oct. 16th. One was observed to be dying at 8.10 p.m. As it was paralysed and evidently in pain, it was then killed. P. M. *Negative*.

Oct. 18th. The other was found dead at 9.15 p.m. P. M. *Negative*.

(iv) Two experiments made with a view to testing Dr. N. Gamaleia's supposition that the microbes of chicken-cholera are constantly present in the intestines of normal pigeons.

On pages 146-148, in Progress Report No. I, I produced a literal translation of Gamaleia's article, "Contribution to the Etiology of Chicken-cholera, &c.," in which he records, among other things, having been successful in obtaining bacteria of chicken-cholera out of the intestines of normal pigeons in only slightly virulent varieties which, in order to be able to kill pigeons or fowls, must first be transferred to susceptible animals, viz., rabbits and *Zieseln*. In connection with this subject I mentioned already one experiment with a negative result. The material for experiment was in that case derived from a dead young chick sent for examination. I now add two experiments, for which the material was derived from healthy pigeons. The results were also negative.

(1) Sept. 27th, at 3.50 p.m.—

A healthy pigeon† was killed by chloroform-narcosis. The contents of the small and large intestines and part of the contents of the stomach (the latter containing green food) were taken under antiseptic precautions. The whole was placed together in a test-tube and mixed and shaken with about 10 ccm. of sterile rabbit-broth. This tube was for a while placed in a water-bath of 37° C.

Of this mixture 1 ccm. was injected subcutaneously into each of two rabbits by means of a sterilized pointed glass-tube.

Results:

(a) Sept. 28th.—One rabbit was found dead at 6 p.m. P. M. *Negative*.

A pigeon inoculated at 10.30 a.m. on the 29th Sept. with a platinum-loop full of heart-blood from this rabbit was still alive at 10.45 a.m. on the 5th Oct., when it was removed from its cage. A half-grown rabbit inoculated at 10.45 a.m. with one platinum-loop full, and a full-grown rabbit, inoculated at 11.30 a.m. on the 29th Sept. with five platinum-loops full of the same heart-blood, were both alive at 4 p.m. on the 8th Oct., when they were removed from their hutch.

(b) Oct. 8th. The other was still alive at 4 p.m., when it was removed from its hutch.

(2) Oct. 3rd, at 10.40 a.m.—A healthy pigeon was killed by chloroform-narcosis. The contents of the intestines were collected under antiseptic precautions, mixed and shaken in a sterile glass-tube with sterile rabbit-broth, and warmed as before.

Of this mixture injections were made (analogously to the first experiment) into two rabbits.

At 11.10 a.m.—

A half-grown rabbit received $\frac{1}{2}$ ccm. of the mixture.

A full-grown rabbit received 1 ccm. of the mixture.

Results:

Oct. 11th. Both of these rabbits were alive at 9 a.m., when they were removed from their hutch.

OSCAR KATZ.

* So it does on November 25th.

† This pigeon and the next one were among a consignment of twelve purchased at the Sydney markets. The remaining pigeons did not show any signs of illness later on.

TABLE IV (a).
SHOWING results of experiments (by feeding) on indigenous Birds.

Names of birds.	Date and time of feeding.	Infected food as placed in each cage.		Results.	Remarks.
		Description of infected food.	Quantity of such liver and heart-blood for each cage.		
Two Wekas..... (in one cage)	Oct. 12th, 11.5 a.m....	Liver and heart blood from rabbit No. 22 of Inoculation Series XI, Table I, page 162	10 g.*	Both were still alive on October 19th	They ate all the food at once.
Two Magpies	„ 11.10 a.m....	do do do	10 g.	One was found dead at 6.35 a.m. on October 13th (i.e., between 18 h. 50 m. and 19 h. 25 m. after being fed). P.M., <i>Positive</i> .† The other was found dead at 1 p.m. on the same day (i.e., between 25 h. 25 m. and 25 h. 50 m. after being fed). P.M., <i>Positive</i> .	They ate all the food at once.
Two Laughing Jackasses (in one cage)	„ 11.15 a.m....	do do do	10 g.	One was found dead at 3.5 p.m. on October 17th (i.e., between 122 h. 45 m. and 124 h. 50 m. after being fed). P.M., <i>Negative</i> . The other was still alive on October 19th.	They had eaten all the food in five minutes.
Two Butcher-birds and one Blue Jay. (in one cage)	„ 11.20 a.m....	do do do	10 g.	One Butcher-bird was found dead at 6 a.m. on October 13th (i.e., between 10 h. 30 m. and 18 h. 40 m. after being fed). P.M., <i>Positive</i> . The other Butcher-bird was found dead at 9.20 a.m. on the same day (i.e., between 21 h. 10 m. and 22 h. after being fed). P.M., <i>Positive</i> . The Blue Jay was found dead at 2.10 p.m. on the same day (i.e., between 26 h. 30 m. and 26 h. 50 m. after being fed). P.M., <i>Positive</i> .	They had eaten all the food in a quarter of an hour.
Two Gallahs	„ noon.....	do do do (mixed with 0.6 p.c. salt-solution and mashed up with crushed maize)	1 g.	One was found dead at 7.30 a.m. on October 14th (i.e., between 37 h. and 43 h. 30 m. after being fed). P.M., <i>Positive</i> . The other was still alive on October 19th.	They had eaten about half in 2½ hours, and in 5 hours had eaten all.
Two Wonga Pigeons and one Bronze-wing Pigeon. (in one cage)	12.20 p.m....	do do do	1½ g.	One Wonga Pigeon was found dead at 12.48 a.m. on October 14th (i.e., between 35 h. 36 m. and 36 h. 28 m. after being fed). P.M., <i>Positive</i> . The Bronze-wing Pigeon was found dead at 12.30 p.m. on October 13th (i.e., between 23 h. 10 m. and 24 h. 10 m. after being fed). P.M., <i>Positive</i> . The other Wonga Pigeon was still alive on October 19th.	They had eaten about half in 2 hours, and in 4½ hours had eaten all.
Two Quail	12.25 p.m....	do do do (a similar mixture mashed up with bread crumbs)	½ g.	One was found dead at 6 a.m. on October 13th (i.e., between 9 h. 30 m. and 17 h. 35 m. after being fed). P.M., <i>Positive</i> . The other was still alive on October 19th.	They had eaten all in an hour.

Controls : A full-grown rabbit fed upon cabbage-leaves infected with 1 g. of the same material as above (mixed with 0.6 p.c. salt-solution) died 33 h. 50 m. after being fed. P.M., *Positive*.
A half-grown rabbit fed upon cabbage-leaves infected with ½ g. of the same mixture, died between 37 h. and 42 h. 50 m. after being fed. P.M., *Positive*.

* 28.35 grammes (g) = 1 ounce; 1½ grammes = 1 dram.

† Each time when death was due to infection caused by the microbes of chicken-cholera, the result of P.M. examination is noted as *Positive*; when death was due to causes other than infection by these microbes, the result of P.M. examination is noted as *Negative*.

TABLE IV. (b).

SHOWING results of further experiments (by feeding and inoculation) on the indigenous Birds surviving from the experiments as detailed in Table IV (a).—

Names of birds.	Date and time of further treatment.	Nature of further treatment.	Quantity of liver or liver-blood in each case.	Results.	Remarks.
Two Wekas (kept, after treatment, in one cage).	Oct. 19th, 9.45 a.m. " 10.10 a.m.	One was inoculated with liver-blood from rabbit No. 34. Inoculation Series XVII, Table 1, page 162. The other was fed upon liver from the same rabbit.	1 platinum loopful (about $\frac{1}{200}$ ccm.) 10 g.	Both were still alive on October 29th.	The one which was fed (separately from the inoculated one) ate all at once.
One Laughing Jackass ..	" 10.20 a.m.	Fed on the same material	7½ g.	Was still alive on October 29th.....	In half-an-hour it had eaten all but a small piece, and in 3½ hours it had eaten all.
One Wonga Pigeon	" 10.40 a.m.	Do do do (mixed with 0.6 p.c. salt-solution and mashed up with crushed maize).	1 g.	Was found dead at 7.15 a.m. on October 22nd (i.e., between 59 h. 20 m. and 68 h. 35 m. after being fed). P.M., Positive.	It had eaten all in half-an-hour.
One Gallah	" 10.50 a.m.	Do do do	1 g.	Was still alive on October 29th	In an hour it had eaten more than half, and in 3½ hours it had eaten all.
One Quail	" 10.55 a.m.	Do do do (a similar mixture mashed up with bread crumbs).	½ g.	Was found dead at 12.25 p.m. on October 20th (i.e., between 25 h. 5 m. and 25 h. 30 m. after being fed). P.M., Positive.	In an hour it had eaten nearly all, and in 2 hours had finished all.

Controls: (a). Two half-grown rabbits, in one hutch, were fed upon cabbage leaves infected with 1½ g. of the same material as above (mixed with 0.6 p.c. salt-solution) for the two. One died between 22 h. 45 m. and 24 h. 40 m. after being fed. P.M., Positive. The other died between 94 h. 25 m. and 98 h. 35 m. after being fed. P.M., Negative.

(b). A half-grown rabbit inoculated with one platinum loopful (= about $\frac{1}{200}$ ccm.) of the liver-blood (as used above) died between 13 h. 20 m. and 21 h. 35 m. after being fed. P.M., Positive.

TABLE IV (c).

SHOWING results of further experiments (by inoculation) on the indigenous Birds surviving from the experiments as detailed in Table IV (b).

Names of Birds.	Date and time of inoculation.	Inoculated (by way of injection) with	Results.	Remarks.
Two Wekas (in one cage)	Oct. 29th, 10.45 a.m. " 29th, 10.50 a.m.	$\frac{1}{10}$ ccm. (= 1 minim) of heart-blood from a rabbit dead between 9 h. 5 m. and 17 h. 15 m. after inoculation with a virulent broth-culture of the microbe of chicken-cholera. do do do	Both were still alive on November 2nd.*	The firstmentioned was the one that had been inoculated before, as recorded in Table IV (b).
One Laughing Jackass ..	" 29th, 10.40 a.m.	do do do	It was found dead at 2.5 p.m. on November 1st (i.e., between 71 h. 20 m. and 75 h. 25 m. after inoculation). P.M., Positive.	A half-grown rabbit inoculated with a good platinum loopful of heart-blood from this jackass died between 11 h. 15 m. and 12 h. 35 m. after inoculation. P.M., Positive.
One Gallah	" 29th, 11.5 a.m.	do do do	It was found dead at 7.15 a.m. on October 30th (i.e., between 11 h. 40 m. and 20 h. 10 m. after inoculation). P.M., Positive.	

Control: A full-grown rabbit inoculated with a like quantity of the same material died between 11 h. 15 m. and 19 h. 40 m. after inoculation. P.M., Positive.

* Both were still alive on November 25th.

TABLE V.

SHOWING Results of certain Experiments on Fowls and Pigeons.

(a) FIRST EXPERIMENT (feeding).

Fowl or pigeon.	Date and time of feeding.	Description of food.	Quantity of such food.	Results.	Remarks.
Fowl (No. 1) (Rooster)	Oct. 5th, 10.10 a.m.	Bread infected with (coagulated) heart-blood from Rabbit No. 2, Inoculation Series I., Table I., page 162.	½ g.	Still alive on Oct. 14th. For further treatment <i>vide (b)</i> .	It ate all the food at once.
Fowl (No. 2) (Hen)	Oct. 5th, 10.30 a.m.	Do. do.	1 g.	Do. do.	It had eaten all but a few crumbs in 3½ hours.
Pigeon (No. 1)	Oct. 5th, 10.55 a.m.	Do. do. (heart-blood mixed with 0.6 p.c. salt-solution and mashed up with crushed maize).	½ g.	Do. do.	The exact time after which this pigeon had eaten or nearly eaten the food was not specially noted. It was, however, observed to be very slow in proceeding to eat.
Pigeon (No. 2)	Oct. 5th, 11.10 a.m.	Do. do.	½ g.	Do. do.	Do. do.

(b) SECOND EXPERIMENT (feeding).

Fowl or pigeon.	Date and time of feeding.	Description of food.	Quantity of such liver.	Results.	Remarks.
Fowl (No. 1) (Rooster)	Oct. 14th, 11.10 a.m.	Liver from Rabbit No. 31, Inoculation Series XVI., Table I., page 162.	5 g.	Still alive on Oct. 19th. For further treatment <i>vide (c)</i> .	It ate all the food at once.
Fowl (No. 2) (Hen)	Oct. 14th, 11.15 a.m.	Do. do.	2½ g.	Was found dead at 2 p.m. on Oct. 15th P.M., <i>Negative</i> .	Do. do.
Pigeon (No. 1)	Oct. 14th, 11.30 a.m.	Do. do. (mixed with 0.6 p.c. salt-solution and mashed up with crushed maize).	½ g.	Still alive on Oct. 20th. For further treatment <i>vide (d)</i> .	It had eaten nearly all in 2 hours, and in 6½ hours had eaten all.
Pigeon (No. 2)	Oct. 14th, 11.35 a.m.	Do. do.	½ g.	Still alive on Oct. 19th. For further treatment <i>vide (c)</i> .	It had eaten about half in 2 hours, and in 5½ hours had eaten all.

(c) THIRD EXPERIMENT (feeding).

Fowl or pigeon.	Date and time of feeding.	Description of food.	Quantity of such liver.	Results.	Remarks.
Fowl (No. 1) (Rooster)	Oct. 19th, 10.15 a.m.	Liver from Rabbit No. 34 of Inoculation Series XVII., Table I., page 162.	10 g.	Still alive on Oct. 20th. For further treatment <i>vide (d)</i> .	It ate all the food at once.
Pigeon (No. 1)					Not experimented upon this date. For further treatment <i>vide (d)</i> .
Pigeon (No. 2)	Oct. 19th, 11.5 a.m.	Do. do. (mixed with 0.6 p.c. salt-solution and mashed up with crushed maize).	1 g.	Do. do.	It had eaten very little in 2 hours, and in 3 hours had eaten about half. It was not until the following morning (say after 20 hours) that it was observed to have eaten all.

(d) FOURTH EXPERIMENT (inoculation).

Fowl or pigeon.	Date and time of inoculation.	Inoculated (by way of injection) with—	Results.	Remarks.
Fowl (No. 1) (Rooster)	Oct. 29th, 11.10 a.m.	½ ccm. (= 1 minin) of heart-blood from a Rabbit dead between 9h. 5m. and 17h. 15m. after inoculation with a virulent broth-culture of the microbe of chicken-cholera.	Still alive on Nov. 2nd.*	
Pigeon (No. 1)	Oct. 29th, 11.20 a.m.	Do. do.	Was found dead at 7.15 a.m. on Oct. 30th (i.e., between 11h. 10m. and 10h. 55m. after inoculation). P.M., <i>Positive</i> .	
Pigeon (No. 2)	Oct. 29th, 11.30 a.m.	Do. do.	Was found dead at 7.15 a.m. on Oct. 30th (i.e., between 11h. and 10h. 45m. after inoculation). P.M., <i>Positive</i> .	

* Still alive on November 26th.

163 ROYAL COMMISSION OF INQUIRY INTO SCHEMES FOR THE EXTERMINATION

PROGRESS REPORT (No. III) ON EXPERIMENTS WITH THE MICROBES OF CHICKEN CHOLERA.

To the Chairman, Experiment Committee, Rabbit Commission.

Rodd Island, 5 December, 1888.

At the Meeting held in Melbourne on the 15th October last, the Commission resolved to have the following experiment carried out at Rodd Island:—

“That the Rodd Island enclosure be divided into two equal parts, A and B, by rabbit-proof netting, the two divisions to be separated by a clear space of 1 yard. Division A to include, as far as possible, existing burrows; new burrows to be formed in Division B. That fifty healthy rabbits be turned loose in each division; that the rabbits in each division be fed and sheltered in like fashion; that five rabbits, specially marked, be separately fed with green stuff, to which, in the case of each rabbit, 2 ccm. of broth containing chicken-cholera microbes have been added, and that, after the meal, these rabbits be placed in Division A; that at the close of another week the process be repeated; that at the close of another week the experiment be terminated.

“That the five rabbits first fed with microbes, if they should die, be left in the enclosure; that other rabbits, subsequently dying in either enclosure, be also left, provided that great nuisance does not arise; that as soon as possible after the death of any rabbit in either enclosure, some blood be obtained from it with as little disturbance of the body as possible, and be examined so as to determine whether death was due to chicken-cholera; that, subject to the general intent of these experiments, Dr. Katz be authorized to exercise his discretion in matters of detail.”

I subsequently suggested that the whole enclosure (exclusively of the shed and stable adjoining it)* had better be utilized with a view to the above experiment, in so far as the “control” experiment with fifty rabbits did not appear to be necessary. The experiment should then be carried out with double the number of rabbits specified in the foregoing communication. This modification being afterwards approved of, and a sufficiently large number of rabbits having been received since the 27th October last, I was able to proceed with the experiment on the 7th November.

Up to this date 174 rabbits had been sent, fresh from the country, through the Rabbit Branch, Lands Department, Sydney. They were, however, in such a poor condition that some forty had died before the 6th November, and it looked, indeed, as if not many of the different consignments would be left over for some time thence. So it proved to be afterwards; and in view of such a state of affairs, which were anything but encouraging, I applied at once for more rabbits which, however, were received rather too late.†

In the following I make first some general remarks with regard to this experiment; next I give the history of the infected rabbits, *i.e.*, those which were treated with the microbes of chicken-cholera as prescribed; and lastly, the history of the uninfected rabbits, *i.e.*, those which were not treated as the former, but with which they were kept together.

General Remarks.

The enclosure used is known from previous reports. In it there was a number of artificial burrows which were mostly old ones, formerly used, only here and there slightly altered (*vide* Diagram VIII, A1, 2, 3, B, C), added to which was D (*vide* Diagram VIII). A description of the arrangement of these burrows (there were about 185 running feet of burrow), of their depth, width and coverings, has been given previously (*vide* Progress Report No. I) to which I may, therefore, refer.

In the enclosure were two feeding places and two tins for water near those feeding places (*vide* Diagram VIII). Near one of the posts supporting the roof of the enclosure was a small space shaded off by means of boards, and in this space was hung a thermometer for taking the temperature of the shaded air. (*vide* Diagram, *sh*). Out of the ground near it, a small trench was dug and covered in the same way as the burrows; in addition it was covered with a piece of rabbit-proof netting fixed so as to prevent the rabbits from interfering. In this trench was placed a thermometer for taking the underground temperature (*vide* Diagram *tr.*, *vide* also the appended table of temperatures).

The rabbits were fed regularly twice a day, morning and evening, on dry lucerne and some green stuff, usually barley.

The burrows were uncovered from time to time, in all eight times, as will be mentioned again later on, and re-covered each time soon afterwards.

I may add that the enclosure was all over accessible to the rays of the sun for from seven to eight hours a day.

History of the Infected Rabbits.

The plan of the experiment was to feed three batches of rabbits of ten specimens each, in three times, at intervals of a week, on green stuff infected with 2 ccm.‡ of broth-culture of the microbes of chicken-cholera for each rabbit. That would have been in all thirty rabbits to be infected and to be turned loose in the enclosure; but instead of this I was enabled for the first time only to place ten infected rabbits in the enclosure, for the second and third times only six were turned loose each time. This was in consequence of partly not having enough fresh rabbits on hand, partly because the hundred uninfected (of which more will be said further below) were gradually dying off to such an extent from some external cause, that the number of infected and uninfected would have been quite out of proportion, had ten been added the second and third times. Before giving an account of the fate of these infected rabbits I must mention what follows.

The broth-cultures used each time for the sprinkling of the food (green cabbage leaves) intended to be given to the rabbits, were derived from the blood of rabbits which died consequently on inoculation with the virus of chicken-cholera in the shape of broth-cultures. I adopted this course as a convenient and at the same time practical one.||

The rabbit-broth used for the cultivation of microbes has been described in Progress Report No. I. The tubes containing the infected broth were placed in the thermostat for twenty-four hours at a temperature of

* *Vide* previous reports on experiments conducted on the Island.

† It should be acknowledged here that the Rabbit Branch of the Lands Department did their utmost as regards the supply of rabbits; but for the lamentable condition of the rabbits forwarded at the end of October and beginning of November, there would have been more than enough for the intended purpose.

‡ One cubic centimetre (ccm.)=sixteen minims.

|| On this occasion I may also mention that a culture of the microbes of chicken-cholera of the seventh and eighth generations which was in the first instance obtained about three months ago, proved just as efficacious or virulent as cultures derived directly from blood.

OF RABBITS IN AUSTRALASIA—CHIEF EXPERT'S REPORT (NO. III). 169

of between 39½°C. and 40°C. (between 103° and 104° Fahr.) and were taken out immediately before being used. The way in which the broth-culture (2 ccm. for each rabbit) was sprinkled on the cabbage-leaves, has been detailed in the report referred to above.

The rabbits were placed in separate hutches, without food, in the afternoon preceding the day on which they were fed. The rabbits used for that purpose were full-grown animals.

Section I.

November 7th :—

The first lot of ten rabbits fed at 10.30 a.m., and turned into the enclosure at 3.30 p.m.

Annotations :—

- (a) Three of the ten had not quite finished their portions of infected food when placed in the enclosure; the other seven had finished eating between 1 and 2 p.m.
- (b) Besides these ten, three rabbits were fed in a similar manner. Of these three, two were found dead at 7.30 a.m., November 8th, P.M., on the one *positive*, on the other *negative*.* The third was found dead at 7.30 a.m., November 10th, P.M., *positive*.
- (c) The above three were left as having eaten more slowly, and less of the infected food than any of the ten placed in the enclosure, and this occurrence may account for the negative result of the P.M. examination in the one case.

November 8th :—

Eight of these ten found dead, of which five (*vide* Diagram a, b, c, d, e) were found at 7.30 a.m., and one (*h*) at noon, all outside the burrows; one (*b*) at mouth of Burrow A3, and another (*d*) at mouth of Burrow C.

Two of the eight (*f, g*) in Burrow B in the afternoon, when all the burrows were uncovered.

November 10th :—

One (*i*) found dead at 7.30 a.m., outside burrows.

November 12th :—

The last (*k*) found dead inside Burrow C, in the afternoon, when the burrows were uncovered.

From four of the nine first mentioned (*a* to *i*) blood was derived,† when, on microscopical examination, the typical bacteria of chicken-cholera could easily be traced; the tenth (*k*), which must have been in the burrow for some time was removed. The P.M. examination yielded a *positive* result.

Section II.

November 14th :—

Six rabbits fed at 10.10 a.m., and placed in the enclosure at 2.10 p.m.

Annotations :—

- (a) Among these six rabbits were three Tasmanian ones, the last of five which had been received on the Island on 20th July last. These three specimens, which were in excellent condition, had to be used from want of other rabbits.
- (b) In addition to these six, two others were fed, intended also for the enclosure, but they must have died suddenly, as they were found dead in their hutches at 1 p.m. the same day, having scarcely touched their portions of infected food.
- (c) Of the six rabbits thus remaining, four had quite finished at 1 p.m.; two had nearly finished eating at 1 p.m., and quite at 2 p.m.

November 15th :—

Two (*l, m*) found dead outside burrows at 7.30 a.m.

One (*n*) Tasmanian dead outside burrows at 2.45 p.m.

November 16th :—

Two (*o, p*) Tasmanian dead inside Burrows A1 and D respectively, in the afternoon, when the burrows were uncovered. Blood was derived from two (*m, o*). Result of microscopical examination, *positive*.

November 19th :—

The last of the six (*q*) found dead inside Burrow D, in the afternoon, when the burrows were uncovered. Blood was derived, but the result of microscopical examination *negative*. Consequently the rabbit was removed; the P.M. examination and a fresh microscopical test verified the former result.

Section III.

November 22nd :—

Six rabbits fed at 10.30 a.m., and placed in the enclosure at 4 p.m.

Annotations :

- (a) The consignments of rabbits, of which these six formed part, had been received on the Island the previous day.
- (b) Of these six, two had quite finished eating the infected food at 2 p.m., and three had half finished; two of these three had quite finished at 4 p.m., when removed to the enclosure, the third had then not fully finished. The sixth had eaten only a little at 2 p.m., and had only a little left at 4 p.m., when put into the enclosure.

November 23rd :—

One (*r*) found dead outside burrows at 7 a.m.

November 24th :—

One (*s*) found dead, at noon, when burrows were uncovered.

November 25th :—

One (*t*) found dead outside burrows at 7 p.m. Blood was derived from two (*r* and *t*). Results : *Positive*.

November 29th (expiration of term of experiment) :—

Two (*u, v*) found dead inside Burrows A3 and C respectively, in the afternoon, when the burrows were uncovered; *u* and *v* removed, P.M. on one (*u*) *positive*; on the other (*v*) *negative*.

The last (*w*) of the above six was still alive on the 29th. (It died at 5 p.m., December 3rd, P.M. *negative*.)

From the foregoing account it will be seen that *twenty-two* rabbits in all were given food infected with the microbes of chicken-cholera, and placed in the enclosure as follows :—*Ten*, November 7th.—*Six*, November 14th.—*Six*, November 22nd. Of these *twenty-two* rabbits, *twenty-one* died, while the *twenty-second* was still alive on November 29th, when the experiment was terminated. Of the *twenty-one*, *three* were removed from the enclosure, *one* (*k*) found dead inside the burrow, belonging to the first lot (P.M. *positive*); *one* (*q*) from the second, *one* (*v*) from the third lot (P.M. in both cases *negative*).

Thus *eighteen* rabbits were left in the enclosure at the spot where they died, until the conclusion of the experiment. *Twelve* of these *eighteen* rabbits were found outside, the remaining *six* inside the burrows, as may be seen from the appended Diagram. That these *eighteen* rabbits did succumb to the effects of the infected meal given to them, was proved partly by the positive results of the direct microscopical examination of blood derived from a certain number which were picked out at random each time, partly by direct control experiment (first lot).

Footing on a great number of observations, I may state that it is nearly always an easy enough matter to tell from the mere touching and handling of a dead rabbit, whether it died of "chicken-cholera" or in consequence of some other indifferent cause. Not only in rabbits dead of "chicken-cholera" does

rigor

* Each time when death was due to infection caused by the microbes of chicken-cholera, the result of P.M.—or microscopical examination, is noted as *positive*; when death was due to causes other than infection by these microbes, the result of the examination is noted as *negative*.

† This was done each time by means of a clean sterilised glass-tube, which had been drawn out in the flame into a fine end of some length. By pushing this fine end through a suitable spot at either the left or the right side of the thorax, from which spot the hair had been previously removed, a sample of liver was derived. The opening thus made into the body closed up again after the tube had been taken out, and in this way the body was not perceptibly disturbed.

170 ROYAL COMMISSION OF INQUIRY INTO SCHEMES FOR THE EXTERMINATION.

rigor mortis set in sooner than is the case in animals dying off otherwise, as was only too frequently experienced among rabbits on the Island, where at the time no other experiments with diseases similar to this special septicæmia (chicken-cholera) were made, but also this *rigor mortis* is extremely well marked and lasting for a longer time than usual.

Besides, rabbits which are observed to die (as I had opportunity now and then to observe) as having partaken of food infected with the virus of chicken-cholera (or having been inoculated), exhibit by their behaviour some time before death such characteristic symptoms, that it is not well possible to mistake these symptoms for those manifested by rabbits which die otherwise as they did on the Island.

History of the Uninfected Rabbits.

November 7th, *one hundred* rabbits, mostly full-grown and only a few half or three-quarter grown, were turned loose in the enclosure at 2.30 p.m., shortly before the first lot of *ten* infected rabbits were placed in it. In the evening of the same day, and on the morning of the next day (November 8th), *five* in all were found dead. These were thereupon removed, and fresh ones put in their place. Rabbits subsequently dying were not substituted by fresh ones; even if such had been admissible, it would have been impossible, for the simple reason that there were not any fresh rabbits to spare.

From the afternoon of November 8th to November 14th, when the second lot of *six* infected rabbits were let loose, no less than *fifty-two* had died.

From November 15th to November 22nd, when the third lot of *six* infected rabbits were let loose, *seventeen* had died.

From November 23rd to November 29th (conclusion of the experiment) *ten* had died.

Thus out of *one hundred* uninfected rabbits in the enclosure, no less than *seventy-nine* died, partly inside and partly outside the burrows, from 8th to 29th November, leaving only *twenty-one* live rabbits. From these *twenty-one*, however, *one* has to be deducted as having escaped, somehow or other, from the enclosure into the adjoining stable, where it was found November 14th, and when it was used otherwise. So that at the close of the experiment only *twenty* out of the original *one hundred* were left over.

Of the *seventy-nine* rabbits which died, not one died in consequence of infection by the bacteria of chicken-cholera—neither did the *five* which died shortly after the beginning of the experiment, and which were replaced by others (*vide* above). I do not hesitate to say that I did not expect it to be otherwise, to go by what I had gleaned by previous experience. The dead (infected) rabbits were lying in the enclosure all the while; of course they began to putrefy; and for some time there was a swelling of the bodies in consequence of the accumulation of gas in the body cavities; but that was all. The carcasses could not, for the time being, be expected to break up so as to allow the blood, the carrier of infection, to be scattered about. The rabbits in the enclosure did not in any way gnaw at, or visibly interfere with the bodies of their dead companions; nor was there any necessity for them to do so, since they were well attended to as regards feeding, which was always done under the utmost precautions, so as not to introduce infectious material from without.

There being much space in the enclosure (which measures 100 ft. x 80 ft.) the living rabbits were not compelled to be in close proximity to the dead (infected) rabbits, except that one of the latter (*vide* Diagram e) lay at a very short distance from one of the feeding places and watering tins; another (*vide* Diagram n) not far from the feeding place at the stable-end of the enclosure.

Being almost certain that all the dead (uninfected) rabbits did not succumb to "chicken-cholera," to judge from the mere aspect which the carcasses offered, and from the behaviour of the rabbits some time before dying (as I often had an opportunity of seeing such rabbits die), taking also into consideration the skeleton-like appearance of most of them, and the analogous dying-off of rabbits kept in stock,—I had the rabbits removed from the enclosure as soon after their death as possible. In each case out of the seventy-nine (or eighty-four, if the five taken out at the beginning and substituted by others are counted), a *post-mortem* examination was made, that is to say, they were cut open, and their organs inspected. In more than one-half of these cases blood (taken from the liver or heart) was submitted to a careful microscopical examination. Neither the autopsy of the bodies themselves, nor the microscopical examination of the blood derived from them (in the majority of instances) proved that death was due to septicæmia ("chicken-cholera"), so far as is evidenced, on the one hand, by the anatomy of the organs, which failed to show any characteristic appearances; on the other hand, by the results of the microscopical examination of the blood, which was found free from the bacteria of chicken-cholera.

All this huge number of rabbits which died out of the hundred, must have died from causes other than chicken-cholera; most likely from the effects of the starvation which they had, no doubt, to undergo to a certain extent before they were sent to the Island from the then dry country round Hay, N.S.W.

Owing to such an unsuitable supply of rabbits, the experiment cannot by any means possess that value which it would have had if all the numerous rabbits received had been equal to the demands to be put on them.* But even if the experiment had not suffered in the indicated manner, I doubt whether, under analogous conditions, any favourable results would have been obtained with regard to the question of the transmission of the virus from rabbits which die consequently on being fed on virulent material, to healthy rabbits mixed with the former. A satisfactory and decisive answer as to this point can, after all, only be given by experiments conducted under natural conditions: these, of course, can only be had in the rabbit-infested country itself.

As other experiments with the microbes of chicken-cholera are not yet quite completed, I will report on them separately, at a subsequent early date.

These experiments are:

- (1.) Experiments with a view to ascertaining whether rabbits, which having been infected with the microbes of "chicken-cholera" are allowed to die and to remain for some time at a place where poultry are kept, are dangerous to the same.
- (2.) Experiments on indigenous crows.
- (3.) Experiments with a view to ascertaining the effects of desiccation on the microbes of chicken-cholera.
- (4.) Further experiments having reference to Dr. Gamaleia's discovery of the constant occurrence of the microbes of chicken-cholera in the normal intestines of pigeons.

OSCAR KATZ.

TABLE

*The fact that a small percentage of the rabbits which had been given infected food (*vide* above) did not succumb in consequence, may be attributed to their having eaten too small a proportion, and perhaps too late to be efficacious.

OF RABBITS IN AUSTRALASIA—CHIEF EXPERT'S REPORT (NO. III). 171

TABLE of Temperatures, both in the shade and underground (bottom of burrows), in enclosure. The temperatures are given in the centigrade scale ($+ 1^{\circ} \text{C.} = \frac{9}{5}^{\circ} \text{Fahr.} + 32 = 33\frac{1}{5}^{\circ} \text{Fahr.}$; $+ 20^{\circ} \text{C.}$ (*e.g.*) = ($\frac{9}{5}^{\circ} \text{Fahr.} \times 20$) + 32 = 68°Fahr.). General remarks on the weather are found in the last column.

Date. 1898.	Temperatures.					General remarks on the weather.	
	In air (shaded), or underground.	At					
		7 a.m.	11 a.m.	3 p.m.	7 p.m.		10-30 p.m.

172 ROYAL COMMISSION OF INQUIRY INTO SCHEMES FOR THE EXTERMINATION

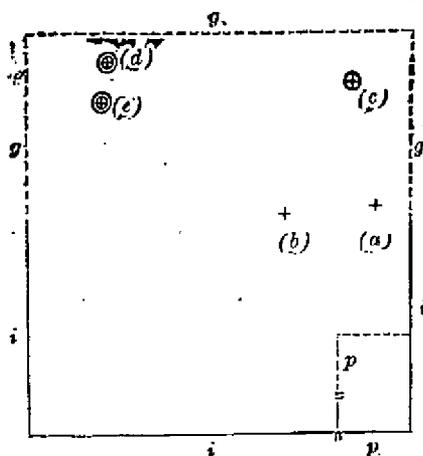

PROGRESS REPORT (No. IV) ON EXPERIMENTS WITH THE MICROBES OF CHICKEN-CHOLERA.

To the Chairman, Experiment Committee, Rabbit Commission.

Rodd Island, 17 December, 1888.

- (1.) *Experiments with a view to ascertaining whether rabbits, which having been infected with the microbes of chicken-cholera are allowed to die, and to remain for some time at a place where poultry are kept, are dangerous to the same.*

At the Meeting held in Melbourne on October 15th last, the Commission resolved that, from time to time, rabbits infected with the microbes of chicken-cholera should be placed in the Aviary (on Rodd Island), containing some fowls and pigeons, or other birds. The rabbits should be allowed to die and remain there; in case of death of any birds the cause of death should be ascertained.

The aviary erected on the island, in the N.E. corner, is a light framework, the southern half of which is covered, on the roof and sides, with sheets of corrugated iron (Diagram, *i*; *p p* is the double door); the other, northern half, is covered with both wide-meshed netting and wire-gauze (Diagram, *g*). The floor is 15 ft. square, the height of the walls is 8 ft., the height from the floor to the summit of the gable end is 13 ft. The greater portion of the aviary was accessible to the sun for nearly all day.

At the beginning of the experiment the aviary contained nine fowls, of which three had been there for some time (left over from a former consignment of twelve), and six which had been received from the markets on November 8th. Besides, there were twelve pigeons, also obtained fresh from the markets. Neither the fowls nor the pigeons had so far come into contact with rabbits treated with "chicken-cholera." The experiment was begun November 9th and terminated December 14th. Within this period three batches of infected rabbits were turned into the aviary at different times, viz., on November 9th, on November 22nd, and on November 28th.

*History of the Rabbits placed in the Aviary.**Section I.*

November 9th, 10 a.m.—

Three rabbits, two full-grown and one not quite full-grown, were fed on cabbage-leaves sprinkled with 2 ccm. of a fresh virulent broth-culture of the microbes of chicken-cholera for each rabbit. Two having finished their portions of infected food at 12:15 p.m., were placed in the aviary at 12:30 p.m. on the same day.

Results:

November 10th.—One observed to die at 10 a.m. [Diagram, +] (*a*); the other observed to die at 12:7 p.m., under typical symptoms [Diagram, +] (*b*).

The third rabbit mentioned above was left in the hutch in which it was fed—it had quite finished eating its food at 1:30 p.m.—as control. It was found dead November 10th, at 7:30 a.m. P.M., *Positive*.

Section II.

November 22nd, 11 a.m.—

Three full-grown rabbits having besides others, arrived on the Island on the previous day, were given cabbage-leaves sprinkled with 2 ccm. of a fresh broth-culture for each rabbit (at the same time six other rabbits were similarly fed, as may be seen on p. 169 of Progress Report No. III).

The three rabbits, which were very slow in eating, although they had been left without food for some time, as was always done in analogous cases, were placed in the aviary at 7 p.m., the same day.

Results:

November 23rd.—One rabbit found dead 7 a.m. [Diagram, ⊕] (*c*). As "control" may be taken a rabbit, fed at the same time as being among the six turned loose into the main enclosure on November 22nd. The microscopical examination of blood derived from that particular rabbit, which was found dead at 7 a.m., November 23rd, yielded a *positive* result. (*Vide* p. 169, Progress Report No. III).

November 27th.—The two other rabbits being still alive were removed from the aviary.

Section III.

November 28th, 11 a.m.—

Three rabbits fed on green barley-leaves, sprinkled with 2 ccm. of a fresh broth-culture for each rabbit, were placed in the aviary at 3:15 p.m., the same day.

Two of these had eaten their portions of infected food at noon, the third at 1 p.m.

Results:

November 29th.—One found dead at 7:30 a.m. [Diagram, ⊕] (*d*). Microscopical examination of a sample of liver-blood, derived from the dead rabbit without much disturbing it, *Positive*. (Immense numbers of typical bacteria).

December 1st.—One found dead at 6 p.m.; seen alive an hour before. [Diagram, ⊕] (*e*). Microscopical examination of a sample of liver-blood, derived as before, *Positive*.

December 14th.—The third rabbit being still alive was taken out of the aviary.

Thus five rabbits, as having died of "chicken-cholera," were allowed to remain in the aviary; two since November 10th, one since November 23rd, two since November 29th and December 1st respectively, up to December 14th, when the experiment was terminated.

History

History of the Fowls and Pigeons in the Aviary.

November 10th.—Two pigeons, which were ailing some time, found dead at 7:30 a.m. P.M., *Negative*.

November 13th.—One hen found dead at 7:30 a.m. P.M., *Negative*.

November 17th.—One pigeon found dead. P.M., *Negative*.

November 29th.—One rooster found dead at 7:30 a.m. P.M., *Negative*.

December 7th.—One pigeon found dead at 8 a.m. P.M., *Negative*.

December 11th.—One pigeon found dead at 8:30 a.m. P.M., *Negative*.

December 14th.—One pigeon found dead at 8 a.m. P.M., *Positive*.

(Characteristic appearance of organs; immense numbers of bacteria in blood. Rabbit inoculated with small quantity of this blood, died of "chicken-cholera" in less than 10 hours after inoculation).

Thus, during the course of the experiment, in all six pigeons and two fowls died; but it was only once, viz., in the case of the pigeon* of December 14th, that a positive result was obtained.

It must be mentioned that during the term of the experiment both fowls and pigeons were observed in the aviary to peck the dead rabbits laying about. When the latter were removed ultimately, the three rabbits which died first (*Vide* Diagram, *a, b, c*), presented only fragments scattered in different directions. The two that died last (*d, e*) were not dismembered, but they were pecked open and their flesh and entrails almost entirely missing.

(2) *Experiments on Indigenous Crows.*

Among the indigenous birds experimented upon some time ago [*Vide* Progress Report No. II], crows were not included; but being of opinion that it would not be superfluous to know, what effect the microbes of chicken-cholera had on them, I requested Mr. Taylor, of the Rabbit Branch, Lands Department, Sydney, to cause some to be caught near Hay, New South Wales, and to be forwarded to the Island. Accordingly, on the 8th and 10th November last, I received eight crows in all, of which, however, two died soon after arrival here. The remaining six appeared in good health, although at first they were a little sluggish. They belonged to the species *Corone australis*, Gould; found all over Australia, including Tasmania. I am told on good authority that there is very little difference between the two species of crows described from Australia; one is the above-mentioned, and the other is *Ceruus coronoides*, Vig. and Horsf., which is said not to occur in Tasmania.

I enumerate the experiments upon the six crows in chronological order:—

(i) November 13th, 11 a.m. :—

Two of the crows, kept in one box with plenty of space in it, were inoculated (under the skin over the pectoral muscle on one side) with fresh virulent liver-blood, taken from a rabbit which died of "chicken-cholera" on inoculation.

One received $\frac{1}{10}$ ccm. = 1 minim } of such blood.
The other received $\frac{1}{2}$ ccm. = $\frac{1}{2}$ minim }

Results :

November 15th.—The one which had been inoculated with 1 minim of blood, was found dead at 7:30 a.m. P.M., *Positive*. (Appearance of the organs resembling, to some extent, that of the organs of poultry dead of chicken-cholera. Immense numbers of typical bacteria in the blood).

December 1st.—The other which had received only $\frac{1}{2}$ minim of blood, was still alive on this date, when it was used otherwise, as will be seen below.

(ii) November 13th, 12:35 p.m. :—

Four crows, which were accommodated in a commodious specially-fitted stall in the stable, and which had not been trouted so far, were fed on the livers of two rabbits which had succumbed to "chicken-cholera" on feeding.

Annotations :

(1) The crows, although not being fed as usual on the morning of that day, were very slow in eating the pieces of liver placed in their stall on a soup-plate.

(2) The feeding had, from want of rabbits at the time, to be discontinued until later (*vide* below).

Result :

December 1st.—The four crows were still alive.

(iii) December 1st to 7th.—

In the stall which contained the above four crows, and into which was turned the one which had been inoculated previously with $\frac{1}{2}$ minim of virulent blood, were placed *seven* consecutive days, in the mornings, the carcasses, each time, of two rabbits which died of "chicken-cholera" on inoculation (in connection with the desiccation experiments *p.* 174 of this Report).

Annotations :

(1) The dead rabbits (*fourteen* in all), before being given to the crows, had been deprived of their entrails (the liver, heart, kidneys, and lungs were left), and as there were more on hand than were required at the time, they were kept in a cool place, so that the carcasses were still fresh when placed in the crows' stall, with the exception of one (out of the last feeding), in which putrefaction had already set in.

(2) During the above-mentioned period the crows did not receive any other food. Water, of course, was always provided.

Results :

December 4th.—One found dead at 9:30 a.m. (alive at 8:15 a.m.). P.M., *Positive*. (Carcass stiff; blood coagulated, and of a tarry appearance; hyperemia of intestines; contents of small intestines consisting of slimy, yellowish masses, stained here and there with extravasated blood; spleen apparently enlarged, cherry-coloured. Immense numbers of bacteria of chicken-cholera in the blood. A healthy rabbit inoculated with a small quantity of such blood, succumbed promptly. Cultures derived from blood of this rabbit were further tested so that with regard to this crow there cannot be any doubt as to the cause of its death).

December 9th.—One found dead at 8:30 a.m., P.M., *Positive*.

The three remaining crows, among them the previously inoculated one, were still alive on

(iv) December 14th, when, at noon, they were inoculated with fresh virulent blood, derived from the liver of a rabbit that died of "chicken-cholera" on inoculation. Of these three crows, two, of which one was inoculated before, received 1 minim each of the blood; the third $\frac{1}{2}$ minim.*Results :*

December 17th.—All three crows were still alive, three days after inoculation.†

To judge from the results of these experiments we may say, generally, that the microbes of chicken-cholera are only to a certain extent fatal to indigenous crows. Small doses of the virus, it appears, are not efficacious enough to be fatal; on the other hand, inoculation of larger quantities of virulent

* After December 14th up to December 17th, one more death occurred, viz., that of a hen, which was found dead 7 a.m., December 15th. The P.M. examination and successful inoculation of some heart-blood of this hen into a healthy rabbit was undoubted proof of the cause of death having been chicken-cholera. It cannot, however, be decided whether this hen died in consequence of infection from the dead rabbits which were in the aviary up to the 14th, or infection from the droppings of the pigeon which, having been found dead December 14th, was shown to have succumbed to chicken-cholera.

† As all three were still alive some considerable time after the inoculation, it was evident that they proved altogether insusceptible to this treatment.

174 ROYAL COMMISSION OF INQUIRY INTO SCHEMES FOR THE EXTERMINATION

virulent material, or repeated feedings on such, say, for a week without interruption, become dangerous to them. The previous treatments of the crows mentioned under (iii) and (iv) of the above experiments, may have had something to do with the surviving of the greater portion of them (iii), or of all of them (iv).

(3.) *Experiments with a view to ascertaining the effects of desiccation on the microbes of chicken-cholera.*

In accordance with a desire expressed by the Commission at the Melbourne Meeting on October 15th last, I have carried out a number of experiments with a view to testing the influence of desiccation on the microbes of chicken-cholera.

It should be mentioned here that, as more than one observer tells us, the virus of chicken-cholera becomes innocuous by drying up, and that this peculiarity in the life-history of those microbes furnishes one of the easy and practical means of getting rid of them, wherever they are deposited in poultry-yards. The bacteria of chicken-cholera are not known to form spores or seeds (as, for instance, the anthrax-bacilli do), by means of which they are able to live under adverse circumstances.

I have to record three series of experiments.

The general plan of procedure was as follows:—A number of silk-threads—of the kind used in surgery—of 1 centimètre in length and $\frac{1}{2}$ to $\frac{3}{4}$ millimètre in thickness, were placed in a sterile cotton-wool-plugged test-tube, and after having been thoroughly moistened with distilled water, were exposed in the steam sterilizer to steam of 100° C. (212° Fahr.) for two hours. The moisture remaining in the silk-threads and in the tube, was got rid of by placing the latter in a copper-box heated up to 100—105° C. (212—221° Fahr.) as long as required.

The virulent material to be tested for its resistance to desiccation consisted, on the one hand, of blood taken from the liver of rabbits which died on inoculation, on the other hand, of fresh broth-cultures derived directly from blood of rabbits newly dead of "chicken-cholera" on inoculation.

The silk-threads referred to above were impregnated with either blood or culture.

In case they were to be impregnated with blood, they were placed on cut-surfaces of the liver, where they remained until they were completely soaked. The livers of all the rabbits used were, I may mention, not otherwise diseased.

In case the threads were to be charged with broth-culture, a small quantity of the latter was placed, by means of a sterile pipette, in a sterile watch-glass, where they remained for some time.

The silk-threads, thus treated either with blood or culture, were then transferred to different places where they could dry up, as will be seen from what follows below. Within certain intervals a silk-thread of both the one and the other description was inoculated into a rabbit each, whereby the virulence or non-virulence of the administered material was to be ascertained. The threads were in each case deposited in small pouches, produced under the skin of the rabbits on the left side of the belly.

I think it necessary to say that every detail of the experiments was managed under due precautions.

Series I.

Silk-threads saturated, Nov. 28th, 11 a.m., with fresh liver-blood (containing large numbers of bacteria), and others saturated with fresh broth-culture of the microbes (this culture had been in the thermostat for a day at 39—39½° C., and for another day in the room at a temperature up to 25° C.), were placed on a piece of sterilized brass-wire gauze in a desiccator over chloride of calcium. This desiccator was placed, immediately after the threads were put in, in the cupboard of a room, where the temperature kept pretty even.

The virulence of the material employed (blood and broth-culture) was controlled by means of inoculation of a silk-thread impregnated with either blood or culture into a rabbit each. Both rabbits died promptly of "chicken-cholera," ten and twelve hours, respectively, after inoculation.

Silk-threads were taken out of the desiccator and inoculated into rabbits after 2, 4, 6, 8, 10, 12, 24, 36, 48, 72, 96, 120, 144 hours from the beginning of the experiment.

Within this period of six days, from Nov. 29th to Dec. 5th, the temperature near where the desiccator stood fluctuated between 21½° C. and 18° C.

Details about temperatures are given in the following table:—

Date	Temperatures.	
November 29th	Between 11 a.m. and 11 p.m.:	Highest, 21½° C. Lowest, 21° C.
" 30th	" 11 a.m. " 11 p.m.:	" 20° C. " 19° C.
December 1st	" 11 a.m. " 10 p.m.:	" 18½° C. " 18° C.
" 2nd	" 10 a.m. " 5 p.m.:	" 19½° C. " 18° C.
" 3rd	" 10 a.m. " 10 p.m.:	" 20° C. " 18½° C.
" 4th	" 9 a.m. " 9 p.m.:	" 21½° C. " 19° C.
" 5th	At 11 a.m. 21½° C.

The result was that the blood, which was under the influence of desiccation for three days at the above temperatures, was still able to infect a rabbit and cause it to perish of "chicken-cholera" (about twenty-one hours after inoculation), whereas after four, five, and six days from the beginning, the desiccated blood had lost its virulence.

On the other hand, the desiccated broth-culture preserved its virulence so far, that after two days from the beginning it was still able to kill a rabbit (about twenty-seven hours after inoculation), whereas it was not any longer efficacious when inoculated after three, four, five, and six days desiccation.

Series II.

Silk-threads saturated, December 7th, 10 a.m., with fresh liver-blood (containing large numbers of bacteria), and other saturated with fresh broth-culture (having been for twenty-four hours in the thermostat at 40° C.—37° C.), were placed on a thin layer of sterilized sandy soil at the bottom of a shallow basket, made of fine brass-wire netting. (The bottom of this dry basket had been bent up a little where the sandy soil was put on). The basket was then immediately after placed on a piece of wood, at a distance of about 2½ feet from the ground, in the main enclosure, at a spot which was shaded off by means of a wooden post and boards, so as to leave the spot only at the south side free and accessible. The basket was sheltered from rain by putting coverings over the top of the boards mentioned.

The virulence of the original material (blood and broth-culture) was tested by inoculating rabbits, one with silk-thread charged with blood, and the other with silk-thread containing broth-culture. Both rabbits died of "chicken-cholera," ten and twenty-one hours, respectively, after inoculation.

The effect of the drying-up of the silk-threads was ascertained by inoculating rabbits after 4, 8, 12, 24, 48, 72, 96, 120 hours from the beginning. Within this period, from December 7th, 10.15 a.m., to December 12th, 10.15 a.m., the thermometer in the shaded place registered temperatures of between 20½° C. (lowest) and 29½° C. (highest).

The

OF RABBITS IN AUSTRALASIA—CHIEF EXPERT'S REPORT (NO. IV). 175

The following table contains details about the temperatures, and general remarks on the atmosphere during that time:—

Date.	Temperatures in the Shaded Place.		Remarks.
December 7th	Between 10.15 a.m. and 2.15 p.m.:	Highest 25° C.; lowest 23½° C.	Air dry. Light S. breeze all day.
	2.15 p.m. „ 6.15 p.m.:	24½° C.; „ 22° C.	
	6.15 p.m. „ 10.15 p.m.:	22° C.; „ 21° C.	
8th	9.40 a.m. „ 10.15 a.m.:	28½° C.; „ 27½° C.	Air dry. Very calm.
	10.15 a.m. „ 4.30 p.m.:	28½° C.; „ 25° C.	
	4.30 p.m. „ 9.50 p.m.:	25° C.; „ 22½° C.	
9th	9.30 a.m. „ 11.30 a.m.:	21½° C.; „ 21½° C.	Air dry. S. breeze all day.
	11.30 a.m. „ 10 p.m.:	22½° C.; „ 21° C.	
10th	8.15 a.m. „ 9.45 a.m.:	27½° C.; „ 26° C.	Air dry, until afternoon, when thunderstorm set in with rain for about half an hour.
	9.45 a.m. „ 2.15 p.m.:	29½° C.; „ 25½° C.	
	2.15 p.m. „ 10 p.m.:	25½° C.; „ 21° C.	
11th	8.30 a.m. „ 4 p.m.:	26½° C.; „ 25½° C.	S. breeze morning. E. breeze afternoon. Strong E. wind evening.
	4 p.m. „ 10 p.m.:	25½° C.; „ 21½° C.	
12th	8.30 a.m. „ 10.15 a.m.:	22½° C.; „ 20½° C.	Calm morning.

The result was this:—

The blood thus exposed to desiccation preserved its virulence when inoculated after four, eight, and twelve hours; when inoculated after twenty-four hours and more from the beginning, it had lost its efficacy on rabbits.

The desiccated broth-culture proved virulent only, when inoculated four hours after the beginning of the experiment. The rabbit succumbed to "chicken-cholera" twenty-six hours after inoculation. Subsequent inoculations, eight, twelve, and more hours after the beginning, were attended with negative results.

Series III.

Silk-threads saturated, December 7th, 10 a.m., with virulent material (blood and broth-culture) derived from the same sources as the material used in *Series II*, were placed on sterilized dry sandy soil, which in a thin layer covered the bottom of a small shallow wire-gauze basket, similar to that in *Series II*.

Annotation:

Control of virulence as in *Series II*.

At 10.10 a.m., same day, this basket was placed on some available spot on the Island; this spot was accessible to the sun's rays all day long. The bottom of the wire-basket was placed flat on the perfectly dry sandy surface of that spot. This latter was also accessible to the wind or breeze prevailing during the experiment.

The silk-threads remained there from 10.10 a.m. to 6.10 p.m., i.e., for eight hours. Within this period rabbits were inoculated 1, 2, 4, 6, and 8 hours from the time the silk-threads were exposed.

A thermometer was laid on the soil near where the basket with the silk-threads stood. Details about the temperatures at the surface of the soil during the course of the experiment are given in the accompanying table.

December 7th:—

10.15 a.m., 45° C.; 10.45 a.m., 50° C.—Sunshine for about ten minutes.
 11.15 a.m., 47° C.—Sunshine for about ten minutes since last observation.
 11.45 a.m., 42½° C.—Few minutes sunshine.
 12 noon, 35° C.—Cloudy for about twelve of last fifteen minutes.
 12.15 p.m., 38° C.—About five minutes sunshine.
 12.45 p.m., 36° C.—About five minutes sunshine.
 1.10 p.m., 39½° C.—A few minutes sunshine.
 1.45 p.m., 42½° C.—About fifteen minutes sunshine.
 2.15 p.m., 38½° C.—About twenty minutes sunshine.
 2.45 p.m., 36½° C.—Two or three minutes sunshine.
 3.15 p.m., 38½° C.—A little sunshine.
 3.45 p.m., 33½° C.—Very cloudy.
 4.15 p.m., 29½° C.—Very cloudy.
 4.45 p.m., 30½° C.—Sunshine for about twenty minutes.
 5.15 p.m., 28° C. }
 5.45 p.m., 26° C. } Sun completely obscured.

From this table there may be seen that the sun was often prevented from making his appearance, by clouds passing by. The day was free from rain, the air was dry, and a southerly breeze was blowing during the time of the experiment.

The result was: the blood exposed to desiccation in this manner proved infectious after one, two, six, and eight hours' exposure (when the experiment was terminated). The rabbits inoculated succumbed to "chicken-cholera" in, respectively, twenty-one, twenty, between thirty and forty, and twenty-eight hours after inoculation. But strange to say, the silk-thread inoculated after four hours' exposure, proved inefficacious in so far as the rabbit was still alive (December 17) ten days after inoculation.*

On the other hand, the silk-threads soaked with broth-culture, exposed in exactly the same way, soon lost their efficacy. It was only the first time, after one hour's exposure of the silk-threads, that the inoculation of such a thread proved fatal to a rabbit. It died of undoubted "chicken-cholera," between fifty-nine and sixty-nine hours after inoculation. In all the remaining cases, two and more hours after the beginning of the experiment, the rabbits did not become infected.

From the results thus obtained, we learn again that desiccation in general is fatal to the microbes of chicken-cholera. The higher the temperature during the process of desiccation, the less time is required to kill the microbes.

Desiccation of virulent blood lying on, or impregnating small objects, such as the silk-threads used, cause the virus to die off less quickly than is the case with virulent broth-cultures exposed to desiccation under the same circumstances. The reason for this probably is that the superficial portions of the blood drying up, are able to protect the deeper portions for a longer time than is the case with broth-cultures attached to, or saturating small objects, where, by virtue of the composition of the broth, less protection can be afforded to the deeper portions by the superficial ones.

The fact that a virulent broth-culture of the microbes of chicken-cholera very soon ceases to be efficacious when exposed, in a thin layer, to desiccation at summer temperatures such as they exist here, must, in my opinion, to a large extent account for the surviving, now and then, of wild rabbits, which during

* It died at about 5.30 p.m., December 18th. P.M., Negative.

176 ROYAL COMMISSION OF INQUIRY INTO SCHEMES FOR THE EXTERMINATION

during summer months were given (in shaded hutches) cabbage or barley leaves sprinkled with small portions of such a culture, but which were very slow in beginning to eat the infected food or in finishing it up, so that meanwhile the liquid spread on it was enabled to dry up.

(4.) *Further experiments having reference to Dr. Gamaleia's discovery of the constant occurrence of the microbes of chicken-cholera in the normal intestines of pigeons.*

In Progress Reports Nos. I and II, I have given notice of Dr. Gamaleia's discovery which, however, I had so far not been able to confirm. I give now a few additional experiments in connection with this subject, but the results were equally negative.

(i) November 23rd, 5 p.m.—

One of two pigeons, taken out of a consignment of twelve obtained from the Sydney markets, on 8th November—the remaining ten were with two others placed in the aviary, where they were used for the experiment recorded under (1) of this report—was killed by chloroform-narcosis. The contents of the intestines, including a portion of the contents of the stomach, were derived under proper precautions, and thoroughly mixed and shaken with about 10 ccm. of sterile, distinctly alkaline rabbit-broth in a test-tube.

- (a) Of this mixture 1 ccm. each was injected into a full-grown and a half-grown rabbit soon afterwards. (On microscopical examination, the heart-blood of the pigeon was found to be free from micro-organisms; the organs appeared normal.)

Results :

November 29th.—The half-grown rabbit observed lying dead at 7.30 a.m. P.M., *Negative* (both as regards appearance of organs and microscopical examination of liver-blood).

December 2nd.—The full-grown being still alive was removed from its hutch at 10 a.m.

- (b) The above mixture was, after the 2 ccm. had been taken out, put into the thermostat, where it remained for about 24 hours at 39½° C.

November 24th, 5.30 p.m.—

A full-grown rabbit received ¼ ccm. = 4 minims,

A half-grown rabbit received ¼ ccm. = 2 minims,

of the culture obtained from the mixture.

Results :

November 25th.—The half-grown rabbit observed to die at 7.30 a.m. P.M., *Negative*.

November 30th.—The full-grown died at 11.30 a.m. P.M., *Negative*.

(ii) December 11th, noon.—

The remaining of the two pigeons was killed by chloroform-narcosis. About half the contents of the intestines, including part of the contents of the stomach, were transferred to a spacious test-tube containing about 15 ccm. of sterile rabbit-broth, which was of a distinctly alkaline reaction.

The mixture after being well-shaken showed still a slightly alkaline reaction. The tube was at once placed in the thermostat at 38° C. to 38½° C., for about twenty-four hours.

- December 12th, 1 p.m.—Of the culture obtained (showing now a slightly acid reaction), a very vigorous full-grown doe received (subcutaneously) 1 ccm.; a rabbit not quite full-grown, ½ ccm.

Results :

December 17th.—Both rabbits were still alive.*

OSCAR KATZ.

PROGRESS REPORT (No. V.) ON EXPERIMENTS WITH THE MICROBES OF CHICKEN-CHOLERA.

To the Chairman, Experiment Committee, Rabbit Commission.

Rodd Island, 9 March, 1889.

At a Meeting held in Melbourne, December, 1888, the Commission passed the following resolution:—

“That in the opinion of the Commission the large experiment recorded in Progress Report No. III by Dr. Katz is not satisfactory, owing to the great mortality which occurred among the rabbits under experiment, independently of chicken-cholera. The Commission, therefore, resolves that as soon as a sufficient supply of healthy rabbits be obtained, the Chairman of the Experiment Committee be authorized to make another large experiment, which shall be on the lines prescribed in Mr. Bell's resolution of 15th October last (already communicated to Dr. Katz); and that the half of the enclosure at Rodd Island, used for the control experiment, be carefully disinfected in the first instance.”

The experiment was begun on the 12th February last, as already communicated to the Secretary of the Commission in a letter of that date. It was terminated on the 5th instant, three weeks afterwards.

The reasons for its being thus delayed were, as already pointed out to the Secretary of the Commission in a letter of the 4th February last, on the one hand, the slow progress in the reparation of damages caused at the Island in consequence of a fire there on the 2nd January last; on the other hand, an insufficient number of rabbits.

On the 7th January the Rabbit Branch, Lands Department, Sydney, began to send rabbits in various consignments coming from Carrathool, near Hay, a distance of about 420 miles from Sydney. If they had remained all alive, there would have been at my disposal 161 rabbits at the end of that month; but, as it was, about half the number only were left over at that time, the others having died. So I had to wait till the 12th February, the date of beginning the experiment, and even then the control-division (see below) was short of several rabbits which were put in not until two days afterwards, as will be seen later on. The rabbits were sent in wooden boxes, in which they were nearly always fairly well accommodated, as far as space was concerned. The following account shows how many consignments were received, and at what dates, how many were found dead on arrival, where the rabbits were placed on the Island, and how many died up to the beginning of the experiment this year:—

1889.

- (1). January 7—Fourteen (14), all alive.
- (2). „ 10—Sixteen (16), all alive.
- (3). „ 12—Fifteen (15); of these 10 alive and 5 dead.
- (4). „ 17—Twenty three (23), all alive.
- (5). „ 18—Sixteen (16), all alive.
- (6). „ 19—Fifteen (15); of these 14 alive and 1 dead.
- (7). „ 21—Twenty-three (23); of these 6 alive and 17 dead.
- (8). „ 23—Sixteen (16), all alive.
- (9). „ 26—Fifteen (15), all alive.

These

* The last-mentioned (having received ¼ ccm.) died January 1st, 1889.

These nine consignments of rabbits were placed under the verandah of the laboratory, in clean, spacious hutches, which were scrupulously kept free from any infective matter. The rabbits were mostly full-grown, but they were not all in such a condition as might have been desired. Up to the 12th February, the date of the beginning of the experiment, 88 had died, leaving only 42, of which 28 were placed in the control-division on that date. (*See below*).

- (10.) January 28—Thirteen (13), all alive.
 (11.) „ 30—Eighteen (18), all alive.
 (12.) February 9—Thirty-two (32), all alive.

Of these three consignments of 63 rabbits, which on arrival were placed in spacious boxes in the shed adjoining the main enclosure, 3 died up to the 12th February; on that date 50 were placed in the disease-division (*see below*), the remaining 10 in the control-division. (*See below*.)

- (13.) February 14—Twenty (20); of these 18 alive and 2 dead.

Immediately after their arrival 14 of them were placed in the control-division.

- (14.) February 18—Twenty (20), all alive. •
 (15.) „ 20—Ten (10), all alive.
 (16.) „ 25—Twelve (12); of these 4 alive and 8 dead.
 (17.) „ 27—Twelve (12), all alive.

These were placed in the hutches under the verandah (*see above*), whence specimens were taken whenever required. The mortality among those left there was moderate.

I desire to have it clearly understood that the mortality among the rabbits before the beginning of the experiment was entirely independent of “chicken-cholera.”

In the following will be found first, general remarks of interest with reference to the arrangement of the experiment; next, the history of the rabbits in the two divisions of the enclosure, one of which may be called disease-division, the other, as already mentioned, control-division.

General Remarks.

The enclosure was divided into two portions by means of rabbit-netting, with a clear space of one yard between (*see Diagram IX*). The two portions were not exactly the same as regards size; the one, the disease-division, being somewhat larger than the control-division. Prior to the date of the experiment under consideration, there were, in what is now called disease-division, several artificial burrows which, except a few alterations here and there, are in the new experiment the same as before. They are named again A, 1, 2, 3, B, C. In order to save as far as possible the last mentioned one, the fence was drawn in the way shown in the Diagram, and not right across the width of the enclosure. There were about 136 feet of running burrow in this particular division. In the now control-division, which adjoins the shed (*Diagram IX*), is an old artificial burrow D, which is now hardly altered; a fresh burrow is E. The total of running feet of burrow in this division amounts to about 95. During the course of the experiment, the rabbits in both divisions disturbed the arrangement of the burrows slightly, in so far as they were burrowing sideways here and there in the artificial burrows, but only to a limited extent, and succeeded in burrowing out to the surface, thus creating new openings in those burrows.

Although the whole enclosure had been used, from the 7th to the 29th November last year, for the carrying out of the experiment recorded in Progress Report No. III, I did not think it necessary to specially disinfect it for the purpose of the new experiment. From the end of November, after the former experiment, some twenty rabbits were left there till the 24th January, without anyone contracting “chicken-cholera.” During the interval, sunshine and wind could act on, and must have proved disastrous to, any chicken-cholera microbes that might have been deposited there. Then again, one portion of the enclosure was, in view of the new experiment, reserved as control-division, stocked with a considerable number of rabbits; of these, I may just as well mention beforehand, not a single one died of “chicken-cholera.”

In each of the divisions was one feeding-place, one trough for water, and one similar trough for bran. The rabbits in both divisions were fed alike, morning and evening. The bulk of the food, which consisted of dry lucerne, green barley, now and then cabbage-leaves and bran, was given in the evening, as a large portion of the rabbits were, throughout nearly the whole experiment, in the burrows during the day.

Each of the divisions of the enclosure was accessible to the rays of the sun for fully eight hours a day.

The soil in the enclosure is, as already known, of a loose, sandy nature. I may add that a small proportion of the surface-area is taken up by rocks (sandstone) being partly on a level with the soil-surface, partly more or less projecting. They are in the neighbourhood of the burrows in the disease-division and near Burrow D in the control-division. At the beginning of the experiment there were a few spots, in either division, of fresh grass, but this disappeared quickly on the first day.

Temperatures were recorded at regular intervals during the term of experiment, viz.:—(1) of air shaded, as in the experiment, Progress Report No. III (*Diagram IX, sh.*); (2) underground, for which purpose served a trench, at about the same spot as before (*Diagram, tr.*); (3) of the surface of the soil; for this purpose a spot between the two fences was selected, where a thermometer was placed flat on the ground (*Diagram, th.*). There was hardly an object of significance which prevented the sun from shining right on to this spot nearly all day.

History of the Rabbits in the Disease-division.

The arrangement was to turn into this division fifty (50) healthy rabbits (uninfected), to which three batches of five rabbits for each were to be added, which had been fed on fresh cabbage-leaves infected with 2 ccm. of a virulent broth-culture of the microbe of chicken-cholera for each rabbit. These batches of rabbits, thus infected, to follow one another at intervals of one week.

A.—Infected Rabbits.

The rabbits used for this purpose were full-grown vigorous animals.

The cultures of the microbes were made in rabbit-broth, as before, which was charged with a small quantity of fresh heart-blood of rabbits which died of “chicken-cholera” consequent on inoculation with virulent culture of the microbes.

The tubes containing the infected broth were at once placed in the thermostat, where they remained for twenty-four (24) hours at a temperature of 38° C.* After that time the rabbits were ready to receive the green food to be infected with the cultures. The

* Throughout this experiment I employed cultures incubated at that temperature, which is lower than that employed on the occasion of the enclosure-experiment recorded in Progress Report No. III. The temperature then was 39–40° C. The reason for so doing is because the microbes appear to grow, in broth, better at a temperature of about 38° C. than at other temperatures. I cannot for the moment find the reference, but I think it is Hueppe, who says that the optimum of growth for the microbes of chicken-cholera is between 37–38° C.

178 ROYAL COMMISSION OF INQUIRY INTO SCHEMES FOR THE EXTERMINATION

The way in which the culture, 2 ccm. for each rabbit, was sprinkled over the leaves, has been described previously.

The rabbits were fed in separate hutches, in which they were placed in the afternoon of the preceding day. They were starved somewhat prior to the time of feeding on the infected meal.

All the infected rabbits let loose in the disease-division were, of course, specially marked; each batch receiving different marks. The marks were narrow stripes, produced on the flanks by clipping off some hair.

Section I.

February 12th.

The first batch of *five* rabbits fed at and after 11.30 a.m., and turned into the disease-division at 2 p.m.

Annotation:—

The rabbits soon began to eat; when seen at 2 p.m. they had all finished their portions of infected food.

Control:—

Of *four* rabbits fed under the same conditions, *one* was found dead at 7 a.m., *one* died at 9.50 a.m., and *one* was found dead at 12 noon, 13th February; the *fourth* did not succumb until 10 a.m., 14th February. P.M., in all cases, *Positive*.

February 13th.

One found dead at 7 a.m., near mouth of Burrow C. [Diagram IX. (a)].

One died at 10 a.m., outside burrows [Diagram (b)].

One was seen in a dying state near mouth of Burrow B. at 12 noon, when it suddenly rushed into this burrow, where it was found lying dead the following day [Diagram (d)].

February 14th (Burrows uncovered 10 a.m.).

One found dead inside Burrow A₂ [Diagram (c)], about one foot from the mouth of this burrow.

One, the last, found dead inside Burrow C. [Diagram (e)].

Section II.

February 19th.

The second batch of *five* rabbits fed at and after 12 noon, and placed in the disease-division at 2.30 p.m.

Annotation:—

All the rabbits had finished eating their portions of infected food when seen at 2 p.m.

Control:—

Five rabbits fed under the same conditions. Of these only *one* had finished eating at 2 p.m., a *second* at 3 p.m., *two* very nearly at 3 p.m., while the *fourth* was very slow in beginning to eat; it having not touched the food at 5.30 p.m., but this had nearly all disappeared at 7.30 p.m.

Of these *five* control-rabbits, *one* was found dead at 7 a.m.; *one* died at 10 a.m., 20th February. The *three* remaining ones were found dead on 21st February (*two* at 7.10 a.m., *one* at 10.30 p.m.) The last-mentioned was an exceedingly vigorous rabbit, the same which, as mentioned above, was very slow in eating the infected cabbage-leaves. P.M. in all *five* cases, *Positive*.

February 20th.

One found dead at 7 a.m. outside burrows, near mouth of Burrow C [Diagram (f)].

One found dead at 9 a.m. in the mouth of Burrow A₁, its head being outside [Diagram (g)]. This rabbit must have died between 8 a.m. and that hour.

One found dead at 12.15 p.m. outside burrows [Diagram (h)].

One found dead at 4.45 p.m. outside burrows, in a shallow excavation of the soil, covered by a stone [Diagram (i)].

February 21st. (Burrows opened at 10 a.m.)

One, the last, found dead in Burrow B, about one foot from the mouth of it [Diagram (k)].

Section III.

February 26th.

The third batch of *five* rabbits fed at and after 12 noon, and placed in the disease-division at 2.30 p.m.

Annotation:—

All the rabbits when seen at 2.15 p.m. had finished eating their portions of infected food.

Control:—

Four rabbits fed under the same conditions; a *fifth* not quite full-grown, received only about $\frac{1}{2}$ ccm. of both-culture on a cabbage-leaf. This last-mentioned rabbit and *two* of the former were found dead at 7.10 a.m., 27th February; the *two* others were found dead the same day at 4.30 p.m. and 7 p.m., respectively.

P.M. made in *four* cases, *Positive*.

[The *one* last dead, was not examined, but put in place of one infected, that died in the disease-division: Diag. (m); see below.]

February 27th.

Four found dead at 7.10 a.m. outside burrows [Diag. (l), (m), (n), (o)]. (About rabbit (m) see further below.)

February 28th.

One, the last, found dead in Burrow A₃, about one foot from the mouth of it [Diag. (p)].

From the foregoing account it will be seen that *fifteen* infected rabbits were placed in the disease-division:—*five* on February 12th, *five* on February 19th, *five* on February 26th.

They all died promptly; the majority of them must have died in less than twenty hours.

Nine out of the *fifteen* died outside, *five* inside the burrows, and *one* (g) half outside and half inside. Among the former (nine) is included one (i), which lay dead in a hollow covered over by a stone, and which was easily accessible.

With one exception, the carcasses of the rabbits remained on the spot, where they were found lying, until the end of the experiment, without any microscopical examination of their blood being made. The exception referred to is a rabbit (m), which forming one of the last batch of *five* rabbits placed in the disease-division on the 26th February, was found dead the following day. This rabbit was removed, and, on being cut open, showed on the left side of chest and belly extensive bruises, which must have accelerated its death, as putrefaction of the organs had already set in when it was examined, soon after having been found dead. However, the blood clearly showed the presence of numerous bacteria of chicken-cholera. An unusually vigorous buck, inoculated with a small quantity of this blood, succumbed to "chicken-cholera" somewhat less than twelve hours afterwards. On the following morning the intact carcass of one of the control-rabbits, which had died the previous evening, was put in its place (see above).

The above synopsis shows that other rabbits were treated in a similar manner as those used for the actual experiment. These control-animals died promptly without a single exception. After death they were carefully examined, when it was clearly proved that they had succumbed to "chicken-cholera."*

In view of such control-examinations, it was not at all necessary to derive from the infected rabbits as they perished in the enclosure, samples of blood, and to examine them for chicken-cholera bacteria.

Besides,

* The proof was given (1) by the appearance of the carcasses; (2) by the appearance of the organs at the P. M. examination; (3) by the presence of typical bacteria of chicken-cholera in every sample of blood; (4) by employing, in one case out of each batch of control-rabbits, such blood, and sowing rabbit broth with it, when cultures of these bacteria were obtained, which were successfully used for inoculating rabbits, thus securing fresh virulent blood for further cultures.

Besides, the fresh carcasses in the enclosure offered every appearance of what I may be permitted to term "chicken-cholera" carcasses: very stiff, nostrils often covered with froth. In addition, a few of the rabbits were observed to die under characteristic symptoms.

B.—Uninfected Rabbits.

- February 12th.
Fifty (50) rabbits, with a few exceptions apparently well-conditioned, full-grown animals, were turned into the disease-division at 10 a.m., a few hours before the first batch of infected rabbits was placed in it.
- February 14th (burrows uncovered).
 One dead inside burrows: *Negative*.
- February 16th (burrows uncovered).
 Three dead inside burrows; two of these three, one in Burrow A₁ [Diag. (1); removed], another in Burrow B [Diag. (2) left]: *Positive*. The third: *Negative*.
- February 18th (burrows uncovered).
 One dead in Burrow B [Diagram (3); left]: *Positive*.
- February 19th.
 Two dead outside burrows: *Negative*.
- February 21st (burrows uncovered).
 No change.
- February 22nd.
 Three dead outside burrows: *Negative*.
 One of these was killed because it was observed slowly dying without exhibiting "chicken-cholera" symptoms.
- February 23rd (burrows uncovered).
 Seven dead, of which five inside, one outside burrows, one killed (as above).
 Of the seven, one in Burrow A₂ [Diagram (4); left]: *Positive*.
 All the others: *Negative*.
- February 24th.
 One dead outside burrows: *Negative*.
- February 25th (burrows uncovered).
 Nine dead; of which six outside, three inside burrows: *Negative*.
- February 27th.
 Two dead outside (one killed, as above): *Negative*.
- February 28th (burrows uncovered).
 Three dead, of which two inside, one outside burrows: *Negative*.
- March 1st.
 Two dead outside burrows: *Negative*.
- March 2nd (burrows uncovered).
 One dead inside burrow: *Negative*.
- March 5th (burrows uncovered).
 One dead inside burrow: *Negative*.

There was thus a great mortality among the *fifty* rabbits described as uninfected, not less than *thirty-six* having died within the three weeks the experiment lasted.* But of this huge number only *four* proved to have succumbed to "chicken-cholera," whereas the remaining *thirty-two* perished of causes which had nothing in common with "chicken-cholera."† This unfortunate mortality was somewhat surprising to me, because the bulk of the rabbits used, appeared to be able to hold out for the three weeks, provided they did not take up, meanwhile, the germs of "chicken-cholera." There were two exceptionally heavy losses (independently of "chicken-cholera"); one on the 23rd February, when six were recorded dead (leaving out a seventh which died of "chicken-cholera"); another, two days afterwards, on the 25th February, when not less than nine were found dead. Three were found dead on the 22nd, and three on the 28th. I cannot omit to state that at the time when, or immediately after these batches of rabbits died, the atmosphere was extremely oppressive, and the thermometer registered an excessive heat (see Table of Temperatures, &c., below). These factors had probably something to do with the mortality.

The way in which the thirty-six rabbits, which died out of the fifty, were examined, in order to see whether "chicken-cholera" bacteria had found their way into their bodies or not, was not the same each time. In fourteen cases a sample of liver-blood was derived by means of fine glass-tubing, as described in Progress Report No. III. This sample was stained on cover-glasses and carefully examined under the microscope. *Three* times out of the fourteen this examination yielded a *positive* result, inasmuch as the typical bacteria of chicken-cholera were seen to be present in large numbers. The three respective rabbits, which also by their outward appearance indicated death due to "chicken-cholera," were left where they died [Diag. (2), (3), (4)].

In eleven cases the result of a similar examination of liver-blood being a *negative* one, so far as microbes of chicken-cholera are concerned, the respective rabbits were thereupon cut open, when the result previously arrived at was confirmed, both by inspection of the organs and a repeated microscopical examination of blood (mostly from the liver), in the majority of instances (seven).

On the remaining twenty-two rabbits out of the thirty-six in all, a P.M. examination was made without any preliminary microscopical test, as mentioned before. The result was *negative* in all cases but *one*; this is the rabbit (1) in Burrow A₁, Diagram IX. In sixteen cases liver-blood, in two cases liver and heart-blood, in two cases heart-blood only was examined, in the latter two instances the liver-blood being unsuitable for that purpose. The result of the microscopical examination of blood from two other rabbits, found dead inside Burrow C on the 28th February (see above), not being satisfactory, because the carcasses were already putrefying, a sample of coagulated blood was inoculated into a medium-sized rabbit for each case. One rabbit died fifteen hours after inoculation, but its death was not due to "chicken-cholera." The other rabbit remained alive.

In the synopsis given at the beginning, the results of the examination of the dead rabbits, no matter of what description this examination was, are noted briefly as either *negative* or *positive*, as the case may be. To

* One day, shortly before the experiment terminated, the surviving rabbits were counted both in this and in the control-division, when it was discovered that there was one too much in the disease-division, and one missing in the control-division. One rabbit must have found its way from the one division into the other. The two divisions, as mentioned, were separated from each other by a double fence of rabbit-netting, and that it is not impossible for a wild vigorous rabbit to climb or jump over such fences, will be admitted by everyone who has seen wild rabbits climb or jump.

† At the examination of all the rabbits dying during the experiment, my chief task was, of course, to investigate whether they died of "chicken-cholera" or not. Time did not permit me to extend the investigation much further. However, I noticed that in quite a number of individuals the appearance of the entrails resembled that described by Dr. Wilkinson in Appendix VII of this Report; so they proved to be in anything but healthy condition. Others, again, showed the lungs distinctly pneumatic.

To return to the cases which, on examination, yielded a *positive* result.

As stated, *four* rabbits out of the *thirty-six* in all dead, must be put down as having died of "chicken-cholera." The germs of this disease could not have been supplied but by infected rabbits placed in the disease-division. Two of the originally uninfected rabbits were found dead (inside burrows; carcasses still well preserved) on the 16th February (*i.e.*, somewhat less than four days after the first batch of five infected rabbits was turned loose); one was found dead (inside burrow; carcass still fresh) two days afterwards, on the 18th; one (inside burrow; carcass still pretty fresh) on the 23rd, (*i.e.* somewhat less than four days after the second batch of five infected rabbits was turned loose in the disease-division). The probability, therefore, is that all those four rabbits became infected *after* the death of intentionally infected rabbits turned into the disease-division. The answer to the question, in what particular way this infection took place, is open to conjectures. Considering that the excreted feces of normal rabbits dead of "chicken-cholera," on either feeding or inoculation, do not, as a rule, exhibit anything abnormal in their appearance; considering also, that within the short time which it nearly always takes from the time of infection to death, feces originating from the infected meals can hardly be excreted; and lastly, in view of the negative result of two direct experiments made by me some time ago, [See p. 155, Series IIIa (ii)*, p. 161 (iii.)] it is far from being proved that the excrements of the rabbits which died in the disease-division of "chicken-cholera," were or must have been the means of infection. On the other hand, it was frequently noticed that out of the nostrils in carcasses of infected rabbits lying undisturbed in the disease-division, some days after the death of the animals, a blood-stained liquid exuded which tainted the spot on the soil-surface underneath. Here and there it was also noticed that maggots and ants were at work about the carcasses. All that may have proved a means of transmitting the virus.

That the four rabbits did not die consequent on infection being carried into the disease-division along with food, or by means of flies coming from places where infectious material existed at the time on the Island, must be taken as granted, because, as already mentioned above, not a single death from "chicken-cholera" occurred among the rabbits in the adjacent control-division. These rabbits were, perhaps, more liable to infection from without, because their division was separated only by a plain fence of rabbit-netting from the shed in which the feeding of the different batches of rabbits, partly kept there in hutches as control, partly placed in the disease-division, was done.†

History of the Rabbits in the Control-division.

Thirty-eight (38) rabbits mostly full-grown, but, in the majority, not so well-conditioned as those placed in the disease-division, were turned loose here at 10:30 a.m., the 12th February. This number was twelve short of fifty, the intended number which was to have been placed there, but the remaining could not be placed with the others until two days afterwards, when a fresh supply of rabbits came to hand. Instead of twelve, however, fourteen were put in on that date, because two out of the original thirty-eight died a few hours after being put in the enclosure. Leaving these two out of the question altogether, I found that, at the conclusion of the experiment on the 5th inst., only *twenty-one* had been left over, twenty-nine having died, partly inside, partly outside the burrows,‡ during the time; most of them (twenty-three) within eleven days from the beginning of the experiment. There were six dead on one day, on the 14th, and nine on the 23rd.

All the dead rabbits out of this division were at once taken into the laboratory. Their outward appearance, as well as the autopsy, proved that death could not have been caused by "chicken-cholera" in any case. The microscopical examination of blood, nearly always derived from the liver, in seventeen cases taken out of the twenty-nine, yielded a *negative* result in each case.

The result of this experiment is thus different from that obtained a few months ago, as recorded in Progress Report No. III. In that experiment, where the arrangements were at variance with those of the last experiment, the result was throughout a *negative* one, that is to say, of fresh rabbits, exposed to others which were infected with, and died of "chicken-cholera," not one took the disease. That experiment was unsatisfactory also from another point of view, *viz.*, the fact that the rabbits used then were in anything but good condition; the mortality among them was equal to 80 per cent.

The mortality encountered in the experiment dealt with in this report was also great; of 50 rabbits in the disease-division, 36, or 72 per cent., having died. But among these 36 were 4 which it was shown had died of "chicken-cholera," so that, by deducting these 4, the mortality (irrespective of "chicken-cholera") was 64 per cent. (in the control-division 58 per cent.).

The question now arises: are we entitled to utilize the result of this experiment so as to draw from it definite conclusions as to the probable result of the application of "chicken-cholera" as a means of exterminating rabbits on a large scale? In my opinion only to a certain extent. From the result of the experiment under consideration, we may perhaps derive that, under conditions such as existed in this case, the disease may be transmitted, somehow or other, from one rabbit to another; but, as it appears, only in a very small degree. The conditions in the rabbit-infested districts certainly differ, not only from the abovementioned, but also from each other, so that without having the result of actual trials under the different conditions as the open country offers them, it is impossible to give a decisive answer. At all events, so far as the experiments on Rodd Island have gone, it cannot by any means be said that "chicken-cholera" of rabbits manifested itself as a disease readily communicable from rabbit to rabbit. From the mere reason, however, that wild rabbits exhibit an extraordinary susceptibility to the microbes of "chicken-cholera," and that, as I must agree with Pasteur, the susceptibility is greater in the case of rabbits than in that of birds, trials in the open, provided, of course, the arrangements be unobjectionable, would be at once interesting and instructive.

OSCAR KATZ.

TABLE

* The inoculation proved successful, Series IIIa, (i).
 † It should also be mentioned here that the feeding of the rabbits in the two divisions fell to the Handy Man at the Island who never touched or handled, or had anything to do with infectious material, as for instance chicken-cholera carcasses. He was instructed to use a special pair of goshies while in the disease division. When the divisions were inspected, that is to say when the burrows were uncovered and re-covered, the position of dead rabbits sketched, dead rabbits examined and taken away, goshies were worn by every one of us while in the disease-division, besides adopting ordinary precautions.
 ‡ Burrows in this division were inspected always on the same day when those in the disease-division were examined.

OF RABBITS IN AUSTRALASIA—CHIEF EXPERT'S REPORT (NO. V). 181

TABLE of Temperatures, of air (shaded), of the surface of the soil (not shaded), and underground (bottom of burrow), in enclosure. They are given in the centigrade scale. In the last column may be found general remarks on the weather during the course of the experiment.

Date. 1889.	Air (shaded), surface of soil, underground.	Temperatures					General remarks on the weather.

Rodd Island, 30 April, 1889.

Additional Experiments with the Microbes of Chicken-Cholera.

THE two wekas last mentioned in Table IV (c), page 166 of the Report, were inoculated on the 8th instant, one (hen) with 4 minims ($\frac{1}{4}$ ccm.), the other (rooster) with about half that quantity of virulent liver-blood of a rabbit newly dead of chicken-cholera.

The rooster was found dead in the morning of the 10th instant; but although the heart-blood showed, besides other bacilli, moderate numbers of the microbes of chicken-cholera—a healthy rabbit inoculated with a small quantity of this heart-blood succumbed promptly to “chicken-cholera”—I am, to judge from the *post-mortem* appearances, inclined to consider the presence of chicken-cholera bacteria in the blood of this bird as not being due to an infection proper by these microbes.

The other weka (hen), although appearing somewhat distressed the first two or three days, is still alive and well.

The rooster—a very robust specimen—last mentioned in Table V (d), page 167 of the Report, was inoculated again on the 8th instant, this time with 4 minims ($\frac{1}{4}$ ccm.) of virulent liver-blood as above. It died of “chicken-cholera” the following day, 27 hours after inoculation.

The three crows, last mentioned on page 173 of the Report, were inoculated again on the 8th instant, this time with 4 minims ($\frac{1}{4}$ ccm.) each of virulent liver-blood as above. All perished of “chicken-cholera”; one the following day, 27 hours after inoculation; another found dead on the morning of the 10th; the third died between 6 p.m. and 7:30 p.m. on the 10th.

Other experiments, having for their object the question, how wild Australian rabbits which have been fed on *sterilised* cultures of the microbes of chicken-cholera, behave when subsequently fed on *active* or *virulent* cultures of these microbes, are not yet completed.

Report on Cultures of Ribbert's Bacillus of Intestinal Diphtheria of Rabbits

On the 11th instant I received three tubes containing agar-agar cultures of the bacillus of rabbit-diphtheria, sent by Professor Ribbert, of Bonn, through the Agent-General for New South Wales, in London.

Two of these tubes showed the culture-masses on the inclined surface of the agar-agar; all attempts to obtain fresh cultures from them proved futile. Nutrient gelatine and agar-agar differently sown with portions of them remained sterile throughout. From the contents of the third tube, in which the culture-material was visible not only at the surface but also in the depth of the agar-agar, not inclined, a *micrococcus* was obtained, and not the desired bacillus. This, therefore, had lost its vitality also in this case. The micrococcus in question grows in thick whitish layers on gelatine, which does not become liquified by it.

SECTION XII.

INVESTIGATION into Fowl Diseases with a view to ascertain whether Fowl-cholera exists in the Australasian Colonies or not.

- (a) Report of inquiries in Victoria, conducted by Mr. A. N. Pearson.
- (b) Reports of supposed outbreaks in New South Wales.
- (c) Report of supposed outbreak on the North Grey Downs, New Zealand, by Dr. Symes.
- (d) Report on supposed outbreaks in Tasmania.
- (e) Report by Dr. Katz, Chief Expert to the Commission, on actual examination of fowls or blood of fowls, supposed to have died from fowl-cholera.

- (a) Report of inquiries in Victoria, conducted by Mr. A. N. Pearson.

Department of Agriculture, Agricultural Laboratory,

Dear Dr. Wilkinson:

19 and 21, Queen-street, Melbourne, 27 June, 1888.

The following tabulated list embodies the results of my inquiries in Victoria, relative to the occurrence of fowl-cholera. It will be seen that while there are several cases in which the symptoms described and the apparent presence of a highly infectious disease strongly suggest the identity of our colonial fowl-cholera with the European disease, yet the identity is not proved. Still I am by no means convinced that we have not here the true European fowl-cholera, or at any rate a disease closely similar to it; and I think the search should be carried on energetically. Dr. Salmon, of the United States Agricultural Department (*vide* U. S. Dept. of Agric. Report, 1880), when he turned his attention to the American fowl-cholera, was similarly unsuccessful at first in obtaining definite results, notwithstanding that a fatal contagious disease, resembling fowl-cholera, was widely distributed throughout the country; afterwards he was successful.

I think that if Dr. Katz were free to go to any locality in the colonies to examine outbreaks of the disease at their commencement, he would ere long obtain the much desired microbes.

Yours faithfully,

Dr. W. C. Wilkinson, M.L.A.,
Chairman, Experiment Committee.

A. N. PEARSON.

RESULTS

RESULTS of my inquiries in Victoria relative to the occurrence of Fowl-cholera.

F. W. Elsner, F.R.C.S.I., 189, Church-street, Richmond, Melbourne.—24 April, 1888.	Dr. Elsner states that an attack of chicken-cholera occurred amongst his fowls in October, 1887. He was not then aware that there were any doubts as to the existence of fowl-cholera wherever fowls were congregated; he recognized it as the disease known as chicken-cholera, in England, and did not therefore specially examine for chicken-cholera symptoms, but having searched for diphtheria symptoms destroyed the carcasses. Has now made all the arrangements for bacteriologically investigating any future outbreak. Owing, however, to the approach of winter, and the thoroughness with which the former outbreak was stamped out, he has been unable to get another case, and sporadic cases are not likely to occur until next hot weather.
James M. Nickinson, Shire Secretary, Shepparton.—2 May, 1888.	On 2nd October, some of the fowls were ill, passed large watery evacuations, stood or lay about the yard with gaping mouths, and when obliged to run let their wings droop and drag in the sand, generally falling over after running a little way. Next day one hen was found dead on nest, stretched and stiff, <i>rigor mortis</i> extremely well marked, arms relaxed and protruding, without marks of violence or evidence of diphtheria. Blood thick and tarry. During the same day, two more hens died, presenting the same appearances; during the following night, four hens were seen to drop off the roost dead; the next day three more hens died. The fowls were then turned out into the yard, the fowl-house cleaned out, white-washed, fumigated with sulphur; the fowls themselves at night being fumigated on their perches. The ducks which had formerly inhabited the fowl-house were turned out, as they kept the floor moist. The ducks and fowls had formerly been fed together; but were now fed separately. The ducks were not affected by the disease, nor were the geese, the horse, the mare in foal, the dogs, the cat, nor were a neighbour's goats and pet birds affected by the disease. All members of the household partook of eggs and fowls from the fowl-house, but no one was attacked by any disorder. Mr. Nickinson had a number of pure Cochins and Brahmas, and also some crosses between them. Three months ago these fowls were seized with some disease, which no one in the neighbourhood could identify. The fowls became "mopy," declined to leave the roost, and when off the roost soon returned; they refused food; no discharge from nostrils or beaks, excrement green and slimy. In most cases fowls are dead within 48 hours of beginning of attack; and generally to see a fowl "mopy," is to find it dead within 24 hours.
*Joseph Knight, J.P., Victoria, Member of Council of Agricultural Education, Mooroodna.—10 May, 1888. George Lee, Beulah Hill, Diamond Creek, near Melbourne.—4 May, 1888.	The best birds were penned up; but although the disease started in these pens, the greatest mortality has been outside. Has only six or seven fowls left, having lost over sixty. Mr. Knight stated that he had seen Mr. Nickinson's fowls at Shepparton. A disease having the same symptoms is very prevalent about Mooroodna. Mr. Lee states that about a fortnight ago, a disease broke out amongst his fowls and already more than fifty are dead, and nearly all the others are suffering from it. The symptoms are first:—A slight streak of yellow and white in the droppings, which increases rapidly until the motions sometimes change to green, at other times watery with small lumps. All is the same colour. The fowl squats about, the crop becomes large and hard, and the birds die in from one to six days. A few recover, but are very weak.
James Crawford, Canary Island, South.—23 May, 1888.	NOTE.—Subsequently two of these fowls were obtained from Mr. Lee; one was dead before being sent; the other died on the way. A hen was placed in the box in which they had been sent, and kept there for a week, its food being mixed with the old droppings of the dead fowls; but it did not contract the disease. Some blood and secretions were taken in vacuum tubes to Dr. Katz, who examined them with negative results. These two cases were the last of the outbreak, no more of Mr. Lee's fowls being afterwards attacked. Last spring, Mr. Crawford's poultry suffered greatly from the so-called fowl-cholera, a large number of the common fowls, and the whole of a fine flock of turkeys having been lost in consequence. The same disease is beginning to break out again.
John Wedd, Ravenswood Station.—17 May, 1888. H. R. Danforth, Allan's Flat.—22 May, 1888. ———, Lower Homebush.—27 May, 1888.	Many of his neighbours have lost nearly all their fowls through some disease never before seen in the vicinity. States that his valuable imported fowls are dying from chicken-cholera, causing him a loss of £20 a day. This correspondent, who does not wish his name published, states that since going to reside at Homebush has yearly lost many fowls from a disease; his neighbours also suffer in the same way. The symptoms are:—In January and February, the fowls mope about, will not eat, and are purged, with green or yellow droppings.
* R. B. Kerr, Rabbit Inspector, Bacchus Marsh.—25 April, 1888.	About a fortnight earlier could have procured lots of fowls which were suffering from a disease having the symptoms of fowl-cholera, but they are all now dead. A disease is breaking out among the fowls of the Manager of the National Bank at Bacchus Marsh. (Subsequently one of these fowls was obtained, and put in a box for despatch to Melbourne, but died during Mr. Kerr's absence.)
* G. W. Robinson, Shire Engineer, Berwick.—25 April, 1888.	States that fowl-cholera was reported to be very severe about a month ago on a neighbouring farm. The farmers endeavour to conceal the fact of their having the disease.
* Richard Mackay, Taralgon.—24 April, 1888. Marmaduke N. Richardson, Compton, Princes-street, Kew.—24 April, 1888. ———, Prahran.—25 April, 1888.	Last year thirty of his fowls died within a few days, and everyone showed the symptoms of fowl-cholera; diarrhoea and drowsiness being specially noticeable. Has frequently seen his fowls suffering from a fatal disease which he supposed to be diarrhoea. Has lost several birds.
S. A. Hutchinson, Booligal, N.S.W.—13 May, 1888.	This correspondent, who desires his name should not be published, states that he purchased the previous week a number of fowls from a dealer. Some of these birds are now taken with loud and difficult breathing, a kind of cough approaching suffocation, a discharge at the beak, and loss of appetite. The disease is infectious, and has spread to some fowls bred on the place. Forwards the last of four fowls which died quite suddenly, as if in a fit. While quietly feeding, they dropped suddenly, gave a faint flap of the wings and a caw, and were then dead. (This fowl arrived several days afterwards, in a high state of putrefaction, with 8s. carriage to be paid.)

* These correspondents had previously received from me the following description of the symptoms of fowl-cholera:—Loss of appetite generally; diarrhoea, with yellow evacuations, sometimes changing to green, and sometimes slimy with streaks of blood; ruffling of the feathers and drooping of the wings; extreme drowsiness or "moping," weakness and staggering. Death generally in from two to four days.—A.N.P.

184 ROYAL COMMISSION OF INQUIRY INTO SCHEMES FOR THE EXTERMINATION

Abstract of letter from Dr. T. W. Elsner, F.R.C.S.I., 189, Church-street, Richmond, Melbourne, addressed to Mr. A. N. Pearson.

In October, 1887, Dr. Elsner had an attack of cholera amongst his fowls. At this time he was not aware that there was any doubt as to the existence of the malady wherever fowls were congregated, so that he did not make a particular examination of the dead fowls, believing that it was the same disease as the one called by the name of chicken-cholera in England. The question, however, having arisen as to the identity of the fowl-cholera in this country with that of Europe, he had made arrangements to submit any further specimens obtainable to the crucial test of cultivation experiments, for which he was fully provided, he himself having a Zeiss microscope with $\frac{1}{2}$ inch oil immersion lens, &c., and Mr. Stone, of the Technological Laboratory, at the Technological Museum, having all the cultivation apparatus.

Unfortunately, he had so effectually stamped out the disease amongst his own fowls, by suitable sanitary measures, that up to the date of writing he had been unable to obtain a single case; nor was it likely that any sporadic case would occur until next hot weather.

The symptoms of the disease amongst his fowls were the passage of large watery evacuations. They stood about the yard with gaping mouths, and when obliged to run allowed their wings to droop and drag in the sand, generally falling over after running a little way. The next day one hen was found dead on the nest, stretched out stiff, *rigor mortis* being extremely well marked; arms relaxed and protruding, without marks of violence or evidence of diphtheria. The blood was found thick and tarry, and refused to run from the vessels. In the course of the day two more hens died with appearances in every way similar. At night four hens died and the next day three. Steps were then taken to stamp out the disease, by thoroughly cleaning and disinfecting the fowl-house. The ducks which lived in the same fowl-house were not attacked, nor were the geese attacked. A mare and foal in an adjoining stable were entirely without symptoms of disease.

Letter from John Nicholson, Esq., M.D., of Benalla, Victoria, in reference to fowl disease.

H. Mahon, Esq.,—

Dear Sir,

Benalla, 3 May, 1888.

As I have no personal experience of the appearance presented in chicken-cholera, I do not know whether the disease about which I telegraphed to you has any marked resemblance to it. I will therefore content myself by putting you in possession of the facts which induced me to communicate with you.

A patient of mine happened to mention that many of his fowls were dying from some disease which was very rapid in its course, and that a fowl apparently well one day might drop off its perch during the night. He said that he lost some nearly every night. I requested him to send me one which had recently died, and on the following morning he sent me a young rooster which had died the previous night. I made an examination of it, and found that *rigor mortis* had not set in, although it was cold; there were no signs of decomposition, as the flesh and internal organs were quite fresh; the mouth was normal, and there was no obstruction to trachea or gullet. The crop and gizzard contained a quantity of wheat in process of digestion. There was nothing abnormal about them. The heart was empty, as were also the blood-vessels generally. The liver was red, but apparently normal, possibly somewhat enlarged, as was also the spleen. Kidneys and lungs healthy. The intestines for their whole extent were somewhat congested, and contained blood-stained mucus, with streaks of blood, in some places of considerable extent, scattered through it. There was no feculent matter, except a small quantity of soft amber-coloured matter in the cloaca, and the caecal appendages. These latter also contained sanious fluid. The intestinal discharges before death had evidently been of a dark red-brown sanious character. Acting on this information I wired you, and went to the farm of my informant to look at his fowls. Two were pointed out to me as affected, and I brought them home with me. They looked dull, but there was no appearance of diarrhoea at the vent. The motions were greenish, but entirely soft, not like that seen in the cloaca of the dead fowl. These fowls have not died, and they continue to feed, but are still dull. There is no drooping of the wings or tail.

May 4th.—I had written so far last night, but have to add that these fowls died this morning, and I have sent you the intestines of one of them, also the spleen and a loop of intestine of the other one. The blood in the tubes was taken from the right cavity of the heart, the fowl being still warm. *Post-mortem* appearances were of a negative character, as there was no hemorrhage as in the one first examined. The pericardium contained a little serum. The intestine examined was not congested; contents pulsatious.

I shall be glad to hear how the experiment succeeds (I have inoculated one fowl) to-day. Any further information I shall be happy to give.

Yours, &c.,

JNO. NICHOLSON, M.D.

(b) Reports of supposed outbreaks in New South Wales.

Mr. Hugh Mahon,—

Sir,

Byng-street, Orange, 13 May, 1888.

I see by the local paper of yesterday that the Commission *re* the rabbit question, wish to get fowls suffering from cholera. My fowls are now dying from what we suppose to be that complaint. I will give you the full particulars of my experience this summer, which may be useful to the Commission, as it goes to prove that chicken-cholera is not taken from fowls by other birds and animals. Early in September I had six or seven clutches of chicks hatched. When from one to two weeks old they became ill from purging of the bowels, and all but three or four died. By this time several other clutches were out. I put these in a different building, but they died the same. I then sent to Sydney for a pair of Houdan fowls, which I put in a small yard, together with a few good hens of mixed breeds, and only set eggs laid in this pen. A larger proportion of these lived than before, but the complaint had taken another form: Instead of purging, the chickens chirped about for several days (getting ill when about five weeks old), their stomachs swelled and became black looking, then they died. I opened several and found the intestines swelled and inflamed; also the gizzard was very much larger than natural, and also inflamed. The purged chicks I gave sopped bread, with pepper and sulphur; to the swelled chicks I gave castor-oil, sulphur, pepper, salt, mixed in bread or oatmeal; but not one that took sick recovered. Out of 320 chicks I have only reared over 40. The general feed of the chicks and fowls was corn, wheat, dry and boiled potatoes, boiled and mashed, and cabbage cut up small and sprinkled about the yard. The last chicken came out about six weeks ago (as the weather is too cold here now), and nearly all are dead. The French, Spanish, and game chicks all died. A few common and the Houdan-crossed lived in the largest proportion. Thus for seven months we had this fowl disease in the yards, covering three-quarters of an acre of ground, pailed in. During this time one of my grand-children, between 3 and 4 years old, was always among the chickens, several grey-hound dogs, a terrier, while she had young pups she was in an out-room where several clutches of chickens were dying; a number of guinea pigs, and doves in boxes with wire fronts, are about, and the ailing chicks stood about in the sun in front of these cages constantly; also a Rosehill parrot hangs outside. None of these animals have been affected in any way.

A fortnight ago a fresh outbreak came on the full-grown fowls, and they are dying daily since; the symptoms of this is purging, of a white and green colour, some yellow and brown, and some with a clot of light coloured blood in it. I have given the fowls wheat boiled with pepper and salt, and lime mixed into it when cold. A few are recovering. This morning two were dead, and two are ill. All the summer I had the fowl-houses swept every day, washed frequently with lime, and with carbolic acid in water, and sulphur burnt in them. The last fortnight I have had the places whitewashed every morning, floor and perches, so as to destroy the microbes, but apparently to no purpose.

If the French doctors, who seem to understand these complaints, would give the Government a recipe for the cure of chicken-cholera, and it was published in all the country papers, it would be as much a national benefit, as the destruction of the rabbits. The last twelve years this fowl disease comes every autumn, and clears off hundreds of poultry. I have made inquiries, and find that this summer this complaint has killed the chickens generally, both about the town and district, and it will be but a matter of time when there will be no fowls to send to market. Should the Commission think proper to send a competent, scientific person up at once, they can see my fowls and their surroundings, or, if they wish, you can telegraph to me, and I will send you a couple of dead fowls.

Yours respectfully,

MRS. C. E. McNEILLY,

Byng-street West, Orange.

Dear

OF RABBITS IN AUSTRALASIA—INVESTIGATION INTO FOWL DISEASES. 185

Dear Sir,

I have a few fowls suffering from what I suppose is chicken-cholera. They are dying quickly, so if you require them, you should send at once for them.

4, Jesmond Place, Bourke-street, Surry Hills, Sydney.

Yours truly,

L. T. LOHR.

I went to see the diseased fowls, which suffered from what is generally termed "scab."

OSCAR KATZ.

Dear Sir,

I believe chicken-cholera has been amongst the fowls at Genrie for some years. We have lost a large number each year, generally after rain during the warm weather, but even now occasional ones die from the same symptoms. The liver swells to an enormous size, and the droppings of the birds dirties them greatly; they sicken and die very rapidly, as it seems too late to dose them when noticed sick, they are too far gone. Sheep have been for the last three years in paddocks of about 30 acres, and the fowls constantly wandering and feeding in those paddocks. The bodies of the fowls have been burnt or buried when found, but doubtless many have not been found. No sheep have died in these paddocks. If of any acceptance, I would send you either a sick fowl, if possible, or one as soon as found dead, or the inside if you desire.

Yours truly,

E. W. SEVERNE.

Genrie, Ponto Railway Station, 11th May, 1888.

I wired to above address. Specimen of fowl received 31st May.—O.K.

Mrs. SEVERNE sends Dr. Katz a chicken fresh dead for his inspection, and should be very glad indeed to know the nature of the disease, as she has lost about 100 since last December, the most dying during the long hot weather of January and February. This disease has shown itself every year for the last four years during those months.

Genrie, Ponto Railway Station, 30 May.

To the Secretary of the Royal Commission for the Extermination of Rabbits,—

Sir,

I have the chicken-cholera now raging among my poultry, and I can supply you with same. At present we have no rabbits here to try the experiment with.

Deep Creek, Narrabri, 8 May, 1888.

I remain, &c.,

J. BRAKE.

This cholera kills my fowls in one day. They look to be healthy one day and die the next. I have no remedy to stop same.

To Oscar Katz, Esq.,—

Dear Sir,

I have forwarded to you two fowls. Died last night with the disease, and I hope you will receive the same.

Deep Creek, Narrabri, 3 June, 1888.

Yours respectfully,

J. BRAKE.

They are packed in a biscuit tin. Shall I send any more on?

I wired to the above address. On 4th June one specimen of fowl received.—O.K.

(c) Report of supposed outbreak on the North Grey Downs, New Zealand, by Dr. Symes.

(Extract from the *N. Z. Country Journal*, March, 1888.)

THE existence in Canterbury of the fatal disease of poultry, known as chicken or fowl cholera, was made known by the interesting letter of Mr. J. Ronaldson in the *Press* of 23rd February last; and in view of the attention drawn to this disease by M. Pasteur as a remedy for the rabbit pest, I considered the matter of sufficient interest to call for special investigation. I accordingly visited the district on the 25th, 26th and 27th February, and made inquiries at a large number of farms, examining as closely as possible the localities and circumstances of the epidemic. I have not yet been able to ascertain the exact limits of the district over which the disease extends, but the information hitherto obtained appears to show that the disease commenced in the neighbourhood of Amberley, not less than three years ago, and that during the last two years it has extended over the farms near Balcairn, Sefton, and Leichfield. It will be of great assistance towards the further investigation of the disease, if persons noticing it in other places will kindly communicate with the writer, or with the editor of the journal. Nearly every farm in these districts has suffered from the epidemic; the exceptions being very few indeed. Whenever the disease appears in a poultry yard, it usually carries off from 50 to 90 or even 95 per cent. of the fowls and turkeys within a month or two and sometimes within a week, while the ducks and geese invariably escape. It appears to be a very uncommon disease, as I could not hear of any person in the district who had ever seen it before. This epidemic presents the leading features of fowl-cholera; thus, it is extremely fatal, at any rate in its earlier phases, killing almost every fowl attacked within twenty-four hours; and is characterized by diarrhoea with excessive thirst. The best description I can find of fowl-cholera is in the last edition of Wright's work on poultry, 1885, p. 187. He says:—"During the last few years American and Continental yards have been devastated by disease previously unknown, to which the name of chicken-cholera has been generally given, and of late some cases have occurred in England. In true chicken-cholera there is a sudden and violent accession of thirst, accompanied with diarrhoea; the droppings being at first of a greenish character, and by degrees becoming thin and whitish. Great weakness becomes rapidly manifested, the fowl falling about, usually by the water fountain; and in some cases cramps also supervene. The bird also presents a peculiar anxious look about the face.

It will be noticed in the symptoms described further on, that the droppings were generally yellow, instead of greenish, but this is of little importance, as in either case it implies excessive discharge of bile, which may be either green or yellow according to certain circumstances. I made many inquiries as to the supposed cause of the disease, but the great variety of opinions expressed was alone sufficient to show that there is no recognized cause. Having made some personal study of human cholera in its native home, India, the distribution of which is closely connected with water supply, I naturally devoted special attention to the conditions of water supply to the poultry affected, and I venture to suggest the following propositions, as at least worthy of more extended investigation:—

1. The disease occurs principally on farms which possess no stream of running water.
2. In nearly every case, ducks and geese are kept on the farm affected; and in the few exceptional cases they are kept on farms adjoining.
3. The water pumped into tins or troughs for the poultry is necessarily very limited in quantity, and is quickly polluted by the ducks and geese.

4. There is reason to believe that the fowls and turkeys are liable to be affected by polluted water which would not injure ducks and geese.

The obvious objection to this theory is that similar conditions as to water supply have prevailed for many years in this district, whereas the disease is only recent; but it must be borne in mind that the germs of disease take a certain period of time to develop; thus, at the German Medical Congress, held at Wiesbaden, in September, 1887, Dr. Hueppe, after alluding to the relationships existing between the epidemics of infectious diseases, and the depth of the water level below the surface of the ground, laid down the following conclusion as a fundamental basis of modern medicine:—

“That the excitants of infectious disease must be specific organisms, and this specificity may be either absolute or else evolved during long periods of time from local putrefactive process.” (*British Medical Journal*, Jan. 21, 1888.)

We do not know the period of time required to evolve the germs of fowl-cholera from local putrefactive processes, but assuming that the necessary conditions have been present on the Mount Grey Downs for twenty years, and that no infection has been introduced from elsewhere, the study of this outbreak may afford valuable information as to the origin and course of epidemic infectious disease. The experimental inoculation of rabbits with the fowl-cholera existing on the Mount Grey Downs will, subject to the approval of the Government, form the subject of a future article. I now proceed to give the notes taken at the time of a few of the more important visits made by me in the district. I desire to acknowledge the kind assistance rendered to me in this inquiry by Mr. Ensor, of Mount Grey, and by Mr. Vaughan, of Sefton, who both placed traps and horses at my disposal. I am also much indebted to Mr. Ronaldson, of Balcairn, for giving me the benefit of his local knowledge and introducing me to various farmers.

Case 1. Mrs. M'Ewen, near Sefton, visited on 26 February, 1888, states that she has kept fowls on this farm for about twenty years, and has never lost but one or two occasionally before this summer. In November last she had 150 fowls, divided into two sets. One set of fifty were at a cottage about 6 chains from the homestead. On the first Friday in November last she saw them all looking quite well. On the following Monday she noticed some of them were ill. The next morning six were dead. The following morning about a dozen more were dead; and so on, until the following Monday, by which time the whole flock of fifty fowls were dead, with the exception of a solitary rooster, which it was considered advisable to kill. The second flock of about 100 fowls were kept at the homestead. The same epidemic appeared amongst them a few weeks later in November. Although the two flocks were kept separate, it is probable that some communication may have existed. When the second flock began to die Mrs. M'Ewen disposed of them all except four, which are still alive and well. A fresh lot of fowls were obtained in January. The disease has not reappeared; and Mrs. M'Ewen has now about 100 fowls, all well.

The symptoms of the disease were the same as will be described later on.

The conditions relating to the disease are as follows:—

1. *Water*.—No running water exists there. Fresh water is pumped every day into iron vessels, and is used in common by fowls, ducks, geese, and turkeys. The well is 45 feet deep, and supplies excellent water. A good many ducks and geese are kept, and they dirty the drinking water provided for the poultry very quickly.

2. *Premises*.—The whole of the premises are kept scrupulously clean. Open fowl-houses are used, and the fowls are never shut up in them. The disease appeared equally early and equally virulent in the fowls roosting outside as in those roosting in the fowl-house.

3. *Infection*.—Mrs. M'Ewen cannot trace any source of infection from elsewhere. She has not bought any fresh fowls for twenty years, and it is three or four years since she has received a present of any. She has paid great attention to poultry, and never saw any disease resembling this before. The dead fowls were buried at once.

4. *Other Circumstances*.—The first flock of fifty were remarkably fine young fowls, of good but mixed breeds, fed mostly on wheat. It is worthy of note that the turkeys escaped the disease, which is quite exceptional. No other stock suffered. No milk was given to the poultry.

Case 2.—Mr. John Stuart, Balcairn, visited by me on 26 February, 1888. Has kept fowls here for twenty years, without any illness amongst them until last November, at which time he had 150 fowls, besides other poultry. The disease commenced in wet weather, and was very severe at first, carrying off about 100 fowls in the first month. Since then it has been gradually diminishing, the total mortality being now 120.

Symptoms.—Mr. Stuart has observed the fowls die in from six to twenty-four hours from the first appearance of illness, at the commencement of the epidemic; but now that the disease is disappearing, the fowls are longer ill, and often linger for a week. Also, many now recover, whereas at first none did. The first indication, is yellow droppings, like yolk of egg; the fowl drinks incessantly, refuses food, and is much purged; it appears stiff, the wings droop, the comb gets blue or black, and the bird mopes.

Conditions.—Water: There is no permanent stream of water, and that which is pumped for the poultry is soon polluted by the ducks and geese. Six ducks and twelve geese are there at present, but a larger number of ducks are usually kept. There is an open shed for the fowls, but they roost principally in the trees and fences. There are no turkeys. The farm-yard is occupied more or less constantly by three pet sheep, ten calves, six pigs, horses, dogs, cats, and poultry. Mr. Stuart does not know how the infection was introduced, as the disease having been prevalent in his neighbourhood for the past two years, he has carefully avoided bringing home any fresh fowls. He has not buried any of the dead fowls, because they are immediately devoured by the dogs and cats. He has noticed that the dogs and cats suffer no ill effects from eating the dead fowls; nor has any illness occurred amongst the other stock on the farm. Pure-bred fowls were the first affected, especially Houdans and Hamburgs, and the roosters were affected more quickly than the hens. The age made no difference. At the time the complaint commenced, the food had just been changed from wheat to oats; it was changed back to wheat, but it made no difference. Milk is fed to the poultry, and distributed in shallow holes made purposely in the stiff clay ground. Sulphur and castor oil have been tried as medicine without result. Infusion of blue-gum leaves is now being tried.

Case 3.—Mrs. Hugh M'Coll, Balcairn, visited by me on 27th February, 1888. Has kept fowls here about four years. Never saw any illness amongst the fowls until eighteen months ago, when she had eighty fowls

fowls, of which sixty died in two months, about September and October, 1886. The premises were cleaned and all rubbish burned. The disease did not reappear until January, 1888; since then she has lost twelve fowls. She always keeps about a dozen geese, but no ducks at present. There is no running water, and the geese use the water pumped for the fowls. In 1886 the old birds suffered most, and in 1888 the young birds. There is no fowl-house. The symptoms observed are the same as described by Mr. Stuart. The cats and dogs eat the dead fowls with impunity. There is no history of infection.

Case 4.—Mr. John Dron, Balcairn, visited by me on 26th February, 1888. Has been here twelve years, and never saw any special illness among the fowls until a year ago, when about fifty died in a few months. The disease seems to come and go, and after an interval of freedom three died last week. There is no running water, and ducks use the water which is pumped into a shallow tin for the fowls, and render it very dirty. Has not noticed any fowl ill over twenty-four hours.

Case 5.—Mr. Donald Cameron, Saltwater Creek, visited by me on 27th February. Is one of the oldest residents in the district, and has always kept a large quantity of ducks and geese, as well as fowls. Has never seen any illness among any of the poultry, although chicken-cholera has been very prevalent all round him for two years past. The Saltwater Creek runs through his premises.

Case 6.—Mrs. John Topp, near Saltwater Creek, visited on 27th February, 1888. Has kept fowls here for six months, and recently lost ten out of thirty. There is no running water, and the water pumped for the fowls is polluted by the ducks and geese. She had nine turkeys which all died of the same complaint just before the fowls commenced to die. Mrs. Topp was previously in Amberley, where, in November, 1885, she lost five turkeys and thirty fowls from the same complaint. Her sister, Mrs. Retallich, at Amberley, has recently lost all her turkeys and a number of fowls from this complaint. The symptoms are the same as described by Mr. Stuart.

Case 7.—Mrs. John Dick, near Saltwater Creek, visited 27th February, 1888. Has kept fowls here four or five years. Never saw any illness until spring of 1886, when she lost fifty-four out of sixty fowls in about two months. The disease has never returned. There were twenty-four ducks, but no geese nor turkeys.

Case 8.—Mr. Samuel D. Wilson, near Saltwater Creek. Lost about fifty out of one hundred fowls in June and July, 1886, and the disease has not since returned. He does not himself keep ducks or geese, but his neighbour Mrs. Dick's ducks often visit a small creek which runs through his farm and supplies his own fowls with drink. His fowls are not shut up.

Case 9.—Mrs. Fitz-Patrick, Sefton, visited 27th February, 1888. Has kept fowls here for twenty-five years and never saw any illness among them until February, 1886, when out of over one hundred fowls all but seven died in one month. The disease has not reappeared. She had then over fifty ducks, forty geese, six turkeys, four guinea-fowls, eight pigs, twelve calves, nine cows, nine horses. The water used by the fowls is dirtied by the other stock. All the turkeys died from the same complaint, and a pony died of scouring about three months later, after feeding on grass where the fowls had been running. The fowls generally died within twenty-four hours. The symptoms corresponded exactly with those previously described.

Case 10.—Mrs. Wornall, Leithfield Terrace, visited 27th February, 1888. Has kept fowls here twenty-eight years and never saw any illness among them until two years ago, when out of fifty-four fowls forty-seven died. She had not kept ducks nor geese for two or three years previously, but the disease had been prevalent among her neighbours for some time. There is no running water. Clean water or milk is put into the trough every morning for the fowls, and no other stock had access to the fowls' trough. The premises are particularly clean. The fowls were shut in a fowl-house at night, and were always loose in the day time. The fowls were a very fine well-bred lot. They exhibited the same symptoms as described, and dropped off their perches, three or four or seven at a time. All the pure-bred fowls died.

Case 11.—Mrs. Ashby, Leithfield Terrace, visited 27th February, 1888. Has kept fowls here ten years, and never had any illness among them until April, 1885, when she lost thirty out of fifty fowls in one month. The complaint did not return until July, 1887, when she lost twenty-three out of forty. She has only one duck and no geese. The water pumped for the fowls does not appear to be used by other stock. The fowls are shut up at night and run loose in the day time. The premises are clean. The complaint was prevalent in the neighbourhood before the fowls were attacked.

Case 12.—Mrs. Wilson, Sefton Road, visited 27th February, 1888. Has kept fowls here twenty years, and never saw any illness among them until July, 1886, when out of over one hundred fowls all but fourteen died in six weeks. No fowl-house is used. There is no running water, and the ducks and geese use the water pumped for the fowls. The disease has not returned.

Case 13.—Mrs. O'Connor, Balcairn, visited 27th February, 1888. Had fifty fowls last winter, of which all but eight died. In addition to the symptoms described, Mrs. O'Connor noticed some of the sick fowls run round in a circle and then drop, becoming at once as stiff as though dead for two days. There is no running water, and that used by the fowls is used by pigs and other stock; but the evidence as to ducks and geese is indefinite.

I visited many other farms with the result of confirming the above statements.

The perusal of these cases must tend to relieve any anxiety as to the danger of fowl-cholera affecting either cattle, sheep or human beings. Moreover, the study of fowl-cholera is of especial interest in assisting us to learn more of the nature and mode of origin of various other epidemic diseases, both of man and animals, and enabling us, in virtue of such knowledge, to prevent or cure such disease.

I will conclude this article with the following quotation from the *British Medical Journal* of 21st January, 1888:—

"Pasteur has shown that pathogenic (or disease producing) bacteria undergo modifications of virulence by transmission through susceptible animals, the lower grades of virulence protecting against the higher. Hensbe, who had previously argued that the four diseases—cattle plague, swine plague, rabbit septicæmia, and fowl-cholera, must be nearly related, has made a series of experiments, which not only support the idea, but show that the bacteria of these four diseases, when attenuated either by culture or by transmission, are mutually protective against each other."

(d) Report on supposed outbreaks in Tasmania. Letters from R. Travers Solly, Esq., Under Secretary, Tasmania, to the Secretary, Rabbit Commission:—

Dated 5th May and 10th June, 1888, and replying to letter from Secretary, Rabbit Commission, requesting that if possible tubes containing blood of fowls suffering from chicken-cholera might be supplied. Mr. Harrison, an officer under the Inspector of Stock states, that it is very difficult to get information concerning any present outbreak of the disease, as people are very reticent about the matter. But, in the spring of 1887 at Cambridge, the whole of Mr. T. Evans' fowls (some 70) died off rapidly, showing little previous symptoms of disease. Mr. W. J. J. Reynolds, of Sandy, also lost about forty in a similar manner; the fowls were previously, to all appearance, perfectly healthy, some of them laying; but each fowl died within a few hours of being attacked by the disease, whatever it was. Mr. Archibald Park, M.R.C.V.S., England, states, that from reliable sources he learns that some disease has completely destroyed every fowl in the yards; but that it has since died out, the poultry yards being again stocked. For many years he has heard of great mortality amongst poultry in different parts of the Colony, but nothing definite has come under his observation from which the causes of such mortality could be deduced.

(e) Reports by Dr. O. Katz, Chief Expert to the Commission, on actual examination of fowls or blood of fowls supposed to have died from fowl-cholera.

Case I.—From Dr. Jackson, of Homebush, near Sydney, 4th May, 1888.

Object—Dead fowl.

On microscopic examination of the liver bacilli were found much larger than the microbes of fowl-cholera, and only in small numbers.

Inoculation of material from the liver of the fowl into a mouse resulted in the death of the animal after three days; but organisms could not be found in the blood.

Cultivation experiment with liver-tissue of fowl yielded pure cultures of a bacillus, morphologically similar to that observed directly in the fresh liver; but the appearance of the bacterial cultures (colonies) did not correspond to that of the bacillus of fowl-cholera.

Case II.—From Dr. Nicholson, Benalla, Victoria, 7th May, 1888.

Object—Blood from fowls in capillary tubes.

On cultivation in nutritive gelatine colonies were obtained, in rather large numbers, of a bacillus, which had nothing to do with that of fowl-cholera.

The pure culture of this micro-organism (first generation) inoculated into the subcutaneous cellular tissue of the breast of a healthy young fowl did not infect it. The animal, however, died on the 27th May, ten and a-half days after inoculation, from some other cause.

Case III.—Through Mr. A. N. Pearson, from Melbourne, 16th May, 1888.

Object—Blood in capillary tube.

Inoculation of some of this blood into a healthy fowl had no infective power. The animal, however, also died on the 27th May, ten days after inoculation; but the microscopic examination of blood yielded negative results, so far as micro-organisms are concerned.

Case IV.—From Mrs. C. E. McNeilly, of Byng-street west, Orange, New South Wales, 17th May, 1888.

Object—Four dead fowls.

Post-mortem examination without any positive result.

Microscopic examination of blood of two of the above specimens showed a few bacteria.

Inoculation of blood from one of the two specimens into a healthy fowl yielded a negative result.

Case V.—From Mrs. Severne, Genrie, Ponto Railway Station, New South Wales, 31st May, 1888.

Object—Dead fowl.

Microscopic examination of blood without positive result.

Inoculation of blood into a healthy fowl had not the slightest effect.

Case VI.—From Mr. J. Brake, Deep Creek, Narrabri, New South Wales, 4th June, 1888.

Object—Dead fowl.

Post-mortem and microscopic examinations yielded negative results.

Inoculation of liver-tissue into a healthy fowl was without effect.

Case VII.—From Dr. Symes, New Zealand, through Sir James Hector; received from Mr. Hamlet, Government Analyst, Sydney, 13th June, 1888.

Object—A dozen capillary tubes containing blood from diseased fowl.

Microscopic examination of the blood failed to show presence of any bacteria.

Inoculation of the contents of two tubes into two healthy fowls remained without effect.

Culture experiment with above blood in nutritive gelatine (after Esmarch's method) likewise yielded a negative result, inasmuch as the gelatine was still sterile after about a week, with the exception only of one or two contaminations.

Case VIII.—From Mr. Lindsay Thompson, Burwood, near Sydney, 18th August, 1888.

Object—Two dead chickens.

Result of examination for fowl-cholera negative.

Case IX.—From the same, 13th September, 1888.

Object—One dead chick.

Result of examination (microscopically and inoculation of rabbits), negative.

Thus, in none of the above nine cases could the disorder of which the above fowls died be identified as fowl-cholera; but, in order to form a definite opinion as to whether this infectious disease exists in Australasia or not, further examinations are required and must be continued for some time.

SECTION XIII.

DESCRIPTION of the Symptoms and Post-mortem Appearances caused by Fowl-cholera in Poultry; prepared by Dr. O. Katz.

Dr. F. A. Zürn, Professor of Veterinary Sciences at Leipzig University, in his work entitled "Die Krankheiten des Hausgeflügels" (Diseases of Domestic Poultry), Weimar, 1882, gives the following detailed account of what bears on the above subject:—

Symptoms.—After referring to the statement made by Salmon, that the first symptom of this devastating disease (fowl-cholera) is the depositing of an intensely yellow urine—in contradistinction to the normally lime-water-like urine—which, though voided from the cloaca along with fæces, can be distinguished from the latter, and that the urine is yellow also in the ureter and cloaca of birds dead of fowl-cholera, he says

says that he never noticed this peculiarity, and that also other observers as Semmer, Ferroncito, and Pasteur do not mention it. The Professor then continues: "The beginning of the disease is marked, as a rule, by sadness, apathy, and want of appetite; it is only in exceptional cases that the sick birds take food nearly until death. They isolate themselves from their healthy companions, drop their wings, and appear very dull and languid. Soon a severe diarrhœa sets in, the voided fœces are thin, but still soft and coherent, and of yellowish-white colour; later on they become watery, being of a greenish appearance and mixed with mucus; the feathers round the opening of the cloaca are much polluted with fœcal matter. As an exception, the patients vomit, throwing out quite thin greenish masses. Usually the sick poultry are extremely thirsty. The diarrhœa exhausts the sick considerably; their weakness soon becomes so great that they are scarcely any longer able to stand on their legs; therefore, they rest on the ground or soil, with their bellies closely attached to the cool surface; now and then they try to stand up, but, staggering as they are, they do not keep themselves upright for a long time; soon they sit down again, trembling, with their plumage ruffled in a high degree, and their eyelids closed as if in sleep; it is only occasionally that they utter a hoarse sound. The comb and the throat-lobes, which at the beginning showed a bluish-red tint, become violet by-and-by—before the death of the animal sometimes even bluish-black. The weakness is accompanied by a rapidly increasing emaciation. The body-temperature is raised by 1—1.5° C. (1½—2½° Fahr.), more rarely by 2° C. (3½° Fahr.), above the normal [up to 43.5° C. (110½° Fahr.)]. The death ensues under convulsions, more rarely without such; in the former case the animal's head becomes drawn down to the breast.

"The disease frequently takes only a short time, 1½—3 days, only occasionally weeks, before death follows. It occurs that seemingly quite healthy birds which were just eating, or which otherwise seemed normal, die almost suddenly; on the other hand a bird may linger for a week and longer before the misery reaches its end."

Such are, on the whole, the symptoms of domestic poultry which have contracted the disease in the natural way, or of poultry which prove themselves susceptible to experiments by way of feeding with the virus of fowl-cholera.

Inoculations of this virus, or of material carrying it, into normal birds are, as a rule, followed by quick death. It is only seldom that a week or more elapses until death. For instance, I inoculated a pigeon and a fowl, each with a small quantity of virulent gelatine-culture of the microbe of fowl-cholera. The pigeon died in less than twenty hours; the fowl did not succumb until after somewhat more than ten and a half days, within which period it failed to show any typical symptoms. That it died of veritable fowl-cholera was afterwards clearly proved.

Post-mortem Appearances.—"Fowls, geese, and ducks, which have been ill for some time before dying, are in a decidedly emaciated condition; birds which have been ill only for a short time show the flesh still well preserved, firm, and of normal colouration. The chief appearances, at the autopsy, are presented by the small intestines. Their contents represent thin, yellow masses, made up of mucus, *débris*, epithelia of intestines, and very small portions remaining from feeding; often they are stained with blood. The mucous membrane of the intestines is infiltrated with scrous masses, softened, turgid, with its blood-vessels gorged and offering a tree-like appearance."

Besides the intense intestinal inflammation, with numerous hæmorrhages, as a rule, and sometimes even ulcerations, the spleen and liver are usually enlarged, soft, and of darker colour than normal. The pericardium and the heart are mostly altered, inasmuch as the former is seen to have exuded a watery or fibrinous liquid, and the latter has at its surface numerous spots due to extravasated blood. The lungs are darker in colour than usual, very juicy, and rich in blood.

(It is, I think, out of place here to add a description of the appearances which are found at the spot where birds have been *inoculated* with the virus of fowl-cholera.)

Finally, it remains to say, in every case of fowl-cholera, the causal excitors of this disease, the microbes or bacteria of fowl-cholera, are present in the blood of the dead or sick subjects.

SYMPTOMS and Post-mortem Appearances as described by M. Pasteur.

"L'ANIMAL en proie à cette affection est sans force, chancelant, les ailes tombantes. Les plumes du corps soulevées lui donnent la forme en boule. Une somnolence invincible l'accable. Si on l'oblige à ouvrir les yeux, il paraît sortir d'un profond sommeil et bientôt les paupières se referment, et le plus souvent la mort arrive sans que l'animal ait changé de place, après une muette agonie. C'est à peine si quelquefois il agite les ailes pendant quelques secondes. Les désordres intérieurs sont considérables.*

"Le mal s'insinue soit par les premières voies digestives, soit, et le plus souvent, par les intestins, généralement très enflammés et quelquefois ulcérés sur une grande longueur, dans la portion d'ordinaire qui suit le gésier, rapelant par leurs lésions celles de la fièvre typhoïde.

"Le sang est rempli de microbes, et les organes internes sont couverts assez fréquemment de pus et de fausses membranes, principalement du côté des anses intestinales, par où le microbe paraît avoir visiblement pénétré."†

Translation.

The animal subjected to this affection is devoid of strength, tottering in its gait, and suffers its wings to fall. The feathers of the body being raised up give it a ball-like appearance. A somnolence which it is powerless to withstand takes possession of it. On being compelled to open its eyes, it seems as if awakening from a profound slumber, and the eyelids are soon closed again, and most often after a silent agony death supervenes without the animal having changed its position. Exceptionally it agitates its wings for some seconds. There are considerable internal disorders.

The disease affects an entrance either by the most anterior parts of the digestive tract, or (and this is usually the case) by the intestines, which are generally inflamed, and sometimes ulcerated throughout a large extent, commonly in the part following the gizzard, presenting lesions which call to mind those present in typhoid fever.

The blood is full of microbes, and the internal organs are very frequently covered with pus and with false membranes, principally on the side of the intestinal loops where the microbe seems to have visibly penetrated.

APPENDIX I.

SCHEMES for the Extermination of Rabbits by Disease, as classified and reported on by the Correspondence Committee.*

* Omitted by direction of the Honorable the Colonial Secretary, on the ground that the particulars given might be said to be a "disclosure" within the meaning of the Proclamation of the Government of New South Wales, dated 31st August, 1887.—See the Final Report of the Commission, and Minutes of Proceedings attached thereto.

APPENDIX II.

EXPENDITURE by the Governments of the several Colonies in connection with Rabbit Destruction.

NEW SOUTH WALES.

STATEMENT of Expenditure each year, under the Rabbit Act, from the passing of the Act to the 30th September, 1888.*

Year.	Service	Amount.			Total.		
		£	s.	d.	£	s.	d.
1883	Salaries, &c.	10,467	8	11	40,673	17	9
	Subsidies	30,206	8	10			
1884	Salaries, &c.	30,321	1	7	127,029	2	9
	Subsidies	96,708	1	2			
1885	Salaries, &c.	34,988	2	9	84,078	5	5
	Subsidies	49,090	2	8			
1886	Salaries, &c.	43,873	3	11	140,063	7	2
	Subsidies	96,190	3	3			
1887	Salaries, &c. †	28,270	8	7	307,987	2	3
	Subsidies †	279,716	13	8			
To 30 Sept., 1888	Salaries, &c. †	29,255	3	0	32,404	12	4
	Subsidies †	3,149	9	4			
		£ 732,236			7	8	

The total cost of erecting the rabbit-proof fence from Narramine to Bourke, a distance of 202 miles 20 chains was £17,065 2 10½

The total cost of erecting the rabbit-proof fence from Bourke to the Queensland border, a distance of 84 miles, was 6,932 0 9

£23,997 3 7½

£756,233 11 3¼

* Furnished by Henry C. Taylor, Esq., Superintendent, Rabbit Branch, Lands Department, Sydney.

† These amounts represent sums for which notices have been issued by this Department, but £58,000 of which has not yet been paid.

VICTORIA.*

AMOUNTS provided by Parliament for the destruction of Rabbits on unoccupied Crown Lands.

1879-80 (Financial Year)	£1,280
1880-81 "	2,600
1881-82 "	10,000
1882-83 "	12,000
1883-84 "	10,000
1884-85 "	12,000
1885-86 "	33,000
1886-87 "	25,422
1887-88 "	25,422

£131,724

The above amounts include all expenditure on supervision, travelling, poisons, materials, wages, cartage, &c., incurred in working the unoccupied Crown lands, but do not include the cost of erecting the rabbit and wild dog proof fencing between mallee blocks and allotments, and on the South Australian border.

In the Victorian Year-book, 1886-7, it is stated that in the ten years ending with 1886 close upon twenty-nine millions of rabbit-skins, valued at about £209,000, had been exported from Victoria, exclusive of

* From information supplied by A. Morrah, Esq., Secretary for Lands, Melbourne.

APPENDIX.

191

of those used in the Colony. The exports reached a maximim in 1882 of £37,538 ; in 1885 they commenced to show a rapid falling off, and in 1886 amounted only to £6,800. The following are the actual figures :—

EXPORT of Rabbit-skins from Victoria, 1877-1886.

Year.	Skins Exported.		Year.	Skins Exported.	
	Number.	Value.		Number.	Value.
1877	700,565	£ 5,790	1883	4,245,596	£ 30,364
1878	711,844	6,206	1884	4,963,371	37,243
1879	1,036,372	7,322	1885	3,424,259	23,548
1880	3,309,108	21,674	1886	910,609	6,800
1881	4,473,108	32,217	Total	28,704,564	£208,702
1882	4,929,432	37,538			

During the twelve months ending 26th July, 1887, nearly three-quarters of a million (702,632) rabbits were sent to the Melbourne market.

It is also stated in the Year-book that a few years ago upwards of £15,000 were expended on one estate alone in efforts to clear the land of the pest. And it is estimated that, including the expenditure of private individuals, shire councils, and the Government, as well as the depreciation in the grazing value of the land, the loss to the Colony during the ten years 1877-87, owing to the depredations of the rabbits, has amounted to £3,000,000.

SOUTH AUSTRALIA.

STATEMENT of Annual Expenditure by the South Australian Government on Rabbit Destruction, for the seven years ending 30th June, 1888.

1881-82	£21,555 14 10
1882-83	21,658 4 9
1883-84	5,991 18 5
1884-85	26,579 5 3
1885-86	19,653 0 8
1886-87	26,829 1 1
1887-88	6,327 13 2
Total	£128,594 18 2

J. W. GOYDER,

Surveyor-General.

This account is exclusively for expenditure incurred in the destruction of rabbits, to the exclusion of other vermin.—J.W.G.

NEW ZEALAND.

THE Annual Expenditure for Destruction of Rabbits on Crown Lands was as follows :—

1882-83	£4,847 0 0
1883-84	3,886 5 6
1884-85	2,873 4 7
1885-86	2,057 17 10
1886-87	2,315 0 0
1887-88	2,473 10 8

£18,452 17 7

The above sums do not include payment to agents, and for labour, material, natural enemies, and general contingencies. Nor do they include £12,530 voted for the South Canterbury rabbit-proof fence in 1887-88.

Up to August, 1886, the owners of private lands destroyed rabbits at their own expense, but since that date a subsidy, not to exceed £10,000 per annum, has been authorized for payment to local boards.

The rabbit skins exported were as follows :—

1882-83	8,922,756
1883-84	9,892,341
1884-85	9,869,065
1885-86	8,892,372
1886-87	9,900,692
1887-88	12,125,871

59,603,097

There were thus close upon 60,000,000 rabbits killed, the skins of which were exported. Mr. A. Dillon Bell considers that an allowance of half as many, i.e., 30,000,000, must be made for those the skins of which were not exported; and reckoning the cost of obtaining a marketable skin at 3d., and of an unmarketable skin at 1½d., he estimates the direct expenditure on rabbit destruction during the six years at about £937,500. This of course is only an estimate, and it does not take into account the indirect loss due to the diminished grazing value of the land.

Mr. Lianca, a Member of the New Zealand Legislature, by another method of computation, estimated the direct loss at £250,000 per annum, and the indirect loss at an equal sum.

TASMANIA.

TASMANIA.

From May 1883 to January 1888, the Government expenditure on rabbit destruction amounted to £82,882. Since the beginning of 1888 Government expenditure has been limited to the cost of destroying rabbits on unoccupied Crown lands, together with half the cost on occupied Crown lands.

The skins exported were as follows :—

1883	1,735,857
1884	1,730,620
1885	2,872,896
1886 (in part)	184,862

The official returns (which, of course, are necessarily incomplete) give a total of 3,700,526 rabbits destroyed in 1885, thus showing that there were about one-third more rabbits killed than skins exported.

QUEENSLAND.

The expenditure in this Colony has been mainly limited to the construction of a rabbit-proof barrier fence along portions of the New South Wales and South Australian borders. The total expenditure up to December, 1887, was £59,736 15s.

APPENDIX III.

LETTERS from M. Pasteur, extracted from Papers on Rabbit Destruction, submitted to the Legislative Assembly of New South Wales and ordered to be printed (March, 1888.)

[Translation.]

Sir,

Pasteur Institute, Paris, 8 January, 1888.

I have the honor to submit this communication, in reply to the official notification published by your direction in the *Temps*, of Paris, and in conformity with the accompanying cutting that I have extracted from that paper.

The delegates whom I am sending to Australia will leave Marseilles for Melbourne on the 8th of February next.

With the hope that they will be accorded a hearty welcome in Australia and that my scheme will answer all expectations in connection with the destruction of the rabbits that are devastating your fair land, I have the honor to request your acceptance of the assurance of my sincere regard.

The Hon. F. Abigail, &c.

L. PASTEUR.

To Sir Saul Samuel, K.C.M.G., Agent-General for New South Wales,—

Paris, 5 January, 1888.

Upon the destruction of rabbits in Australia and New Zealand.

THE *Revue des Deux-Mondes* in its issue of the 15th August, 1887, has published an article by Mons. C. de Varigny, from which I make the following extracts :—

“Suddenly enriched by the War of Secession in the United States, which enhanced the price of wool by checking its production in America, the Australian Colonies all at once found themselves in possession of considerable revenues.

“Zealous imitators of English customs, they conceived a passion for the chase, and founded Acclimatization Societies in Australia and New Zealand for the purpose of importing hares and rabbits from Europe. It became a perfect mania, a storm of madness that pervaded the whole Colony. * * * Every large landed proprietor had but one idea, that of creating hunting preserves for his amusement. The soil and climate were both so admirably suited to the rabbits, which in England only have from four to six litters of three or four young ones in the course of the year, that in Australia they had as many as ten litters in the year with eight or ten young ones at a birth.

“Fruitless efforts were made to enclose the land with network, for they burrowed underneath it and gained the open to the intense chagrin of the landowners, whose redoubled endeavours and exertions only served to increase their numbers. They have been so successful that to-day this pest is making New Zealand and Australia desolate. Market gardens are laid waste; and districts, which a few years ago yielded 150 bushels of barley, and from 75 to 80 bushels of wheat per hectare (about 2½ acres) have been abandoned, all cultivation, except in certain localities, having become an impossibility.

“Mons. Crawford mentions the case of a large landowner who, after having expended £40,000 sterling (1,000,000 francs) in endeavouring to get rid of this scourge, was compelled to abandon the attempt. On certain holdings their number is estimated at hundreds of thousands, and every year the tax increases with their numbers. Possessed of marvellous voracity they eat the vegetation down to the very root, and convert enormous tracts of pasture lands, which would support from five and twenty to thirty sheep per hectare, into barren and dusty areas. The vineyards have been ruined, and up to the present time the methods employed for the destruction of these animals have achieved no perceptible results. They are hunted, slaughtered, and poisoned, and yet they swarm like ants.

“Mons. Williamson states, that during a journey that he made with a representative of the Government, they noticed that throughout the entire district the vegetation had disappeared. Enormous hordes of rabbits scoured the country, scarcely taking the trouble to move out of the way of their buggy. The ground riddled with burrows, would only admit of their travelling with extreme caution. The rabbits, says he, are everywhere, over the track, and over the plain; they gambol about in troops, and chase each other over the sandhills; and they are seen sitting in hundreds at the entrances of their burrows. Driven to bay in one direction they find refuge in another, and they increase with such rapidity that a universal deluge is the only thing that would give a satisfactory account of them.”

The following publication has recently confirmed the foregoing remarks.

On the 9th of November and 2nd of December, 1887, the paper *Le Temps*, of Paris, published the following official notice issued by the Government of New South Wales :—

[Here follows a literal version of the Gazette notice, offering a reward of £25,000 for a method of exterminating the rabbits.]

A very few days before this news was published by *Le Temps* I had received from a resident in New Zealand an account of the depredations that the rabbits were also committing in that island. On

On the 27th November, 1887, I wrote the following letter to *Le Temps*, which was published on the 29th of that month.

Copy of letter attached herewith :—

“To the Editor of *Le Temps*.

“Paris, 27 November.

“YOUR paper announced a few days ago that the Government of New South Wales was so powerless to contend with a plague of a peculiar nature—the rapid increase of rabbits—that it was offering a reward of 625,000 francs for the discovery of a process that would ensure their extermination. Considerable portions of New Zealand, as badly devastated as Australia, have been abandoned by the owners, who have given up the breeding of sheep through their inability to feed them. Every winter the rabbits are killed by millions, but this wholesale slaughter appears to have no effect so far as any diminution in their number is concerned. Will you permit me through the medium of *Le Temps*, to convey some suggestions to those distant lands, which if given effect to may be attended by a certain amount of success.

“Up to the present time mineral substances, especially preparations of phosphorus, have been used for the destruction of this pest. In having recourse to these means has not a wrong course been pursued? What can such mineral poisons avail in the destruction of animals whose propagation is characterized by such alarming vitality? They certainly prove fatal in the locality where they are laid; but to cope with living creatures is it not essential, if I dare say so, that a poison should be employed endowed with a vitality similar to their own, and like it, able to increase with the same marvellous fecundity? I would like an attempt to be made to carry death into the burrows of New South Wales and New Zealand by communicating a disease to the rabbits that would become epidemic. One such exists which is known by the name of ‘chicken-cholera,’ and has engrossed my closest attention while engaged in the studies of my laboratory. This disease is equally suitable for rabbits. Now, among the experiments that I have made, I find the following :—I collected a certain number of fowls within a limited space, and by administering food soiled with the microbe, which is the cause of the chicken-cholera, they were not long in dying. Poultry-yards are sometimes depopulated by epidemics of this disorder, the propagation of which is undoubtedly ascribable to the excretions of the first sick fowls that pollute the ground and the food. I am of opinion that the same thing would happen with the rabbits, and that they, upon returning to their burrows to die there, would communicate the disease to others, who in their turn would assist to spread the contagion. But how are the first rabbits to introduce the destroying disease into their systems? Nothing is easier.

“Around a burrow I would erect a light fence, enclosing a certain spot to which the rabbits resort in search of food. Experiments have taught us that it is easy to cultivate the microbe of chicken-cholera in a state of perfect purity, and on as large a scale as may be desired, in the broth of any kind of meat. With this broth of microbes the food of the rabbits should be sprinkled, and they dying here and there would spread the disease in all directions.

“I may add that the parasite of the disease that I have just spoken about is harmless to farm-yard animals, except, of course, fowls; but there is no necessity for the latter to feed in the open country.

“I have no doubt that there are persons in the infested districts who are quite prepared to make use of the method proposed, a most simple one, and, in every respect worthy of a trial.

“Kindly accept, Mr. Editor, this assurance of my most sincere respect.

“PASTEUR.”

Immediately after the despatch of this letter I had the curiosity to make experiments on the rabbits themselves. I remembered that chicken-cholera is very easily communicable to rabbits, though I had never made a special study of the rodents. I had often seen them die in cages that had not been disinfected after fowls had succumbed to cholera in them. It is an open question, and one which has been answered in the affirmative by many, whether chicken-cholera is not simply the septicæmia of rabbits, formerly diagnosed by Dr. Davaine.

I was very soon convinced of the facility with which the least meal given to rabbits, after the food has been tainted with the germ of the microbe of chicken-cholera, will speedily entail the death of the rodents.

I recapitulate some of the experiments that were made by Mons. Loir, a student attached to my laboratory, at my instigation :—

On the 27th November five rabbits were put into a box; they remained there without food until 6 o'clock in the evening. At that hour 100 centigrammes of a virulent growth of chicken-cholera were placed in a small basin where the leaves of a cabbage were soaking. These leaves were allowed to drain, and were then given to the five rabbits to be eaten, and in 5 minutes they had finished their meal. At midnight three fresh uninfected rabbits are placed with the others.

At 8 o'clock in the morning of the 28th November the five infected rabbits seemed ill. At 11 o'clock, that is to say, seventeen hours after their meal, two of them were dead. The remaining three died at 3 o'clock in the afternoon, twenty hours after their meal.

On the 28th of November, at 7 in the evening, one of the rabbits that had been confined on the previous day at midnight with those that had eaten the tainted food was found to be dead. The two other rabbits did not become sick.

At 5 o'clock on the evening of Saturday, the 3rd of December, some cabbage leaves—upon which 10 centigrammes of virulent growth of chicken-cholera had been spread, diluted with 100 centigrammes of sterilized water—were given to four rabbits. At midnight all the food had disappeared some hours before, and four fresh rabbits were placed with the others.

At 8 o'clock in the morning of the 4th of December, two of the rabbits seemed unwell. At 11 o'clock one of them was dead; at 2 o'clock two others died, and at 4 o'clock the last of those that had eaten was dead.

The carcasses were left in the box with the fresh rabbits that were put there at midnight on the previous day.

On the 5th of December one of the rabbits was found to be dead; one on the 6th; a third on the 7th; and the fourth died on the 9th of December. All of these were tame rabbits.

On the 17th of December 10 centigrammes of the growth of chicken-cholera were administered to a wild rabbit on a cabbage leaf. On the 18th it was dead.

In all the foregoing instances it has been placed beyond doubt that death was owing to the microbe of chicken-cholera.

On the 3rd of December and succeeding days experiments were made on the following animals:—Swine, dogs, goats, sheep, rats, and always by the infection of their food: not one of these animals became indisposed.

What is more, its operation on the rabbits is so rapid that there is little or no necessity to increase their supply of food; and, on resuming my previous experiments with fowls, I am convinced that they even would not succumb if allowed to remain on ground which the rabbit food had only partly succeeded in contaminating. Fowls are far less susceptible to the disease than rabbits.

Chicken cholera soon dies upon exposure to the atmosphere. It loses its intensity at 51° centigrade a temperature by no means uncommon, so I am informed, during the summer in Australia; but it would never be necessary to devote attention to the rabbits during the heat of the day.

The preservation of the microbe of chicken-cholera, on the other hand, is attended with no difficulty, and when not exposed to the atmosphere it will last for years; so that the most powerful germs will always be procurable. The experiments that I have already reported on to the Academy of Sciences furnish sufficient evidence of the fact.

The cultivation of chicken-cholera may be made from the broth obtained from many different animals. One of the cheapest might undoubtedly be prepared from the flesh of rabbits.

It follows, from the foregoing experiments, that not only do the rabbits that have taken the food impregnated with the microbe die off very quickly—in less than four and twenty hours—but also that the companions of such rabbits, though they have not eaten the infected food, died off in great numbers.

I reserve the question of the mode of contagion—it is a point that I will inquire into later on. Is it true that the rabbits inhabiting one burrow do not consort with the denizens of adjacent burrows?

One may look forward without any misgiving to the success of the method in the case where the rabbits belonging to one burrow do not come in contact with those from neighbouring burrows, and do not spread the contagion after they have become infected.

The disease is so easily communicable through the instrumentality of their food that even if the possibility of contagion from the infected to the non-infected rabbits did not exist the destruction of these animals would be none the less easy.

In my letter to *Le Temps* I refer to the erection of light network around the burrows. This contrivance would now be unnecessary.

I picture to myself an experiment on a large scale in the following manner:—Around one or more burrows I would have a certain quantity of the grass mowed down, which would be gathered together by rakes within reach of the rabbits before they went out in the evening. This grass, tainted with the microbe germ, would be devoured by the rabbits as soon as they came across it in their way. A fence would be powerless to stop them and compel them to eat. There would thus be a repetition to a certain extent of the Reims experiment, which I am about to narrate.

It was most desirable that an experiment on a large scale should be made.

An opportunity for the accomplishment of this desideratum under particularly favourable circumstances soon presented itself.

The widow Pommery, proprietress of the great Champagne establishment that bears her name, has sent me the following letter, after the perusal of mine that appeared in *Le Temps*:—

“Sir,

“Reims, 3 December, 1887.

I have a paddock at Reims, over my cellars, 8 hectares in extent, which is entirely surrounded by walls. I conceived the foolish idea of placing rabbits there for the purpose of providing some town hunting for my grandchildren.

“These creatures have increased to such an extent, and undermine the ground to that degree, that I am anxious to destroy them. Ferrets are unable to dislodge them from the large mounds of chalk in which they have taken refuge.

“If it will be convenient for you to make an experiment of the process that you recommend for the destruction of rabbits in Australia I offer you an easy means of doing so.

“EVE POMMERY.”

Very soon afterwards I learned from my clever correspondent that through fear of seeing the rabbits in her paddock by force of hunger endeavouring to extend their subterranean galleries to an illimitable extent, and endanger the stability of the arches of the cellars, she had for some considerable time thought that they might be confined to their burrows near the surface by giving them a daily meal of lucerne or hay sprinkled about in the vicinity of their burrows. It will be readily understood, therefore, what an easy matter it would be to try and exterminate the rabbits in Madame Pommery's paddock.

On Friday, the 23rd December, I despatched Mons. Loir to Reims for the purpose of sprinkling the day's food with a fresh growth of the microbe of chicken-cholera.

As usual, the food was consumed in a few minutes. The result was something marvellous.

On the 26th of December Madame Pommery wrote to me in the following terms:—“On Saturday morning (consequently the day after the fatal meal) nineteen dead rabbits were counted outside the burrows. No one visited the paddock on Sunday. On Monday morning thirteen more dead rabbits were counted, and since Saturday not a single rabbit has been seen on the ground. Moreover, as a light fall of snow took place during the night, no traces of their footmarks have been discernible in the neighbourhood of the chalk mounds.”

As a rule, rabbits die in their burrows. The thirty-two dead bodies that were found on the ground in the paddock represent but a very small minority of the dead, as will be seen later on.

In another letter, dated Tuesday, the 27th of December, Madame Pommery writes:—“The lucerne (that which was scattered round the burrows on Monday evening) has not been touched, and, moreover, no footprints have been seen in the snow. Everyone of them is dead.”

And Madame Pommery, alluding to the English papers which had freely criticised my scheme, copies of which she courteously forwarded to me, adds:—“What becomes of the English critiques in the face of such a result? A paddock of eight hectares, swarming with rabbits, has become a field of death. Mons. Pasteur poisons one ordinary meal for the rabbits, and a few days afterwards nothing lives; every one is put an end to—every one is dead.”

How many rabbits are dead in the burrows? It is difficult to determine exactly. Nevertheless, Madame Pommery informs me, in a letter that I have received to-day, the 5th of January, “That the work-

men

men estimate the number of rabbits that used each day to come and eat the eight enormous trusses of hay that were daily scattered about their burrows at much more than a thousand."

Madame Pomery adds further, that wherever the least trace of the chalk mounds is visible, the usual resort of the rabbits, heaps of carcasses of two, three, four, and five rabbits may be seen.

In concluding this article, I have the honor to state, for the information of the Agent-General, that it is my intention to despatch two experts to Australia and New Zealand for the purpose of putting into practice in those remote countries the process that I have just explained.

Finally, I express the hope that my labour may be permitted to compete for the reward of £25,000 sterling that has been lately offered by the Government of New South Wales for the extermination of rabbits in Australia.

Kindly accept, Mr. Agent-General, the expression of my sincere regard.

L. PASTEUR,

Of the Institute of France, and of the Royal Society of London.

45, rue d'Ulm, à Paris.

In order to prevent any misconception the original text of M. Pasteur's communications is subjoined:—

“ Paris, le 5 janvier 1888.

“ Sur la destruction des lapins en Australie et dans la Nouvelle-Zélande.

“ *La Revue des Deux-Mondes* a publié, dans son numéro du 15 août 1887, un article de M. C. de Varigny, dont j'extraits les passages suivants :

“ Enrichis subitement par la guerre de Sécession aux États-Unis qui fit hausser le prix des laines, en arrêtant la production américaine, les colons de l'Australie se trouvèrent tout à coup disposer de revenus considérables.

“ Imitateurs zélés des coutumes anglaises, ils se prirent de passion pour la chasse, et fondèrent en Australie et à la Nouvelle-Zélande des Sociétés d'acclimatation pour importer d'Europe des lièvres et des lapins. Ce fut une véritable rage, un vent de folie qui souffla sur la colonie. . . . Tout grand propriétaire n'eut plus qu'une idée : se créer une chasse réservée. Le sol et le climat convenaient si merveilleusement aux lapins, qui en Angleterre ont de quatre à six portées par an, de trois à quatre petits, qu'en Australie ils eurent jusqu'à dix portées par an, de huit à dix petits chacune.

“ Vainement on tenta d'enclore les terrains de treillis, ils creusaient par-dessous et gagnaient le large, au grand désespoir des propriétaires qui redoublaient d'efforts et de soins pour en accroître le nombre. Ils ont si bien réussi que, aujourd'hui, cette peste désole la Nouvelle-Zélande et l'Australie. Les jardins maraichers sont dévastés ; les terrains qui produisaient, il y a quelques années, 150 boisseaux d'orge et de 75 à 80 de blé, à l'hectare, durent être abandonnés, toute culture, dans certains districts, étant devenue impossible.

“ M. Crawford cite l'exemple d'un grand propriétaire qui, après avoir dépensé 40,000 livres sterling (1 million de francs) pour se débarrasser de ce fléau d'un nouveau genre, fût obligé d'y renoncer. Sur certaines fermes, on évalue leur nombre à des centaines de mille, et, chaque année, leur taille augmente avec leur nombre. D'une voracité extraordinaire, ils mangent l'herbe jusqu'à la racine et convertissent d'immenses pâturages, qui nourrissaient vingt-cinq à trente moutons à l'hectare, en terrains dénudés et poussiéreux. Les vignobles ont été ruinés et, jusqu'ici, les moyens employés pour détruire ces animaux n'ont abouti à aucun résultat appréciable. On les chasse, on les tue, on les empoisonne, et ils fourmillent.

“ M. Williamson dépose que, dans une excursion qu'il fit avec un Délégué du Gouvernement, ils reconnurent que dans tout le district l'herbe avait disparu. Des bandes d'énormes lapins parcouraient le pays, s'écartant à peine pour faire place à leur voiture.

“ Le sol, raviné de terriers, ne permettait d'avancer qu'avec précaution. ‘ Partout des lapins, ’ dit-il, ‘ sur la route et dans la plaine ; ils gambadent en troupe, se poursuivent dans les sables ; on les voit assis par centaines à l'entrée de leurs terriers. . . . Traqués sur un point, ils se réfugient sur un autre, et ils se multiplient avec une rapidité telle qu'un cataclysme de la nature pourra seul en avoir raison.’ ”

“ La publication suivante vint donner récemment une confirmation aux récits qui précèdent.

“ Le 9 novembre et le 2 décembre 1887, le journal *le Temps*, de Paris, publiait l'avis officiel suivant, émané du Gouvernement de la Nouvelle-Galles du Sud :—

“ Direction des Mines, Sydney, le 31 août 1887.

“ Il est donné avis, par la présente, que le Gouvernement de la Nouvelle-Galles du Sud payera la somme de 625,000 fr. (£25,000) à quiconque fera connaître et démontrera, à ses frais, une méthode ou un procédé encore inconnu dans la colonie, pour exterminer d'une manière efficace les lapins, procédé assujéti aux conditions suivantes :

“ 1° Que cette méthode ou ce procédé recevra, après un essai d'une année, l'approbation d'une Commission nommée à cet effet par le Gouvernement, avec l'avis du Conseil exécutif ;

“ 2° Que telle méthode ou tel procédé sera, d'après l'opinion de la dite Commission, inoffensif aux chevaux, moutons, chameaux, chèvres, porcs et chiens, et ne présentera pas l'emploi de matières ou substances qui pourraient leur nuire.

“ 3° La Commission sera tenue de ne pas divulguer les détails de ces méthodes ou de ces procédés, à moins que cette Commission ne décide d'expérimenter la dite méthode ou le dit procédé.

“ Toutes les Communications relatives à ce qui précède doivent être adressées à the Honorable F. Abigail, Secretary for Mines, Sydney (Nouvelle-Galles du Sud). ”

“ Très peu de jours avant que cette nouvelle fût publiée par le journal *le Temps*, j'avais reçu d'un habitant de la Nouvelle-Zélande le récit des désastres que les lapins occasionnent également dans cette île.

“ Le 27 novembre 1887, j'écrivis au journal *le Temps* la lettre suivante, qui fût insérée le 29 novembre :

“ Paris, 27 novembre.

“ A Monsieur le Directeur du *Temps*.

“ Votre journal annonçait, il y a peu de jours, que le Gouvernement de la Nouvelle-Galles du Sud était tellement impuissant à lutter contre un fléau d'un genre particulier—la pullulation des lapins—qu'il proposait un prix de 625,000 fr. pour la découverte d'un procédé destiné à leur extermination. Des portions

portions considérables de la Nouvelle-Zélande, non moins ravagées que l'Australie, sont abandonnées par les fermiers, qui renoncent à l'élevage des moutons par l'impossibilité de les nourrir. Chaque hiver on tue les lapins par millions, sans que ce carnage paraisse en diminuer le nombre. Voulez-vous me permettre de faire parvenir dans ces lointains pays, par l'organe du *Temps*, certaines idées dont l'application pourrait peut-être avoir quelque succès ?

« On a employé jusqu'à présent, pour la destruction de ce fléau, des substances minérales, notamment des combinaisons phosphorées. En s'adressant à de tels moyens, n'a-t-on pas fait fausse route ? Pour détruire des êtres qui se propagent selon les lois d'une progression de vie effrayante, que peuvent de tels poisons minéraux ? Ceux-ci tuent sur place là où on les dépose ; mais, en vérité, pour atteindre des êtres vivants, ne faut-il pas plutôt, si j'ose le dire, un poison comme eux doué de vie, et, comme eux, pouvant se multiplier avec une surprenante fécondité ?

« Je voudrais donc que l'on cherchât à porter la mort dans les terriers de la Nouvelle-Galles du Sud et de la Nouvelle-Zélande, en essayant de communiquer aux lapins une maladie pouvant devenir épidémique.

« Il en existe une que l'on désigne sous le nom de *choléra des poules* et qui a fait l'objet d'études très suivies dans mon laboratoire. Cette maladie est également propre aux lapins. Or, parmi les expériences que j'avais instituées, ce trouve celle-ci : je rassemblais dans un espace limité un certain nombre de poules, et, en leur donnant une nourriture souillée par le microbe qui est la cause du choléra des poules, elles ne tardaient pas à périr. Les basses-cours sont quelquefois ravagées par de véritables épidémies de ce mal, dont la propagation est due, sans nul doute, aux déjections des premières poules malades qui souillent le sol et les aliments.

« J'imagine que la même chose arriverait pour les lapins, et que, rentrant dans leurs terriers pour y mourir, ils communiqueraient la maladie à d'autres, qui pourraient la propager à leur tour. Mais comment faire pour que les premiers lapins ingèrent dans leur corps le mal destructeur ? Rien n'est plus facile.

« Autour d'un terrier, je placerais une barrière volante entourant un certain espace où les lapins viendraient chercher leur nourriture. Des expériences nous ont appris qu'il est facile de cultiver, en état de pureté parfaite et sur une échelle aussi grande qu'on peut le désirer, le microbe du choléra des poules, dans des bouillons de viandes quelconques. De ces liquides pleins de microbes, on arroserait la nourriture des lapins qui, bientôt, iraient périr ici et là et répandre le mal partout.

« J'ajoute que le parasite de la maladie dont je viens de parler est inoffensif pour les animaux des fermes, excepté, bien entendu, pour les poules ; mais celles-ci n'ont pas besoin de vivre en pleine campagne.

« Je ne doute pas qu'il n'y ait, dans les pays infestés, des personnes toutes prêtes à appliquer le moyen que je propose, moyen très simple, qui, en tous cas, vaut la peine d'être tenté.

« Veuillez recevoir, Monsieur le Directeur, l'assurance de ma considération la plus distinguée.

« Signé : PASTEUR. »

« Aussitôt après l'envoi de cette lettre, j'eus la curiosité de faire des expériences directes sur les lapins. Je me rappelais que le choléra des poules se communique facilement aux lapins ; mais je n'avais pas fait d'étude suivie sur ces rongeurs ; souvent j'avais vu mourir des lapins qui avaient été placés dans des cages non désinfectées où des poules avaient succombé du choléra. C'est une question de savoir, question résolue affirmativement par plusieurs, si le choléra des poules n'est pas simplement la septicémie des lapins, étudiée autrefois par le Dr. Davaine.

« Je fus bientôt assuré de la facilité avec laquelle le moindre repas donné aux lapins, après avoir souillé la nourriture par une culture du microbe du choléra des poules, entraîne rapidement la mort de ces rongeurs.

« Voici quelques-unes des expériences que j'ai fait faire à M. Loir, étudiant en Médecine attaché à mon laboratoire :

« Le 27 novembre on place dans une caisse cinq lapins ; ils y restent jusqu'à 6^h du soir sans prendre de nourriture ; à 6^h, on met dans une petite cuvette 100^{cc} d'une culture virulente de choléra des poules, où l'on trempe les feuilles d'un chou. On laisse égoutter ces feuilles, puis on les donne à manger aux cinq lapins qui, après quelques minutes, ont achevé leur repas. On place avec eux, à minuit, trois lapins neufs non contaminés.

« Le 28 novembre, à 8^h du matin, les cinq lapins contagionnés paraissent malades. A 11^h, deux sont morts, c'est-à-dire dix-sept heures après le début du repas. Les trois autres meurent à 3^h de l'après-midi, vingt heures après leur repas.

« Le 28 novembre, à 7^h du soir, on trouve mort un des lapins mis la veille, à minuit, avec ceux qui ont mangé le repas infectueux. Les deux autres lapins ne sont pas devenus malades.

« Le samedi 3 décembre, à 5^h du soir, on donne à manger à quatre lapins des feuilles de choux sur lesquelles ont été répandus 10^{cc} de culture virulente de choléra des poules, étendus de 100^{cc} d'eau stérilisé. A minuit, tout le repas a disparu depuis plusieurs heures ; on place avec eux quatre lapins neufs.

« Le 4 décembre, à 8^h du matin, deux lapins semblent tristes. A 11, il y a un mort ; à 2^h, deux autres morts ; à 4^h meurt le dernier de ceux qui ont mangé.

« On laisse les cadavres avec les lapins neufs mis la veille, à minuit, dans la caisse.

« Le 5 décembre, on trouve un de ces lapins mort ; le 6 décembre, un autre ; le 7, un troisième ; enfin le quatrième meurt le 9 décembre.

« Les lapins précédents étaient des lapins domestiques.

« Le 17 décembre, on donne à un lapin de garenne 10^{cc} de culture de choléra des poules, également sur une feuille de chou.

« Le 18 décembre, il meurt.

« Dans tous les cas précédents, on a vérifié que la mort était bien due au microbe du choléra des poules.

« Le 3 décembre et jours d'après, on fait des expériences sur les animaux suivants : porcs, chiens, chèvres, moutons, rats, chevaux, ânes, toujours par contamination des repas. Aucun de ces animaux n'a été malade.

« Il y a plus : l'action sur les lapins est si rapide, il est si peu besoin de multiplier les repas que je suis persuadé, en me reportant à mes anciennes expériences sur les poules, que celles-ci même ne mourraient pas si on les laissait sur le sol que les repas des lapins auraient pu souiller en partie ; elles ont, pour la maladie, beaucoup moins de réceptivité que les lapins.

« Au

“ Au contact de l'air, le choléra des poules meurt assez promptement. Il perd sa virulence à 51° C., température quelquefois atteinte, dit-on, en Australie pendant l'été, mais il ne serait jamais nécessaire de s'occuper des lapins, au milieu du jour, en pleine chaleur.

“ La conservation du microbe du choléra des poules est facile, au contraire, à l'abri de l'air et pendant plusieurs années : on pourra donc toujours se procurer de la semence très virulente. Mes expériences d'autrefois communiquées à l'Académie des Sciences en sont la preuve.

“ Les cultures du choléra des poules peuvent être faites dans les bouillons les plus divers d'animaux quelconques. Un des plus économiques serait sans doute celui qu'on pourra préparer avec la chair des lapins.

“ Il résulte des expériences qui précèdent que, non seulement les lapins qui ont ingéré une nourriture souillée par le microbe meurent très rapidement, en moins de vingt-quatre heures, mais que les lapins associés à ces derniers, qui n'ont point eu d'aliments contaminés, meurent également en grand nombre.

“ Je réserve la question du mode de contagion. C'est un point que j'examinerai plus tard.

“ Est-il vrai que les lapins d'un terrier ne se mêlent pas à ceux des terriers voisins ?

“ On peut envisager, sans appréhension pour la réussite du procédé, le cas où les lapins d'un terrier ne frayeraient pas avec ceux des terriers voisins et n'y porteraient pas la contagion après qu'ils auraient été contaminés.

“ La maladie se communique si facilement par les repas que, alors même que la contagion n'existerait pas, des lapins infectés aux autres non infectés, la destruction de ces animaux n'en serait pas moins facile.

“ Je parle, dans ma lettre au journal *le Temps*, de barrières volantes placées autour des terriers. Cette complication serait inutile.

“ Je me représente l'épreuve en grand de la manière suivante : autour d'un ou plusieurs terriers, je ferais faucher une certaine quantité d'herbe qui serait ramenée ensuite avec des râtaux à la portée des lapins, avant leur sortie du soir. Cette herbe, souillée de la culture du microbe, serait mangée par les lapins dès qu'ils la rencontreraient sur leur passage. Une barrière serait inutile pour les arrêter et les forcer à manger. On aurait ainsi, en quelque sorte, la répétition de l'expérience de Reims, dont je vais parler.

“ Il était bien désirable qu'une expérience pût avoir lieu sur une grande échelle.

“ Le hasard vint bientôt me l'offrir dans les conditions les plus favorables.

“ M^{me} V^{ie} Pommery, de Reims, propriétaire de la grande maison des vins de Champagne qui porte son nom, m'adressa la lettre suivante, après avoir lu ma Note insérée dans le journal *le Temps* :

“ Monsieur,

Reims, le 3 décembre 1887.

“ Je possède à Reims, au-dessus de mes caves, un clos de huit hectares, totalement entouré de murs. J'ai eu la fâcheuse idée d'y mettre des lapins pour procurer une chasse, en ville, à mes petits-enfants.

“ Ces bêtes ont tellement pullulé et minent le sol à un tel point que je désire les détruire. Les furets sont impuissants à les faire sortir de tas énormes de craie où ils se réfugient.

“ S'il pouvait vous être agréable d'expérimenter le procédé que vous préconisez pour la destruction de ces animaux, en Australie, j'offre de vous en faciliter le moyen.

“ Recevez, etc.

“ Signé : V^{ie} POMMERY.

“ Bientôt après, j'appris de mon intelligente correspondante que, dans la crainte de voir les lapins de son clos, poussés par la faim, prolonger outre mesure leurs galeries souterraines et compromettre la solidité des voûtes des caves, on avait eu depuis longtemps l'idée de les retenir dans leurs terriers, non loin de la surface du sol, en leur servant, chaque jour, un repas de luzerne ou de foin distribué autour des terriers. On comprend dès lors aisément combien il était facile de tenter la destruction des lapins du clos de M^{me} Pommery.

“ Le vendredi, 23 décembre, j'envoyai à Reims M. Loir arroser le repas du jour d'une culture récente du microbe du choléra des poules.

“ Comme à l'ordinaire, la nourriture fut consommée dans l'intervalle de quelques minutes. Le résultat en fut pour ainsi dire surprenant.

“ M^{me} Pommery m'écrivit, le 26 décembre :

“ Samedi matin (par conséquent dès le lendemain du repas mortel), on compta dix-neuf morts en dehors des terriers.

“ Le dimanche, le clos ne fut pas visité.

“ Le lundi matin, on compta encore treize morts, et depuis samedi on n'a pas vu un seul lapin vivant courir sur le sol. En outre, comme il était tombé un peu de neige pendant la nuit, on ne vit nulle trace de pattes de lapins autour des tas de craie.

“ En général, les lapins meurent dans leurs terriers. Les trente-deux cadavres trouvés sur le sol du clos devaient donc représenter une très faible minorité parmi les morts, ainsi qu'on le verra tout à l'heure.

“ Dans une autre lettre du mardi 27, M^{me} Pommery m'écrivit :

“ La luzerne (luzerne déposée autour des terriers le lundi soir) n'a pas été touchée et de nouveau on n'a vu nulle trace de pattes imprimées sur la neige. Tout est mort. . . .

“ Et M^{me} Pommery, faisant allusion à des journaux anglais qui avaient beaucoup critiqué le procédé que j'avais proposé, journaux qu'elle avait eu l'obligeance de m'adresser, ajoute :

“ Que deviennent les attaques anglaises en présence d'un tel résultat ? Un clos de 8 hectares fourmillant de lapins, devenu un champ de mort.

“ M. Pasteur empoisonne un repas ordinaire de ces lapins, et les jours suivants rien ne remue ; tout est fini, tout est mort.

“ Combien de lapins sont morts dans les terriers ? Il est difficile de le savoir exactement. Cependant M^{me} Pommery m'informe, par une lettre que je viens de recevoir, aujourd'hui 5 janvier, que les ouvriers estiment à beaucoup plus d'un mille le nombre des lapins qui venaient manger les huit grosses bottes de foin qu'on distribuait chaque jour autour de leurs terriers.

“ D'autre part, ajoute M^{me} Pommery, partout où l'on découvre un peu les monceaux de craie, demeure habituelle des lapins, on voit des tas de cadavres de deux, trois, quatre et cinq lapins.

“ En terminant cette Notice, j'ai l'honneur d'informer le très honorable Agent général que mon intention est d'envoyer en Australie et à la Nouvelle-Zélande deux jeunes savants pour appliquer, dans ces lointains pays, le procédé que je viens d'exposer.

“ J'exprime

“J'exprime enfin le désir que mon travail soit admis à concourir pour le prix de 25,000 livres sterling qui a été proposé récemment par le Gouvernement de la Nouvelle-Galles du Sud pour l'extermination des lapins en Australie.

“Veuillez agréer, Monsieur l'Agent général, l'hommage de ma haute considération.

“L. PASTEUR,

“De l'Institut de France et de la Société royale de Londres,
45, rue d'Ulm, à Paris.”

APPENDIX IV.

M. Pasteur's Letter to the Chief Inspector of Stock of New South Wales.

In connection with a letter addressed to the Under Secretary for Mines, Sydney, by the Secretary of the Pastures and Stock Protection Board of New South Wales, the Under Secretary of the Lands Department forwarded to this Commission, for any action deemed necessary, an extract from the *Sydney Morning Herald* of 8th December, 1888, purporting to be an almost literal translation of a letter addressed by M. Pasteur to Mr. Alex. Bruce, Chief Inspector of Stock. The original of M. Pasteur's letter has been kindly submitted to the Commission by the Chief Inspector of Stock. It is as follows:—

Arbois (Jura), 1^{er} octobre 1888,

en partant pour Paris.

À M. Alex. Bruce, Chef inspecteur du bétail au Département des Mines, à Sydney.

Monsieur le Chef inspecteur,

Je viens de lire la lettre que vous avez adressée à l'éditeur du *Sydney Morning Herald* du 18 août dernier, en réponse à l'article que ce journal avait inséré, le 9 août, sous la signature du Dr. Wigg.

Permettez-moi, Monsieur, de vous complimenter sur la logique de votre argumentation et de vous adresser mes très sincères remerciements pour votre ferme et honnête réponse aux assertions erronées et insinuations malveillantes du Dr. Wigg, à mon égard.

Je ne saurais douter que votre lettre n'ait la plus heureuse influence pour faire connaître la vérité. Par cette lettre, la lumière va commencer à se faire sur deux questions vitales pour l'avenir de votre beau pays.

L'agriculture australienne est aux prises avec deux grands fléaux : la “Cumberland disease,” et la pullulation des lapins.

Mes jeunes représentants, à ma demande, sur le désir de Sir Henry Parkes, ont démontré pour la première fois, d'une manière incontestable, que la “Cumberland disease” est identique au charbon d'Europe (sang de rate des moutons, anthrax ou fièvre Charbonneuse des bestiaux, splenic fever) * * *

Depuis l'année 1881, à la suite de la célèbre expérience de Pouilly-le-Fort, qui a fait le tour de la presse scientifique dans le monde entier, la pratique de la vaccination permet de prévenir la maladie et de réduire dans la proportion la plus considérable la mortalité des moutons et des bestiaux dans les pays infectés. N'en déplaise à vos docteurs, j'ai seul le secret du “vaccin Pasteur.” Que le public en Australie et ses gouvernements ne se laissent pas jeter de la poudre aux yeux par des personnes ignorantes ou intéressées.

Quant au fléau des lapins, je n'ai pas davantage confié à personne le secret de l'application en grand du moyen que j'ai proposé pour l'extermination partielle ou totale de ces rongeurs par l'emploi du choléra des poules. C'est au gouvernement de Sydney que je le ferai connaître s'il y a lieu.

Mes représentants n'ont qu'une chose à faire et je les ai envoyés la faire, à la demande de ce gouvernement : ils ont à démontrer que j'ai proposé un moyen inoffensif pour les animaux domestiques, moyen qui tue les lapins en vingt-quatre heures à la suite d'un seul repas souillé par le microbe, et que ce moyen est contagieux, c'est-à-dire, que les lapins qui ont pris le repas mortel communiquent d'une manière notable la maladie et la mort à des lapins sains auxquels il sont mêlés comme ils le sont dans les terriers. Comment disposer une fabrique de l'ingrédient mortel, comment ingrédier et utiliser au loin cet ingrédient avec toutes ses propriétés, là est mon secret sur lequel la commission n'a rien à voir ni à savoir pour le moment, et que je ne ferai connaître que si le prix, proposé le 31 août 1887, m'est attribué.

J'affirme que nul autre moyen ne peut réussir aussi promptement et aussi radicalement. C'est assez évident par la rapidité et la facilité de communiquer la maladie et la mort.

Je vous autorise, Monsieur l'Inspecteur, à publier cette lettre, si, comme je n'en doute pas, vous la croyez utile à la défense de la vérité.

Cependant, je ne quitterai pas la plume sans vous remercier, ainsi que tous les membres de la Commission de la “Cumberland disease” dont vous faites partie, de l'empressement, plein de bienveillance avec lequel ils ont accueilli mes jeunes délégués.

Il est bien regrettable que je ne puisse en dire autant de plusieurs membres de la Commission des Lapins qui s'imaginent à tort que mon procédé peut être dangereux.

Mais je ne perds pas l'espoir que, lorsque cette Commission comprendra mieux ses intérêts et ceux du public, elle se mettra à la tête de l'application des procédés de M. Pasteur, après avoir obtenu l'agrément et les instructions de M. Pasteur lui-même. Autrement, à quoi pourra servir le laboratoire qu'elle a fait construire à si grands frais ? Il faudra bien qu'il y ait un jour un représentant de M. Pasteur et instruit par lui. Ce malentendu ne peut se prolonger indéfiniment.

Recevez, je vous prie, Monsieur l'Inspecteur, l'assurance de ma haute considération.

L. PASTEUR,

De l'Institut de France et des Sociétés royales de Londres et de Sydney.

APPENDIX V.

REPORT by Dr. Bancroft of the visit of the Commission to Dr. Ellis' House, and of examination of Diseased Rabbits from Tintinallgy.

THE members visiting Dr. Ellis were shown several healthy and diseased rabbits. A rabbit, believed to be suffering from the Tintinallgy disease, was killed, also a healthy animal. The former was much emaciated, but showed no remarkable evidence of disease, except in the liver, which was marked with white spots. These Dr. Bancroft recognized as the liver affection spoken of by him. Bile was removed from the gall-bladder of this rabbit, and under the microscope was found full of oval bodies, easily seen under low powers. The other rabbit was free from the liver disease.

Dr.

Dr. Bancroft said he had kept tame rabbits for experimental purposes during his residence in Australia until an Act of the Queensland Parliament required their destruction. When resident surgeon at the Brisbane Hospital, twenty years ago, he had noticed white spots in the livers of rabbits. The spots contained the same microscopic oval bodies which could be traced through the gall-bladder, and were voided with the excretor. In subsequent years, examining livers of rabbits, the same condition was often to be found, and when rabbits had their livers severely affected they became emaciated. With the greatest care as to cleanliness of the hutches, it was practically found impossible to prevent the rabbits contracting the disease.

The conclusion came to was that the oval bodies were introduced into the stomachs of young rabbits on food soiled with the excrement of their elders. Dr. Bancroft could never dissect out of the parent parasite from the liver, as the creature possessed no definite form. It appeared as an irregular sac, containing the oval bodies in various stages of development.

Of sections made of this parent sac by his son he had specimens to exhibit to the Commission.

At the meeting on April 23, Professor Allen informed the Commission that he had consulted the work of Leuckart on parasites, and found the parasites of the liver of the rabbit had been called by that author *Coccidium oviforme*. The author had been at great pains to elucidate the life history of this parasite. Twenty-six pages of his work were devoted to the subject, from which it appears that the oval bodies discharged by the parent sac are considered the mature animal. On leaving the liver of the rabbit the contents of the oval bodies, the coccidia, are granular; by the time the *Coccidium* arrives at the end of the intestinal tract the granular matter has formed itself into four curved embryos, which are named psorosperms; rabbits, fed with the coccidia so developed into psorosperms, soon begin to suffer from the affection of the liver. There are some accounts of human beings having suffered from the same disease (see pages 221 to 228), but from what can be ascertained the cases are very rare and of little practical interest.

Since the above-mentioned investigations Mr. Thos. Francis has kindly taken micro-photographs of the section of the liver disease above referred to and of the oval bodies, the coccidia, removed from the gall-bladder of Dr. Ellis's diseased rabbit.

JOSEPH BANCROFT, M.D.

APPENDIX VI.

ABSTRACT of Life History of *Coccidium Oviforme*.

Prepared by Professor Allen from Leuckart's "Parasites of Man (1886)."

THE liver of the rabbit is not unfrequently found penetrated with white nodules, which, in more or less considerable numbers, grow gradually to the size of a hazel-nut, and excite painful affections, in the course of which the animal often dies. In many warrens the disease become a serious epidemic, so that hardly a single healthy animal is to be found. On section of the nodules, a cheesy or purulent, sometimes yellow-coloured, mass exudes, in which a microscopic examination reveals, besides cell debris, a countless number of oval or egg-shaped bodies; and myriads of similar structures may be found in the bile within the gall-bladder.

These nodules in the liver have been examined by many observers during the past fifty years. They were at first variously classed as tubercles, or cancers, or flukes, or as modifications of the cells of the liver or of the bile-ducts. But it is now certain that they are due to the multiplication of gregarinoid parasites in the bile-ducts. Each nodule consists of a congeries of dilated bile-ducts, which, though originally of small size, have enlarged and perhaps opened into one another. The walls of the nodules have been thickened by chronic inflammatory processes, so as to present a thick layer of fibro-nucleated tissue. The dilated ducts may open into one another so freely that only a central cavity is left, from whose walls processes of fibro-nucleated tissue may project into the interior in villous form. These processes are for the most part relics of the thickened tissue between the dilated ducts. The epithelium lining the cavities is partly in a normal state, but in general it is profoundly altered—many cells are modified by the growth of parasites within them; others are shed from the surface, being replaced by a kind of colloid matter. The pulpy contents of the cavities are not purulent; the opacity is due to the presence of minute egg-shaped bodies, 0.033 to 0.037 millimètres long, and 0.015 to 0.02 millimètres broad, having thick smooth shells. These bodies are imbedded in granular detritus, with nuclei, remains of cells, and shed epithelial elements. Some of these bodies, probably the younger, are slender, having, in many cases, a double shell and uniformly diffused granular contents. Others, presumably the older, are broader and more bulging, their granular matter being collected into a central ball, the space between it and the shell being filled with clear fluid which acquires a somewhat firm consistency. In the slender forms the shell has a thin outer layer and a thick inner layer; and it would seem that the thin outer shell disappears when the cells begin to assume the bulging form, and at one end, usually the narrower, a micropylar opening becomes visible in the inner shells. Within the granular ball in the centre of the bulging forms, an ill-defined clear sphere not infrequently appears, resembling a nucleus, but incapable of being stained. It is simply an aggregation of the ground substance which binds the granules together.

These egg-like parasites, which are called coccidia, do not remain permanently in the dilated ducts. Some of them escape through narrow communications, which still exist, into the large bile-ducts, and so pass to the gall-bladder and onwards into the intestines, being finally expelled with the fæces. No further changes of any importance occur in the coccidia during their progress along the ducts or through the intestines. After leaving the body of their first host or bearer, these parasites have an incubation period varying in duration from weeks to months. Their shells are already so strong that neither chromic acid nor bichromate of potash in solutions of ordinary strength do any injury to the life of the organisms.

The stages of development which proceed outside of the body of the first host are simple, and may be watched in specimens kept in water. The central granular mass divides into four, perhaps after first dividing into two. The clear nucleus-like body in the centre of the mass undergoes similar division, and thus four rounded or spheroidal segmentation spherules or spores are formed, differing from the original granular mass only in their smaller size (0.009 to 0.01 millimètres). These spores become lengthened and

and ovoid; a thin but tolerably firm envelope forms on their surface, and their substance is differentiated into a homogeneous transparent C-shaped rod, whose convexity is in contact with the envelope, while its ends are thickened and highly refracting, its concavity embracing the remains of the granular mass. Each rod is about 0.006 millimètres in diameter.

"At this stage the development of the coccidia is for the meantime, in my opinion, complete. Like the eggs of entozoa containing embryos, they await an opportunity to gain access into a new host, and this opportunity can hardly fail, for the coccidia, brought to the exterior with the faeces, undergo exactly the same changes in the rabbit warren as in our glass vessels, and will therefore rapidly populate these places with countless germs."

The germs usually find entrance into their subsequent host while still within the coccidium shells. After being swallowed, the C-shaped rods escape from their envelopes in the stomach, draw themselves into rods, become amœboid in characters, and reach the liver by the common bile-duct. In the small bile-ducts they bore into the epithelial cells and are converted into new coccidia. The smallest germs which Leuckart could distinguish in the cells of the bile-ducts were slightly granular roundish masses of protoplasm of about 0.009 to 0.01 millimètres in diameter, containing a large nucleus-like spot, with enclosed nucleoli. The biliary cells enclosing them become greatly swollen in transverse diameter. The germs within increase till they form spherical balls, about 0.026 millimètres in diameter, consisting of granular protoplasm with a clear nucleus. The germs now fill the cells, so that the latter form only narrow limiting envelopes to the germs. The germs next become oval, and a shell rapidly forms and thickens around them under the cellular envelopes. Then this envelope is destroyed, and the germs, now transformed into coccidia, lie free in the dilated biliary passages.

The experiments of Rivolta tend to show that coccidia must pass through their incubation stage before they can develop in a new host. Coccidia whose central mass has not been segmented may be administered to new animals without result.

Coccidia in the liver may be of fatal importance. Their growth lessens the quantity, and deteriorates the quality of the bile; it interferes with the circulation of blood through the liver, and interferes with the glycogenic function of that organ, so that, according to Cohnheim, diabetes cannot be produced by the usual operation in rabbits infested with coccidia. As soon as the disease has attained a considerable development the animals die. They become very thin after being sickly for some weeks; they lose their appetite and previous activity, begin to breathe quickly and violently, and finally die in convulsions.

"Nor does the rabbit alone thus suffer, but even man, although he is obviously not exposed in the same degree to the possibility of a frequent and numerous introduction of germs, is occasionally infected." Leuckart narrates the case of a stone-breaker who died from the effects of coccidia in the liver, the case being first reported by Gubler, of Paris, in 1858. He says that "the patient perished exactly in the same manner as the infected rabbit." He refers to three other cases in which coccidia were found in the human liver.

Many other forms of gregarinoid parasites are known to occur in animals; for example, one special form is found in the intestines of mice, another form in the intestines of rabbits, dogs, cats, sheep, guinea-pigs, moles, &c., another in fowls, ducks, and geese. These intestinal coccidia cause destruction of the epithelium, swelling, inflammation, and ulceration. Leuckart states that the intestinal form in rabbits is probably quite distinct from the hepatic form, and that the two have never been found associated together. Intestinal coccidia have been found in men in a few instances, the infection being derived possibly from dogs, cats, rabbits, &c.

It must not be imagined that Leuckart's description of the life-history of the coccidia is unchallenged. Several authorities differ from him in various particulars, but the introduction of their views would render the description less clear. Full information may be obtained in Leuckart's "Parasites of Man," translated by Hoyle, pages 202-228.

APPENDIX VII.

REPORTS by Dr. Bancroft and Dr. Wilkinson concerning their visits to Tintinallogy.

WITH the members of the Committee, Messrs. Tabart, Bell, and Dr. Wilkinson, I visited Tintinallogy, travelling from Adelaide by way of Broken Hill and Menindie. The object of this visit was to investigate, as far as possible, the circumstances under which the rabbits at Tintinallogy had died.

Between Speculation Lake and Menindie there are many rabbits burrowing in sandy hillocks, through which cane-grass grows. Rabbits also live and hide in the undergrowth and drifted dead vegetation of the sandy beds of water-courses. In the neighbourhood of the Darling River rabbits hide in lignum, and on the adjoining higher ground burrow among the roots of bushes.

Some miles on the road from Albemarle, and before reaching Tintinallogy, few live rabbits are to be seen, but many skins and skeletons lie about the road sides.

Everywhere in the districts visited near the Darling River the shrubs and trees are barked, even to the height of many feet. Occasionally rabbits fall entangled among the several branches, and here and there their skeletons so remain. Near the station-house of Tintinallogy, occupied by Mr. Reid, no live rabbits are to be seen. At some distance up the river I saw two, also a wild rat. The rabbit skins and bones lie about everywhere, showing that at no distant date rabbits were very numerous on the station. In company with Dr. Wilkinson and Dr. Ellis I made a *post-mortem* examination of rabbits killed for the inspection of the Committee, and beyond general emaciation of their bodies and darkening of the livers, no important pathological condition was noticed. Two white rabbits (albinos) said to have been caught wild, were in the hutches. In Dr. Butcher's preserved specimens were small hydatids, *cysticercus pisiformis*, these I afterwards found in rabbits examined at Albemarle. There was a bottled specimen of a rabbit showing some form of skin disease. I wished to examine this, but did not obtain it. On dissection of rabbits captured for us at Albemarle, no remarkable diseased state was observed. It was brought under our notice that a disease had destroyed a great number of cats, and the bodies of eighteen were seen on the bank of the river. An examination of two cats that died at Tintinallogy, showed inflammation of a portion of the small intestine, the animals dying fat. Specimens of the inflamed intestines are in the possession of Dr. Ellis. The cats, in a great measure, live on rabbits, but it remains for further

further investigation to determine if there be any relation between their diseases. The cysticercus pisiformis of the rabbit leads to a tape-worm in the cat. A form of tape-worm was found in the dead cats, but Dr. Ellis informed me that one cat examined showed only inflammation of the intestine. The temperature of newly caught rabbits was from 108° to 109.5°, showing that hunting them caused a rise of about eight degrees. This confirms the statement of Dr. Ellis, and may have some important bearing on the method of propagation of diseases among rabbits.

Mr. Sadlier drove large numbers into an enclosure made of wire net, with wings of wire net, one hundred yards each. This is an excellent method of capturing rabbits on thickly infested country. The rabbits at Albemarle are said to be now recovering from a very weak condition in which they were a few weeks ago, rain having fallen recently and new herbage grown up.

It is not easy to say from what disease the Tintinallong rabbits died. Rabbits suffer from several morbid states, to which may be added innutrition from eating bark and deficiency of grass, from the heat of the climate in summer weather, from excess of salt in their systems probably, as they consumed all the accessible bark of the old man salt bush (*atriplex nummularia*), many of the clumps of which in consequence died. They also suffer more or less from various parasites. A small nematode worm in the large intestine is abundant. The cysticercus pisiformis, found attached to the mesentery, appears too small to inflict much harm by its bulk. The large New Zealand cyst, called bladder-fluke, has not yet been found by us, or spoken of by residents in Australia. The coccidium (the liver parasite) causes defective nutrition and emaciation. A scorbutic impoverishment of the Tintinallong rabbits from scarcity of fresh food may have led to the scabby skin and intermuscular effusions. This was said not to extend among the confined rabbits of either experimentalist.

The Tintinallong run no doubt was overstocked with rabbits, all accessible bush was barked to a great extent, and in the hot months of the year the animals became muscularly weak.

The shade of the belt of Eucalypti on the river bank was sought by them, and here the disease first began to show its destructive powers. It is known that a wounded rabbit is apt to act fatally on its associates in a burrow. At the time of Dr. Butcher's experiments the animals were hunted about to mix the inoculated with the other rabbits. A form of septicæmia may have been brought about which rapidly extended among the rabbits so unfavourably situated. Still no dissections or microscopic examinations so far have shown this to be the case, and the Committee has had no opportunity of examining rabbits that have died spontaneously.

According to Dr. Butcher's evidence the breeding of rabbits on Tintinallong ceased at the end of September, 1887; many aborted then, and up to the present time there have been no young seen. The sexual organs of the doe rabbits examined by us showed no disposition to pregnancy. Residents of the Darling say that shortly we may expect young rabbits, as the animals are much stronger and in better condition since the recent rains.

The observations of Drs. Butcher and Ellis made on the wild rabbits are at variance on important particulars and take little account of well-known parasitic conditions. Rabbits better fed in Sydney did not die in the same way as those experimented on by Dr. Butcher at Tintinallong. The whole inquiry into rabbit diseases made by Drs. Butcher and Ellis have occupied not more than eight months, and numerous restrictions by the Government fettered the operations. Notwithstanding, there is before us evidence of rabbits being cleared off many miles of the Tintinallong run, a notable fact and well worthy of careful investigation.

It is unfortunate that the interference above referred to prevented Dr. Butcher making experiments when rabbits were numerous at a distance from Tintinallong, as the work done in the district where the disease developed could not be disassociated from the spontaneous operations of unfavourable natural conditions there present.

In confining wild rabbits for experimental purposes, it should not be overlooked that animals newly captured are not easily domesticated, that they injure themselves by violent efforts, that if confined young they generally soon die, and that they rarely or never breed.

Consequently conclusions based on such experiments should be accepted with caution and corrected by control experiments with tame rabbits.

JOSEPH BANCROFT, M.D.

On my way down from Tintinallong I remained some time at Albemarle in order to further investigate the disease amongst rabbits described by Dr. Ellis. Dr. Ellis was staying at Albemarle at the same time, and we went together to a part of the run where this disease was said to have appeared amongst the rabbits. We found that the rabbits were affected in a manner similar to that described by Dr. Ellis before the Commission; and Dr. Ellis himself admitted that we had illustrations of the typical disease. I took back to the station some of the diseased rabbits for further investigation. These rabbits were all caught by us with moderate ease. It was only necessary to follow them up, and sooner or later they fell down and rolled over, apparently not having strength to proceed any further. Weakness, therefore, was an evident symptom of their condition. These rabbits were all extremely emaciated but showed externally no evidence of any particular disease. I made *post mortem* examinations upon several of these rabbits and found the conditions as follows:—Great diminution of sub-cutaneous fat; the fat in some places that remained being gelatinous. The muscles were pale and flabby. On opening the abdomen the bladder was found to be distended with urine in most cases. The peritoneal fluid was in excess—sometimes in marked excess—but perfectly clear and limpid; no signs of peritonitis. In two or three cases coccidium was found in the liver. The spleen was always healthy, and also the kidneys, which were merely pale. The intestinal canal was then examined in all these cases. In every instance, small hemorrhagic patches, often with erosions, and sometimes even with ulcerations, were present on the surface of the stomach. These erosions varied in size and number; sometimes they were as large as a split pea; but for the most part they were about one-half this size. They were numerous both at the cardiac and pyloric end of the organ, but were not limited to these spots. The mucous membrane was generally distinctly thickened and opaque. The contents of the stomach varied somewhat, but consisted for the most part of dry fragments of bark. Sometimes, mixed up with this material, was a considerable quantity of mucus, either in the same fluid state, or, in some cases, forming whitish, opaque, tolerably firm, parchment-like masses, coating this dry vegetable fibre. This dry mucus was most abundant near the pylorus, in one or two cases forming hard firm masses. This dry

mucus material was in this case detached from the mucous membrane on the one hand, and from the contents, on the other hand, with moderate ease. And the material also, to some extent, passed in between the vegetable fibre in the stomach.

In the rest of the intestinal canal there was always a considerable amount of mucus, and the mucous membrane had a distinct ash-grey colour. On clearing away the material in the canal by a thorough washing, small brownish granular spots could be seen in the mucous membrane. On microscopic examination these spots appeared to consist of disintegrated blood. In no case was there any indication of diarrhoea. On the contrary the faeces were well formed, but extremely dry and hard.

Condition of the Liver.—In all those cases where emaciation was pronounced, and hemorrhagic erosions appeared on the wall of the stomach, the liver was of dark bluish colour, sometimes almost black, and the tissue of the organ extremely soft and friable. No fat at all was to be seen between the lobules. The organ, too, was reduced in size. The suprarenal capsules always appeared to be perfectly healthy. The thoracic organs were also healthy to all appearance. The brain and spinal cord were not examined.

Upon these examinations I formed the opinion that the probable cause of emaciation was want of proper food—or this, combined with the taking of improper food. The stomach showed in every case marked evidence of gastric catarrh, and the nature of the contents led me to conjecture that possibly the cause of the catarrh was the nature of the food. But in order to show whether this condition of the stomach was absent in rabbits not suffering from emaciation, I caught some healthy rabbits and examined their stomachs. I also caught other rabbits which were not markedly emaciated, and yet not in good condition. I found that the absence of emaciation was always associated with the absence of catarrh and hemorrhagic erosions in the stomach; and in moderate degrees of emaciation, these hemorrhagic erosions and an increased quantity of mucus appeared in the stomach. I consider that both the morbid condition of the digestive organs and the emaciation are due to a common cause—want of food, or this combined with improper food.

At the same time I examined the state of the livers in order to see whether it was necessary to suppose that other causes than want of food might be responsible for the emaciation. In well-conditioned rabbits the liver has a distinct deep-red colour, but the lobules are marked out by a distinct yellowish-white zone. In rabbits in only moderate condition, this yellowish zone disappeared, the organ still retaining its deep-red colour. As this emaciation became more and more marked, in different cases it was found that the red-brown colour changed more and more into the dark-bluish or bluish-black colour already described as characterizing the livers of these diseased rabbits. Here, too, then, it seemed to me that the changes in the liver in the emaciated rabbit were due to want of proper food. The condition of the liver was in fact one of pronounced atrophy. I examined the blood, but only observed that there was a great tendency in the white corpuscles to stick together and form small groups of cells. The urine in several cases deposited a whitish sediment consisting of amorphous granules—no doubt phosphates. I have kept several of the stomachs, which show the conditions above described, so that members of the Commission can examine these for themselves.

W. CAMAC WILKINSON, M.D., London.

P.S.—While I was at Albemarle, I took the trouble to investigate the method employed at the station for poisoning rabbits. Strychnine was the poison used, and this was dissolved in sulphuric acid. The strength was about four grains to the ounce; wheat was then soaked in the solution. According to the calculations of the manager of the station, three or four grains of wheat would kill a full-grown rabbit. I found that two or three drops of the solution of strychnine killed a full-grown rabbit very quickly. I then experimented with the wheat soaked in the solution of strychnine. I began with nine grains. This was the grain which was being extensively distributed over the ground immediately about the homestead for the purpose of killing the rabbits. Nine grains had no effect. I increased the number of grains to twenty, then to thirty, and then to forty; in every case feeding the rabbit with the wheat by the hand—even forty grains had no effect; I therefore concluded that experiments with poisons, performed by station hands, were not to be trusted.

W. CAMAC WILKINSON.

APPENDIX VIII.

REPORT on the Parasitic Diseases affecting Rabbits in the Wairarapa District.

Professor A. P. W. Thomas, M.A., F.L.S., F.G.S., to the Hon. the Minister of Lands (Stock Branch).

University College, Auckland, 20th February, 1889.

AN interim report on the present subject was submitted to the Hon. the Minister of Lands in May, 1888 (Parliamentary Paper H.—18, 1888). Since that time my experiments have been completed, and I am now able to speak more definitely of the value of the disease as a means of combating the rabbit-pest. The delay in concluding the report has been due to the slow development of the bladder-worm disease, and the time required to work out the results of a very extensive series of experiments on more than forty animals, including rabbits, dogs, cats, ferrets, and sheep. These experiments have been carried out single-handed, and with no assistance except in the feeding of the numerous animals under observation.

The report will be arranged under the following heads:—

- I. The decrease of rabbits in the Wairarapa, and the causes to which it has been assigned.
- II. Observations and experiments on the parasitic diseases of rabbits found in the Wairarapa.
 1. The bladder-worm (*Cœnurus serialis*): its nature. Mode of studying its development.
 2. Experiments on rabbits. Development of the bladder-worm.
 3. Experiments on carnivorous animals with the bladder-worm.
 4. Tape-worm (*Tania serialis*) reared in the dog: its character.
 5. Is the *Cœnurus* of the rabbit distinct from that of the sheep?
 6. Smaller bladder-worm of the rabbit (*Cysticercus pisiformis*).
 7. Coccidia of the rabbit's liver.
 8. Other parasites of the rabbit.
- III. Value of the diseases as a means of dealing with the rabbit-pest:—
 1. General conditions to be satisfied by any disease used as a remedy for the rabbit-pest.
 2. Value of the bladder-worm. Conditions for the spread of the disease.
 3. Value of the liver-coccidia.
 4. How far is the reduction of rabbits by parasitic disease possible?
 5. Summary.

I. THE DECREASE OF RABBITS IN THE WAIRARAPA.

The rabbits in the Wairarapa district, and especially on the plain, have unquestionably been greatly diminishing in numbers during the last few years. The diminution has been attributed to the following causes: (1) Poisoning—chiefly with phosphorized grain in the winter time; (2) trapping, and the use of dogs; (3) the liberation of the natural enemies—viz., cats, ferrets, and, more recently, stoats and weasels; (4) parasitic diseases—viz., that caused by the bladder-worm.

It is, I believe, generally admitted by stock-owners and farmers in the Wairarapa that the winter poisoning by means of phosphorized grain, followed up by rabbiting during the rest of the year, has been the most efficient cause of the decrease of the rabbits. A very large number of ferrets—probably not fewer than three thousand—and a considerable number of cats have been turned out, and more recently stoats and weasels have been liberated. It is not easy to gauge with accuracy the amount of destruction accomplished amongst the rabbits by animals which seek concealment from the eyes of man; but I was able to satisfy myself that both ferrets and cats are numerous in some places, at least, and that they appear to render good service.

With reference to the fourth cause, it is well known that it has been claimed that the bladder-worm has been largely instrumental in reducing the rabbits, and that it affords a remedy for the rabbit-pest worthy of the reward offered by the New South Wales Government.

It will be desirable, therefore, to describe the life-history and effects of this and other parasites, as shown both by my observations in the Wairarapa and by experiments in the laboratory, somewhat fully. We shall then be in a better position to form a correct estimate of the value of the disease with reference to the rabbit-pest.

II. OBSERVATIONS AND EXPERIMENTS ON THE PARASITIC DISEASES AFFECTING RABBITS IN THE WAIRARAPA.

Some hundreds of rabbits were examined by me in the Wairarapa, and I found in them the five following parasites, most of which were widely spread in the district: (1) Bladder-worm (*Cœnurus serialis*); (2) smaller bladder-worm (*Cysticercus pisiformis*); (3) Coccidia, producing a disease of the liver; (4) mites, producing a form of itch or scab; (5) lice. Of these the bladder-worm (*Cœnurus serialis*) and the liver-coccidia are by far the most important to us, for they are the cause of greater injury to rabbits.

1. *The Bladder-worm* (*Cœnurus serialis*.)

The bladder-worms (incorrectly called "bladder-flukes") are well-known to be the larval forms of tape-worms. Two distinct kinds were found by me in rabbits in the Wairarapa; but one of these appeared to be rare, and is not of so much importance as the second and larger form. This latter is shown by my experiments to be the larval form of a particular kind of tape-worm inhabiting the intestine of the dog.

A rabbit infested by this bladder-worm has one or more swellings in connection with the muscles of the body. This may have a more external position on one of the limbs or on the outside of the trunk, neck, or head, in which case it may at once attract attention; or it may have a more internal position, and be found in the cavity of the abdomen or chest. (See fig. , Plate I, which represents a rabbit with such a swelling on the left side of the face, and the white fur towards the angle of the jaw being brought into sight by the swelling.)* When the rabbit is dissected and the swelling examined, a bladder is found imbedded in the muscular tissue. The bladders vary in size according to their stage of development, but are often of the size of a fowl's egg, while the largest I have seen was $3\frac{1}{2}$ in. long and $2\frac{1}{4}$ in. in breadth. The bladder fits closely into a cavity in the muscles, this cavity having a smooth lining of connective tissue. This lining, of course, is simply formed by the development of the connective tissue which unites the bundles of muscular fibres. It is usually thin, and is sometimes of extreme tenuity, forming merely a surface-covering. The bladder-worm itself consists of a delicate white membrane, enclosing a cavity filled with a clear serous fluid. The outer surface of the bladder is sometimes smooth and rounded as an egg; sometimes it shows numerous lobes and processes. To one side of its inner surface are attached a large number of round white bodies rather smaller than a mustard-seed (See Plate I, figs. 7 and 8). Examination with the microscope shows that each of these bodies consists of the head of a tape-worm, recognizable by its four suckers and crown of hooks, situated within a small sac or pouch-like involution of the wall of the bladder. (See Plate II, fig. 10). These "head-sacs," as we may term them, are placed close together in series or in irregular groups, which are usually elongated. These groups always show a more or less marked radial arrangement. It is clear that we have here an example of that particular form of tape-worm larva to which the name of *Cœnurus*, or many-headed bladder-worm, has been given.

Modes of Studying the Development of the Bladder-worm.—It is a well-established fact in the natural history of the tape-worm that the larval form is found in one animal, whilst the corresponding adult form is found in the intestine of some other animal, which preys upon the bearer of the larval form. It is, of course, usually the natural enemy of the animal harbouring the larval form which serves as the bearer or host of the adult tape-worm. The question, therefore, to be decided by my inquiries was, which of the natural enemies of the rabbit served as the carrier. The only carnivorous animals occurring in the district which fed upon the rabbits were dogs, cats, ferrets, and hawks. Stoats and weasels had been introduced into the district, but the bladder-worm was known to exist there long before their introduction. Hawks were far less open to suspicion than dogs, cats, and ferrets, and I therefore endeavoured to discover whether any one or more of these three animals served as bearer of the supposed tape-worm. There were two ways of attacking the problem: the first was to ascertain whether the bladder-worm, if given to these animals, would develop within them into a tape-worm; the second was to discover whether these natural enemies of the rabbit, living near rabbit-warrens where the bladder-worm was prevalent, harboured any tape-worm, and, if such a tape-worm were found, then to administer its eggs to rabbits, and watch for the development of bladder-worms within them. Both methods were adopted, and both have led to the same result, namely, that the dog, and the dog only, is the bearer of the adult tape-worm of which this bladder-worm is the larval form.

A wild ferret and two wild cats were obtained from the immediate neighbourhood of a rabbit-warren where the bladder-worm was relatively abundant, and were examined. All three were free from tape-worm. On the other hand, it was found on inquiry that the rabbiters' dogs were commonly infested with tape-worms. At the Dry River Run, indeed, all the dogs were said to be so troubled. Specimens of their tape-worms were therefore obtained, and were found to include two kinds, one (a single specimen only) the well-known

Tœnia

* The illustrations of Professor Thomas' report have not been reproduced.

Tenia elliptica, and the other a kind I was led to regard with much suspicion. The dogs, it should be stated, from which the tape-worms were obtained had been bred on the estate, and had never left the rabbit's home except to go rabbiting. They had been fed chiefly on rabbit, often uncooked, and only occasionally on mutton. The presence of the *Tenia elliptica* was explained by the fact that the larval form of this tape-worm is found in the dog-louso (*Trichodectes canis*), but the other tape-worm found, in great numbers, was most naturally referable to the rabbit or sheep on which the dogs were fed. The head of this tape-worm was not at first obtainable, but in order to test the supposition, ripe joints of the tape-worm were administered to rabbits. These ripe joints, it should be said, contained great numbers of minute ova, in each of which a mature embryo was already present. I soon found that the experiment gave positive results, and that the embryos developed in the rabbit into bladder-worms. Subsequently, as material was available, other rabbits were infected, in order to ascertain more exactly the effects of the disease.

2. Experiments on Rabbits. The Development of the Bladder-worm.

The first rabbit fed with eggs of the dog's tape-worm died thirteen days after infection. On dissecting it no bladder-worms were seen at first, but it was noticed that the muscles were marked with irregular thick yellowish or reddish lines, and careful examination showed that the lines were the tracks of young bladder-worms, marked by a granular matter due to the irritation of the tissues. At the somewhat thicker end of each track a minute translucent bladder of about the size of a pin's head (more exactly, from 0.6mm. to 1.6mm. in length) was found in the midst of the granular material. A very large number of these minute bladders were found in this rabbit—indeed, I estimated the total number as being at least five hundred. A second rabbit, fed with a smaller number of tape-worm eggs, died on the twenty-first day after infection, and about a score of bladder-worms were found in it, and, corresponding with the longer period allowed them for development, they had attained a larger size of— $\frac{1}{8}$ in. (1.1mm.—2.5mm.). Although none of these little bladders showed as yet any trace of the formation of the tape-worm heads, the source from which the eggs had been obtained, and other evidence, induced me to state in the Interim Report that the generic connection between the bladder-worm of the rabbit and the tape-worm of the dog was sufficiently demonstrated. Further experiments on over a score of rabbits and a number of dogs have fully confirmed the opinion then expressed.

I have found that the bladders first show signs of the formation of the tape-worm heads about the fourth week. The smallest bladder-worm in which I have seen any trace of the formation was just four weeks old, and was only $\frac{1}{8}$ in. in length. As a rule, the rudiments of the heads (or, rather, head-sacs) do not appear till the worm has attained the size of a pea, *i.e.*, about $\frac{1}{4}$ in. or $\frac{1}{2}$ in. in length. At the end of seven weeks the bladders, usually oval in form (and measuring $\frac{1}{2}$ in. in length by $\frac{1}{3}$ in. in breadth), carry more numerous head-sacs, some of them being more advanced than others. As the development proceeds the bladder becomes larger, whilst the number of head-sacs increases. In the fifteenth week the bladders may be from 1 in. to 1½ in. in length, and the head-sacs are approaching their full size and are very numerous. (Pl. I., fig. 7). I have counted 211, 295, and 424 respectively in three bladder-worms obtained from the same rabbit on the hundred-and-first day after infection. Amongst those heads which are nearly or quite mature may, however, be found others which are in various earlier stages of development. The size of the bladder-worm, and also, apparently, the number of heads, may go on increasing for some months longer. A bladder-worm 2½ in. in length contained 740 head-sacs, whilst the largest I have seen was 3½ in. by 2¼ in., and contained nearly a thousand heads.

It should be mentioned that there is a considerable amount of variation in the rapidity or extent of development of the different bladder-worms of the same age, and found in the same rabbit. The statements given above apply, therefore, to the average length of time required for the different degrees of development. Moreover, the development of the bladders may be arrested at any stage, but more especially during the earlier stages. I have found in several cases bladder-worms which had died and were undergoing disintegration. The death of the parasite may be due either to an unsuitable position in which it has settled, or it may be due, especially in the earlier stages, to the resistance which the tissues of the rabbit offer, in a greater or less degree, to the foreign organism. The bladder-worm being dead, its walls lose their elasticity and are ruptured, whilst the collapsed walls of the bladder are converted into a cheesy mass, which seems to be slowly absorbed. I have seen reason to believe that at times very many of the bladders fail to reach their full development, perishing during the first few weeks of their growth; and this is, of course, a point of much importance when we desire to estimate the effect of the bladder-worm on the rabbit.

By comparing the different stages in the development of the bladder-worms we are able to trace the origin and mode of development of the tape-worm heads. They generally originate in small sacs or pouches formed by the growth inwards of certain parts of the wall of the bladder. At the bottom of this sac the tissue thickens, and gives rise to the four suckers and the rostellum, with its crown of hooks, characteristic of the tape-worm head (Plate I., fig. 10). The heads are developed, as it were, inside out. The opening of this sac becomes constricted, but is never entirely closed, a small aperture being left (Plate I., fig. 9). The heads are always restricted to one-half of the bladder, and their arrangement will be best understood by reference to figs. 6-8, Plate I. The long, irregular groups or series in which the heads are disposed have a roughly-radiate arrangement, which is most marked in the younger specimens. In the larger bladder-worms, with more numerous heads, the groups may be broader and less regular. Fig. 8 shows such a bladder-worm pinned out to show the heads more clearly. In this the radiate arrangement is less marked than usual, but is still clearly traceable.

I should mention here that in the older specimens small bladders are not infrequently found outside of, but in contact with, a large central bladder. They are evidently derived by budding from the surface of the older bladder-worm, for, although they are sometimes found quite free and detached, yet in many cases I have found them still connected with the parent bladder-worm by a wide or by a narrow slender stalk. These daughter-bladders give rise to tape-worm heads precisely in the same way that the parent does. This mode of multiplication may be compared with the formation of daughter-cysts in the *Echinococcus*—the "hydatid" of man and some of the domestic animals—by external budding. I have also observed cases in which the bladder-worm of the rabbit has given rise to daughter-bladders by internal budding; but these are not so numerous as cases of external budding.

It has been stated that the bladder-worms were found by me only in the muscles. They are found in all the muscles of the body except those of the distant parts of the limbs, where perhaps the conditions

as to temperature or liability to injury are unfavourable. I have found them even in the muscles moving the eyeball, on the walls of the heart, in the diaphragm, and even, in two cases, in the unstriated muscle of the wall of the intestine. In no case, however, did I find a bladder-worm in any other organ. Special search was made for them in the brain and spinal cord, but without success. As the bladder-worm grows larger it frequently projects on the surface of the muscle, so that it may seem to lie external to it, and project, for instance, into the cavity of the abdomen. But even in such cases careful examination almost invariably shows a thin sheet of musculo-fibres spread over the projecting bladder-worm.

When the eggs of the tape-worm are swallowed by the rabbit the secretion of the stomach destroys the strength of the shell, so that the embryo is able to escape. This embryo is armed with six hooks (see figs. 1 and 2, Plate I), by means of which it works its way into the wall of the alimentary canal, and thus gains access either to the lymphatics or the blood-vessels. Thence it may be carried with the blood-stream to the various organs of the body. On reaching the ultimate ramifications of the blood-vessels the embryo appears to bore through the wall of some capillary. The commencement of the track found in early stages in the muscles may probably indicate the point at which it leaves the blood-vessel. We have seen that the bladder-worms are only found in the muscles, but we may readily believe that many embryos are led by chance to take up their abode in other organs of the body, but that they fail to develop there. Even where the bladder-worms were most numerous they only represented a very small proportion of the eggs which had been given to the rabbit.

All rabbits are not equally susceptible to the bladder-worm disease. Some individuals seem to furnish a specially suitable home for the development of the bladder-worm, and great numbers of the parasites may be found in them. Sometimes the number is so great that they produce a considerable disturbance in the system, owing probably to the numerous points of local inflammation set up. Hence, such rabbits may die during the first two or three weeks after infection. Other rabbits, again, affording less suitable conditions for the development of bladder-worms, a comparatively small number of them are found. Yet other rabbits may enjoy complete immunity, the bladder-worm being quite unable to develop within them. Some of my rabbits were fed several times with tape-worm eggs, but all attempts to infect them failed. I obtained evidence showing that the younger rabbits were more susceptible than the older ones; but on this point my observations were necessarily limited, as all the experiments were conducted on wild rabbits, and at the time of the year no very young rabbits were obtainable. But, although young rabbits are more susceptible, yet it is only some of the older rabbits which enjoy immunity from the disease.
