

INQUIRY INTO VULNERABLE ROAD USERS

Organisation: Private Citizen
Name: Mr Andrew Cox
Date Received: 27/07/2010

THIS PAGE INTENTIONALLY BLANK

Submission for vulnerable road users.
Andrew Cox, 28 July 2010

My submission focusses on two areas – best practices around separation and equipment.

International best practices for separation / collision avoidance

Australia's cycle infrastructure severely lags the rest of the world with regard to infrastructure.

Cycle traffic mixed mode separation in China, specifically Shanghai, involves the use of 2.5 to 3 metre one way bike lanes combined with raised and ground level 'motor vehicle only' arterial roads for faster fossil fuelled vehicles.

The volume of cycle traffic in China is far greater than Australia and should be a target for a future city that focusses on renewable energy sources, global warming and population growth.

If you want people who do not cycle to take up cycling, then the right thing to do is to campaign for or design in road conditions which make cycling into an appealing option. That is what the Dutch have done. Everywhere. It is the key to the high cycle usage and high cycle safety figures. (David Hembrow, 2008)

Instead of catering to ever more motor vehicles by expanding roadways and parking facilities, Dutch, German and Danish cities have focused on serving people, making their cities people-friendly rather than car-friendly, and thus more liveable and more sustainable than American and British cities. ... In 2004, for example, Berlin (3.4 million inhabitants) had 860 km of completely separate bike paths, 60 km of bike lanes on streets, 50 km of bike lanes on sidewalks, 100 km of mixed-use pedestrian-bike paths and 70 km of combined bus-bike lanes on streets (City of Berlin, 2007). Amsterdam (735 000 inhabitants) and Copenhagen (504 000 inhabitants) each have roughly 400 km of completely separate bike paths and lanes (City of Amsterdam, 2003a; City of Copenhagen, 2004). Even much smaller cities, however, have extensive cycling facilities. For example, there are 320 km of bike paths and lanes in Muenster, Germany (278 000 inhabitants), over 500 km in Odense, Denmark (185 000 inhabitants), and over 420 km in Groningen, the Netherlands (181 000) (City of Muenster, 2004; Dutch Bicycling Council, 2006; City of Odense, 2007). (Pucher, 2008)

Key policies and innovative measures used in Dutch, Danish and German cities to promote safe and convenient cycling

Extensive systems of separate cycling facilities

- Well-maintained, fully integrated paths, lanes and special bicycle streets in cities and surrounding regions

- Fully coordinated system of colour-coded directional signs for bicyclists

- Off-street short-cuts, such as mid-block connections and passages through dead-ends for cars

Intersection modifications and priority traffic signals

- Advance green lights for cyclists at most intersections

- Advanced cyclist waiting positions (ahead of cars) fed by special bike lanes facilitate safer and quicker crossings and turns

- Cyclist short-cuts to make right-hand turns before intersections and exemption from red traffic signals at T-intersections, thus increasing cyclist speed and safety

- Bike paths turn into brightly coloured bike lanes when crossing intersections

- Traffic signals are synchronized at cyclist speeds assuring consecutive green lights for cyclists (green wave)

- Bollards with flashing lights along bike routes signal cyclists the right speed to reach the next intersection at a green light

Traffic calming

- Traffic calming of all residential neighbourhoods via speed limit (30 km/hr) and physical infrastructure deterrents for cars

- Bicycle streets, narrow roads where bikes have absolute priority over cars

- 'Home Zones' with 7 km/hr speed limit, where cars must yield to pedestrians and cyclists using

the road

Bike parking

- Large supply of good bike parking throughout the city
- Improved lighting and security of bike parking facilities often featuring guards, video-surveillance and priority parking for women

Coordination with public transport

- Extensive bike parking at all metro, suburban and regional train stations
- 'Call a Bike' programmes: bikes can be rented by cell phone at transit stops, paid for by the minute and left at any busy intersection in the city
- Bike rentals at most train stations
- Deluxe bike parking garages at some train stations, with video-surveillance, special lighting, music, repair services and bike rentals

Traffic education and training

- Comprehensive cycling training courses for virtually all school children with test by traffic police
- Special cycling training test tracks for children
- Stringent training of motorists to respect pedestrians and cyclists and avoid hitting them

Traffic laws

- Special legal protection for children and elderly cyclists
- Motorists assumed by law to be responsible for almost all crashes with cyclists
- Strict enforcement of cyclist rights by police and courts

Source: Information provided directly to authors by bicycling coordinators in the Netherlands, Denmark and Germany (Pucher, 2008)

RECOMMENDATION summary:

- invest in well designed cycle paths, either totally separate from road traffic or with minimum 2.5 metre wide channels.
- Develop government policies in line with International Best Practices as described above.

International best practice equipment

Light Electric Vehicles

Separation risks aside, one of the biggest obstacles to getting people who have not cycled for a while is the ability to cycle around Sydney's cycle paths or roads due to the gradients that need to be climbed.

The present standard of light electric bike that is openly accessible to the Sydney / Australian population is severely restricted in its functionality by having an upper legal limit of 200 watts; above this they require registration and compliance with Australian Design Rules for vehicles.

It is my understanding that the EU standard is currently being considered for application to Australia. This would raise the limit to 250 watts, and, as has been found in Europe, this is still woefully inadequate to be of true utility to the Australian public who live in a hilly environment or on hot days when pedal powered cycling will necessitate a shower on return home.

The EU standard would also outlaw 'throttles' which allow LEV riders infinite control over the power delivered by the motor. Anyone who has ridden an EU standard and a USA standard bike will know that the throttle available on the USA standard is far more enjoyable and easier and more consistent to control than the EU model.

An average rider is able to create about 400 watts of continuous power, with bursts up to twice that. Surely a motor should be allowed to provide what most cyclists can also provide without assistance.

Light-weight electric vehicles are incredibly useful for the following:

- reducing carbon emissions

- short trips of a few kms when a second car might normally be used, e.g. for daily shopping
- commuting to work without requiring a shower once you arrive
- riding to public transport such as train stations or bus stops
- intra-factory transit on private property

To the average car driver who has approximately 74,000 watts under the hood the Sydney cycling environment might seem flat, however, even a 5% or 10% slope such as George Street in the city centre or parts of Parramatta road can seem like a mountain. If the bike is also being useful in reducing carbon use and congestion by substituting for a car journey, for example carrying a water melon and perhaps the nightly vegetables, or picking up young ones from school, then even a short slope can be enough to deter a person from using an electric powered or electric assisted bike under the current regulations.

Cycle Helmets

Contrary to popular belief cycle helmets detract from getting people back on the road cycling and do little to improve safety. I myself do not ride a bicycle on the street due to separation issues and do not wish to ride on bike paths as I am forced to wear a helmet, even if I am out for a lazy Sunday afternoon ride away from other traffic.

So, where do helmets and fluorescent clothing fit in ? For some individuals, merely wearing such a thing improves their own feeling of safety to the level that they will ride. However, these items do little to improve actual safety and can have a negative effect on the subjective safety of other people due to making cycling look dangerous. Where cycling has a high degree of subjective safety, as it does here, no-one wears these safety aids. Dutch cyclists are safer without them than cyclists elsewhere are with them. (Hembrow, 2008)

More reasons to revoke cycle helmet laws:

Abuse of civil liberties

Cycling is NOT dangerous

- driving is

- obesity is

- smoking is

- but cycling is NOT

Statutory helmet promotion single-handedly passing cost of cycling to consumers, allowing government to ignore previous recommendations for genuine cycling infrastructure & motorist education

Drastically reduced cycling rates by 40%

Actual head injuries remained the same, suggesting an increase in head injuries

Inconclusive data on how much protection bicycle helmets give

Laboratory tests on bicycle helmets indicate a possible increased risk of "Diffuse Axonal Injury"

Currently not recommended for certain 'headforms', namely Headform AA (4 year olds & under)

Correlation to Australia's status as the "Fattest Nation in the World"

(<http://freedomcyclist.blogspot.com>)

RECOMMENDATION summary:

- Introduce a vehicle class of 'light-weight electric vehicle' (LEV) with limitations. 2 or 3 wheels, electric motor only (not petrol), motor power not exceeding 1000 watts(for example) / 100kg gross mass, speed limited to less than 30km/h on urban roads.
- Modify laws in line with other country's best practices. Allow electrically assisted bicycles with throttles for better controllability and motors up to approximately 750 watts (~1 horse power). Light-weight bikes to have an electric only speed limitation of approximately 25 to 30 km/h. In any case, this speed limitation is often a de-facto limit due to the design of motor used in most modern electric bikes.
- Remove any tariffs or barriers to implementing electric assisted bikes.
- Provide tax or insurance incentives for people to use an electric powered light-weight bike instead of a second car.

- Make light weight electric vehicle helmets highly recommended in high traffic areas, but not a crime to not wear one, especially in light traffic conditions and on separated cycle ways or short transits between these.

Making Cycling Irresistible: Lessons from The Netherlands, Denmark and Germany

JOHN PUCHER and RALPH BUEHLER

Bloustein School of Planning and Public Policy, Rutgers University, New Brunswick, New Jersey, USA

(Received 9 July 2007; revised 16 October 2007; accepted 11 November 2007)

ABSTRACT *This article shows how the Netherlands, Denmark and Germany have made bicycling a safe, convenient and practical way to get around their cities. The analysis relies on national aggregate data as well as case studies of large and small cities in each country. The key to achieving high levels of cycling appears to be the provision of separate cycling facilities along heavily travelled roads and at intersections, combined with traffic calming of most residential neighbourhoods. Extensive cycling rights of way in the Netherlands, Denmark and Germany are complemented by ample bike parking, full integration with public transport, comprehensive traffic education and training of both cyclists and motorists, and a wide range of promotional events intended to generate enthusiasm and wide public support for cycling. In addition to their many pro-bike policies and programmes, the Netherlands, Denmark and Germany make driving expensive as well as inconvenient in central cities through a host of taxes and restrictions on car ownership, use and parking. Moreover, strict land-use policies foster compact, mixed-use developments that generate shorter and thus more bikeable trips. It is the coordinated implementation of this multi-faceted, mutually reinforcing set of policies that best explains the success of these three countries in promoting cycling. For comparison, the article portrays the marginal status of cycling in the UK and the USA, where only about 1% of trips are by bike.*

Introduction

For readers in many countries, the title of this article might sound so impossible as to seem absurd. Most Britons and Americans, for example, must find cycling quite resistible indeed, since they make only about 1% of their trips by bike. Cycling conditions in most countries—including the UK and the USA—are anything but safe, convenient and attractive (Pucher *et al.*, 1999; McClintock, 2002; Pucher and Dijkstra, 2003; Tolley, 2003). Bicycling in much of the industrialized world is a marginal mode of transport, occasionally used for recreational purposes but rarely used for practical, everyday travel needs. Moreover, the

social distribution of cycling tends to be very uneven, with young men doing most of the cycling, while women cycle far less, and the elderly hardly cycle at all.

Thus, it may come as a surprise to sceptical readers that there are technologically advanced, affluent countries that have managed to make cycling a mainstream mode of transport, a perfectly normal way to get around cities. In the Netherlands, Germany and Denmark, cycling levels are more than ten times higher than in the UK and the USA. Dutch, German and Danish women cycle as often as men, and rates of cycling fall only slightly with age. Moreover, cycling is distributed evenly across all income groups. In the Netherlands, Germany and Denmark, cycling is truly for everyone and for all trip purposes.

Moreover, cycling in those countries is not viewed as requiring expensive equipment, advanced training, or a high degree of physical fitness. Nor are cyclists forced to muster the courage and willingness to battle motorists on streets without separate bike lanes or paths. On the contrary, Dutch, German and Danish cyclists ride on simple, inexpensive bikes, almost never wear special cycling outfits, and rarely use safety helmets. Even timid, risk-averse and safety-conscious individuals can be found cycling, unlike the many millions of Americans and Britons who are terrified by the mere thought of getting on a bike.

As documented in this article, cycling was not always thriving in the Netherlands, Germany and Denmark. Cycling levels plummeted in all three countries from about 1950 to 1975 (Dutch Bicycling Council, 2006). It was only through a massive reversal in transport and urban planning policies in the mid-1970s that cycling was revived to its current successful state. In 1950, cycling levels were higher in the UK than they are now in Germany: almost 15% of all trips. Just as in these other countries, cycling in the UK plummeted from 1950 to 1975, but British cycling never recovered. It continued to fall to its current level of 1.3% of trips, only slightly higher than the 0.9% bike share of trips in the USA (U.S. Department of Transportation, 2003; Department for Transport, 2007).

While history, culture, topography and climate are important, they do not necessarily determine the fate of cycling. Government policies are at least as important: transport policies, land-use policies, urban development policies, housing policies, environmental policies, taxation policies and parking policies. In many respects, the UK and the USA have given the green light to the private car, almost regardless of its economic, social and environmental costs. In sharp contrast, cycling has prospered in the Netherlands, Germany and Denmark over the past three decades precisely because these countries have given the red light, or at least the yellow warning light, to private cars. Instead of catering to ever more motor vehicles by expanding roadways and parking facilities, Dutch, German and Danish cities have focused on serving people, making their cities people-friendly rather than car-friendly, and thus more liveable and more sustainable than American and British cities.

There are many good reasons to encourage more cycling. It causes virtually no noise or air pollution and consumes far less non-renewable resources than any motorized transport mode. The only energy cycling requires is provided directly by the traveller, and the very use of that energy offers valuable cardiovascular exercise. Cycling requires only a small fraction of the space needed for the use and parking of cars. Moreover, cycling is economical, costing far less than both the private car and public transport, both in direct user costs and public infrastructure costs. Because it is affordable by virtually everyone, cycling is among the most equitable of all transport modes. In short, it is hard to beat cycling when

it comes to environmental, social and economic sustainability. Consequently, both the European Union (EU) and the USA have officially recognized the importance of cycling as a practical mode of urban transport and endorse the dual objectives of raising cycling levels while increasing cycling safety (U.S. Department of Transportation, 1994, 2004; European Conference of the Ministers of Transport, 2004).

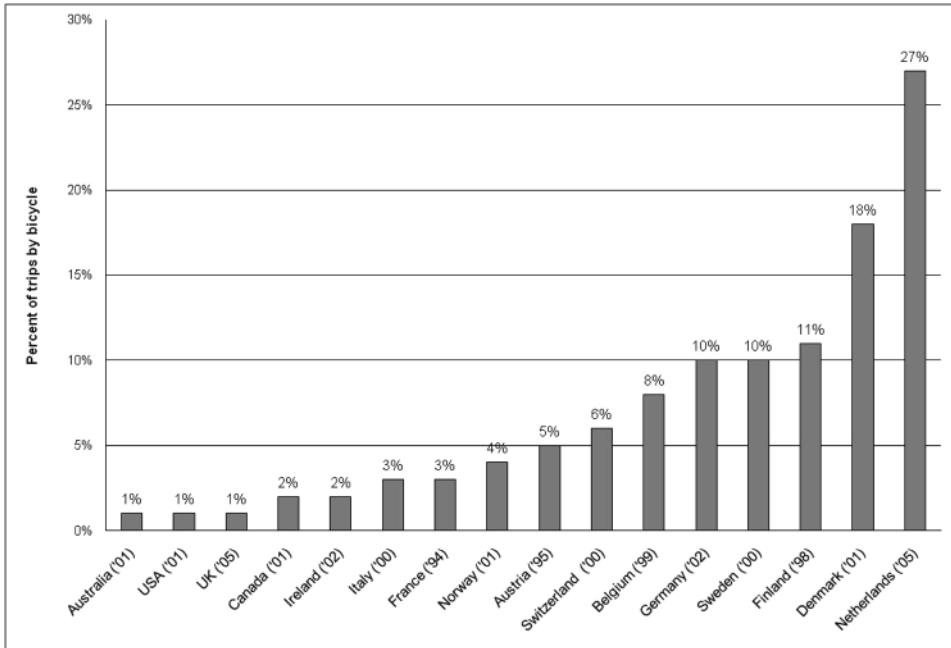

As shown in this article, countries vary greatly in the degree to which these stated objectives have been met. The Netherlands, Denmark and Germany have been at the forefront of policies to make cycling safe, convenient and attractive, while the UK and the USA have lagged far behind. Differences between these countries in cycling levels are enlightening because all five of them are democratic, capitalist, affluent societies with nearly universal car ownership. The success of cycling does not depend on poverty, dictatorial regimes or the lack of motorized transport options to force people onto bikes. This article shows how the Netherlands, Denmark and Germany have managed to make cycling a popular, mainstream way of getting around cities.

First, however, we document differences among countries in their overall levels of cycling, in bike trip purposes, and in the gender, age and income levels of cyclists. Differences in cycling safety explain some of the difference in cycling levels among countries; thus, the article contains an entire section with comparisons of cycling fatality and injury rates and trends over time. Subsequent sections summarize the range of policies and programmes used in the Netherlands, Denmark and Germany to promote cycling by a broad spectrum of society and at the same time improve cycling safety. The article concludes with an overall assessment of the lessons that can be learned from these countries to make cycling safer, more convenient and more attractive in other countries as well.

Variations among Countries in Overall Cycling Levels

As shown in Figure 1, there are large differences among Australia, the USA, Canada and European countries in the bike share of trips, ranging from a low of 1% in Australia, the UK and the USA to 27% in the Netherlands. These differences in the bike share of trips roughly parallel differences in the average distance cycled per person per day, an alternative way of measuring and comparing cycling levels among countries. Averaging over the entire population of each country, the European Conference of the Ministers of Transport (2004) estimated that per capita cycling per day ranges from 0.1 km in Spain, Greece and Portugal to 2.5 km in the Netherlands (see Figure 2). Denmark (1.6 km) and Germany (0.9 km) immediately follow the Netherlands in distance cycled per inhabitant. The USA and the UK are both at the low end of the spectrum, averaging 0.1 km and 0.2 km of cycling per person per day, respectively.

These national averages hide large variations in cycling levels between cities within each country, as shown in Figure 3. With only a few exceptions, however, even the most bike-oriented cities in the UK, Australia, Canada and the USA generally have bike shares of travel that are lower than the least bike-oriented cities in the Netherlands, Denmark and Germany. No British, Canadian, Australian or American city even approaches the bike share of trips in most Dutch and Danish cities. Only a few German cities have bike mode shares lower than 5%, while all Canadian, Australian and American cities, and most British cities, have bike shares that low.

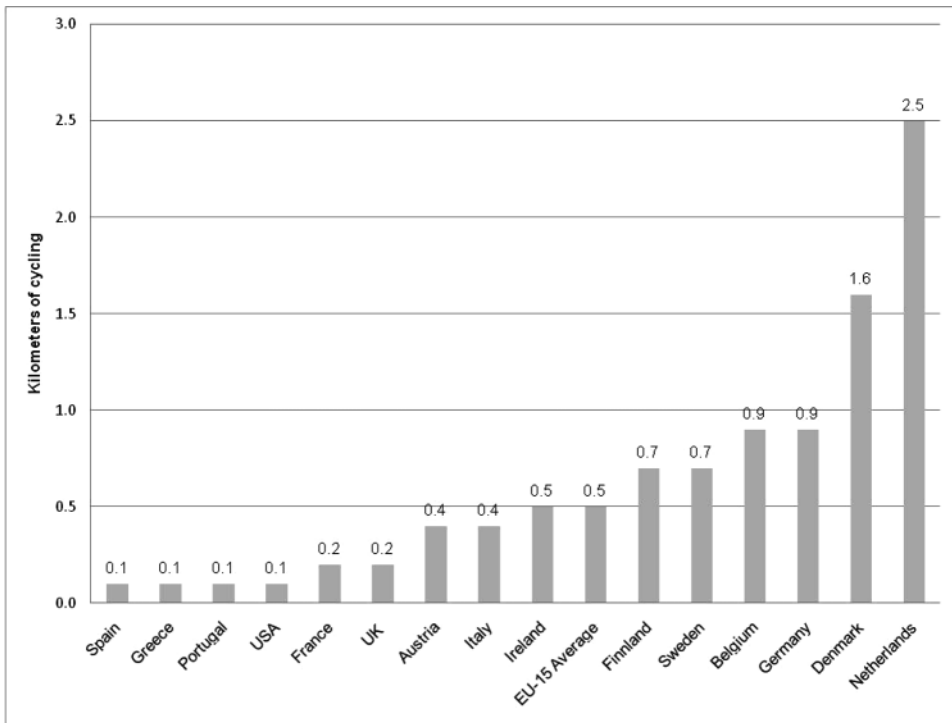

Sources: European Union (2003); German Federal Ministry of Transport (2003); U.S. Department of Transportation (2003); European Conference of the Ministers of Transport (2004); Department for Transport (2005); Organisation for Economic Cooperation and Development (2005); Netherlands Ministry of Transport (2006); Australian Bureau of Statistics (2007)

Figure 1. Bicycle share of trips in Europe, North America and Australia (percentage of total trips by bicycle).

These statistics on cycling levels reflect data from national ministries of transport, central statistical bureaus and supplementary city travel surveys. They are not entirely comparable because travel surveys vary somewhat according to variable definitions, data collection method and frequency, target population, sample size and response rates (Kunert *et al.*, 2002). At the very least, however, such travel surveys facilitate approximate comparisons of different levels of cycling among countries and cities, and whatever their limitations, they are the best available sources of information.

One might expect that Europeans cycle more than Americans due to shorter trip lengths in European cities. Indeed, a considerably higher percentage of all trips in European cities are shorter than 2.5 km: 44% in the Netherlands, 37% in Denmark and 41% in Germany, compared to 27% in the USA (German Federal Ministry of Transport, 2003; U.S. Department of Transportation, 2003; National Statistical Office of Denmark, 2005; Statistics Netherlands, 2007). In the UK, only 30% of trips are shorter than 2.5 km, much closer to the American level, perhaps due to more extensive sprawl in Britain than in the Netherlands, Denmark and Germany (Department for Transport, 2007).

Even controlling for trip distance, however, the Dutch, Danes and Germans make a much higher percentage of their local trips by bike. As shown in Figure 4, both Americans and Britons cycle for only 2% of their trips shorter than 2.5 km, compared to 37% in the Netherlands, 27% in Denmark and 14% in Germany. That pattern also holds for the progressively longer trip distance categories shown in Figure 4. For trips between 2.5 and 4.4 km, for example, Americans and Britons make just 1% of their trips by bike, compared to much higher bike mode

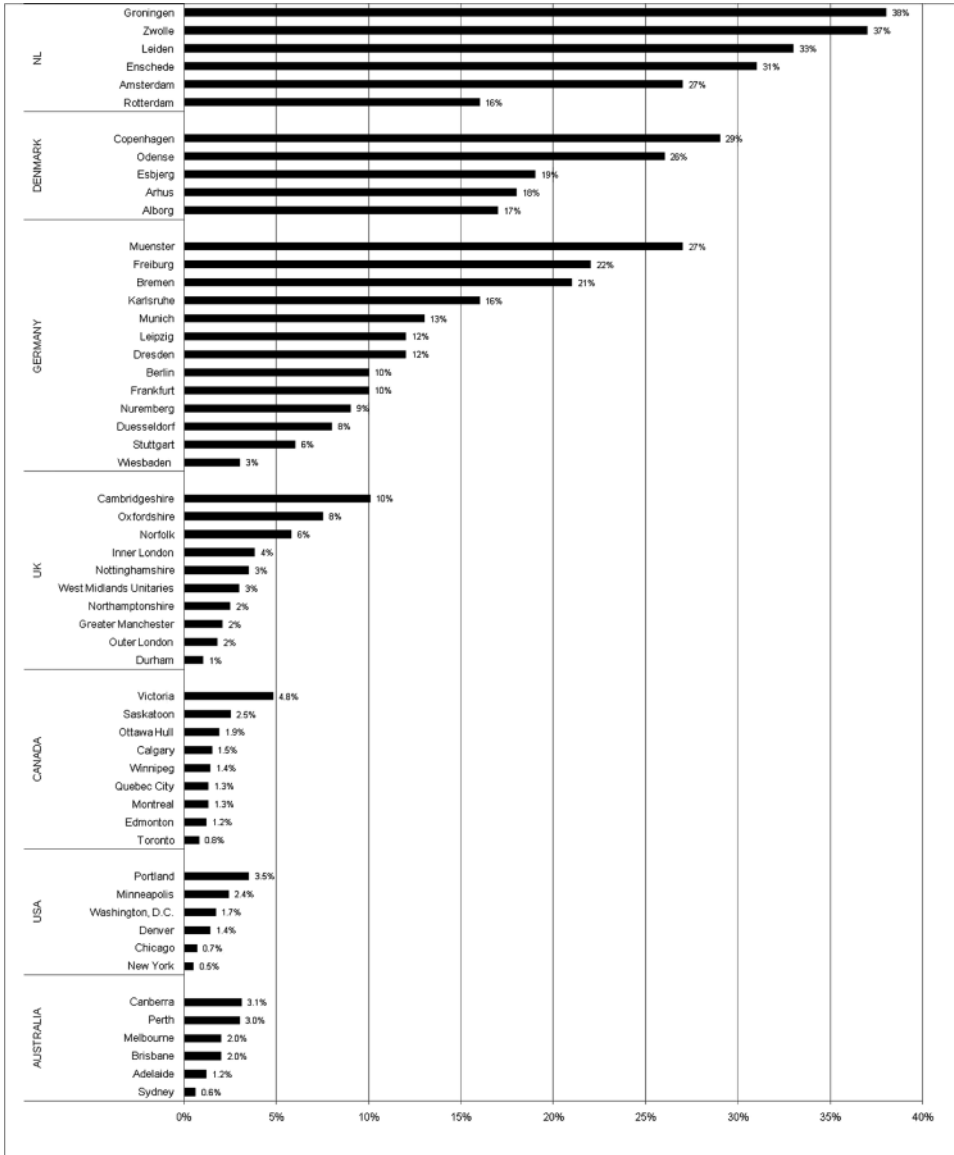

Sources: European Union (2002); U.S. Department of Transportation (2003)

Figure 2. Kilometres cycled per inhabitant per day in Europe and the USA.

shares for the same trip distance in the Netherlands (37%), Denmark (24%) and Germany (11%).

Northern Europeans—even Britons—are far more likely than Americans to cycle for practical, utilitarian purposes. Travel to work or school accounts for only 11% of all bike trips in the USA, compared to 28% in Germany, 30% in the UK, 32% in the Netherlands and 35% in Denmark. Even more strikingly, shopping trips account for only 5% of all bike trips in the USA, compared to 20% in Germany, 22% in the Netherlands and 25% in Denmark (U.S. Department of Transportation, 2003; German Federal Ministry of Transport, 2003; Netherlands Ministry of Transport, 2006; Danish Ministry of Transport, 2007; Department for Transport, 2007). Roughly three-fourths of all bike trips in the USA are for recreation, compared to 38% in Germany, 35% in the UK, 27% in the Netherlands and only 10% in Denmark.

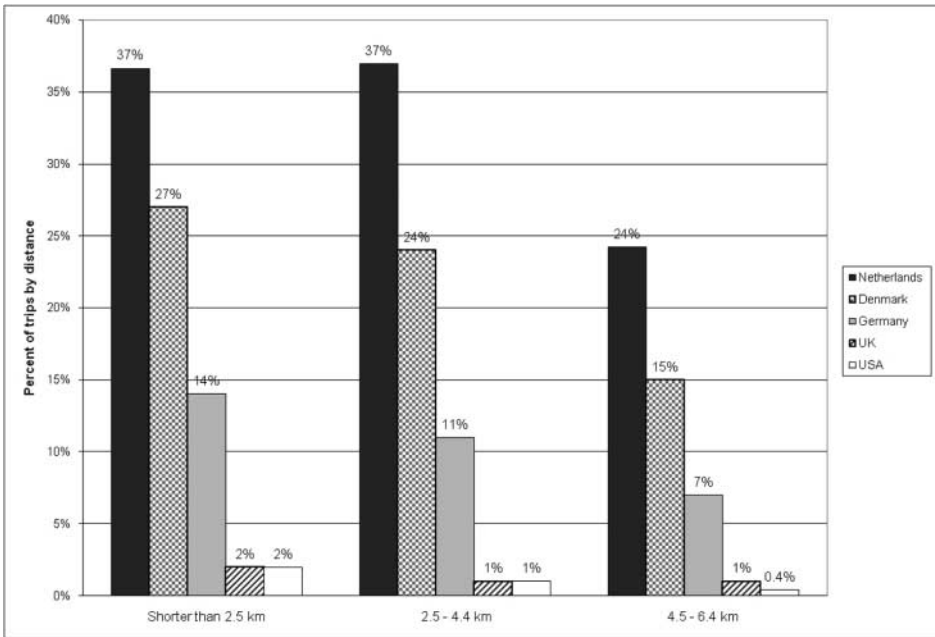

The Netherlands, Denmark and Germany have been among the most successful countries at promoting cycling for daily travel. Since all three countries are quite affluent, their high levels of cycling are not due to an inability to afford more expensive transport modes. Indeed, levels of car ownership in the three countries are among the highest in the world. The case of Germany is particularly noteworthy. Although it has a much higher level of car ownership than the UK, the bike share of trips in Germany is almost ten times higher in Germany than in the UK. Clearly, high levels of car ownership do not preclude cycling. Thus, an examination of the successful pro-cycling policies and programmes in the Netherlands, Denmark and Germany may provide especially useful lessons for increasing cycling in other countries with high incomes and widespread car ownership.

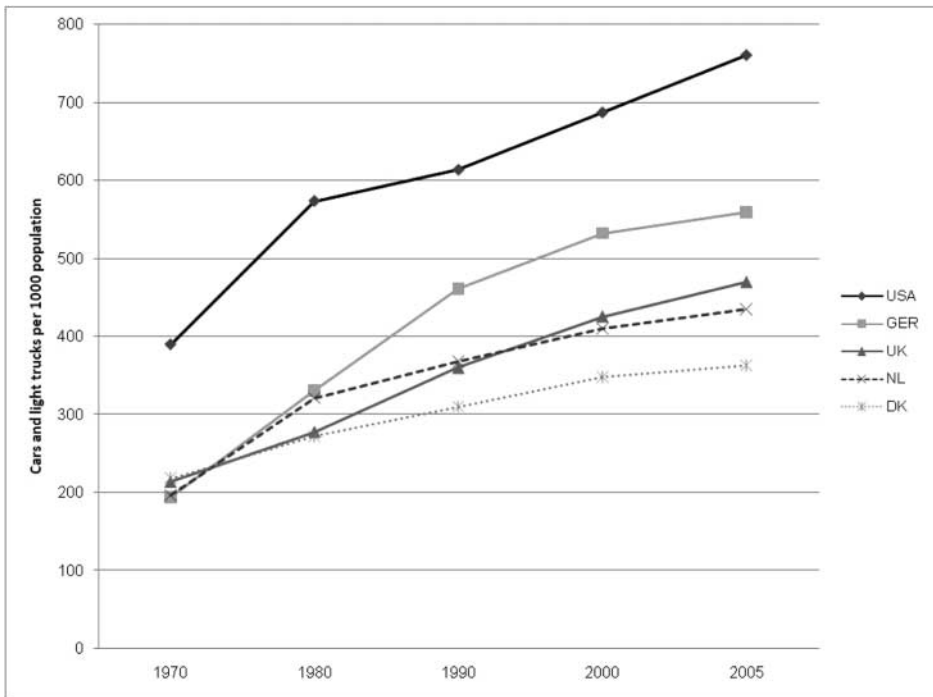

Figure 3. Bike share of trips in selected cities in the Netherlands, Denmark, Germany, the UK, Canada, the USA and Australia (2000–2005). Note: UK data are for counties.

One can view the same information in another light. As shown in Figure 5, car ownership per capita has increased in the Netherlands, Denmark and Germany over the past few decades but remains much lower than in the USA. That is partly due to high taxes on car ownership and use in most European countries. But it is also due to excellent alternatives to the private car in the Netherlands, Denmark and Germany, including cycling as well as walking and public transport. As is most evident in Denmark and the Netherlands, safe and convenient cycling reduces the need for car ownership.

Figure 5. Trend in car and light truck ownership per 1000 population in the USA, Germany, the UK, the Netherlands and Denmark (1970–2005).

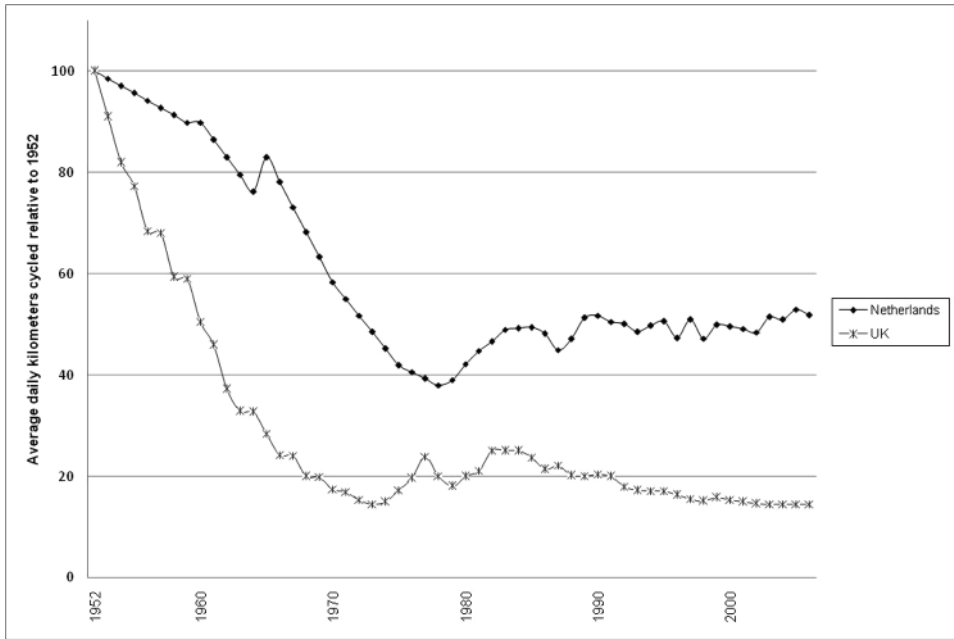

Some readers might assume that bicycling levels in Europe have been consistently high. In fact, cycling fell sharply during the 1950s and 1960s, when car ownership surged and cities started spreading out. From 1950 to 1975, the bike share of trips fell by roughly two-thirds in a sample of Dutch, Danish and German cities, from 50%–85% of trips in 1950 to only 14–35% of trips in 1975 (Dutch Bicycling Council, 2006). Similarly, a study by the City of Berlin (2003) found that the number of bike trips there fell by 78% from 1950 to 1975. During that 25-year period, cities throughout the Netherlands, Denmark and Germany focused on accommodating and facilitating increased car use by vastly expanding roadway capacity and parking supply, while largely ignoring the needs of pedestrians and cyclists (Hass-Klau, 1990).

In the mid-1970s, transport and land-use policies in all three countries shifted dramatically to favour walking, cycling and public transport over the private car. The policy reform was a reaction to the increasingly harmful environmental, energy and safety impacts of rising car use (Hass-Klau, 1990; Pucher, 1997; European Conference of the Ministers of Transport, 2004; Dutch Bicycling Council, 2006). Most cities improved their bicycling infrastructure while imposing restrictions on car use and making it more expensive. That policy reversal led to turnarounds in the previous decline of bike use. From 1975 to 1995, the bicycling share of trips in the same, previously cited sample of Dutch, Danish and German cities rose by roughly one-fourth, resulting in 1995 bike shares of 20–43%. In Berlin, the total number of bike trips nearly quadrupled from 1975 to 2001 (increasing by 275%), reaching 45% of the 1950 bicycling level (City of Berlin, 2003). The rebound in cycling from 1975 onward was not enough to offset the huge declines from 1950 to 1975. Nevertheless, it was a significant accomplishment and provides evidence of the powerful impact of policy on travel behaviour. It is especially impressive given continuing growth in per-capita income, car ownership and suburban development in all three countries over the past three decades.

The Netherlands and the UK provide striking contrasts in their long-term cycling trends (see Figure 6). Over the period 1952 to 1975, cycling in the UK fell by 80%, compared to a drop of 62% in the Netherlands. Cycling in both countries rebounded somewhat during the ten years from 1975 to 1985. In the next 20 years, however, cycling resumed its long-term decline in the UK, whereas cycling levels continued to increase in the Netherlands. The overall result is that by 2006, the cycling level in the UK was less than a seventh of its 1952 level (13%), while cycling in the Netherlands was at slightly more than half of its 1952 level (52%).

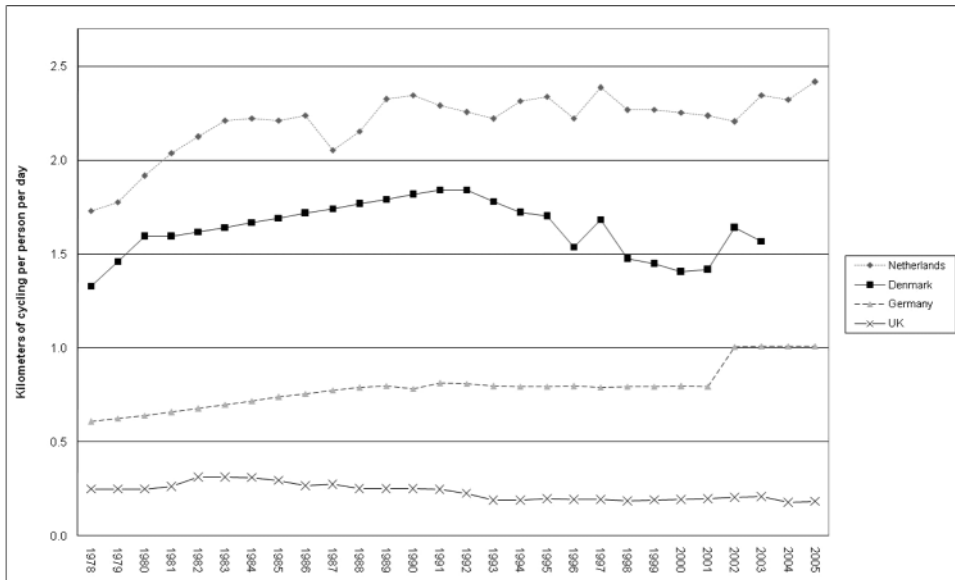

Analysis of national aggregate data for the past few decades confirms a rebound in cycling in the Netherlands, Denmark and Germany since the 1970s. As shown in Figure 7, average daily kilometres cycled per inhabitant rose in all three countries from 1978 to 2005: from 0.6 to 1.0 in Germany, from 1.3 to 1.6 in Denmark and from 1.7 to 2.5 in the Netherlands. In both the Netherlands and Denmark, the strongest growth in cycling was from the mid-1970s until the early 1990s. By comparison, average daily kilometres cycled in the UK have fallen almost continuously since 1978, declining by a third: from 0.3 to 0.2.

Not only do the Netherlands, Denmark and Germany have high and growing levels of cycling, but their cyclists comprise virtually all segments of society (see Figure 8). Women are just about as likely to cycle as men, making 45% of all bike trips in Denmark, 49% in Germany and 55% in the Netherlands. While cycling is

Sources: Department for Transport (2007); Netherlands Ministry of Transport (2007)

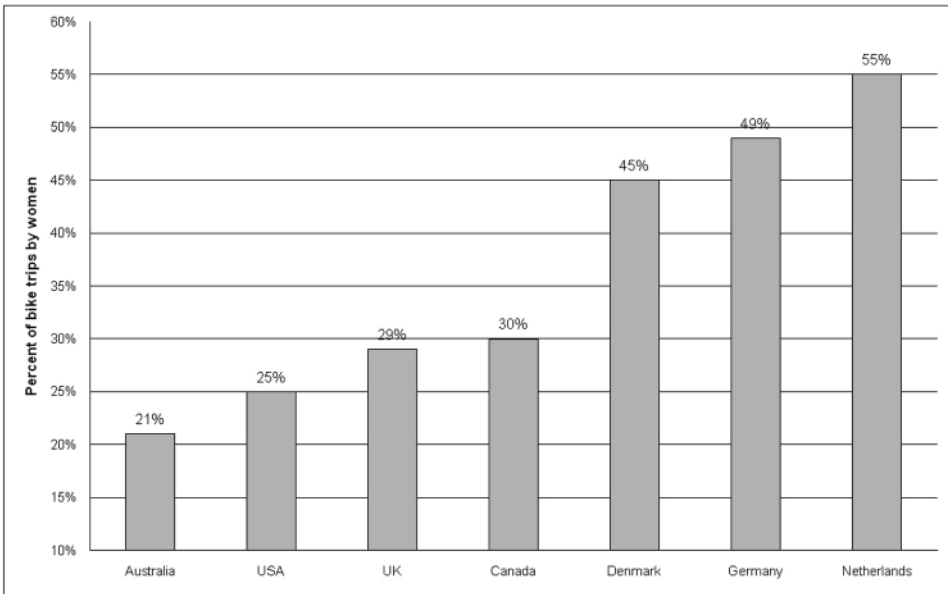

Figure 7. Trend in kilometres cycled per inhabitant per day in the Netherlands, Denmark, Germany and the UK (1978–2005).

gender-neutral in those three countries, men dominate cycling in the UK and the USA, where they make 72% and 76% of all bike trips, respectively.

Another dimension of cycling’s universality in the Netherlands, Denmark and Germany is the representation of all age groups. Children and adolescents have the highest rates of cycling in almost every country. As shown in Figure 9, however, cycling levels in the Netherlands, Denmark and Germany remain high even among the elderly. In Germany, the bike share of trips rises steadily from 7% among 18- to 24-year olds to 12% for those 65 and older. The bike share of trips declines with age in Denmark, but even among those aged 70–74 years old, cycling accounts for 12% of all trips, the same as among Germans who are 65 and older. The Dutch elderly double that percentage, making 24% of all their trips by bike.

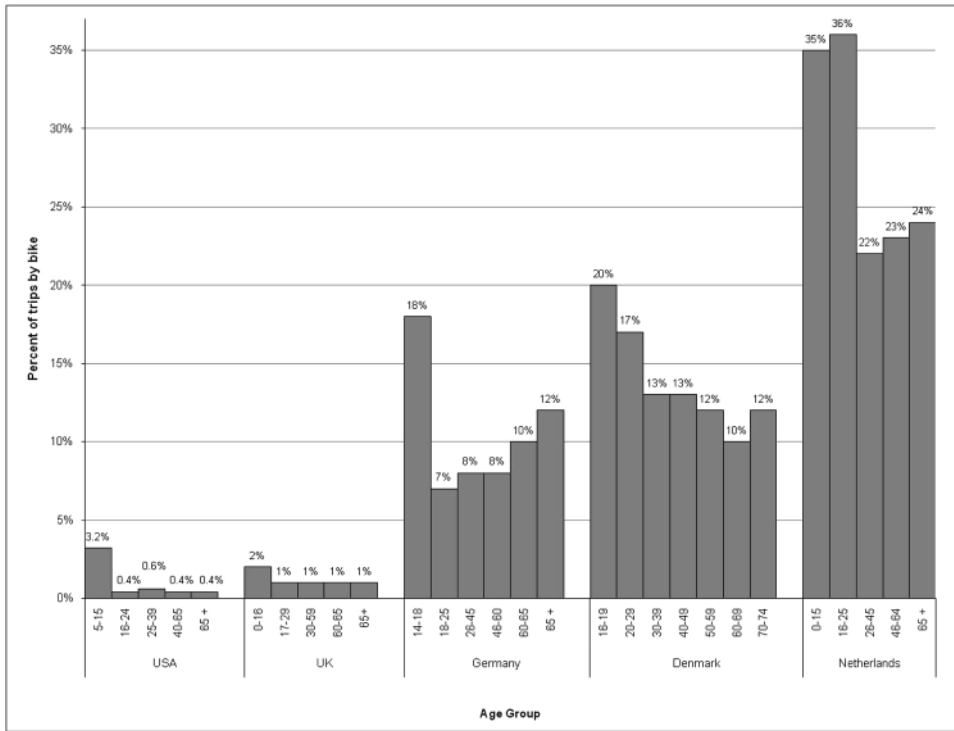

Cycling rates are low for all age groups in the USA, but they also decline with age: from 3.2% among children 5–15 years old to only 0.4% of trips for those 40 and older (see Figure 9). Similarly, the bike share of trips falls from 2% among British children to 1% among older age groups. The bike share of trips for the Dutch elderly is 24 times higher than for British elderly and 60 times higher than for American elderly. The bike share of trips for both the German and Danish elderly is 12 times higher than for British elderly and 30 times higher than for American elderly.

Rates of cycling are similar across different income classes, not only in the Netherlands, Denmark and Germany, but also in the UK and the USA (German Federal Ministry of Transport, 2003; U.S. Department of Transportation, 2003; Department for Transport, 2006; Danish Ministry of Transport, 2007; Statistics Netherlands, 2007). In the Netherlands, Germany and the UK, low-income

Figure 8. Women’s share of total bike trips in Australia, the USA, the UK, Canada, Denmark, Germany and the Netherlands (2000–2005).

Sources: German Federal Ministry of Transport (2003); U.S. Department of Transportation (2003); Danish Ministry of Transport (2005); Statistics Netherlands (2005); Department for Transport (2007)

Figure 9. Bicycling share of trips by age group in the USA, the UK, Germany, Denmark and the Netherlands (2000–2002).

groups cycle only slightly more than high-income groups. By comparison, the poor in the USA cycle for a slightly lower percentage of their trips than the affluent, but the difference is negligible (0.8% vs. 0.9%). Thus, cycling appears to be the most equitable of all transport modes, at least in terms of usage across income classes.

The remainder of this article examines how Germany, the Netherlands and Denmark have succeeded in making cycling a safe and convenient way to get around their cities.

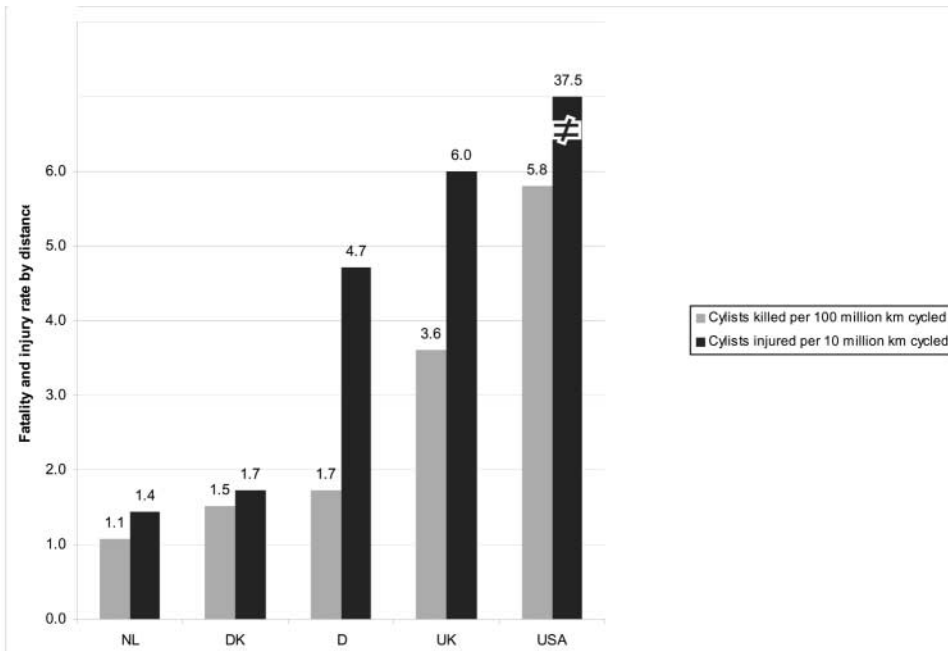

Trends in Cycling Safety

Perhaps the most important reason for the higher levels of cycling in the Netherlands, Denmark and Germany—especially among women, children and the elderly—is that cycling is much safer there than in the USA and the UK. Both fatality and injury rates are much higher for cyclists in the USA and the UK than in Germany, Denmark and the Netherlands. Averaged over the years 2002 to 2005, the number of bicyclist fatalities per 100 million km cycled was 5.8 in the USA and 3.6 in the UK, compared to 1.7 in Germany, 1.5 in Denmark, and 1.1 in the Netherlands (see Figure 10). Thus, cycling is over five times as safe in the Netherlands as in the USA and more than three times as safe as in the UK. That might explain why the Dutch do not perceive cycling as a dangerous way to get around. Cycling in

Germany and Denmark is not quite as safe as in the Netherlands, but it is three to four times safer than in the USA and twice as safe as in the UK.

Serious cycling injuries outnumber cycling fatalities roughly ten-fold in most countries (Organisation for Economic Cooperation and Development, 2007). Thus, it is important to consider non-fatal injury rates as well. Figure 10 compares non-fatal injury rates per 10 million km cycled side by side with fatality rates per 100 million km cycled. For all five countries, these statistics rely on police reports. Without exception, the cycling safety ranking for countries is the same for injuries as for fatalities. Thus, the Netherlands has the lowest non-fatal injury rate as well as the lowest fatality rate, while the USA has the highest non-fatal injury rate as well as the highest fatality rate. Indeed, the non-fatal injury rate for the USA is about 8 times higher than for Germany and about 30 times higher than for the Netherlands and Denmark. The injury rate in the UK is second highest, but much lower than in the USA.

The cyclist injury rate for the USA seems extremely high relative to the other countries. Yet it vastly underestimates total cycling injuries. It only includes cycling injuries resulting from crashes with motor vehicles on roadways and reported by the police (U.S. Department of Transportation, 2007). By comparison, the Center for Disease Control and Prevention (2007), the official public health agency of the U.S. Government, reports ten times more cycling injuries per year (479 963 vs. 45 000 in 2005), based on reports from emergency rooms of hospitals. As documented by the Organisation for Economic Cooperation and Development (2007), the official statistics of other countries also underestimate total cyclist injuries to varying

Sources: Danish Ministry of Transport (2007); Department for Transport (2007); German Federal Ministry of Transport (2007); Netherlands Ministry of Transport (2007); U.S. Department of Transportation (2007)

Figure 10. Fatality rates and non-fatal injury rates in the Netherlands, Denmark, Germany, the UK and the USA (2004–2005).

degrees. The documented ten-fold underreporting in the USA highlights the poor and variable quality of data on cycling injuries.

There are always problems comparing injury statistics across different countries because of differences in definitions and methodologies of data collection (Pucher and Dijkstra, 2000, 2003). Whether a cycling injury is reported in official statistics depends on the type of injury, where it occurs, whether it involves a motor vehicle, and whether it requires emergency medical assistance or a hospital visit. Many, if not most, cycling injuries are not reported at all. Even serious cycling injuries are underreported, as shown by the American case. Thus, the cycling injury rates reported in Figure 10 are less accurate and less comparable than the corresponding fatality rates. Nevertheless, both measures indicate much safer cycling in the Netherlands and Denmark than in the UK and the USA, with Germany in between.

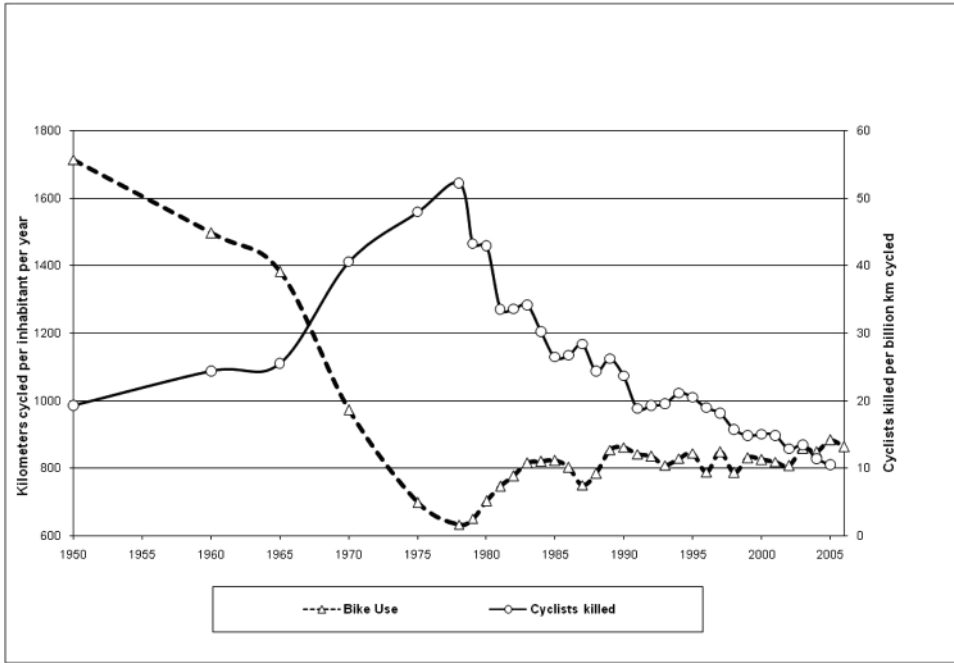

As shown in Figure 11, Germany, Denmark and the Netherlands have greatly improved cycling safety since 1970. Although levels of cycling have increased in all three countries over the past 35 years (as already shown in Figure 7), the total number of cycling fatalities has declined by over 70%. Fatalities fell by 60% in the UK over the same period, but the amount of cycling also decreased. The least improvement in cycling safety has been in the USA, where fatalities fell by only 30%.

Longer term data are available for the Netherlands. They dramatically portray the strong relationship between cycling safety and levels of cycling (see Figure 12). During the 1950s and 1960s, car use rose rapidly in the Netherlands. Insufficient supply of both roadways and separate cycling facilities generated dangerous

Figure 12. Inverse trends in cycling fatality rates and annual kilometres cycled per inhabitant in the Netherlands (1950–2005).

traffic conflicts and an alarming increase in cycling fatalities (Dutch Bicycling Council, 2006; Netherlands Ministry of Transport, 2006). As the cyclist fatality rate per billion km cycled rose by 174% from 1950 to 1978, the average km cycled per inhabitant fell by 65%. Since the mid-1970s, Dutch cities have undertaken massive improvements to cycling infrastructure and restricted car use (Netherlands Ministry of Transport, 1999, 2006). The result has been an 81% fall in the cyclist fatality rate from 1978 to 2006, thus encouraging a 36% increase in km cycled per inhabitant. This statistical relationship, of course, does not prove causation, but there is every reason to believe that increased safety is a key to promoting more cycling (Rietveld and Daniel, 2004).

There is also reason to believe that more cycling facilitates safer cycling. The phenomenon of ‘safety in numbers’ has consistently been found to hold over time and across cities and countries. Fatality rates per trip and per km are much lower for countries and cities with high bicycling shares of total travel, and fatality rates fall for any given country or city as cycling levels rise (Jacobsen, 2003).

Most surveys show that the perceived traffic danger of cycling is an important deterrent to more widespread cycling (Noland, 1994; Dutch Bicycling Council, 2006). Women and the elderly appear to be especially sensitive to such traffic danger (Garrard *et al.*, 2008). Many American parents do not allow their children to cycle for the same reason. As shown in Figure 10, cycling in the USA is indeed dangerous in comparison with other countries. Thus, making cycling safer is surely one of the keys to increasing overall cycling levels in the USA, particularly among women, the elderly and children.

In the USA, much of the effort to improve cyclist safety has focused on increasing helmet use, if necessary by law, especially for children. Thus, it is important to emphasize that the much safer cycling in northern Europe is definitely *not* due to widespread use of safety helmets. On the contrary, in the Netherlands, with the safest cycling of any country, less than 1% of adult cyclists wear helmets, and even among children, only 3–5% wear helmets (Dutch Bicycling Council, 2006; Netherlands Ministry of Transport, 2006). The Dutch cycling experts and planners interviewed for this article adamantly oppose laws to require the use of helmets, claiming that helmets discourage cycling by making it less convenient, less comfortable and less fashionable. They also mention the possibility that helmets would make cycling more dangerous by giving cyclists a false sense of safety and thus encouraging riskier riding behaviour. At the same time, helmets might reduce the consideration motorists give cyclists, since they might seem less vulnerable if wearing helmets (Walker, 2007).

German and Danish cycling planners seem far more supportive of increased helmet use, especially among children (Danish Ministry of Transport, 2000; German Federal Ministry of Transport, 2002; City of Muenster, 2004; Andersen, 2005; Boehme, 2005). There have been extensive promotional campaigns in these two countries to encourage more helmet use, but there are no laws requiring helmet use, not even for young children. In 2002, 33% of German children aged 6–10 years wore helmets while cycling, compared to 9% of adolescents aged 11–16 and 2% of Germans aged 17 or older. In 2006, 66% of Danish school children aged 6–10 wore helmets, compared to 12% among school children 11 years or older, and less than 5% among adults.

Government Roles in Funding and Planning Cycling Facilities and Programmes in The Netherlands, Denmark and Germany

Due to the mostly local, short-distance trips made by bike, policies and programmes to promote safe and convenient cycling are usually carried out at the municipal level (European Conference of the Ministers of Transport, 2004). Local governments in the Netherlands, Germany and Denmark have been planning, constructing and funding bicycling facilities for many decades, at least since the 1970s but much earlier in some cities. Municipalities are responsible for making the specific plans that reflect the particular conditions and needs of the local context. Cycling training, safety and promotional programmes are usually carried out at the local level as well, even if they are mandated and funded by higher levels. At the intermediate level, states, counties and regional governments provide additional policy guidance, coordination and funding, as well as some direct planning and construction of cycling facilities that serve rural areas or provide links between municipalities.

Central government involvement in cycling has been more recent, evolving gradually since about 1980 and providing overall goals, design guidelines, research support, model projects, coordination and funding. The Netherlands, Denmark and Germany all have official National Bicycling Master Plans (Netherlands Ministry of Transport, 1999; Danish Ministry of Transport, 2000; German Federal Ministry of Transport, 2002). Each of these plans sets forth the overall goal of raising levels of cycling for daily travel while improving cycling safety. They also propose various strategies to achieve these dual goals: better design of lanes, paths and intersections; more and better bike parking; coordination with public transport; and cycling safety

and promotion campaigns. Although the Master Plans vary from one country to another, they generally focus on the federal government's role in fostering research, dissemination of best practice information, and funding and evaluation of a wide range of experimental, innovative projects.

Federal governments usually bear the cost of bicycling facilities built along national highways and contribute significantly to financing long-distance bicycling routes that cross state boundaries (European Conference of Ministers of Transport, 2004). In Germany, for example, the federal government contributed over €1.1 billion to doubling the extent of bikeways along federal highways from 1980 to 2000, and is now devoting €100 million per year for further bikeway extensions, cycling research and demonstration projects. In addition, about €2 billion a year in revenues from the motor fuel tax are earmarked for a special urban transport investment fund, which provides 70–85% federal matching funds for state and local governments wanting to build cycling facilities (paths, lanes, bridges, traffic signals, signs, parking, etc.). From 1990 to 2006, the Dutch Central Government contributed an average of €60 million per year to various cycling projects, including €25 million per year specifically for bike parking at train stations. In addition, the Dutch Central Government provides €1.8 billion a year for provinces to spend on transport projects, including cycling facilities. By comparison, the Danish Central Government has no regular funding for cycling projects but since 2000 has contributed about €2 million a year to various demonstration projects.

The EU has been playing a modest but increasing role in promoting cycling (European Conference of Ministry of Transport, 2004). Its Interreg programme, for example, helps finance transnational and cross-border bikeway projects. That EU funding fits in nicely with the European Cyclists' Federation's (ECF) VeloEuro programme to expand and integrate long-distance bicycling routes throughout Europe. The EU contributes towards the funding of missing bike route connections between countries and of cycling facilities in underdeveloped regions. The EU also facilitates bicycling research and the exchange of best practice information among EU countries, just as national governments do this within each country.

How to Make Cycling Safe and Convenient

Many policies and programmes are necessary to make cycling safe and feasible for a broad spectrum of the population. Table 1 summarizes seven categories of measures that have been widely adopted in Dutch, Danish and German cities. Their success in making cycling so appealing is largely attributable to the coordinated implementation of all of these measures, so that they reinforce the impact of each other in promoting cycling. Indeed, that is perhaps the key lesson to be learned: the necessity of a coordinated, multi-faceted approach.

Due to space limitations, we can only provide a few details to describe the nature and extent of the seven types of measures. The following discussion serves mainly to provide some representative examples of what Dutch, Danish and German cities have been doing to raise cycling levels and make it safer. Most of the information cited below was provided directly to the authors by bicycling coordinators and planners in the ministries of transport of the Netherlands, Denmark and Germany and in two case study cities in each country (Amsterdam and Groningen; Copenhagen and Odense; Berlin and Muenster).

Figure 13. Separate cycling facilities in Odense are so safe and convenient that they attract men and women, young and old. Raised kerbs separate the bike path from the car lane on one side and from the footpath on the other side.

Source: Troels Andersen, City of Odense

Bike Paths and Lanes

Especially from the mid-1970s to the mid-1990s, separate facilities such as bike paths and lanes expanded greatly in all the three countries. In Germany, the bikeway network more than doubled in length, from 12 911 km in 1976 to 31 236 km in 1996 (German Federal Ministry of Transport, 1998). In the Netherlands, the bikeway network doubled in length, from 9282 km in 1978 to 18 948 km in 1996 (Statistics Netherlands, 1999; Pucher and Dijkstra, 2000). National, aggregate statistics for the period since the mid-1990s are not available, but data for individual cities suggest continued expansion, albeit at a much slower rate than previously. The main focus now appears to be on improving the specific design of cycle paths and lanes to improve safety.

In 2004, for example, Berlin (3.4 million inhabitants) had 860 km of completely separate bike paths, 60 km of bike lanes on streets, 50 km of bike lanes on sidewalks, 100 km of mixed-use pedestrian-bike paths and 70 km of combined bus-bike lanes on streets (City of Berlin, 2007). Amsterdam (735 000 inhabitants) and Copenhagen (504 000 inhabitants) each have roughly 400 km of completely separate bike paths and lanes (City of Amsterdam, 2003a; City of Copenhagen, 2004). Even much smaller cities, however, have extensive cycling facilities. For example, there are 320 km of bike paths and lanes in Muenster, Germany (278 000 inhabitants), over 500 km in Odense, Denmark (185 000 inhabitants), and over 420 km in Groningen, the Netherlands (181 000) (City of Muenster, 2004; Dutch Bicycling Council, 2006; City of Odense, 2007).

Table 1. Key policies and innovative measures used in Dutch, Danish and German cities to promote safe and convenient cycling**Extensive systems of separate cycling facilities**

- Well-maintained, fully integrated paths, lanes and special bicycle streets in cities and surrounding regions
- Fully coordinated system of colour-coded directional signs for bicyclists
- Off-street short-cuts, such as mid-block connections and passages through dead-ends for cars

Intersection modifications and priority traffic signals

- Advance green lights for cyclists at most intersections
- Advanced cyclist waiting positions (ahead of cars) fed by special bike lanes facilitate safer and quicker crossings and turns
- Cyclist short-cuts to make right-hand turns before intersections and exemption from red traffic signals at T-intersections, thus increasing cyclist speed and safety
- Bike paths turn into brightly coloured bike lanes when crossing intersections
- Traffic signals are synchronized at cyclist speeds assuring consecutive green lights for cyclists (green wave)
- Bollards with flashing lights along bike routes signal cyclists the right speed to reach the next intersection at a green light

Traffic calming

- Traffic calming of all residential neighbourhoods via speed limit (30 km/hr) and physical infrastructure deterrents for cars
- Bicycle streets, narrow roads where bikes have absolute priority over cars
- 'Home Zones' with 7 km/hr speed limit, where cars must yield to pedestrians and cyclists using the road

Bike parking

- Large supply of good bike parking throughout the city
- Improved lighting and security of bike parking facilities often featuring guards, video-surveillance and priority parking for women

Coordination with public transport

- Extensive bike parking at all metro, suburban and regional train stations
- 'Call a Bike' programmes: bikes can be rented by cell phone at transit stops, paid for by the minute and left at any busy intersection in the city
- Bike rentals at most train stations
- Deluxe bike parking garages at some train stations, with video-surveillance, special lighting, music, repair services and bike rentals

Traffic education and training

- Comprehensive cycling training courses for virtually all school children with test by traffic police
- Special cycling training test tracks for children
- Stringent training of motorists to respect pedestrians and cyclists and avoid hitting them

Traffic laws

- Special legal protection for children and elderly cyclists
- Motorists assumed by law to be responsible for almost all crashes with cyclists
- Strict enforcement of cyclist rights by police and courts

Source: Information provided directly to authors by bicycling coordinators in the Netherlands, Denmark and Germany

The bicycling networks in all these cities include numerous off-street short-cut connections for cyclists between streets and traversing city blocks to enable them to take the most direct possible route from origin to destination. The result of such a wide range of facilities is a complete, integrated system of bicycling routes that permit cyclists to cover almost any trip either on completely separate paths and lanes or on lightly travelled, traffic-calmed residential streets.

Not only has the network of separate cycling facilities greatly expanded since the 1970s, but also their design, quality and maintenance have continually

improved to ensure safer, more convenient and more attractive cycling with each passing year. In addition, many cities in the Netherlands, Denmark and Germany have established a fully integrated system of directional signs for cyclists, colour-coded to correspond to different types of bike routes. That system of signage often extends to entire regions, states and even countries for long-distance routes (City of Copenhagen, 2002; Andersen, 2005; City of Muenster, 2007).

All large cities and most medium-sized cities in the Netherlands, Denmark and Germany provide detailed maps of their cycling facilities. Some cities have recently introduced Internet bike route planning to assist cyclists in choosing the route that best serves their needs. In Berlin and Odense, for example, cyclists can enter their origin and destination as well as a range of personal preferences, such as speed, on-street or off-street facility, avoiding intersections and heavy traffic, etc. (Andersen, 2005; City of Berlin, 2007). The Internet programme shows the optimal route on a map and provides all relevant information about time, average speed, bike parking and public transport connections. This bike route planning is even possible while en route, using the LCD display of a mobile phone.

The provision of separate cycling facilities is undoubtedly the cornerstone of Dutch, Danish and German policies to make cycling safe and attractive. They are designed to feel safe, comfortable and convenient for both young and old, for women as well as men, and for all levels of cycling ability. Separate facilities are not sufficient but they are certainly necessary to ensure that cycling is possible for a broad spectrum of the population (Garrard *et al.*, 2008).

Figure 14. This traffic-calmed street in Freiburg, Germany restricts car speeds to 30km/hr and gives cyclists and pedestrians priority over motorists. Most residential streets in German cities are traffic calmed, thus making them ideal for cycling, even without any special facilities such as lanes or paths.

Source: John Pucher

Traffic Calming

It is neither possible nor necessary to provide separate bike paths and lanes on lightly travelled residential streets, but they constitute an important part of the overall cycling route network. Thus, Dutch, Danish and German cities have traffic-calmed most streets in residential neighbourhoods, reducing the legal speed limit to 30 km/hr (19 mph) and often prohibiting any through traffic. In addition, many cities—especially in the Netherlands—introduced considerable alterations to the streets themselves, such as road narrowing, raised intersections and crosswalks, traffic circles, extra curves and zigzag routes, speed humps and artificial dead-ends created by mid-block street closures. Cycling is almost always allowed in both directions on all such traffic-calmed streets, even when they are restricted to one-way travel for cars. That further enhances the flexibility of bike travel (Boehme, 2005; City of Berlin, 2007; City of Groningen, 2007; City of Odense, 2007).

The most advanced form of traffic calming—the ‘woonerf’ or ‘Home Zone’—imposes even more restrictions, requiring cars to travel at walking speed. Pedestrians, cyclists and playing children have as much right to use such residential streets as motor vehicles; indeed, motor vehicles are required to yield to non-motorized users.

In the Netherlands, Denmark and Germany, traffic calming is usually area-wide and not for isolated streets. That ensures that thru-traffic gets displaced to arterial roads designed to handle it and not simply shifted from one residential street to another.

Related to traffic calming, almost every city has created extensive car-free zones in their centres, mainly intended for pedestrian use but generally permitting cycling during off-peak hours (City of Copenhagen, 2002; City of Amsterdam, 2003b; City of Muenster, 2004). In some Dutch cities, these car-free zones specifically include cycling facilities such as bike lanes and parking (Dutch Bicycling Council, 2006). The combination of traffic calming of residential streets and prohibition of cars in city centres makes it virtually impossible in some cities for cars to traverse the city centre to get to the other side. Cars are forced to take various circumferential routes instead, thus mitigating the congestion, pollution and safety problems they would cause in dense city centres.

Another kind of traffic calming is the so-called ‘bicycle street’, which has been increasingly adopted in Dutch and German cities. These are narrow streets where cyclists are given absolute traffic priority over the entire width of the street. On normal streets, cyclists are usually expected to keep as far to the kerb (or lane of parked cars) as possible, so as not to interfere with motor vehicle traffic. On bicycling streets, however, cyclists can ride anywhere they want, even if that means obstructing cars. Cars are usually permitted to use the streets as well, but they are limited to 30 km/hr (or less) and must yield to cyclists and give special consideration to avoid endangering them. In Muenster, for example, there were already 12 bicycling streets in 2007, and they have been so successful that the city has plans to add another 10 bicycling streets in the coming years (City of Muenster, 2007).

Traffic calmed residential neighbourhoods, car-free city centres, and special bicycle streets all greatly enhance the overall bicycling network in Dutch, Danish and German cities. Most importantly, they offer much safer, less stressful cycling than streets filled with fast-moving motor vehicles. Since most bike trips start at home, traffic calming of neighbourhood streets is crucial to enabling bike trips to

Figure 15. This contra-flow lane in Copenhagen enables cyclists to ride in both directions, while cars are restricted to one direction. The roadway has been deliberately narrowed through the provision of bike parking. In effect, these modifications have turned it into a bicycling street, where cyclists outnumber motorists.

Source: Jennifer Dill

start off in a safe, pleasant environment on the way to the separate bike paths and lanes that serve the rest of the trip.

The available empirical evidence shows that traffic calming improves overall traffic safety. The benefits tend to be greatest for pedestrians, but serious cyclist injuries also fall sharply. Moreover, most studies report large increases in overall levels of walking and cycling. There are, of course, many different kinds of traffic calming. It is conceivable that one or another specific kind of traffic calming measure (perhaps roundabouts or speed humps) might detract from cycling safety in some circumstances. Overall, however, the evidence is overwhelming that traffic calming enhances both pedestrian and cyclist safety by reducing speeds on secondary roads (Herrstedt, 1992; Webster and Mackie, 1996; Transport for London, 2003; Morrison *et al.*, 2004).

Intersection Modifications

While bike paths and lanes help protect cyclists from exposure to traffic dangers between intersections, they can pose safety problems when crossing intersections. Thus, Dutch, Danish and German planners have worked continuously on perfecting the designs of intersections to facilitate safe cyclist crossings (City of Copenhagen, 2002; City of Berlin, 2003; Dutch Bicycling Council, 2006). The extent and specific design of intersection modifications vary, of course, from city to city, but they generally include many of the following:

Figure 16. Green wave for cyclists in Odense, Denmark. Bright green lights on the bollards along the path pulsate in a wave-like forward motion guiding cyclists to the next green traffic signal at 20km/hr. If cyclists keep pace with the green wave, they get green traffic signals at all intersections.

Source: Troels Andersen, City of Odense

- special bike lanes leading up to the intersection, with advance stop lines for cyclists, far ahead of waiting cars;
- advance green traffic signals for cyclists, and extra green signal phases for cyclists at intersections with heavy cycling volumes;
- turn restrictions for cars, while all turns allowed for cyclists;
- highly visible, distinctively coloured bike lane crossings at intersections;
- special cyclist-activated traffic lights;
- timing traffic lights to provide a 'green wave' for cyclists instead of for cars, generally assuming 14–22 km/hr bike speed, depending on type of route;
- insertion of traffic islands and bollards in roadway to sharpen turning radius of cars and thus force them to slow down when turning right; and
- realigning bike pathways a bit further away from their parallel streets when they approach intersections to help avoid collisions with right-turning cars.

Given the very nature of roadway intersections, it is virtually impossible to avoid all conflicts between motor vehicles and cyclists, but Dutch, Danish and German planners have done a superb job of minimizing these dangers.

Bike Parking

Extensive bike parking of various sorts is available throughout most Dutch, Danish and German cities. Local governments and public transport systems themselves directly provide a large number of bike parking facilities. Moreover, private developers and building owners are required by local ordinances to

Figure 17. This bike path in Amsterdam swerves to the right several meters to increase cyclist safety when crossing the intersection. The increased distance between the main road and the bike path crossing gives motorists and cyclists more time to see each other and thus avoid collisions. The traffic island with two bollards forces a sharp turning radius for right-turning cars, forcing them to slow down. Cyclists get an advance green light via the two sets of traffic signals shown on the post to the far right, further increasing their speed and safety.

Source: Lewis Dijkstra

provide specified minimum levels of bike parking both within and adjacent to their buildings (City of Berlin, 2005; Dutch Bicycling Council, 2006).

Aside from the large number of bike racks throughout these cities, the most visible and most innovative aspect of bike parking policy is the provision of state-of-the-art parking facilities at train stations. Immediately adjacent to Muenster's main train station, for example, there is a modern, attractive 'bike station' (built in 1999) that offers secure, indoor parking for 3300 bikes as well as bicycle sales, repairs, washing, and cycling touring services. The station has direct access to all train platforms (Boehme, 2005). Amsterdam, Groningen and Odense offer similar, high-capacity bike parking facilities at their main train stations (Langenberg, 2000; City of Groningen, 2007; City of Odense, 2007). Moreover, virtually every train station throughout Dutch, Danish and German metropolitan areas offers bike parking of some sort. In the Berlin region, there were 24 600 bike-and-ride parking spots at train stations in 2005 (including metro, suburban rail and regional rail), with 7000 additional bike parking spots planned by 2010 (City of Berlin, 2007).

Many city centres also offer special bike parking facilities. The City of Odense, for example, recently added 400 sheltered bike racks near its main shopping area as well as a state-of-the-art automatic, secure parking station (Andersen, 2005). Groningen offers 36 major bike parking facilities in its town centre, including seven that are guarded to prevent bike theft (Dutch Bicycling Council, 2006). Amsterdam has 15 guarded bike parking facilities in its downtown shopping area (City of

Figure 18. Deluxe parking for 3,300 bikes at the main train station and bus terminal in Muenster, Germany. The bike ramp connects the street level to the bike parking level, from which there is direct access for cyclists to all train platforms. All bus stops are at ground level just to the left of the bike station.

Source: Peter Berkeley

Amsterdam, 2007). In 2007, Muenster added a secured, indoor parking facility for 290 bikes adjacent to its main shopping district (City of Muenster, 2007). The City of Copenhagen installed 3300 bike parking spaces in the town centre to facilitate cycling for shopping and entertainment trips (City of Copenhagen, 2007).

Clearly, the provision of convenient, secure, sheltered bike parking is essential to cyclists, just as car drivers need parking for their cars. The current policy focus in Dutch, Danish and German cities is to increase the security of bike parking, since bike theft is a major problem.

The random parking of bikes in public spaces can obstruct pedestrians on sidewalks and is considered by some to be a visual eyesore. Thus, the supply of bike parking is being expanded not only for greater cyclist convenience but also to deal with the clutter of randomly parked bikes. Somewhat similar to car parking in the USA, there never seems to be enough bike parking. In spite of Muenster's superb bike parking facility at the main train station, for example, there are still over 10 000 bikes parked in the nearby sidewalks, plazas and alleys, and most of those are not in racks (City of Muenster, 2004).

Integration with Public Transport

Most Dutch, Danish and German cities have integrated cycling with public transport. Public transport companies and city planners in northern Europe have

increasingly recognized the key role that bicycling plays as a feeder and distributor service for public transport. Thus, copious bike parking is provided at train stations in the city centre as well as at outlying stations along the rail network (North-Rhine Westphalia Ministry of Transport, 2004). In cities such as Muenster, many suburban residents use a bike to reach the nearest suburban rail station, park it there, and then take the train to the city centre, where they continue their trip with another bike they have parked at the main train station (City of Muenster, 2004). Most rail systems charge an additional fee for cyclists to take their bikes on suburban trains, metros and trams. Moreover, many systems prohibit bikes on vehicles during rush hours, and even if permitted, it can sometimes be less convenient than keeping bikes at parking facilities at both ends of the trip.

Most Dutch, Danish and German cities we surveyed do not permit bikes to be taken onboard regular city buses, and most buses do not come equipped with bike racks (City of Amsterdam, 2007). That contrasts starkly with the USA, where over 50 000 urban transit buses in 2007 had bike racks to facilitate bike and ride (American Public Transportation Association, 2007). It appears to be the one area where American transit systems do a better job of coordinating cycling with transit. The northern European approach is to provide bike parking facilities at major bus terminals, bus route interchanges and even some suburban bus stops. Bike-and-ride facilities at bus stops are not nearly as extensive, secure and comfortable as those at rail stations, but they help offset the lack of bike racks on buses.

Another form of bike-transit integration is the provision of bike rentals at virtually every major Dutch, Danish and German train station and many suburban stations as well. The German Railways' 'Call a Bike' programme in Berlin is especially innovative. It permits anyone with a mobile phone and credit card to rent one of more than 3000 German Rail bikes placed all over the city. One simply calls up the 'Call a Bike' number, provides credit card information (charged per minute of bike use), and then receives the access code used to unlock the bike (German Railways, 2007). The bike can be left at many different locations throughout the city instead of being returned to the point of origin. The same 'Call a Bike' service is offered by German Railways in other major cities such as Hamburg, Cologne, Frankfurt and Munich, with a total of over 10 000 such rental bikes.

There is an even more extensive public transport bike programme in the Netherlands. In 2007, over a hundred Dutch railway stations provided quick and easy discount bike rentals, operated by OV-Fiets. Payment is made via a special account linked to a season ticket for public transport or a special OV-Fiets membership card (OV-Fiets, 2007).

Training and Education

Dutch, Danish and German children receive extensive training in safe and effective cycling techniques as part of their regular school curriculum. Most children complete such a course by the fourth grade. It includes both classroom instruction and 'on the road' lessons, first on a cycling training track just for children and then on regular cycling facilities throughout the city. Real police officers test the children, who receive official certificates, pennants and stickers for their bikes if they pass the test. Since many children get to school by bike, training in safe cycling is considered essential to ensure their safety (German Federal Ministry of Transport, 2002). But it also gets kids off to a lifetime of safe cycling skills. And since all school-children are included, it means that girls as well as boys start cycling at an early age.

Another crucial element in cyclist safety is training motorists to be aware of cyclists on the roadway and to avoid endangering them. In general, motorist training in the Netherlands, Denmark and Germany is far more extensive, more thorough, and more expensive than in the USA. Motorists are legally responsible for collisions with children and elderly cyclists, even if they are jaywalking, cycling in the wrong direction, ignoring traffic signals, or otherwise behaving contrary to traffic regulations (German Federal Ministry of Transport, 2002; Netherlands Ministry of Transport, 2006). The priority legal status of non-motorists puts motorists on the defensive and forces them to drive with special attention to avoiding endangering cyclists and pedestrians.

Traffic Laws

As suggested by the previous section, traffic laws in the Netherlands, Denmark and Germany give special consideration to the especially vulnerable situation of cyclists vis-à-vis motor vehicles (German Federal Ministry of Transport, 2006). Thus, they generally require the motorist to make special efforts to anticipate potentially dangerous situations and pro-actively avoid hitting cyclists. Moreover, motorists are generally assumed to be legally responsible for most collisions with cyclists unless it can be proven that the cyclist deliberately caused the crash. Having the right of way by law does not excuse motorists from hitting cyclists, especially children and elderly cyclists.

For the most part, traffic laws intended to protect cyclists and pedestrians from motor vehicles are far more strictly enforced by the police and courts in the Netherlands, Denmark and Germany than in the USA. Moreover, cyclists disobeying traffic laws are also more likely to be ticketed than in the USA. In combination with comprehensive and rigorous training of motorists and cyclists, the strict enforcement of traffic laws surely contributes to safer driving behaviour by motorists and safer cycling by cyclists.

Promotional Events

Although the provision of safe and convenient cycling facilities is the key approach to promoting cycling, virtually all Dutch, Danish and German cities have various programmes to stimulate interest and enthusiasm for cycling by all groups. Table 2 includes a partial listing of typical promotional measures used by six cities we specifically surveyed: Amsterdam and Groningen (Netherlands), Copenhagen and Odense (Denmark), and Berlin and Muenster (Germany). There were many other creative and interesting programmes as well, but Table 2 conveys the sorts of promotional measures undertaken.

Promotional activities tend to be more extensive in Denmark and Germany than in the Netherlands, where cycling levels are already so high that the focus is more on safer cycling than on more cycling, although the two are directly related, as noted earlier.

Complementary Taxation, Parking and Land-Use Policies

Most of the above policies refer to measures that make cycling safer and more convenient. Many other important government policies encourage cycling indirectly. Several different categories of such complementary policies are listed in Table 3.

Table 2. Cycling promotion in the Netherlands, Denmark and Germany**Access to bikes**

- Free use of distinctive, simple City Bikes parked throughout the city, as in Copenhagen
- Easy, convenient and inexpensive bike rentals at train stations and throughout the city, such as the 'OV-Fiets' and 'Call a Bike' programmes in the Netherlands and Germany, respectively
- Company bikes loaned for free to employees who can use them during the day for short business trips
- Tax breaks to purchase a bike in the Netherlands
- Convenient air pumps for bikes in city centre
- 'Park and Bike': discount bike rentals for motorists who park their cars and bike for the rest of the journey

Bike trip planning

- Bicycling websites with extensive information for cyclists on bicycling routes, activities, special programmes, health benefits of cycling, bikes and bike accessories, etc.
- Flexible Internet bike trip planning tool allows finding the most comfortable or quickest route by bike tailored to the specific preferences and needs of each person
- Comprehensive bike maps for most cities as well as most regions and states

Public awareness campaigns

- Focus on health benefits of cycling, such as the 'Get Rid of the Sack' programme in Odense targeted at overweight middle-aged men with pot-bellies who need more exercise
- Special fun programmes for young children, such as the 'Cycling Duckie' in Odense, which distributes candy, balloons, free bike accessories and other gifts to children learning to cycle
- Cycling ambassador programmes that send well-trained cyclists to residential neighbourhoods to serve as role models of safe cycling and help with cycling promotion, distributing newsletters and information
- Annual bicycling festivals and car-free days that promote the environmental advantages of bicycling, display the latest bike models and accessories, and disseminate various other relevant information for bike enthusiasts
- Wide range of cycling competitions for different ages and skill levels
- Special guided bike tours for seniors

Public participation in bike planning

- Regular surveys of cyclists to assess their satisfaction with cycling facilities and programmes and to gather specific suggestions for improvement
- Bike councils that provide a platform for opinion exchange among stakeholders from businesses, the bike industry, the city administration, research institutes, universities, bike experts and citizen advocacy groups, such as the 'Fahrrat' in Berlin

Source: Information provided directly to authors by bicycling coordinators in the Netherlands, Denmark and Germany

For example, many Dutch, Danish and German cities impose a range of restrictions on car use, including limits on speeds, turns, direction of travel, and in some cases prohibit car use altogether, such as in car-free zones. Similarly, the provision of road capacity and parking facilities is far less generous than in American cities (Newman and Kenworthy, 1999; Transportation Research Board, 2001). Indeed, roadway and parking supply have been deliberately reduced in many Dutch, Danish and German cities over the past few decades in order to discourage car use in the city centre (Dutch Bicycling Council, 2006). The many restrictions on car use and parking reduce the relative speed, convenience and flexibility of car travel compared to cycling (Rietveld and Daniel, 2004).

Moreover, sales taxes on petrol and new car purchases, import tariffs, registration fees, license fees, driver training fees and parking fees are generally much higher in Europe than in the USA (Pucher, 1995; Nivola, 1999; Transportation Research Board, 2001; European Union, 2006). That results in overall costs of car ownership and use two to three times higher in Europe. That higher cost discourages car use

Table 3. Taxation, parking and land-use policies that encourage cycling indirectly**Automobile speed limitations in cities**

- Traffic calming of residential neighbourhoods limits cars to speeds of 30 km/hr or less
- 'Home Zones' in many neighbourhoods give cyclists and pedestrians equal rights to road use and limit cars to *walking speed* (about 7 km/hr)
- Car-free zones, one-way streets and artificial dead-ends make car travel through the city centre slow and inconvenient
- Turn restrictions for cars but not for cyclists
- Almost no limited access highways (motorways) in city centres
- Strictly enforced speed limits and traffic rules in cities (such as police cameras at intersections)
- Frequent random speed limit enforcement checks by the police
- Advance stop lines and traffic signal priority for cyclists

Road and parking capacity limitations

- Limited number of car parking places in city centres
- Parking management schemes limit easy car access to urban neighbourhoods, often with resident-only parking or strict time limits
- Replacing car parking facilities with bike parking instead
- Combined bus-bike lanes that permit bike use but prohibit car use
- Deliberately narrowed roads in city centres force cars to drive slowly
- Special bicycle streets that sharply limit car speeds and give cyclists priority in roadway use over the entire width of the road

Taxation of automobile ownership and use

- High taxes and fees on car purchase, ownership and use
- Especially high excise and sales taxes on petrol
- High hourly parking rates in city centre, even in medium-size cities
- High fees and strict training requirements for obtaining a driver's licence (over €1500 in Germany)

Strict land use planning policies

- Most land beyond already built-up areas is off-limits for new development
- Most new development occurs adjacent to already built-up areas, which keeps overall population densities high compared to the USA
- Transport and land-use planning are integrated at several levels of government, with regional coordination that fosters cooperation between adjacent communities
- Many local governments specifically require cycling and walking facilities for new suburban developments, thus reducing the need for car use
- Mixed-use zoning keeps trip distances short and feasible by bicycle and on foot
- Less strict separation of land uses than in the USA, thus enabling natural development of mixed-use neighbourhoods

Sources: Pucher (1995); Nivola (1999); Bratzel (1999); Alterman (2001); Transportation Research Board (2001); Pucher and Dijkstra (2003); European Conference of the Ministers of Transport (2004); Banister (2005); Dutch Bicycling Council (2006); Netherlands Ministry of Transport (2006); Schmidt and Buehler (2007)

to some extent and thus promotes alternative ways of getting around, including cycling, which is surely one of the cheapest of transport modes.

Finally, land-use and urban-design policies in Dutch, Danish and German cities are generally much stricter than in the USA and provide more government controls on low-density sprawl and the long-trip distances that usually generates (Nivola, 1999; Alterman, 2001; Transportation Research Board, 2001; Schmidt and Buehler, 2007). Moreover, mixed-use zoning and transit-oriented developments have a long history in Europe. They facilitate the proximity of residential areas to commercial establishments, schools, churches and a range of services. The resulting trip distances are shorter and thus more bikeable than those in the USA.

For the most part, these complementary taxation, parking and land-use policies are not specifically intended to promote cycling. Nevertheless, they provide dramatically more favourable pre-conditions for cycling than in the USA.

The situation in the UK appears to be far less favourable to cycling than in the Netherlands, Denmark and Germany (Goodwin, 1999; McClintock, 2002; Tolley, 2003; Banister, 2005; Banister *et al.*, 2007). Interviews conducted by the authors in 2007 with a wide range of transport specialists throughout the UK suggest that British metropolitan areas have a greater supply of motorways and car parking than is typical of the Netherlands, Denmark and Germany. Car-free city centres are less common in the UK, traffic calming of residential neighbourhoods is far less widespread, speed limits are generally higher, and many firms provide financial incentives to buy cars and drive them to work. Moreover, land-use controls tend to be less strict than in the rest of northern Europe. The lack of good coordination between land-use and transport has resulted in more low-density suburban sprawl, often strewn along the extensive motorway system surrounding many British cities (Banister, 2005). Clearly, none of the above factors is conducive to cycling. Combined with the lesser extent and inferior quality of cycling facilities in most British cities, these unfavourable conditions might help explain why only slightly more than 1% of trips (1.3%) in the UK were made by bike in 2005.

One interesting exception in the UK is the congestion pricing scheme in London since 2003, which has helped increase cycling levels by 30% (Transport for London, 2007a, b). Cycling in London has grown not only due to the restriction of car use but also by the simultaneous provision of expanded and improved cycling facilities.

Conclusions: Policies to Make Cycling Irresistible

The most important approach to making cycling safe and convenient in Dutch, Danish and German cities is the provision of separate cycling facilities along heavily travelled roads and at intersections, combined with extensive traffic calming of residential neighbourhoods. Safe and relatively stress-free cycling routes are especially important for children, the elderly, women and for anyone with special needs due to any sort of disability. Providing such separate facilities to connect practical, utilitarian origins and destinations also promotes cycling for work, school and shopping trips, as opposed to the mainly recreational cycling in the USA, where most separate cycling facilities are along urban parks, rivers and lakes or in rural areas.

As noted in this article, separate facilities are only part of the solution. Dutch, Danish and German cities reinforce the safety, convenience and attractiveness of excellent cycling rights of way with extensive bike parking, integration with public transport, comprehensive traffic education and training of both cyclists and motorists, and a wide range of promotional events intended to generate enthusiasm and wide public support for cycling.

Would such pro-cycling policies as those listed in Tables 1 and 2 be possible in a country like the USA? Some of the same policies are already used, but to a much lesser extent, in many American cities (Pucher *et al.*, 1999). Moreover, there has been considerable expansion of such measures in recent years, with even more expansion planned. Generous federal funding has helped finance 6165 km of bike lanes, 3483 km of multi-use bike-ped paths and 36 195 bike parking racks in the 50 largest U.S. cities (Thunderhead Alliance, 2007). Bike parking at rail stations has

been increasing, and as noted earlier, over 50 000 buses in the USA already come equipped with bike racks to facilitate bike and ride. Moreover, all states now have federally funded Safe Routes to School programmes designed to help children walk or bike to school.

With the highest bike share of work trips (4%) of the 50 largest U.S. cities, Portland, Oregon, probably has the country's most successful bicycling programme (City of Portland, 2007a, b, c). Portland has more than tripled the total annual number of bike trips since 1991. That is partly due to a range of pro-bike measures such as vastly expanding its bikeway network, increasing bike parking and integrating cycling with bus and rail systems. In addition, bicycling in Portland benefits from the country's most famous land-use planning reforms, which have restricted leap-frog suburban sprawl and encouraged compact, mixed-use development conducive to shorter, more bikeable trips. Portland has also reduced the supply of car parking in the city centre while improving public transport services. Very few American cities can boast of such an integrated range of policies to promote cycling.

While Portland has been a model bicycling city, Chicago and New York provide some impressive examples of what can be done to promote cycling even in two megacities which for decades had been extremely hostile to cycling. In the past ten years Chicago has added over 160 km of bike lanes and paths, established a city-wide cycling network, installed 7000 racks for bike parking and equipped over 2000 buses with racks to encourage bike and ride. Moreover, the latest official bicycling plan calls for further expansion to create an 800 km bikeway network (City of Chicago, 2007). New York has added 392 km of bike paths and lanes in the past ten years and plans an additional 900 km of bike paths and lanes in the coming ten years (New York City Department of Transportation, 2007a). From 2001 to 2007, New York installed over 3000 new bike racks. Official city plans call for a network of 2880 km of bike lanes and mixed-use greenway paths by 2030. Cycling levels in both Chicago and New York have increased considerably. Annual cordon counts conducted by the City of New York at a wide range of locations throughout Manhattan indicate that cycling levels more than doubled (116% increase) between 2000 and 2007 (New York City Department of Transportation, 2007b).

In short, such pro-bike 'carrot' policies are indeed possible even in a car-oriented country like the USA. By comparison, there is almost no political support in the USA for adopting and implementing the sorts of car-restrictive 'stick' policies listed in Table 3 that indirectly encourage cycling in the Netherlands, Denmark and Germany. In those three countries, car use is far more expensive and much less convenient than in the USA due to a host of taxes and restrictions on car ownership, use and parking. Moreover, strict land-use policies foster relatively compact, mixed-use developments that generate more bikeable, shorter trips. Promoting cycling is surely not the main purpose of such policies, but they clearly provide important incentives and supportive conditions for cycling.

With very few exceptions, such as Portland, Oregon, neither car-restrictive measures nor stringent land-use controls have yet been politically acceptable in American cities (Pucher *et al.*, 1999; Banister *et al.*, 2007). The public and the media vigorously oppose even slight increases in the petrol tax, for example, and thus discourage politicians from even considering increased taxation on car use. Similarly, there is little support for restrictions on car parking, speeds and passage of cars through city centres and residential neighbourhoods. Thus, there appears to be only very limited potential for implementation in the USA of these crucial 'stick' approaches that would encourage cycling.

Even in a city such as New York, where a majority of residents have no cars, it has been an uphill battle trying to approve the proposed congestion pricing scheme for Manhattan. It would involve a charge of \$8 for cars and \$21 for trucks to enter Manhattan south of 86th Street on weekdays between 6 am and 6 pm (New York City Department of Transportation, 2007a). Both Mayor Bloomberg (of New York City) and Governor Spitzer (of New York State) strongly support congestion pricing, and the U.S. Department of Transportation has offered \$353 million in subsidy to help finance the programme. The plan remains highly controversial, however, and a combined state and city commission has been established to evaluate it. The federal government has set a deadline of 31 March 2008 for final city and state approval of the congestion pricing plan, and a deadline of 31 March 2009 for its implementation. Based on the London experience, it seems likely that congestion pricing in New York would increase cycling levels, especially since the city plans to greatly expand its cycling facilities at the same time.

The key to the success of cycling policies in the Netherlands, Denmark and Germany is the coordinated implementation of the multi-faceted, mutually reinforcing set of policies summarized in Tables 1, 2 and 3. Not only do these countries implement far more of the pro-bike measures, but they greatly reinforce their overall impact with highly restrictive policies that make car use less convenient as well as more expensive. It is precisely that double-barrelled combination of 'carrot' and 'stick' policies that make cycling so irresistible.

Acknowledgements

The authors are deeply indebted to a host of colleagues around the world for their assistance and advice in writing this article. They include national and local cycling coordinators, city planners, transport researchers, national statistical experts, department of transport officials and public health experts, listed here alphabetically: Peter Berkeley, Mia Birk, Stefan Boehme, Frank Borgman, Noah Budnick, Linda Christensen, Andy Clarke, Marie Demers, Lewis Dijkstra, Jennifer Dill, Bernhard Ensink, Bent Flyvbjerg, Per Garder, Jan Garrard, Roger Geller, Martina Guettler, Susan Handy, Peter Herwig, Ria Hilshorst, Peter Jacobsen, Roland Jannermann, Niels Jensen, Cor van der Klaauw, Jutta Kloas, Thomas Krag, Patrick Lingwood, Hugh McClintock, Randy Neufeld, Wolfgang Richter, Piet Rietveld, Harry Rutter, Warren Salomon, Birgit Schmidt, Kristen Steele, Peter Strang, Steve Weber, John Whitelegg, and Bert Zinn. The authors also thank two anonymous referees for their helpful suggestions on improving the original version of the article.
